Refer to Section 2.3 on page 134 for the register boundary addresses.
24 Quad-SPI interface (QUADSPI)

24.1 Introduction

The QUADSPI is a specialized communication interface targeting single, dual- or quad-SPI flash memories. It can operate in any of the three following modes:

- **indirect mode:** all the operations are performed using the QUADSPI registers.
- **automatic status-polling mode:** the external flash memory status register is periodically read and an interrupt can be generated in case of flag setting.
- **memory-mapped mode:** the external flash memory is mapped to the device address space and is seen by the system as if it was an internal memory.

Both throughput and capacity can be increased two-fold using dual-flash mode, where two Quad-SPI flash memories are accessed simultaneously.

24.2 QUADSPI main features

- Three functional modes: indirect, automatic status-polling, and memory-mapped
- Dual-flash mode, where 8 bits can be sent/received simultaneously by accessing two flash memories in parallel
- SDR and DDR support
- Fully programmable opcode for both indirect and memory-mapped modes
- Fully programmable frame format for both indirect and memory-mapped modes
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- MDMA trigger generation for FIFO threshold and transfer complete
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

### 24.3.3 QUADSPI command sequence

The QUADSPI communicates with the flash memory using commands. Each command can include five phases: instruction, address, alternate byte, dummy, data. Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phase must be present.

NCS falls before the start of each command and rises again after each command finishes.

**Instruction phase**

During this phase, an 8-bit instruction, configured in INSTRUCTION bitfield of QUADSPI_CCR[7:0] register, is sent to the flash memory, specifying the type of operation to be performed.

Most flash memories can receive instructions only one bit at a time from the IO0/SO signal (single-SPI mode), the instruction phase can optionally send 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the IMODE[1:0] bitfield of QUADSPI_CCR[9:8] register.

When IMODE = 00, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

**Address phase**

In the address phase, 1-4 bytes are sent to the flash memory to indicate the address of the operation. The number of address bytes to be sent is configured in the ADSIZE[1:0] bitfield of QUADSPI_CCR[13:12] register. In indirect and automatic status-polling modes,
address bytes to be sent are specified in the ADDRESS[31:0] bitfield of QUADSPI_AR register, while in memory-mapped mode, the address is given directly via the AXI (from the Cortex or from a DMA).

The address phase can send 1 bit at a time (over SO in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ADMODE[1:0] bitfield of QUADSPI_CCR[11:10] register.

When ADMODE = 00, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

Alternate-byte phase

In the alternate-byte phase, 1-4 bytes are sent to the flash memory, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the [1:0] bitfield of QUADSPI_CCR[17:16] register. The bytes to be sent are specified in the QUADSPI_ABR register.

The alternate-bytes phase can send 1 bit at a time (over SO in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ABMODE[1:0] bitfield of QUADSPI_CCR[15:14] register.

When ABMODE = 00, the alternate-byte phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-mode is used and only two cycles are used for the alternate bytes. In this case, the firmware can use quad-mode (ABMODE = 11) and send a byte with bits 7 and 3 of ALTERNATE set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low). In this case, the upper two bits of the nibble to be sent are placed in bits 4:3 of ALTERNATE, while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE must be set to 0x8A (1000_1010).

Dummy-cycle phase

In the dummy-cycle phase, 1-31 cycles are given without any data being sent or received, in order to give time to the flash memory to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in the DCYC[4:0] bitfield of QUADSPI_CCR[22:18] register. In both SDR and DDR modes, the duration is specified as a number of full CLK cycles.

When DCYC is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

The operating mode of the dummy-cycles phase is determined by DMODE.

In order to assure enough “turn-around” time for changing data signals from output mode to input mode, there must be at least one dummy cycle when using dual or quad mode to receive data from the flash memory.

Data phase

During the data phase, any number of bytes can be sent to, or received from the flash memory.
In indirect and automatic status-polling modes, the number of bytes to be sent/received is specified in the QUADSPI_DLR register.

In indirect-write mode the data to be sent to the flash memory must be written to the QUADSPI_DR register. In indirect-read mode the data received from the flash memory is obtained by reading the QUADSPI_DR register.

In memory-mapped mode, the data which is read is sent back directly over the AXI to the Cortex or to a DMA.

The data phase can send/receive 1 bit at a time (over SO/SI in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ABMODE[1:0] bitfield of QUADSPI_CCR[15:14] register.

When DMODE = 00, the data phase is skipped, and the command sequence finishes immediately by raising NCS. This configuration must only be used in only indirect write mode.

### 24.3.4 QUADSPI signal interface protocol modes

#### Single-SPI mode

This legacy SPI mode allows just one single bit to be sent/received serially. In this mode, data are sent to the flash memory over the SO signal (whose I/O shared with IO0). Data received from the flash memory arrive via SI (whose I/O shared with IO1).

The different phases can each be configured separately to use this mode by setting the IMODE/ADMODE/ABMODE/DMODE fields in QUADSPI_CCR register to 01.

In each phase which is configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).

This is the case even for the dummy phase if DMODE = 01.

#### Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 10.

In each phase which is configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.

In the dummy phase when DMODE = 01, IO0/IO1 are always high-impedance.

#### Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.
The different phases can each be configured separately to use quad-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 11.

In each phase which is configured in this mode, IO0/IO1/IO2/IO3 are all are at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE = 11, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in quad-SPI mode. If none of the phases are configured to use quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the QUADSPI is active.

**SDR mode**

By default, the DDRM bit (QUADSPI_CCR[31]) is 0 and the QUADSPI operates in single-data rate (SDR) mode.

In SDR mode, when the QUADSPI drives IO0/SO, IO1, IO2, IO3 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the QUADSPI assumes that flash memories also send the data using CLK falling edge. By default (when SSHIFT = 0), the signals are sampled using the following (rising) edge of CLK.

**DDR mode**

When the DDRM bit (QUADSPI_CCR[31]) is set to 1, the QUADSPI operates in double-data rate (DDR) mode.

In DDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals in the address/alternate-byte/data phases, a bit is sent on each of CLK falling and rising edges.

The instruction phase is not affected by DDRM. The instruction is always sent using CLK falling edge.

When receiving data in DDR mode, the QUADSPI assumes that flash memories also send the data using both CLK rising and falling edges. When DDRM = 1, the firmware must clear SSHIFT (bit 4 of QUADSPI_CR). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

---

**Figure 135. Example of a DDR command in quad-SPI mode**

![Example of a DDR command in quad-SPI mode](image-url)
**Dual-flash mode**

When the DFM bit (bit 6 of QUADSPI_CR) is 1, the QUADSPI is in dual-flash mode, where two external quad-SPI flash memories (FLASH 1 and FLASH 2) are used in order to send/receive 8 bits (or 16 bits in DDR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the flash memories uses the same CLK and optionally the same NCS signals, but each have separate IO0, IO1, IO2, and IO3 signals.

The dual-flash mode can be used in conjunction with single-, dual-, and quad-SPI modes, as well as with either SDR or DDR mode.

The flash memory size, as specified in FSIZE[4:0] (QUADSPI_DCR[20:16]), must reflect the total flash memory capacity, which is double the size of one individual component.

If address X is even, then the byte which the QUADSPI gives for address X is the byte at the address X/2 of FLASH 1, and the byte which the QUADSPI gives for address X+1 is the byte at the address X/2 of FLASH 2. In other words, bytes at even addresses are all stored in FLASH 1 and bytes at odd addresses are all stored in FLASH 2.

When reading the flash memories status registers in dual-flash mode, twice as many bytes must be read compared to doing the same read in single-flash mode. This means that if each flash memory gives 8 valid bits after the instruction for fetching the status register, then the QUADSPI must be configured with a data length of 2 bytes (16 bits), and the QUADSPI receives one byte from each flash memory. If each flash memory gives a status of 16 bits, then the QUADSPI must be configured to read 4 bytes to get all the status bits of both flash memories in dual-flash mode. The least-significant byte of the result (in the data register) is the least-significant byte of FLASH 1 status register, while the next byte is the least-significant byte of FLASH 2 status register. Then, the third byte of the data register is FLASH 1 second byte, while the forth byte is FLASH 2 second byte (in the case that the flash memories have 16-bit status registers).

An even number of bytes must always be accessed in dual-flash mode. For this reason, bit 0 of the data length bitfield (QUADSPI_DLR[0]) is stuck at 1 when DFM = 1.

In dual-flash mode, the behavior of FLASH 1 interface signals are basically the same as in normal mode. FLASH 2 interface signals have exactly the same waveforms as FLASH 1 during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each flash memory always receives the same instruction and the same address. Then, during the data phase, the BK1_IOx and BK2_IOx buses are both transferring data in parallel, but the data that are sent to (or received from) FLASH 1 are distinct from those of FLASH 2.

**24.3.5 QUADSPI indirect mode**

When in indirect mode, commands are started by writing to QUADSPI registers, and data are transferred by writing or reading the data register, in the same way as for other communication peripherals.

When FMODE = 00 (QUADSPI_CCR[27:26]), the QUADSPI is in indirect-write mode, where bytes are sent to the flash memory during the data phase. Data are provided by writing to the data register (QUADSPI_DR).

When FMODE = 01, the QUADSPI is in indirect-read mode, where bytes are received from the flash memory during the data phase. Data are recovered by reading QUADSPI_DR.
The number of bytes to be read/written is specified in the data length register (QUADSPI_DLR). If QUADSPI_DLR = 0xFFFF_FFFF (all 1s), then the data length is considered undefined and the QUADSPI simply continues to transfer data until the end of flash memory (as defined by FSIZE) is reached. If no bytes are to be transferred, DMODE (QUADSPI_CCR[25:24]) must be set to 00.

If QUADSPI_DLR = 0xFFFF_FFFF and FSIZE = 0x1F (max value indicating a 4-Byte flash memory), then in this special case, transfers continue indefinitely, stopping only after an abort request or after the QUADSPI is disabled. After the last memory address is read (at address 0xFFFF_FFFF), reading continues with address = 0x0000_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE = 1. In the case of undefined number of data, the TCF is set when the limit of the external SPI memory is reached according to the flash memory size defined in QUADSPI_CR.

**Triggering the start of a command**

Essentially, a command starts as soon as firmware gives the last information that is necessary for this command. Depending on the QUADSPI configuration, there are three different ways to trigger the start of a command in indirect mode. The commands starts immediately:

- after a write is performed to INSTRUCTION[7:0] (QUADSPI_CCR), if no address is necessary (when ADMODE = 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
- after a write is performed to ADDRESS[31:0] (QUADSPI_AR), if an address is necessary (when ADMODE ≠ 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
- after a write is performed to DATA[31:0] (QUADSPI_DR), if data needs to be provided by the firmware (when FMODE = 00 and DMODE != 00)

Writes to the alternate byte register (QUADSPI_ABR) never trigger the communication start. If alternate bytes are required, they must be programmed before.

As soon as a command is started, BUSY (bit 5 of QUADSPI_SR) is automatically set.

**FIFO and data management**

In indirect mode, data go through a 32-byte FIFO which is internal to the QUADSPI. FLEVEL[5:0] (QUADSPI_SR[13:8]) indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE = 00), the firmware adds data to the FIFO when it writes QUADSPI_DR. Word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If the firmware adds too many bytes to the FIFO (more than is indicated by DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

Byte/halfword accesses to QUADSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[4:0] is used to define a FIFO threshold. When the threshold is reached, FTF (FIFO threshold flag) is set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there are data in the FIFO after the last byte is read from the flash memory, regardless of the FTHRES setting.
In indirect-write mode, FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when FTF is set. FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data is transferred by the CPU or DMA).

In indirect-read mode when the FIFO becomes full, the QUADSPI temporarily stops reading bytes from the flash memory to avoid an overrun. The reading of the flash memory does not restart until 4 bytes become vacant in the FIFO (when \( FLEVEL \leq 11 \)). Thus, when \( FTHRES \geq 13 \), the application must take care to read enough bytes to assure that the QUADSPI starts retrieving data from the flash memory again. Otherwise, the FTF flag stays at 0 as long as \( 11 < FLEVEL < FTHRES \).

24.3.6 QUADSPI automatic status-polling mode

In automatic status-polling mode, the QUADSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

Accesses to the flash memory begin in the same way as in indirect-read mode: if no address is required (AMODE = 00), accesses begin as soon as the QUADSPI_CCR is written. Otherwise, if an address is required, the first access begins when QUADSPI_AR is written. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (QUADSPI_PSMAR) are used to mask the data from the flash memory in automatic status-polling mode. If MASK[n] = 0, then bit n of the result is masked and not considered. If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] (QUADSPI_PSMAR), then there is a match for bit n.

If the polling match mode bit (PMM, bit 23 of QUADSPI_CR) is 0, then “AND” match mode is activated. This means status match flag (SMF) is set only when there is a match on all of the unmasked bits.

If PMM = 1, then “OR” match mode is activated. This means SMF is set if there is a match on any of the unmasked bits.

An interrupt is called when SMF is set if SMIE = 1.

If the automatic status-polling mode stop (APMS) bit is set, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1, and the periodic accesses continue until there is an abort or the QUADSPI is disabled (EN = 0).

The data register (QUADSPI_DR) contains the latest received status bytes (the FIFO is deactivated). The content of the data register is not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and FTF is cleared as soon as the data is read.

24.3.7 QUADSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

It is forbidden to access the quad-SPI flash bank area before having properly configured and enabled the QUADSPI peripheral.

No more than 256 Mbytes can addressed even if the flash memory capacity is larger.
If an access is made to an address outside of the range defined by FSIZE but still within the 256-Mbyte range, then a bus error is given. The effect of this error depends on the bus master that attempted the access:

- If it is the Cortex CPU, bus fault exception is generated when enabled (or an HardFault exception when bus fault is disabled).
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, halfword, and word access types are all supported.

Support for execute in place (XIP) operation is implemented, where the QUADSPI anticipates the next access and load in advance the byte at the following address. If the subsequent access is indeed made at a continuous address, the access is completed faster since the value is already prefetched.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with NCS maintained low, even if no access to the flash memory occurs for a long time. Since flash memories tend to consume more when NCS is held low, the application may want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI_CR) so that NCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without any access since when the FIFO becomes full with prefetch data.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

24.3.8 QUADSPI free-running clock mode

When configured in free-running clock mode, the QUADSPI continuously outputs the clock for test and calibration purposes.

The free-running clock mode is entered as soon as the FRCM bit is set in the QUADSPI_CCR register. It is exited by setting the ABORT bit of the QUADSPI_CR.

When the QUADSPI operates in free-running clock mode:

- the clock is running continuously
- NCS stays high (external device deselected)
- data lines are released (High-Z)
- the BUSY flag of QUADSPI_SR is set

24.3.9 QUADSPI flash memory configuration

The device configuration register (QUADSPI_DCR) can be used to specify the characteristics of the external SPI flash memory.

The FSIZE[4:0] bitfield defines the size of external memory using the following formula:

\[ \text{Number of bytes in flash memory} = 2^{(FSIZE+1)} \]

FSIZE+1 is effectively the number of address bits required to address the flash memory. The flash memory capacity can be up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DFM = 1, FSIZE indicates the total capacity of the two flash memories together.

When the QUADSPI executes two commands, one immediately after the other, it raises NCS high between the two commands for only one CLK cycle by default. If the flash
memory requires more time between commands, the CSHT bitfield can be used to specify the minimum number of CLK cycles (up to 8) that NCS must remain high.

The clock mode (CKMODE) bit indicates the CLK signal logic level in between commands (when NCS = 1).

24.3.10 QUADSPI delayed data sampling

By default, the QUADSPI samples the data driven by the flash memory one half of a CLK cycle after the flash memory drives the signal.

In case of external signal delays, it may be beneficial to sample the data later. Using SSHIFT (bit 4 of QUADSPI_CR), the sampling of the data can be shifted by half of a CLK cycle.

Clock shifting is not supported in DDR mode: SSHIFT must be clear when DDRM bit is set.

24.3.11 QUADSPI configuration

The QUADSPI configuration is done in two phases:
1. QUADSPI peripheral configuration
2. QUADSPI flash memory configuration

Once configured and enabled, the QUADSPI can be used in one of its three operating modes: indirect, automatic status-polling, or memory-mapped mode.

QUADSPI configuration

The QUADSPI is configured using QUADSPI_CR. The user must configure the clock prescaler division factor and the sample shifting settings for the incoming data.

The DDR mode can be set through the DDRM bit. When setting the quad-SPI interface in DDR mode, the internal divider of kernel clock must be set with a division ratio of two or more. Once enabled, the address and the alternate bytes are sent on both clock edges, and the data are sent/received on both clock edges. Regardless of the DDRM bit setting, instructions are always sent in SDR mode.

The FIFO level for either MDMA trigger generation or interrupt generation is programmed in the FTHRES bits.

If a timeout counter is needed, the TCEN bit can be set and the timeout value programmed in the QUADSPI_LPTR register.

The dual-flash mode can be activated by setting DFM to 1.

QUADSPI flash memory configuration

The parameters related to the targeted external flash memory are configured through the QUADSPI_DCR register. The user must program the flash memory size in the FSIZE bits, the chip-select minimum high time in CSHT bits, and the functional mode (Mode 0 or Mode 3) in the MODE bit.

24.3.12 QUADSPI use

The operating mode is selected using FMODE[1:0] (QUADSPI_CCR[27:26]).
Indirect mode

When FMODE is programmed to 00, the indirect-write mode is selected and data can be sent to the flash memory. With FMODE = 01, the indirect-read mode is selected where data can be read from the flash memory.

When the QUADSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in QUADSPI_DLR.
2. Specify the frame format, mode and instruction code in QUADSPI_CCR.
3. Specify optional alternate byte to be sent right after the address phase in QUADSPI_ABR.
4. Specify the operating mode in QUADSPI_CR.
5. Specify the targeted address in QUADSPI_AR.
6. Read/write the data from/to the FIFO through QUADSPI_DR.

When writing QUADSPI_CR, the user specifies the following settings:
- enable bit (EN) set to 1
- timeout counter enable bit (TCEN)
- sample shift setting (SShift)
- FIFO threshold level (FTRHES) to indicate when the FTF flag must be set
- interrupt enables
- automatic status-polling mode parameters: match mode and stop mode (valid when FMODE = 11)
- clock prescaler

When writing QUADSPI_CCR, the user specifies the following parameters:
- instruction byte through INSTRUCTION bits
- the way the instruction has to be sent through the IMODE bits (1/2/4 lines)
- the way the address has to be sent through the ADMODE bits (None/1/2/4 lines)
- address size (8/16/24/32-bit) through ADSIZE bits
- the way the alternate bytes have to be sent through the ABMODE (None/1/2/4 lines)
- alternate bytes number (1/2/3/4) through the ABSIZE bits
- presence or not of dummy bytes through the DBMODE bit
- number of dummy bytes through the DCYC bits
- the way data have to be sent/received (none/1/2/4 lines) through DMODE bits

If neither QUADSPI_AR nor QUADSPI_DR need to be updated for a particular command, then the command sequence starts as soon as QUADSPI_CCR is written. This is the case when both ADMODE and DMODE are 00, or if just ADMODE = 00 when in indirect read mode (FMODE = 01).

When an address is required (ADMODE is not 00) and the data register does not need to be written (when FMODE = 01 or DMODE = 00), the command sequence starts as soon as the address is updated with a write to QUADSPI_AR.

In case of data transmission (FMODE = 00 and DMODE! = 00), the communication start is triggered by a write in the FIFO through QUADSPI_DR.
Automatic status-polling mode

This mode is enabled setting the FMODE bitfield (QUADSPI_CCR[27:26]) to 10. In this mode, the programmed frame is sent and the data retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in QUADSPI_DLR, it is ignored and only 4 bytes are read.

The periodicity is specified in the QUADSPI_PISR register.

Once the status data is retrieved, it can internally be processed:
- to set the status match flag and generate an interrupt if enabled
- to stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in QUADSPI_PSMKR and ORed or ANDed with the value stored in QUADSPI_PSMAR.

In case of match, the status match flag is set and an interrupt is generated if enabled, and the QUADSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in QUADSPI_DR.

Memory-mapped mode

In memory-mapped mode, the external flash memory is seen as an internal memory but with some latency during accesses. Only read operations are allowed to the external flash memory in this mode.

The memory-mapped mode is entered by setting FMODE to 11 in QUADSPI_CCR.

The programmed instruction and frame is sent when a master is accessing the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate linear reads. Any access to QUADSPI_DR in this mode returns zero.

QUADSPI_DLR has no meaning in memory-mapped mode.

24.3.13 Sending the instruction only once

Some flash memories (for example: Winbound) provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. One can take advantage of such a feature using the SIOO bit (QUADSPI_CCR[28]).

SIOO is valid for all functional modes (indirect, automatic status-polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to QUADSPI_CCR. Subsequent command sequences skip the instruction phase, until there is a write to QUADSPI_CCR.

SIOO has no effect when IMODE = 00 (no instruction).
24.3.14 QUADSPI error management

An error can be generated in the following case:

- In indirect mode or automatic status-polling mode when a wrong address is programmed in QUADSPI_AR (according to the flash memory size defined by FSIZE[4:0] in the QUADSPI_DCR), TEF is set and an interrupt is generated if enabled.
  Also in indirect mode, if the address plus the data length exceeds the flash memory size, TEF is set as soon as the access is triggered.
- In memory-mapped mode, when an out-of-range access is done by a master or when the QUADSPI is disabled, a bus error is generated as a response to the faulty bus master request.

When a master is accessing the memory mapped space while the memory-mapped mode is disabled, a bus error is generated as a response to the faulty bus master request.

24.3.15 QUADSPI busy bit and abort functionality

Once the QUADSPI starts an operation with the flash memory, the BUSY bit is automatically set in QUADSPI_SR.

In indirect mode, BUSY is reset once the QUADSPI has completed the requested command sequence, and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

Any operation can be aborted by setting the ABORT bit in QUADSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Note: Some flash memories may misbehave if a write operation to a status registers is aborted.

24.3.16 NCS behavior

By default, NCS is high, deselecting the external flash memory. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (“mode0”, where CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge, as shown in the figure below.

![Figure 136. NCS when CKMODE = 0 (T = CLK period)](MS35319v2.png)
When CKMODE=1 ("mode3", where CLK goes high when no operation is in progress) and DDRM=0 (SDR mode), NCS still falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge, as shown in the figure below.

**Figure 137. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

When CKMODE = 1 ("mode3") and DDRM = 1 (DDR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge, as shown in the figure below. Because DDR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 138. NCS when CKMODE = 1 in DDR mode (T = CLK period)**

When the FIFO stays full in a read operation or if the FIFO stays empty in a write operation, the operation stalls and CLK stays low until firmware services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later, as shown in **Figure 139**.
When not in dual-flash mode (DFM = 0) and FSEL = 0 (default value), only FLASH 1 is accessed. Thus BK2_NCS stays high, if FSEL = 1, only FLASH 2 is accessed and BK1_NCS stays high. In dual-flash mode, BK2_NCS behaves exactly the same as BK1_NCS. Thus, if there is a FLASH 2 and if the application is dual-flash mode only, then BK1_NCS signal can be used for FLASH 2 as well, and the pin devoted to BK2_NCS can be used for other functions.

24.4 QUADSPI interrupts

An interrupt can be produced on the following events:
- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Bits 31:24** **PRESCALER[7:0]: Clock prescaler**  
This bitfield defines the scaler factor for generating CLK based on the quadspi\_ker\_ck clock (value+1).  
0: \( F_{CLK} = F_{quadspi\_ker\_ck} \), quadspi\_ker\_ck clock used directly as QUADSPI CLK (prescaler bypassed)  
1: \( F_{CLK} = F_{quadspi\_ker\_ck}/2 \)  
2: \( F_{CLK} = F_{quadspi\_ker\_ck}/3 \)  
...  
255: \( F_{CLK} = F_{quadspi\_ker\_ck}/256 \)  
For odd clock division factors, CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.  
When setting quad-SPI interface in DDR mode, the prescaler must be set with a division ratio of two or more.  
*Note:* This bitfield can be modified only when BUSY = 0.

**Bit 23** **PMM: Polling match mode**  
This bit indicates which method must be used for determining a “match” during automatic status-polling mode.  
0: AND match mode. SMF is set if all the unmasked bits received from the flash memory match the corresponding bits in the match register.  
1: OR match mode. SMF is set if any one of the unmasked bits received from the flash memory matches its corresponding bit in the match register.  
*Note:* This bit can be modified only when BUSY = 0.

**Bit 22** **APMS: Automatic status-polling mode stop**  
This bit determines if automatic status-polling is stopped after a match.  
0: Automatic status-polling mode is stopped only by abort or by disabling the QUADSPI.  
1: Automatic status-polling mode stops as soon as there is a match.  
*Note:* This bit can be modified only when BUSY = 0.

**Bit 21** Reserved, must be kept at reset value.

**Bit 20** **TOIE: Timeout interrupt enable**  
This bit enables the timeout interrupt.  
0: Interrupt disabled  
1: Interrupt enabled
Bit 19  **SMIE**: Status match interrupt enable  
This bit enables the status match interrupt.  
0: Interrupt disabled  
1: Interrupt enabled  

Bit 18  **FTIE**: FIFO threshold interrupt enable  
This bit enables the FIFO threshold interrupt.  
0: Interrupt disabled  
1: Interrupt enabled  

Bit 17  **TCIE**: Transfer complete interrupt enable  
This bit enables the transfer complete interrupt.  
0: Interrupt disabled  
1: Interrupt enabled  

Bit 16  **TEIE**: Transfer error interrupt enable  
This bit enables the transfer error interrupt.  
0: Interrupt disabled  
1: Interrupt enabled  

Bits 15:13  Reserved, must be kept at reset value.  

Bits 12:8  **FTHRES[4:0]**: FIFO threshold level  
This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag (bit FTF in register QUADSPI_SR) to be set.  
0: In indirect-write mode (FMODE = 00), FTF is set if there are one or more free bytes location left in the FIFO, or indirect-read mode (FMODE = 01), FTF is set if there are one or more valid bytes that can be read from the FIFO.  
1: In indirect-write mode (FMODE = 00), FTF is set if there are two or more free bytes location left in the FIFO, or indirect-read mode (FMODE = 01), FTF is set if there are two or more valid bytes that can be read from the FIFO  
...  
31: In indirect-write mode (FMODE = 00), FTF is set if there are 32 free bytes location left in the FIFO, or indirect-read mode (FMODE = 01), FTF is set if there are 32 valid bytes that can be read from the FIFO.  

Bit 7  **FSEL**: Flash memory selection  
This bit selects the flash memory to be addressed in single-flash mode (when DFM = 0).  
0: FLASH 1 selected  
1: FLASH 2 selected  

**Note**: This bit can be modified only when BUSY = 0. This bit is ignored when DFM = 1.  

Bit 6  **DFM**: Dual-flash mode  
This bit activates dual-flash mode, where two external flash memories are used simultaneously to double throughput and capacity.  
0: Dual-flash mode disabled  
1: Dual-flash mode enabled  

**Note**: This bit can be modified only when BUSY = 0.  

Bit 5  Reserved, must be kept at reset value.
Bit 4  **SSHIFT**: Sample shift

By default, the QUADSPI samples data 1/2 of a CLK cycle after the data is driven by the flash memory. This bit allows the data to be sampled later in order to account for external signal delays.
0: No shift
1: 1/2 cycle shift

The firmware must assure that SSHIFT = 0 when in DDR mode (when DDRM = 1).

*Note: This bitfield can be modified only when BUSY = 0.*

Bit 3  **TCEN**: Timeout counter enable

This bit is valid only when memory-mapped mode (FMODE = 11) is selected. Activating this bit causes the NCS to be released (and thus reduces consumption) if there has not been an access after a certain amount of time, where this time is defined by TIMEOUT[15:0] (QUADSPI_LPTR). This bit enables the timeout counter.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with NCS maintained low, even if no access to the flash memory occurs for a long time. Since flash memories tend to consume more when NCS is held low, the application may want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI_CR) so that NCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without an access since when the FIFO becomes full with prefetch data.
0: Timeout counter is disabled, and thus the NCS remains active indefinitely after an access in memory-mapped mode.
1: Timeout counter is enabled, and thus the NCS is released in memory-mapped mode after TIMEOUT[15:0] cycles of flash memory inactivity.

*Note: This bit can be modified only when BUSY = 0.*

Bit 2  Reserved, must be kept at reset value.

Bit 1  **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is complete. This bit stops the current transfer.

In automatic status-polling or memory-mapped mode, this bit also reset APM or DM bit.
0: No abort requested
1: Abort requested

Bit 0  **EN**: QUADSPI enable

0: QUADSPI disabled
1: QUADSPI enabled

Bits 31:21  Reserved, must be kept at reset value.
24.5.3 QUADSPI status register (QUADSPI_SR)

Address offset: 0x008
Reset value: 0x0000 0000

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 FLEVEL[5:0]: FIFO level
This bitfield gives the number of valid bytes which are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full. In memory-mapped mode and in automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 BUSY: Busy
This bit is set when an operation is on going. This bit clears automatically when the operation with the flash memory is finished and the FIFO is empty.

Bit 4 TOF: Timeout flag
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.
Bit 3 **SMF:** Status match flag
This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (QUADSPI_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 **FTF:** FIFO threshold flag
In indirect mode, this bit is set when the FIFO threshold is reached, or if there is any data left in the FIFO after reads from the flash memory are complete. It is cleared automatically as soon as threshold condition is no longer true.

In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF:** Transfer complete flag
This bit is set in indirect mode when the programmed number of data is transferred or in any mode when the transfer is aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF:** Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

</tr>
</tbody>
</table>

Bits 31:0 DL[31:0]: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes.
A value no greater than 3 (indicating 4 bytes) must be used for automatic status-polling mode.
All 1s in indirect mode means undefined length, where the QUADSPI continues until the end of memory, as defined by FSIZE.
0x0000_0000: 1 byte is to be transferred
0x0000_0001: 2 bytes are to be transferred
0x0000_0002: 3 bytes are to be transferred
0x0000_0003: 4 bytes are to be transferred
...
0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred
0xFFFF_FFFF: undefined length -- all bytes until the end of flash memory (as defined by FSIZE) are to be transferred. Continue reading indefinitely if FSIZE = 0x1F.
DL[0] is stuck at 1 in dual-flash mode (DFM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.
This bitfield has no effect when in memory-mapped mode (FMODE = 10).

*Note: This bitfield can be written only when BUSY = 0.*

</table>

Bit 31 DDRM: Double data rate mode
This bit sets the DDR mode for the address, alternate byte and data phase:
0: DDR mode disabled
1: DDR mode enabled

*Note: This bit can be written only when BUSY = 0.*
Bit 30  DHHC: DDR hold
This bit delays the data output by 1/4 of the QUADSPI output clock cycle in DDR mode:
0: Data output delayed using analog delay
1: Data output delayed by 1/4 of a QUADSPI output clock cycle
This feature is only active in DDR mode.
Note: This bit can be written only when BUSY = 0.
   PRESCALER > 0 is mandatory when DHHC = 1.

Bit 29  FRCM: Free-running clock mode
When this bit is set, the QUADSPI enters free-running clock mode regardless of FMODE bits.
0: Normal mode
1: Free-running clock mode
Note: This bit can be written only when BUSY = 0.

Bit 28  SIOO: Send instruction only once mode
This bit has no effect when IMODE = 00. See Section 24.3.13 for more details.
0: Instruction sent on every transaction
1: Instruction sent only for the first command
Note: This bit can be written only when BUSY = 0.

Bits 27:26  FMODE[1:0]: Functional mode
This bitfield defines the QUADSPI functional mode of operation.
00: Indirect-write mode
01: Indirect-read mode
10: Automatic status-polling mode
11: Memory-mapped mode
Note: This bitfield can be written only when BUSY = 0.

Bits 25:24  DMODE[1:0]: Data mode
This bitfield defines the data phase mode of operation:
00: No data
01: Data on a single line
10: Data on two lines
11: Data on four lines
This bitfield also determines the dummy phase mode of operation.
Note: This bitfield can be written only when BUSY = 0.

Bit 23  Reserved, must be kept at reset value.

Bits 22:18  DCYC[4:0]: Number of dummy cycles
This bitfield defines the duration of the dummy phase. In both SDR and DDR modes, it specifies a number of CLK cycles (0-31).
Note: This bitfield can be written only when BUSY = 0.

Bits 17:16  ABSIZE[1:0]: Alternate-byte size
This bit defines the size of alternate bytes.
00: 8-bit alternate byte
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes
Note: This bitfield can be written only when BUSY = 0.
Bits 15:14 **ABMODE[1:0]:** Alternate byte mode
This bitfield defines the alternate-byte phase mode of operation.
00: No alternate bytes
01: Alternate bytes on a single line
10: Alternate bytes on two lines
11: Alternate bytes on four lines
*Note:* This bitfield can be written only when BUSY = 0.

Bits 13:12 **ADSIZE[1:0]:** Address size
This bit defines address size:
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address
*Note:* This bitfield can be written only when BUSY = 0.

Bits 11:10 **ADMODE[1:0]:** Address mode
This bitfield defines the address phase mode of operation.
00: No address
01: Address on a single line
10: Address on two lines
11: Address on four lines
*Note:* This bitfield can be written only when BUSY = 0.

Bits 9:8 **IMODE[1:0]:** Instruction mode
This bitfield defines the instruction phase mode of operation.
00: No instruction
01: Instruction on a single line
10: Instruction on two lines
11: Instruction on four lines
*Note:* This bitfield can be written only when BUSY = 0.

Bits 7:0 **INSTRUCTION[7:0]:** Instruction
Instruction to be sent to the external SPI device.
*Note:* This bitfield can be written only when BUSY = 0.

### 24.5.7 QUADSPI address register (QUADSPI_AR)

**Address offset:** 0x018

**Reset value:** 0x0000 0000

**Notes:**
- Bits can be written only when BUSY = 0.
24.5.8 QUADSPI alternate-byte register (QUADSPI_ABR)

Address offset: 0x01C
Reset value: 0x0000 0000

Bits 31:0 ADDRESS[31:0]: Address
This bitfield contains the address to be sent to the external flash memory.
Writes to this bitfield are ignored when BUSY = 1 or when FMODE = 11 (memory-mapped mode).
In dual flash mode, ADDRESS[0] is automatically stuck to 0 as the address must always be even.

24.5.9 QUADSPI data register (QUADSPI_DR)

Address offset: 0x020
Reset value: 0x0000 0000

Bits 31:0 ALTERNATE[31:0]: Alternate bytes
Optional data to be send to the external SPI device right after the address.
Note: This bitfield can be written only when BUSY = 0.
24.5.10 QUADSPI polling status mask register (QUADSPI_PSMKR)

Address offset: 0x024
Reset value: 0x0000 0000

Bits 31:0 \(\text{DATA}[31:0]\): Data
Data to be sent/received to/from the external SPI device.
In indirect write mode, data written to this register is stored on the FIFO before it is sent to the flash memory during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In indirect read mode, reading this register gives (via the FIFO) the data which was received from the flash memory. If the FIFO does not have as many bytes as requested by the read operation and if \(\text{BUSY}=1\), the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In automatic status-polling mode, this register contains the last data read from the flash memory (without masking).
Word, halfword, and byte accesses to this register are supported. In indirect write mode, a byte write adds 1 byte to the FIFO, a halfword write 2, and a word write 4. Similarly, in indirect read mode, a byte read removes 1 byte from the FIFO, a halfword read 2, and a word read 4.
Accesses in indirect mode must be aligned to the bottom of this register: a byte read must read \(\text{DATA}[7:0]\) and a halfword read must read \(\text{DATA}[15:0]\).

Bits 31:0 \(\text{MASK}[31:0]\): Status mask
Mask to be applied to the status bytes received in automatic status-polling mode.
For bit \(n\):
0: Bit \(n\) of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic
1: Bit \(n\) of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic

Note: This bitfield can be written only when \(\text{BUSY} = 0\).

24.5.11 QUADSPI polling status match register (QUADSPI_PSMAR)

Address offset: 0x028
Reset value: 0x0000 0000

Bits 31:0 \(\text{MATCH}[31:0]\): Status mask
Mask to be applied to the status bytes received in automatic status-polling mode.
For bit \(n\):
0: Bit \(n\) of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic
1: Bit \(n\) of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic

Note: This bitfield can be written only when \(\text{BUSY} = 0\).
Bits 31:0 MATCH[31:0]: Status match
   Value to be compared with the masked status register to get a match.
   *Note: This bitfield can be written only when BUSY = 0.*

### 24.5.12 QUADSPI polling interval register (QUADSPI_PIR)

Refer to Section 2.3 for the register boundary addresses.
25 Delay block (DLYB)

25.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Quad-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

25.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

25.3 DLYB functional description

25.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

![DLYB block diagram](image-url)
25.3.2 DLYB pins and internal signals

*Table 205* lists the DLYB internal signals.

<table>
<thead>
<tr>

<td>Digital input</td>
<td>Delay block input clock</td>
</tr>
<tr>
<td>dlyb_out_ck</td>
<td>Digital output</td>
<td>Delay block output clock</td>
</tr>
</tbody>
</table>

25.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFR).

*Note:* UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFR register.

*Note:* SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= Input clock)</td>
</tr>
<tr>
<td>x</td>
<td>1</td>
<td>Unit delay</td>
<td>Output clock phase</td>
<td>Length</td>
<td>Length flag</td>
<td>Disabled</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Unit delay (1)</td>
<td>Output clock phase (2)</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.
25.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.

5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

25.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.
25.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

25.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

| Bit 31-2 | Reserved, must be kept at reset value. |
| Bit 1   | SEN: Sampler length enable bit |
| 0       | Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled. |
| 1       | Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled. |

Bit 0 DEN: Delay block enable bit

0: DLYB disabled.
1: DLYB enabled.

25.4.2 DLYB configuration register (DLYB_CFG)

Address offset: 0x004

Reset value: 0x0000 0000

| Bit 31 | LNGF: Length valid flag |
| 0      | This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed. |
| 1      | Length value in LNG is valid. |

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 LNG[11:0]: Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.
Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **UNIT[6:0]**: Delay of a unit delay cell.
These bits can only be written when SEN = 1.
Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **SEL[3:0]**: Phase for the output clock.
These bits can only be written when SEN = 1.
Output clock phase = input clock + SEL[3:0] x unit delay

### 25.4.3  DLYB register map

**Table 207. DLYB register map and reset values**

| Offset  | Register name | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

|         | Reset value   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x004   | DLYB_CFGR     | LNG |     |     | LNG[11:0] | UNIT[6:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         | Reset value   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

Refer to *Section 2.3 on page 134* for the register boundary addresses.
26 Analog-to-digital converters (ADC)

26.1 Introduction

This section describes the ADC implementation:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 is instantiated separately.

Each ADC consists of a 16-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
26.2 ADC main features

- High-performance features
  - Up to 2x ADCs which can operate in dual mode
  - 16, 14, 12, 10 or 8-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Can manage single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by GP-DMA for regular channel conversions with FIFO
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels

- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024x
  - Programmable data right and left shift

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- Each ADC features an external analog input channel
  - Up to 6 fast channels from dedicated GPIO pads
  - Up to 14 slow channels from dedicated GPIO pads

- In addition, there are 5 internal dedicated channels
  - Internal reference voltage ($V_{REFINT}$)
  - Internal temperature sensor ($V_{SENSE}$)
  - $V_{BAT}$ monitoring channel ($V_{BAT}/4$)
  - Connection to DAC internal channels

- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
Analog-to-digital converters (ADC)

- Single mode converts selected inputs once per trigger
- Continuous mode converts selected inputs continuously
- Discontinuous mode

- Dual ADC mode for ADC1 and 2
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{\text{REF}_-} \leq V_{\text{IN}} \leq V_{\text{REF}_+}$

Figure 141 shows the block diagram of one ADC.

26.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see Figure 142: ADC Clock scheme):

1. The ADC clock can be a specific clock source, named adc_ker_ck_input which is independent and asynchronous with the AHB clock.
   It can be configured in the RCC (refer to RCC Section for more information on how to generate the ADC clock (adc_ker_ck_input) dedicated clock).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the system clock or system clock divided by two (adc_sclk). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be different from "00". adc_sclk is equal to sys_ck when HPRE is set to 0, otherwise it corresponds to sys_ck/2.

In both case, the clock divider factor of 2 is applied to the clock provided to the ADC analog block (fadc_ker_ck).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of using the system without additional PLL. In addition, when adc_sclk is twice faster than the adc_hclk clock, the latency between the trigger and the start of conversion is fixed. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock configured through CKMODE[1:0] bits must be compliant with the analog ADC operating frequency specified in the product datasheet.

Note: \( \text{adc\_sclk} \) is the system clock or system clock divided by two: when the AHB prescaler is set to 1 (\( \text{HPRE}[3:0] = 0XXX \) in RCC\_CFGR register), \( \text{adc\_sclk} \) is equal to \( \text{sys\_ck} \), otherwise \( \text{adc\_sclk} \) corresponds to \( \text{sys\_ck}/2 \).

Figure 142. ADC Clock scheme

1. Refer to the RCC section to see how \( \text{adc\_hclk} \) and \( \text{adc\_ker\_ck\_input} \) can be generated.

Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( F_{\text{adc\_hclk}} \geq F_{\text{adc\_ker\_ck}} / 4 \) if the resolution of all channels are 16-bit, 14-bit, 12-bit or 10-bit
- \( F_{\text{adc\_hclk}} \geq F_{\text{adc\_ker\_ck}} / 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio, for all ADC interfaces.

BOOST control

The ADC boost mode can be controlled through the BOOST bitfield in the ADC\_CR register. This bitfield must be set according to the ADC clock setting. Refer to the ADC\_CR register description.
26.4.4 ADC1/2/3 connectivity

ADC1 and ADC2 are tightly coupled and share some external channels as described in the following figures.

ADC3 is instantiated separately, but some inputs are shared with ADC1 and ADC2.

Figure 143. ADC1 connectivity

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
Figure 144. ADC2 connectivity

1. ADCx INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
Figure 145. ADC3 connectivity

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
26.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

26.4.6 ADC deep-power-down mode (DEEPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit deep-power-down mode by clearing bit DEEPWD=0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN=1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

The LDO status can be verified by checking the LDORDY bit in ADC_ISR register (refer to Section 26.3: ADC implementation for the availability of the LDO regulator status).

For the startup time of the ADC voltage regulator, refer to device datasheet for $T_{ADCVREG_STUP}$ parameter.

After ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC deep-power-down mode by setting bit DEEPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

Note: When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC deep-power-down mode (DEEPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or apply again the calibration factor which was previously saved (refer to Section 26.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)).
26.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by writing into bits DIFSEL[19:0] in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{\text{INP}[i]}$ (positive input) and $V_{\text{REF}-}$ (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{\text{INP}[i]}$ (positive input) and $V_{\text{INN}[i]}$ (negative input).

The output data for the differential mode is an unsigned data. When $V_{\text{INP}[i]}$ equals $V_{\text{REF}-}$, $V_{\text{INN}[i]}$ equals $V_{\text{REF}+}$ and the output data is 0x0000 (16-bit resolution mode). When $V_{\text{INP}[i]}$ equals $V_{\text{REF}+}$, $V_{\text{INN}[i]}$ equals $V_{\text{REF}-}$ and the output data is 0xFFFF.

When ADC is configured as differential mode, both input should be biased at $V_{\text{REF}+}/2$ voltage.

The input signal are supposed to be differential (common mode voltage should be fixed).

For a complete description of how the input channels are connected for each ADC, refer to Section 26.4.4: ADC1/2/3 connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage is connected to $V_{\text{INN}[i]}$. As a consequence, channel “i+n”, which is connected to $V_{\text{INN}[i]}$, should not be converted at same time by different ADCs. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable.

26.4.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 11-bits of offset or 160-bits of linearity and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

The calibration is preliminary to any ADC operation. It removes the systematic errors which may vary from chip to chip and allows to compensate offset and linearity deviation.

The calibration factor for the offset to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which is applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which is applied for differential input conversions.
The linearity correction must be done once only, regardless of single / differential configuration.

- Write ADCALLIN = 1 before launching a calibration which runs the linearity calibration same time as the offset calibration.
- Write ADCALLIN = 0 before launching a calibration which does not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting bit ADCAL=1. It can be initiated only when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[10:0] or CALFACT_D[10:0] of ADC_CALFACT register (depending on single-ended or differential input calibration). The 160-bit linearity calibration factor can be accessed using the ADC_CALFACT2 register with ADEN set to 1.

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, it is recommended that a new offset calibration cycle is run before enabling again the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT and ADC_CALFACT2 register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

Refer to the datasheets for the clock cycle requirement for both linear and offset calibration.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD=0, ADVREGEN=1 and verify that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 26.3: ADC implementation for the availability of the LDO regulator status).
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (single-ended input) or ADCALDIF=1 (Differential input). Select if Linearity calibration enable or not by ADCALLIN=1(enabled) or ADCALLIN=0(disabled).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The offset calibration factor can be read from ADC_CALFACT register.
7. The linearity calibration factor can be read from ADC_CALFACT2 register, following the procedure described in Section : Linearity calibration reading procedure (ADEN must be set to 1 prior to accessing ADC_CALFACT2 register).
Software procedure to re-inject a calibration factor into the ADC

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new offset calibration factors.
3. Write LINCALFACT bits with the new linearity calibration factors, following the procedure described in Section : Linearity calibration writing procedure.
4. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 147. Updating the ADC offset calibration factor

![Diagram showing the updating of the ADC offset calibration factor.](MSv41022V1)
Calibrating single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0) and Linearity calibration enable (with ADCALLIN=1). This updates the registers CALFACT_S[10:0] and LINCALFACT[159:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF=1) and Linearity calibration disable (with ADCALLIN=0). This updates the register CALFACT_D[10:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.

Figure 148. Mixing single-ended and differential channels
Linearity calibration reading procedure

Once the calibration is done (ADCAL bit cleared by hardware) with ADCALLIN=1, the 160-bit linearity correction factor can be read using the ADC_CALFACT2 30-bit registers (6 read accesses are necessary).

The six LINCALRDYW1..6 control/status bits in ADC_CR are set when the calibration is complete. When ADEN is set to 1, clearing one of these bits launches the transfer of part of the linearity factor into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit is reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared). The complete procedure is as following:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 26.3: ADC implementation for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
4. Poll LINCALRDYW6 bit until returned value is zero, indicating linearity correction bits[159:150] are available in ADC_CALFACT2[29:0].
5. Read ADC_CALFACT2[29:0].
7. Poll LINCALRDYW5 bit until returned value is zero, indicating linearity correction bits[149:120] are available in ADC_CALFACT2[29:0].
8. Read ADC_CALFACT2[29:0].
10. Poll LINCALRDYW4 bit until returned value is zero, indicating linearity correction bits[119:90] are available in ADC_CALFACT2[29:0].
11. Read ADC_CALFACT2[29:0].
13. Poll LINCALRDYW3 bit until returned value is zero, indicating linearity correction bits[89:60] are available in ADC_CALFACT2[29:0].
14. Read ADC_CALFACT2[29:0].
15. Clear LINCALRDYW2 bit.
16. Poll LINCALRDYW2 bit until returned value is zero, indicating linearity correction bits[59:30] are available in ADC_CALFACT2[29:0].
17. Read ADC_CALFACT2[29:0].
18. Clear LINCALRDYW1 bit.
19. Poll LINCALRDYW1 bit until returned value is zero, indicating linearity correction bits[29:0] are available in ADC_CALFACT2[29:0].
20. Read ADC_CALFACT2[29:0].

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.
The software can access the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
Linearity calibration writing procedure

The six LINCALRDYW1..6 control/status bits in ADC_CR are reset when the calibration has not yet been done or a new linearity calibration factor have been rewritten. It is possible to force directly a linearity calibration factor or re-inject it using the following procedure:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 26.3: ADC implementation for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
3. Write ADC_CALFACT2[9:0] with previously saved linearity correction factor bits[159:150].
4. Set LINCALRDYW6 bit.
5. Poll LINCALRDYW6 bit until returned value is one, indicating linearity correction bits[159:150] have been effectively written.
6. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[149:120].
7. Set LINCALRDYW5 bit.
8. Poll LINCALRDYW5 bit until returned value is one, indicating linearity correction bits[149:120] have been effectively written.
9. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[119:90].
10. Set LINCALRDYW4 bit.
11. Poll LINCALRDYW4 bit until returned value is one, indicating linearity correction bits[119:90] have been effectively written.
12. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[89:60].
13. Set LINCALRDYW3 bit.
14. Poll LINCALRDYW3 bit until returned value is one, indicating linearity correction bits[89:60] have been effectively written.
15. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[59:30].
17. Poll LINCALRDYW2 bit until returned value is one, indicating linearity correction bits[59:30] have been effectively written.
18. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[29:0].
19. Set LINCALRDYW1 bit.
20. Poll LINCALRDYW1 bit until returned value is one, indicating linearity correction bits[29:0] have been effectively written.

Note: The software is allowed to toggle a single LINCALRDYWy bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software is allowed to update the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
26.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 26.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of $t_{\text{STAB}}$ before it starts converting accurately, as shown in Figure 149. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to Section 26.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN=0).

![Figure 149. Enabling / Disabling the ADC](MSv30264V2)
26.4.10 Constraints when writing the ADC control bits

The software can write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the control bits DIFSEL in the ADC_DIFSEL register, ADCx_CCR register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRy, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and eventually converting and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1).

The software is allowed to write the ADC_JSQR register only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).

26.4.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:

- 6 fast analog inputs coming from Analog PADs and GPIO pads (ADCx_INP/INN[0..5])
- Up to 14 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6..19]).
- The ADCs are connected to 5 internal analog inputs:
  - the internal temperature sensor (VSENSE)
  - the internal reference voltage (VREFINT)
  - the VBAT monitoring channel (VBAT/4)
  - DAC internal channels

Refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order:
ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to Section 26.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 only when the context queue is enabled (JQDIS=0 in ADC_CFGR register).

**Temperature sensor, VREFINT and VBAT internal channels**

The internal reference voltage (VREFINT), the temperature sensor (VSENSE), and the VBAT channel are connected to ADC internal channels. Refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals for details.

**Note:** To convert one of the internal analog channels, enable the corresponding analog sources by programming VREFEN, TSEN and VBATEN bits in the ADCx_CCR registers.

### 26.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx, the corresponding ADC_PCSEL bit must be previously configured.

This ADC_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input MUX selects the ADC input according to the SQRx and JSQRx with very high speed, the analog switch integrated in the I/O cannot react as fast as ADC mux does. To avoid the delay on analog switch control on I/O, it is necessary to preselect the input channels which are selected in the SQRx, JSQRx.

The selection is based on the VINP[i] of each ADC input. If ADC1 converts the ADC123_INP2(VINP[2]) as differential mode, ADC123_INP6(VINP[6]) also needs to be selected in ADC_PCSEL.

Some I/Os are connected to several VINP[i] of the ADCx. The control inputs of the analog switch are ORed with the corresponding ADC_PCSEL register bits.
26.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 8.5 ADC clock cycles
- SMP = 011: 16.5 ADC clock cycles
- SMP = 100: 32.5 ADC clock cycles
- SMP = 101: 64.5 ADC clock cycles
- SMP = 110: 387.5 ADC clock cycles
- SMP = 111: 810.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{CONV} = \text{Sampling time} + 7.5 \text{ ADC clock cycles} \]

Example:

With \( F_{adc_{\text{ker}}_{ck}} = 24 \text{ MHz} \) and a sampling time of 1.5 ADC clock cycles (14-bit mode):

\[ T_{CONV} = (1.5 + 7.5) \text{ ADC clock cycles} = 9 \text{ ADC clock cycles} = 0.375 \mu\text{s} \] (14 bit mode for fast channels)

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time for fast and slow channels

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the \( V_{DDA} \) voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low \( V_{DDA} \) voltage by enabling an internal voltage booster through the BOOSTE bit of the SYSCFG_PMCR register.
26.4.14 Single conversion mode (CONT=0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)

ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

26.4.15 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set
Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

**Note:**
To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

*Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section.*

### 26.4.16 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN /= 0x0

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN /= 0x0

**Note:**
In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software trigger (CONT=0, EXTEN=0x0)
  - at any end of conversion sequence (EOS =1)
- In discontinuous mode with software trigger (CONT=0, DISCEN=1, EXTEN=0x0)
  - at end of conversion (EOC=1)
- In all other cases (CONT=x, EXTEN=x)
  - after execution of the ADSTP procedure asserted by the software.

**Note:**
In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTEN /=0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- in single mode with software injected trigger (JEXTEN=0x0)
  - at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN=1
- in all cases (JEXTEN=x)
  - after execution of the JADSTP procedure asserted by the software.
Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.

26.4.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{CONV} = T_{SMPL} + T_{SAR} = [1.5 \text{ min} + 7.5 \text{ 14bit}] \times T_{adc\_ker\_ck}
\]

\[
T_{CONV} = T_{SMPL} + T_{SAR} = 62.5 \text{ ns min} + 312.5 \text{ ns 14bit} = 375.0 \text{ ns} \quad \text{(for } F_{adc\_ker\_ck} = 24 \text{ MHz)}
\]

26.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would re-start a new sequence).
Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

**Note:** In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

26.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

• If bit ADSTART=0, any regular hardware triggers which occur are ignored.
• If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 212 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

</tr>
</tbody>
</table>

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 26.4.22: Queue of context for injected conversions.

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which out of 21 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 26.4.22: Queue of context for injected conversions on page 983.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 153.

**Figure 153. Triggers are shared between ADC master and ADC slave**

Table 214 and Table 215 give all the possible external triggers of the three ADCs for regular and injected conversion.

26.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 154 shows the corresponding timing diagram.
**Note:** When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 20 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 21 ADC clock cycles.

**Auto-injection mode**

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

**Note:** It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

**Figure 154. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.
26.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (sub-group) of \( n \) conversions \((n \leq 8)\) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of \( n \) is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next \( n \) conversions selected in the ADC_SQR registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- DISCEN=1, \( n=3 \), channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ... 
- DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - all the next trigger events relaunch the complete sequence.

Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than \( n \) conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘\( n \)’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.
Example:
- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

26.4.22 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL[4:0] in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)

All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:
- The ADC_JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVMIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and
Hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.

- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):
  - 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out.
  - 2nd trigger, disc. Sequence 1: 2nd conversion.
  - 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
  - 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
  - 5th trigger, discontinuous. Sequence 2: 2nd conversion.
  - 6th trigger, discontinuous. Sequence 2: 3rd conversion.

Note: When queue of context enabled (bit JQDIS=0), only hardware trigger can be used.

**Behavior when changing the trigger or sequence context**

The Figure 155 and Figure 156 show the behavior of the context Queue when changing the sequence or the triggers.

---

**Figure 155. Example of JSQR queue of context (sequence change)**

<table>
<thead>
<tr>
<th>Write JSQR</th>
<th>P1</th>
<th>P2</th>
<th>P3</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>Trigger 1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADC J context (returned by reading JSQR)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADC state</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Parameters:
   - P1: sequence of 3 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 4 conversions, hardware trigger 1
Figure 156. Example of JSQR queue of context (trigger change)

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs

The Figure 157 and Figure 158 show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 157. Example of JSQR queue of context with overflow before conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1
Figure 158. Example of JSQR queue of context with overflow during conversion

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 3 conversions, hardware trigger 1
   - P4: sequence of 4 conversions, hardware trigger 1

It is recommended to manage the queue overflows as described below:
- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 159 and Figure 160 show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

Figure 159. Example of JSQR queue of context with empty queue (case JQM=0)

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1
Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

Figure 160. Example of JSQR queue of context with empty queue (case JQM=1)

Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 161. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.
Figure 162. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 163. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 164. Flushing JSQR queue of context by setting JADSTP=1 (JQM=1)

Queue is flushed and becomes empty (P2 is lost)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 165. Flushing JSQR queue of context by setting ADDIS=1 (JQM=0)

Queue is flushed and maintains the last active context (P2 which was not consumed is lost)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFRGR register.

Queue of context: Programming of the register ADC_JSQR

When the injected conversion queue of context is enabled (JQDIS=0), the ADC_JSQR must be programmed at one register write access. As JL[1:0] register define the number of the injected sequence, corresponding JSQ1 to JSQ4 must be written at same time. If ADC_JSQR is reprogrammed before the injected conversion start, reprogrammed data is put on the queue. When queue of context is empty, ADC_JSQR read back as 0x0000. Register access should not use the ‘read modify write’ sequence.

When ADC_JSQR is programmed when already two contexts are queued, it raises JQOVF flag and generate the interrupt.
26.4.23 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution. The resolution can be configured to be either 16, 14, 12, 10, 8 bits by programming the control bits RES[1:0]. Figure 171, Figure 172, Figure 173 and Figure 174 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 216.

26.4.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

26.4.25 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

26.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JE0C event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 171, Figure 172, Figure 173 and Figure 174.

Note: The data can be re-aligned in normal and in oversampling mode.
Offset

An offset $y$ (y=1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in OFFSETy[25:0] bitfield into ADC_OFRy register. The channel to which the offset is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[25:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

The offset value should be lower than the max conversion value (ex. 16bit mode, offset value max is 0xFFFF).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 217 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

<table>

</tbody>
</table>

When reading data from ADC_DR (regular channel) or from ADC_JDRy (injected channel, y=1,2,3,4), the offset compensation is disabled when ADC_OFRy[25:0] bitfield is reset. Otherwise, the offset for ADC_OFRy[30:26] channel is enabled.

### 16-bit and 8-bit signed format management: RSHIFTx, SSATE

The offset correction sign-extends the data format, resulting in an unsigned 16-bit conversion being extended to 17-bit signed format, for instance.

Three options are offered for formatting 8-bit and 16-bit conversion results.

MSv4.1027V2
For each offset correction channel 1 to 4, a RSHIFT1..4 bit in the ADC_CFGR2 register allows to have the result right-shifted 1-bit and have it fitting a standard 8 or 16-bit format.

Another option is to have the result saturated to the 16-bit and 8-bit signed formats, for the following cases only: RES[2:0] = 000 (16-bit format) and RES[2:0] = 111 (8-bit format).

This mode is enabled with the SSATE bit in the ADC_OFRy register.

The table below summarizes the 3 available use case for 16-bit format.

When oversampling mode is active, the SSATE and RSHIFT1..4 bits are not supported.
ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies of a buffer overrun event when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue to convert unless the software decides to stop and reset the sequence by setting ADSTP to 1.

OVR flag is cleared by software by writing 1 to it.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFRG register:

- **OVRMOD = 0**
  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (8 data) and the new conversion is discarded and lost. If OVR remains at 1, any further conversion is be performed but the resulting data is also discarded.

- **OVRMOD = 1**
  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data.
Figure 175. Example of overrun (OVRMOD = 0)

Figure 176. Example of overrun (OVRMOD = 1)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.
Managing a sequence of conversion without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events or FIFO overflows as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert, and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT bit = 01 or 11 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMNGT of the ADC_CFGR register in single ADC mode, or with bit DAMDF of the ADCx_CCR register in dual ADC mode:

- DMA one shot mode (DMNGT bit = 01).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT bit = 11)
  This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMNGT=01)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.
When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode (DMNGT=11)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

**DMA with FIFO**

The output data register has eight-stage FIFO. Two different DMA requests are generated parallel. When a data is available, “SREQ single request” generated, when 4 data are available, “BREQ burst request” generated. DMA2 can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA2. Please refer to the DMA2 chapter for further information.

### 26.4.28 Managing conversions using the DFSDM

The ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers 16 least significant bits of the regular data register data to the DFSDM, which in turns resets the EOC flag once the transfer is effective.

The data format must be 16-bit signed:

- ADC_DR[31:16] = don’t care
- ADC_DR[15] = sign
- ADC_DR[14:0] = data

Any value above 16-bit signed format is truncated.

### 26.4.29 Dynamic low-power features

**Auto-delayed conversion mode (AUTDLY)**

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.
When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 177).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 178).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 178).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 180).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 181).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:

1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

26.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

![Figure 182. Analog watchdog guarded area](image)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (x=1,2,3).

AWDy (y=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

*Table 220* shows how the ADC_CFGRy registers should be configured to enable the analog watchdog on one or more channels.

**Table 220. Analog watchdog channel selection**

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HTR1[25:0] of the ADC_HTR1 register and LTR1[25:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024).

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

*Table 221* describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

<td>Thresholds</td>
<td></td>
</tr>
</tbody>
</table>

1. The watchdog comparison is performed on the raw converted data before any alignment calculation and before applying any offsets (the data which is compared is not signed).

**Description of analog watchdog 2 and 3**

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

**ADCx_AWDy_OUT signal output generation**

Each analog watchdog is associated to an internal hardware signal ADCx_AWDy_OUT (x=ADC number, y=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCx_AWDy_OUT signal as ETR.
ADCx_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADCx_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCx_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCx_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS=1).

Note: ADCx_AWDy_OUT has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCx_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

26.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 26-bit (16-bit values and OSVR[9:0] = 1024).

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.
The oversampling ratio $N$ is defined using the OSVR[9:0] bits in the ADC_CFGR2 register, and can range from $2x$ to $1024x$. The division coefficient $M$ consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 26 bits ($1024 \times 16$-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

The Table 187 gives a numerical example of the processing, from a raw 26-bit accumulated data to the final 16-bit result.

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every $N$ conversions, with an equivalent delay equal to $N \times T_{\text{CONV}} = N \times (t_{\text{SMPL}} + t_{\text{SAR}})$. The flags are set as follow:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- the end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after $N \times$ sequence length conversions total)
Single ADC operating modes support when oversampling

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[2:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 16-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- the RES[2:0] bits are ignored, comparison is always done on using the full 26-bit values HTRx[25:0] and LTRx[25:0]
- the comparison is performed on the oversampled accumulated value before shifting

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 188 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 188. Triggered regular oversampling mode (TROVS bit = 1)
Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- in continued mode, the accumulation re-starts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- in resumed mode, the accumulation re-starts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequencer is blocked.

The Figure 189 gives examples for a 4x oversampling ratio.

**Figure 189. Regular oversampling modes (4x ratio)**

Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 190 below.

**Figure 190. Regular and injected oversampling modes used simultaneously**

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 191 below.

**Figure 191. Triggered regular oversampling with injection**

Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 192 below shows how the conversions are sequenced.
It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO=1, DISCEN=0, JDISCEN=0, ROVSE=1, JOVSE=1 and TROVSE=1.

**Dual ADC modes support when oversampling**

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

**Combined modes summary**

The Table 222 below summarizes all combinations, including modes not supported.

26.4.32 Dual ADC modes

In devices with two ADCs or more, dual ADC modes can be used (see Figure 193):
- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:
-Injected simultaneous mode
-Regular simultaneous mode
-Interleaved mode
-Alternate trigger mode

It is also possible to use these modes combined in the following ways:
- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don't care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
Figure 193. Dual ADC block diagram

1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 194), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 194. Injected simultaneous mode on 4 channels: dual ADC mode

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.
Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are re-started once the injected conversion is completed.

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master ans slave must be configured with the same sampling time.

Software is notified by interrupts when it can read the data:
- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 195), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:
- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared:
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configuring dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CDR register.
  - both EOC flags are cleared when the DMA reads the ADCx_CDR register.

**Note:** When DAMDF[1:0]=0b10 or 0b11, the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions do not generate a DMA request.
If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the
complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:
- Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

Figure 196. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode
If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is re-started from the master (see Figure 198 below).

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.
Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 199. Alternate trigger: injected group of each ADC

Note: Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.
Injected discontinuous mode enabled (JDISCEN=1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:
- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 200. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0]=00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 201** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected
conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

**Note:** The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Figure 201. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. **Figure 202** shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 202. Case of trigger occurring during injected conversion**

**Combined injected simultaneous plus interleaved**

This mode is selected by programming bits DUAL[4:0]=00011.

It is possible to interrupt an interleaved conversion with a simultaneous injected event. In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. **Figure 203, Figure 204** and **Figure 205** show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 203. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 204. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 205. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 206: DMA Requests in regular simultaneous mode when DAMDF=0b00).

**Figure 206. DMA Requests in regular simultaneous mode when DAMDF=0b00**

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this DAMDF bits must be configured in the ADCx_CCR register:

- **DAMDF=0b10, 32-bit format**: A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADCx_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit.

  **Example:**
  
  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:
  
  1st DMA request: ADCx_CDR2[31:0] = MST_ADC[31:0]
  
  2nd DMA request: ADCx_CDR2[31:0] = SLV_ADC[31:0]

- **DAMDF=0b10, 16-bit format**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-
converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter is truncated to the least 16 significant bits.

Example:
Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: \( \text{ADCx.CDR}[31:0] = \text{SLV_ADC.DR}[15:0] \mid \text{MST_ADC.DR}[15:0] \)
2nd DMA request: \( \text{ADCx.CDR}[31:0] = \text{SLV_ADC.DR}[15:0] \mid \text{MST_ADC.DR}[15:0] \)

Figure 207. DMA requests in regular simultaneous mode when DAMDF=0b10

Figure 208. DMA requests in interleaved mode when DAMDF=0b10
Note: When using multiple-ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF=0b11**: This mode is similar to the DAMDF=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when 4 new 8-bit values are available.

**Example:**

Interleaved dual mode: a DMA request is generated each time 4 data items are available (t0, t1, ... are corresponding to the consecutive sampling instants)

1st DMA request:
\[
\begin{align*}
\text{ADCx}_x\_\text{CDR}[7:0] &= \text{MST\_ADC\_DR}[7:0]_{t0} \\
\text{ADCx}_x\_\text{CDR}[15:8] &= \text{SLV\_ADC\_DR}[7:0]_{t0} \\
\text{ADCx}_x\_\text{CDR}[23:16] &= \text{MST\_ADC\_DR}[7:0]_{t1} \\
\text{ADCx}_x\_\text{CDR}[31:24] &= \text{SLV\_ADC\_DR}[7:0]_{t1}
\end{align*}
\]

2nd DMA request:
\[
\begin{align*}
\text{ADCx}_x\_\text{CDR}[7:0] &= \text{MST\_ADC\_DR}[7:0]_{t2} \\
\text{ADCx}_x\_\text{CDR}[15:8] &= \text{SLV\_ADC\_DR}[7:0]_{t2} \\
\text{ADCx}_x\_\text{CDR}[23:16] &= \text{MST\_ADC\_DR}[7:0]_{t3} \\
\text{ADCx}_x\_\text{CDR}[31:24] &= \text{SLV\_ADC\_DR}[7:0]_{t3}
\end{align*}
\]

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when multiple-ADC mode is selected**

When DAMDF mode is selected (0b10 or 0b11), bit DMNGT[1:0]=0b10 in the master ADC’s ADCx_x_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section: Managing conversions using the DMA*.

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.
DFSDM mode in dual ADC mode interleaved mode

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

This mode is enabled by setting the bits DMNGT[1:0] = 0b10 in the master ADC’s ADC_CFG register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the DFSDM.

The data format must be 16-bit signed:
ADC_DR[31:16] = 0x0000
ADC_DR[15] = sign
ADC_DR[14:0] = data

Any value above 16-bit signed format in any converter is truncated.

DFSDM mode in dual ADC simultaneous mode

The dual mode is not required to use DFSDM in dual ADC simultaneous mode since conversion data are treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with DFSDM interface.

26.4.33 Temperature sensor

The temperature sensor can measure the junction temperature \( T_J \) of the device in the –40 to 125 °C temperature range.

The temperature sensor is internally connected to an ADC internal channel which is used to convert the sensor’s output voltage to a digital value (refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals). The sampling time for the temperature sensor’s analog pin must be greater than the stabilization time specified in the product datasheet.

When not in use, the sensor can be put in power-down mode. 

*Figure 209* shows the block diagram of the temperature sensor.

![Figure 209. Temperature sensor channel block diagram](image)

**Note:** The TSEN bit must be set to enable the conversion of the corresponding ADC internal channel (temperature sensor, \( V_{SENSE} \)).
Reading the temperature

To use the sensor:
1. Select the ADC input channels (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADCx_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting VSENSE data in the ADC data register.
6. Calculate the actual temperature using the following formula:

\[
\text{Temperature (in } ^\circ\text{C}) = \frac{\text{TS}_\text{CAL2}_\text{TEMP} - \text{TS}_\text{CAL1}_\text{TEMP}}{\text{TS}_\text{CAL2} - \text{TS}_\text{CAL1}} \times (\text{TS}_\text{DATA} - \text{TS}_\text{CAL1}) + \text{TS}_\text{CAL1}_\text{TEMP}
\]

Where:
- \(\text{TS}_\text{CAL2}\) is the temperature sensor calibration value acquired at \(\text{TS}_\text{CAL2}_\text{TEMP}\)
- \(\text{TS}_\text{CAL1}\) is the temperature sensor calibration value acquired at \(\text{TS}_\text{CAL1}_\text{TEMP}\)
- \(\text{TS}_\text{DATA}\) is the actual temperature sensor output value converted by ADC

Refer to the device datasheet for more information about \(\text{TS}_\text{CAL1}\) and \(\text{TS}_\text{CAL2}\) calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output VSENSE at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and SENSEEN bits should be set at the same time.

26.4.34 V\text{BAT} supply monitoring

The VBATEN bit of the ADCx_CCR register is used to switch to the battery voltage. As the V\text{BAT} voltage could be higher than V\text{DDA}, to ensure the correct operation of the ADC, the V\text{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect V\text{BAT}/4 to an ADC input channel (refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals).

As a consequence, the converted digital value is one fourth of the V\text{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V\text{BAT}/4 voltage.

Figure 210 shows the block diagram of the V\text{BAT} sensing feature.
Note: The VBATEN bit in ADCx_CCR must be configured to enable the conversion of the corresponding ADC internal channel.

26.4.35 Monitoring the internal voltage reference

The internal voltage reference can be monitored to have a reference point for evaluating the ADC VREF+ voltage level.

The internal voltage reference is internally connected to an ADC input channel (refer to Table ADC interconnection in Section 26.4.2: ADC pins and internal signals).

The sampling time for this channel must be greater than the stabilization time specified in the product datasheet. Figure 210 shows the block diagram of the VREFINT sensing feature.

Note: The VREFEN bit of the ADCx_CCR register must be configured to enable the conversion of the corresponding ADC internal channel (VREFINT).
Calculating the actual $V_{\text{DDA}}$ voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When $V_{\text{DDA}}$ is connected to $V_{\text{REF+}}$, it is possible to compute the actual $V_{\text{DDA}}$ voltage using the embedded internal reference voltage ($V_{\text{REFINT}}$). $V_{\text{REFINT}}$ and its calibration data acquired by the ADC during the manufacturing process at $V_{\text{DDA}} = 3.3$ V can be used to evaluate the actual $V_{\text{DDA}}$ voltage level.

The following formula gives the actual $V_{\text{DDA}}$ voltage supplying the device:

$$V_{\text{REF+}} = 3.3 \, V \times \frac{V_{\text{REFINT \_ CAL}}}{V_{\text{REFINT \_ DATA}}}$$

Where:

- $V_{\text{REFINT \_ CAL}}$ is the $V_{\text{REFINT}}$ calibration value
- $V_{\text{REFINT \_ DATA}}$ is the actual $V_{\text{REFINT}}$ output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between $V_{\text{REF+}}$ and the voltage applied on the converted channel.

For most applications $V_{\text{DDA}}$ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from $V_{\text{DDA}}$:

$$V_{\text{CHANNELx}} = \frac{V_{\text{REF+}}}{\text{FULL\_SCALE}} \times \frac{V_{\text{REFINT \_ CAL}}}{V_{\text{REFINT \_ DATA}}} \times \frac{\text{ADC\_DATA}}{}$$

By replacing $V_{\text{REF+}}$ by the formula provided above, the absolute voltage value is given by the following formula

$$V_{\text{CHANNELx}} = \frac{3.3 \, V \times V_{\text{REFINT \_ CAL}} \times \text{ADC\_DATA}}{V_{\text{REFINT \_ DATA}} \times \text{FULL\_SCALE}}$$

For applications where $V_{\text{DDA}}$ is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{\text{CHANNELx}} = \frac{V_{\text{DDA}}}{\text{FULL\_SCALE}} \times \frac{V_{\text{REFINT \_ DATA}} \times \text{ADC\_DATA}}{}$$

Where:

- $V_{\text{REFINT \_ CAL}}$ is the $V_{\text{REFINT}}$ calibration value
- $\text{ADC\_DATA}$ is the value measured by the ADC on channel x (right-aligned)
- $V_{\text{REFINT \_ DATA}}$ is the actual $V_{\text{REFINT}}$ output value converted by the ADC
- $\text{FULL\_SCALE}$ is the maximum digital value of the ADC output. For example with 16-bit resolution, it is $2^{16} - 1 = 65535$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.
26.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversions for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversions for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Bits 31:13  Reserved, must be kept at reset value.

Bit 12  LDORDY: ADC LDO output voltage ready bit

This bit is set and cleared by hardware. It indicates that the ADC internal LDO output is ready and that the ADC can be enabled or calibrated.

0: ADC LDO voltage regulator disabled
1: ADC LDO voltage regulator enabled

Note: Refer to Section 26.3: ADC implementation for the availability of the LDO regulator.

Bit 11  Reserved, must be kept at reset value.

Bit 10  JQOVF: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 26.4.22: Queue of context for injected conversions for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
1: Injected context queue overflow has occurred

Bit 9  AWD3: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 3 event occurred

Bit 8  AWD2: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 2 event occurred
Bit 7  **AWD1**: Analog watchdog 1 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.
0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 1 event occurred

Bit 6  **JEOS**: Injected channel end of sequence flag
This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Injected conversions complete

Bit 5  **JEOC**: Injected channel end of conversion flag
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Injected channel conversion complete

Bit 4  **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3  **EOS**: End of regular sequence flag
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Regular Conversions sequence complete
Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

- 0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

- 0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
- 1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

- 0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
- 1: ADC is ready to start conversion

  This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.  
  0: Analog watchdog 1 interrupt disabled  
  1: Analog watchdog 1 interrupt enabled  
  *Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

- **Bit 6 JEOSIE**: End of injected sequence of conversions interrupt enable  
  This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.  
  0: JEOS interrupt disabled  
  1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.  
  *Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
Bit 5  **JEOCIE**: End of injected conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
   0: JEOC interrupt disabled.
   1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
   *Note: The software is allowed to write this bit only when JADSTART is cleared to 0 (no injected conversion is ongoing).*

Bit 4  **OVRIE**: Overrun interrupt enable
   This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
   0: Overrun interrupt disabled
   1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
   *Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
   This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
   0: EOS interrupt disabled
   1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
   *Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE**: End of regular conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
   0: EOC interrupt disabled
   1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
   *Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
   This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
   0: EOSMP interrupt disabled.
   1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
   *Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 0  **ADRDYIE**: ADC ready interrupt enable
   This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
   0: ADRDY interrupt disabled
   1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
   *Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
26.6.3 ADC control register (ADC_CR)

Address offset: 0x08
Reset value: 0x2000 0000

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.

- 0: Calibration complete
- 1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

*Note:* The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.

- 0: Writing ADCAL launches a calibration in single-ended inputs mode.
- 1: Writing ADCAL launches a calibration in differential inputs mode.

*Note:* The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in deep-power-down mode.

- 0: ADC not in deep-power down
- 1: ADC in deep-power-down (default reset state)

*Note:* The software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bits is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

- 0: ADC Voltage regulator disabled
- 1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 26.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

The software can program this bitfield only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
Bit 27  **LINCALRDYW6**: Linearity calibration ready Word 6
This control / status bit allows to read/write the 6th linearity calibration factor.
When the linearity calibration is complete, this bit is set. A bit clear launches the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit is reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared).
When the LINCALRDYW6 bit is reset, a new linearity factor 6 value can be written into the LINCALFACT[29:0] of the ADC_CALFACT2 register. A bit set launches the linearity factor 6 update and the bit is effectively set by hardware once the update is done (software must poll the bit until it is set to indicate the write is effective).

*Note:* ADC_CALFACT2[29:10] contains 0. ADC_CALFACT2[9:0] corresponds linearity correction factor bits[159:150].
The software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 26.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT) for details.
The software is allowed to update the linearity calibration factor by writing LINCALRDYWx only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 26  **LINCALRDYW5**: Linearity calibration ready Word 5
Refer to LINCALRDYW6 description.

*Note:* ADC_CALFACT2[29:0] corresponds linearity correction factor bits[149:120].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 25  **LINCALRDYW4**: Linearity calibration ready Word 4
Refer to LINCALRDYW6 description.

*Note:* ADC_CALFACT2[29:0] correspond linearity correction factor bits[119:90].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 24  **LINCALRDYW3**: Linearity calibration ready Word 3
Refer to LINCALRDYW6 description.

*Note:* ADC_CALFACT2[29:0] corresponds linearity correction factor bits[89:60].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 23  **LINCALRDYW2**: Linearity calibration ready Word 2
Refer to LINCALRDYW6 description.

*Note:* ADC_CALFACT2[29:0] corresponds linearity correction factor bits[59:30].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.

Bit 22  **LINCALRDYW1**: Linearity calibration ready Word 1
Refer to LINCALRDYW6 description.

*Note:* ADC_CALFACT2[29:0] corresponds linearity correction factor bits[29:0].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.

Bits 21:17  Reserved, must be kept at reset value.
Bit 16 **ADCALLIN**: Linearity calibration

This bit is set and cleared by software to enable the Linearity calibration.

- 0: Writing ADCAL launches a calibration without the Linearity calibration.
- 1: Writing ADCAL launches a calibration with the Linearity calibration.

*Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **BOOST[1:0]**: Boost mode control

This bitfield is set and cleared by software to enable/disable the boost mode.

- 00: used when ADC clock ≤ 6.25 MHz
- 01: used when 6.25 MHz < ADC clock frequency ≤ 12.5 MHz
- 10: used when 12.5 MHz < ADC clock ≤ 25.0 MHz
- 11: used when 25.0 MHz < ADC clock ≤ 50.0 MHz

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing). When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the BOOST bitfield of the slave ADC is no more writable and its content must be equal to the master ADC BOOST bitfield.*

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

- 0: No ADC stop injected conversion command ongoing
- 1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)*

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

- 0: No ADC stop regular conversion command ongoing
- 1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.
Bit 3  **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

**Note**: The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared).
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTEN=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTEN=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

**Note:** The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

**Note:** The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

**Note:** The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
26.6.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C
Reset value: 0x8000 0000

Bit 31 JQDIS: Injected Queue disable
These bits are set and cleared by software to disable the Injected Queue mechanism:
0: Injected Queue enabled
1: Injected Queue disabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 AWD1CH[4:0]: Analog watchdog 1 channel selection
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel-0 monitored by AWD1
00001: ADC analog input channel-1 monitored by AWD1
.....
10010: ADC analog input channel-19 monitored by AWD1
others: Reserved, must not be used

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 25 JAUTO: Automatic injected group conversion
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).
When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.

Bit 24 JAWD1EN: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).
Bit 23  **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 22  **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 21  **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR Mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR Mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.
Refer to Section 26.4.22: Queue of context for injected conversions for more information.
*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
*When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.*

Bit 20  **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled
*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
*It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*
*When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.*

Bits 19:17  **DISCNUM[2:0]**: Discontinuous mode channel count
These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
000: 1 channel
001: 2 channels
...
111: 8 channels
*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*
*When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.*
Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled
1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off
1: Auto-delayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode
1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

- 00000: Event 0
- 00001: Event 1
- 00010: Event 2
- 00011: Event 3
- 00100: Event 4
- 00101: Event 5
- 00110: Event 6
- 00111: Event 7
- ... 
- 11111: Event 31

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 4:2 **RES[2:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

- 000: 16 bits
- 001: 14 bits in legacy mode (not optimized power consumption)
- 010: 12 bits in legacy mode (not optimized power consumption)
- 101: 14 bits
- 110: 12 bits
- 011: 10 bits
- 111: 8 bits

Others: Reserved, must not be used.

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 1:0 **DMNGT[1:0]**: Data Management configuration

This bit is set and cleared by software to select how ADC interface output data are managed.

- 00: Regular conversion data stored in DR only
- 01: DMA One Shot Mode selected
- 10: DFSDM mode selected
- 11: DMA Circular Mode selected

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

In dual-ADC modes, this bit is not relevant and replaced by control bit DAMDF of the ADCx_CCR register.
### 26.6.5 ADC configuration register 2 (ADC_CFGR2)

</tr>
</tbody>
</table>

Refer to RSHIFT1 description.
Bit 13 **RSHIFT3**: Right-shift data after Offset 3 correction
Refer to RSHIFT1 description

Bit 12 **RSHIFT2**: Right-shift data after Offset 2 correction
Refer to RSHIFT1 description

Bit 11 **RSHIFT1**: Right-shift data after Offset 1 correction
This bitfield is set and cleared by software to right-shift 1-bit data after offset1 correction. This bit can only be used for 8-bit and 16-bit data format (see Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE) for details).
0: Right-shifting disabled
1: Data is right-shifted 1-bit.

Bit 10 **ROVSM**: Regular Oversampling mode
This bit is set and cleared by software to select the regular oversampling mode.
0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bit 9 **TROVS**: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling
0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bits 8:5 **OVSS[3:0]**: Oversampling right shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
0000: No right shift
0001: Shift right 1-bit
0010: Shift right 2-bits
0011: Shift right 3-bits
0100: Shift right 4-bits
0101: Shift right 5-bits
0110: Shift right 6-bits
0111: Shift right 7-bits
1000: Shift right 8-bits
1001: Shift right 9-bits
1010: Shift right 10-bits
1011: Shift right 11-bits

Others: Reserved, must not be used.

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*
Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected Oversampling disabled
1: Injected Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular Oversampling disabled
1: Regular Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 8.5 ADC clock cycles
011: 16.5 ADC clock cycles
100: 32.5 ADC clock cycles
101: 64.5 ADC clock cycles
110: 387.5 ADC clock cycles
111: 810.5 ADC clock cycles

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*
26.6.7  ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x18
Reset value: 0x0000 0000

| Bits 31:30 | Reserved, must be kept at reset value. |
| Bits 29:0  | SMPx[2:0]: Channel x sampling time selection (x = 19 to 10) |

| Bits 31:30 | Reserved, must be kept at reset value. |
| Bits 29:0  | SMPx[2:0]: Channel x sampling time selection (x = 19 to 10) |

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

- 000: 1.5 ADC clock cycles
- 001: 2.5 ADC clock cycles
- 010: 8.5 ADC clock cycles

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 PCSEL[19:0]: Channel x (VinP[x]) pre selection (x = 0 to 19)
These bits are written by software to pre select the input channel at IO instance to be converted.
0: Input Channel x (VinP[x]) is not pre selected for conversion, the ADC conversion result with this channel shows wrong result.
1: Input Channel x (VinP[x]) is pre selected for conversion

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 LTR1[25:0]: Analog watchdog 1 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 1.
Refer to Section 26.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWy)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:0  **HTR1[25:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1. Refer to Section 26.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
### 26.6.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30

Reset value: 0x0000 0000

| Bit 31:29 | Reserved, must be kept at reset value. |
| Bit 28:24 | **SQ4[4:0]**: 4th conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence. |
| Bit 23   | Reserved, must be kept at reset value. |
| Bit 22:18| **SQ3[4:0]**: 3rd conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence. |
|           | **Note**: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 17   | Reserved, must be kept at reset value. |
| Bit 16:12| **SQ2[4:0]**: 2nd conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 2nd in the regular conversion sequence. |
|           | **Note**: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 11   | Reserved, must be kept at reset value. |
| Bit 10:6 | **SQ1[4:0]**: 1st conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 1st in the regular conversion sequence. |
|           | **Note**: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bits 5:4 | Reserved, must be kept at reset value. |
| Bits 3:0 | **L[3:0]**: Regular channel sequence length |
|           | These bits are written by software to define the total number of conversions in the regular channel conversion sequence. |
|           | 0000: 1 conversion |
|           | 0001: 2 conversions |
|           | ... |
|           | 1111: 16 conversions |
|           | **Note**: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]**: 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]**: 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]**: 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]**: 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]**: 5th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:24  **SQ14[4:0]:** 14th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23  Reserved, must be kept at reset value.

Bits 22:18  **SQ13[4:0]:** 13th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17  Reserved, must be kept at reset value.

Bits 16:12  **SQ12[4:0]:** 12th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11  Reserved, must be kept at reset value.

Bits 10:6  **SQ11[4:0]:** 11th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **SQ10[4:0]:** 10th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]**: 16th conversion in regular sequence  
These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence.  
*Note*: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]**: 15th conversion in regular sequence  
These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence.  
*Note*: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
26.6.15 ADC regular Data Register (ADC_DR)

Address offset: 0x40
Reset value: 0x0000 0000

Bits 31:0 RDATA[31:0]: Regular Data converted
These bits are read-only. They contain the conversion result from the last converted regular channel.
The data are left- or right-aligned as described in Section 26.4.27: Data management.
26.6.16 ADC injected sequence register (ADC_JSQR)

Address offset: 0x4C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 20:15</td>
<td>JSQ2[4:0]</td>
<td>JL[1:0]</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:27 **JSQ4[4:0]**: 4th conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]**: 3rd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]**: 2nd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]**: 1st conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).
Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled and if JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

01 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 26.4.22: Queue of context for injected conversions)

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: Event 0

00001: Event 1

00010: Event 2

00011: Event 3

00100: Event 4

00101: Event 5

00110: Event 6

00111: Event 7

... 11111: Event 31:

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).
26.6.17 ADC injected channel y offset register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y-1), (y = 1 to 4)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>SSATE</th>
<th>OFFSET_CH[4:0]</th>
<th>OFFSET[25:16]</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>15</td>
<td>14 13 12 11 10</td>
<td>9 8 7 6 5 4 3</td>
</tr>
</tbody>
</table>

Bit 31 SSATE: Signed saturation Enable
This bit is written by software to enable or disable the Signed saturation feature.
This bit can be enabled only for 8-bit and 16-bit data format (see Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE) for details).
0: Offset is subtracted maintaining data integrity and extending result size (9-bit and 17-bit signed format).
1: Offset is subtracted and result is saturated to maintain result size.

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 30:26 OFFSET_CH[4:0]: Channel selection for the Data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[25:0] applies.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 25:0 OFFSET[25:0]: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]
These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).
When OFFSETy[25:0] bitfield is reset, the offset compensation is disabled.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.
Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[25:0] which is subtracted when converting channel 4.
### 26.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y= 1 to 4)  
Reset value: 0x0000 0000

Analog-to-digital converters (ADC) RM0399

26.6.26 ADC calibration factors register (ADC_CALFACT)

Address offset: 0xC4
Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 \textbf{CALFACT_D[10:0]}: Calibration Factors in differential mode

These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new differential conversion is launched.

\textit{Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).}

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 \textbf{CALFACT_S[10:0]}: Calibration Factors in single-Ended mode

These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended conversion is launched.

\textit{Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).}

1066/3556 RM0399 Rev 4
26.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

26.7.1 ADC x common status register (ADCx_CSR) (x=1/2 or 3)

Address offset: 0x00
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **JQOVF_SLV**: Injected Context Queue Overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADCx+1_ISR register.

Bit 25 **AWD3_SLV**: Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register.

Bit 24 **AWD2_SLV**: Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register.

Bit 23 **AWD1_SLV**: Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register.
Bit 22 **JEOS_SLV**: End of injected sequence flag of the slave ADC
   This bit is a copy of the JEOS bit in the corresponding ADCx+1_ISR register.

Bit 21 **JEOC_SLV**: End of injected conversion flag of the slave ADC
   This bit is a copy of the JEOC bit in the corresponding ADCx+1_ISR register.

Bit 20 **OVR_SLV**: Overrun flag of the slave ADC
   This bit is a copy of the OVR bit in the corresponding ADCx+1_ISR register.

Bit 19 **EOS_SLV**: End of regular sequence flag of the slave ADC
   This bit is a copy of the EOS bit in the corresponding ADCx+1_ISR register.

Bit 18 **EOC_SLV**: End of regular conversion of the slave ADC
   This bit is a copy of the EOC bit in the corresponding ADCx+1_ISR register.

Bit 17 **EOSMP_SLV**: End of Sampling phase flag of the slave ADC
   This bit is a copy of the EOSMP2 bit in the corresponding ADCx+1_ISR register.

Bit 16 **ADRDY_SLV**: Slave ADC ready
   This bit is a copy of the ADRDY bit in the corresponding ADCx+1_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST**: Injected Context Queue Overflow flag of the master ADC
   This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST**: Analog watchdog 3 flag of the master ADC
   This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST**: Analog watchdog 2 flag of the master ADC
   This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST**: Analog watchdog 1 flag of the master ADC
   This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST**: End of injected sequence flag of the master ADC
   This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST**: End of injected conversion flag of the master ADC
   This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST**: Overrun flag of the master ADC
   This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST**: End of regular sequence flag of the master ADC
   This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST**: End of regular conversion of the master ADC
   This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST**: End of Sampling phase flag of the master ADC
   This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST**: Master ADC ready
   This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.
26.7.2 ADC x common control register (ADCx_CCR) (x=1/2 or 3)

Address offset: 0x08
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

</tbody>
</table>

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable
- This bit is set and cleared by software to control VBAT channel.
  - 0: VBAT channel disabled
  - 1: VBAT channel enabled

  *Note:* The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 23 **TSEN**: Temperature sensor voltage enable
- This bit is set and cleared by software to control VSENSE channel.
  - 0: Temperature sensor channel disabled
  - 1: Temperature sensor channel enabled

  *Note:* The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 22 **VREFEN**: VREFINT enable
- This bit is set and cleared by software to enable/disable the VREFINT channel.
  - 0: VREFINT channel disabled
  - 1: VREFINT channel enabled

  *Note:* The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
Bits 21:18  **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256

Others: Reserved, must not be used

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16  **CKMODE[1:0]**: ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- 00: CK_ADCx (x=1 to 23) (Asynchronous clock mode), generated at product level (refer to *Section Reset and Clock Control (RCC)*)
- 01: adc_sclk/1 (Synchronous clock mode).
- 10: adc_sclk/2 (Synchronous clock mode)
- 11: adc_sclk/4 (Synchronous clock mode)

Whatever CKMODE[1:0] settings, an additional divider factor of 2 is applied to the clock delivered to the analog ADC block.

In synchronous clock mode, when adc_ker_ck = 2 x adc_hclk, there is no jitter in the delay from a timer trigger to the start of a conversion.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:14  **DAMDF[1:0]**: Dual ADC mode data format

This bit-field is set and cleared by software. It specifies the data format in the common data register ADCx_CDR.

- 00: Dual ADC mode without data packing (ADCx_CDR and ADCx_CDR2 registers not used).
- 01: Reserved.
- 10: Data formatting mode for 32 down to 10-bit resolution
- 11: Data formatting mode for 8-bit resolution

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:8  **DELAY[3:0]**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes.
Refer to **Table 224** for the value of ADC resolution versus DELAY bits values.

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode.
All the ADCs are independent:
00000: Independent mode

The configurations 00001 to 01001 correspond to the following operating modes: dual mode, master and slave ADCs working together:
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined Interleaved mode + injected simultaneous mode
00100: Reserved.
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 26.4.32: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 26.4.32: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

26.7.4 ADC x common regular data register for 32-bit dual mode (ADCx_CDR2) (x=1/2 or 3)

Address offset: 0x10
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs

In dual mode, these bits alternatively contains the regular 32-bit data of the master and the slave ADC. Refer to Section 26.4.32: Dual ADC modes.

The data alignment is applied as described in Section : Data register; data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE).
### Table 226. ADC register map and reset values for each ADC (offset=0x000 for master ADC, 0x100 for slave ADC) (continued)

Refer to Section 2.3 on page 134 for the register boundary addresses.
27 Digital-to-analog converter (DAC)

27.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer (VREFBUF) section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

27.2 DAC main features

The DAC main features are the following (see Figure 212: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from VREF+ pin or internal VREFBUF reference

Figure 212 shows the block diagram of a DAC channel and Table 229 gives the pin description.

27.4 DAC functional description

27.4.1 DAC block diagram

Figure 212. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 27.3: DAC implementation for channel2 availability.
27.4.2 DAC pins and internal signals

The DAC includes:
- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI clock source (dac_hold_ck).

### 27.4.3 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

**Note:** The ENx bit enables the analog DAC channel x only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

### 27.4.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- **Single DAC channel**
  - There are three possibilities:
    - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
    - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx[15:4] bits (stored into the DHRx[11:0] bits)
    - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx[11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.
Dual DAC channels (when available)

There are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
- 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
- 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 213. Data registers in single DAC channel mode

Figure 214. Data registers in dual DAC channel mode
27.4.5 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_pclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_pclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time tSETTLING that depends on the power supply voltage and the analog output load.

![Timing diagram for conversion with trigger disabled TEN = 0](MSv45319V2)

27.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and VREF+.

The analog output voltages on each DAC channel pin are determined by the following equation:

\[ \text{DAC output} = V_{\text{REF}} \times \frac{\text{DOR}}{4096} \]

27.4.7 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 27.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_pclk cycles after the trigger occurs.
If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

**Note:** TSELx[3:0] bit cannot be changed when the ENx bit is set. When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_pclk clock cycle.

### 27.4.8 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

#### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

### 27.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_pclk clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Figure 217. DAC conversion (SW trigger enabled) with LFSR wave generation**

*Note:* The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
27.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_pclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

![Figure 218. DAC triangle wave generation](ai14715c)

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register. The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
27.4.11 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI low-speed clock (dac_hold_ck) in addition to the dac_pclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation.

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDX[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register
The timings for the three phases above are in units of LSI clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

- 12 cycles are required for sample phase: \( T_{SAMPLEx}[9:0] = 11 \),
- 62 cycles are required for hold phase: \( T_{HOLDx}[9:0] = 62 \),
- and 4 cycles are required for refresh period: \( T_{REFRESHx}[7:0] = 4 \).

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 232. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>( t_{SAMP} ^{(1)(2)} )</th>
<th>( t_{REFRESH} ^{(2)(3)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>( 7 \mu s + (10*R_{BON}*C_{SH}) )</td>
<td>( 7 \mu s + (R_{BON}<em>C_{SH})</em>\ln(2*N_{LSB}) )</td>
</tr>
<tr>
<td>Disable</td>
<td>( 3 \mu s + (10*R_{BOFF}*C_{SH}) )</td>
<td>( 3 \mu s + (R_{BOFF}<em>C_{SH})</em>\ln(2*N_{LSB}) )</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. \( C_{SH} \) is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “\( V_d \)” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires \( \ln(2*N_{LSB}) \) constant time of the DAC.

### Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

- \( C_{SH} = 100 \) nF
- \( V_{DDA} = 3.0 \) V

**Sampling phase:**

\[
t_{SAMP} = 7 \mu s + (10 * 2000 * 100 * 10^{-9}) = 2.007 \text{ ms}
\]

(where \( R_{BON} = 2 \) kΩ)

**Refresh phase:**

\[
t_{REFRESH} = 7 \mu s + (2000 * 100 * 10^{-9}) * \ln(2*10) = 606.1 \mu s
\]

(where \( N_{LSB} = 10 \) (10 LSB drop during the hold phase))

**Hold phase:**

\[
D_v = \frac{i_{\text{leak}} * t_{\text{hold}}}{C_{SH}} = 0.0073 \text{ V} \text{ (10 LSB of 12bit at 3 V)}
\]

\[
i_{\text{leak}} = 150 \text{ nA (worst case on the IO leakage on all the temperature range)}
\]

\[
t_{\text{hold}} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 \text{ ms}
\]
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, $C_{\text{int}}$, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

</table>
The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N} \right) \times G \times V_{\text{ref}} + V_{\text{os}} \]

Where \( V_{\text{OUT}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{os}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{os}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{os}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channel is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{\text{REF}}/2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{\text{DDA}} \) voltage, temperature, \( V_{\text{REF}} \) values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register,
   MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channel calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be
      used during device operation to compensate the output value, else increment
      OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques

to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly

compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in

DAC_CCR register.

Note: A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of

the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is

specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it

enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits

found in the first user calibration in the flash or in back-up registers, then to load/write them

directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

27.4.13 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the

same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A

unique register access is then required to drive both DAC channels at the same time. For

the wave generation, no accesses to DHRxxxD registers are required. As a result, two

output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All

the conversion modes can nevertheless be obtained using separate DHRx registers if

needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2
   bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD,
   DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_pclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_pclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

• Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_pclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_pclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated.
At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the DAC channel2 triangle counter is updated.

### 27.5 DAC in low-power modes

<table>

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in Normal operating mode

1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.
Bits 27:24  **MAMP2[3:0]**: DAC channel2 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bits 23:22  **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable
These bits are set/reset by software.
- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bits 21:18  **TSEL2[3:0]**: DAC channel2 trigger selection
These bits select the external event used to trigger DAC channel2
- 0000: SWTRIG2
- 0001: dac_ch2_trg1
- 0010: dac_ch2_trg2
- ...
- 1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 27.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 17  **TEN2**: DAC channel2 trigger enable
This bit is set and cleared by software to enable/disable DAC channel2 trigger
- 0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_pclk clock cycle later to the DAC_DOR2 register
- 1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_pclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_pclk clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.
Bit 16 **EN2**: DAC channel 2 enable  
This bit is set and cleared by software to enable/disable DAC channel 2.  
0: DAC channel 2 disabled  
1: DAC channel 2 enabled  
*Note: These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel 1 calibration enable  
This bit is set and cleared by software to enable/disable DAC channel 1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.  
0: DAC channel 1 in Normal operating mode  
1: DAC channel 1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel 1 DMA Underrun Interrupt enable  
This bit is set and cleared by software.  
0: DAC channel 1 DMA Underrun Interrupt disabled  
1: DAC channel 1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel 1 DMA enable  
This bit is set and cleared by software.  
0: DAC channel 1 DMA mode disabled  
1: DAC channel 1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel 1 mask/amplitude selector  
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.  
0000: Unmask bit 0 of LFSR/ triangle amplitude equal to 1  
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel 1 noise/triangle wave generation enable  
These bits are set and cleared by software.  
00: wave generation disabled  
01: Noise wave generation enabled  
1x: Triangle wave generation enabled  
Only used if bit TEN1 = 1 (DAC channel 1 trigger enabled).
Bits 5:2 **TSEL[3:0]:** DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1

0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15

Refer to the trigger selection tables in *Section 27.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bit 1 **TEN1:** DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_pclk clock cycle later to the DAC_DOR1 register

1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_pclk clock cycles later to the DAC_DOR1 register

*Note: When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_pclk clock cycle.*

Bit 0 **EN1:** DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

0: DAC channel1 disabled
1: DAC channel1 enabled

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger
- This bit is set by software to trigger the DAC in software trigger mode.
  - 0: No trigger
  - 1: Trigger

  *Note:* This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

  *This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.*

Bit 0 **SWTRIG1**: DAC channel1 software trigger
- This bit is set by software to trigger the DAC in software trigger mode.
  - 0: No trigger
  - 1: Trigger

  *Note:* This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

### 27.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data
- These bits are written by software. They specify 12-bit data for DAC channel2.
27.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2)

This register is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Address offset: 0x18
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 DACC2DHR[11:0]: DAC channel2 12-bit left-aligned data
These bits are written by software which specify 12-bit data for DAC channel2.

Bits 3:0 Reserved, must be kept at reset value.

27.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2)

This register is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Address offset: 0x1C
Reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 DACC2DHR[7:0]: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.
## 27.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.
Bits 27:16 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.
Bits 15:12 Reserved, must be kept at reset value.
Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.

## 27.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD)

Bits 31:20 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.
Bits 19:16 Reserved, must be kept at reset value.
Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.
Bits 3:0 Reserved, must be kept at reset value.
### 27.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD)

Address offset: 0x28
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DAC2DHR[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DAC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel1.

### 27.7.12 DAC channel1 data output register (DAC_DOR1)

Address offset: 0x2C
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bit 31  **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

*Note:*  This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 30  **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value
1: calibration trimming value is equal or greater than the offset correction value

*Note:*  This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 29  **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

*Note:*  This bit is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Bit 28  Reserved, must be kept at reset value.

Bit 27  Reserved, must be kept at reset value.

Bits 26:16  Reserved, must be kept at reset value.

Bit 15  **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14  **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: calibration trimming value is lower than the offset correction value
1: calibration trimming value is equal or greater than the offset correction value

Bit 13  **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12  Reserved, must be kept at reset value.

Bit 11  Reserved, must be kept at reset value.

Bits 10:0  Reserved, must be kept at reset value.
### 27.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38
Reset value: 0x00XX 00XX

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:21  Reserved, must be kept at reset value.

Bits 20:16 **OTRIM2[4:0]**: DAC channel2 offset trimming value

*These bits are available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.*

Bits 15:5  Reserved, must be kept at reset value.

Bits 4:0 **OTRIM1[4:0]**: DAC channel1 offset trimming value

### 27.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C
Reset value: 0x0000 0000

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:26  Reserved, must be kept at reset value.

Bit 25  Reserved, must be kept at reset value.

Bit 24  Reserved, must be kept at reset value.

Bits 23:19  Reserved, must be kept at reset value.
Bits 18:16 **MODE2[2:0]**: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- **DAC channel2 in Normal mode**
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- **DAC channel2 in Sample and hold mode**
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel2 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN2 = 0.*

Refer to Section 27.3: DAC implementation for the availability of DAC channel2.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]**: DAC channel1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:

- **DAC channel1 in Normal mode**
  - 000: DAC channel1 is connected to external pin with Buffer enabled
  - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC channel1 is connected to external pin with buffer disabled
  - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled

- **DAC channel1 in sample & hold mode**
  - 100: DAC channel1 is connected to external pin with Buffer enabled
  - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN1 = 0.*
27.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]**: DAC channel1 sample time (only valid in Sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. In the latter case, the write can be done only when BWST1 of DAC_SR register is low. If BWST1 = 1, the write operation is ignored.

**Note:** It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI clock period.

27.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to Section 27.3: DAC implementation.

Address offset: 0x44
Reset value: 0x0000 0000

|        |                           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x14   | DAC_DHR12R2               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |                           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x18   | DAC_DHR12L2               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |                           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x1C   | DAC_DHR8R2                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.

28 Voltage reference buffer (VREFBUF)

28.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

28.2 VREFBUF functional description

The internal voltage reference buffer supports four voltages\(^{(a)}\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: around 2.5 V.
- VRS = 001: around 2.048 V.
- VRS = 010: around 1.8 V.
- VRS = 011: around 1.5 V (ADC and DAC peripherals are not compatible with this reference voltage setting).

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– V(\text{REF+}) pin pulled-down to V(\text{SSA})</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– V(\text{REF+}) pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– V(\text{REF+}) pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

\(\text{a. The minimum V}_{\text{DDA}}\) voltage depends on VRS setting, refer to the product datasheet.
# 28.3 VREFBUF registers

## 28.3.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00  
Reset value: 0x0000 0002

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

### Bits 31:7
Reserved, must be kept at reset value.

### Bits 6:4 **VRS[2:0]**: Voltage reference scale
These bits select the value generated by the voltage reference buffer.
- 000: Voltage reference set to 2.5 V
- 001: Voltage reference set to 2.048 V
- 010: Voltage reference set to 1.8 V
- 011: Voltage reference set to 1.5 V
- Others: Reserved

*Note: The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).*

### Bit 3 **VRR**: Voltage reference buffer ready
- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

### Bit 2
Reserved, must be kept at reset value.

### Bit 1 **HIZ**: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to Table 237: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

### Bit 0 **ENVR**: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
28.3.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04
Reset value: 0x0000 00XX

Bits 31:6   Reserved, must be kept at reset value.

Bits 5:0    TRIM[5:0]: Trimming code

These bits are automatically initialized after reset with the trimming value stored in the flash memory during the production test. Writing into these bits allows the tuning of the internal reference buffer voltage.

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

28.3.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Refer to Section 2.3 for the register boundary addresses.
29 Comparator (COMP)

29.1 Introduction

The device embeds two ultra-low-power comparator channels (COMP1 and COMP2). They can be used for a variety of functions including:

- wake up from low-power mode triggered by an analog signal
- analog signal conditioning
- cycle-by-cycle current control loop when combined with a PWM output from a timer

29.2 COMP main features

- Selectable inverting analog inputs:
  - I/O pins (different for either channel)
  - DAC Channel1 and Channel2 outputs
  - internal reference voltage and three sub multiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Two I/O pins per channel selectable as non-inverting analog inputs
- Programmable hysteresis
- Programmable speed / consumption
- Mapping of outputs to I/Os
- Redirection of outputs to timer inputs for triggering:
  - capture events
  - OCREF_CLR events (for cycle-by-cycle current control)
  - break events for fast PWM shutdowns
- Blanking of comparator outputs
- Window comparator
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)
- Direct interrupt output to the CPU
29.3 COMP functional description

29.3.1 COMP block diagram

The block diagram of the comparators is shown in Figure 221: Comparator functional block diagram.

Figure 221. Comparator functional block diagram

29.3.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet.
The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- cycle-by-cycle current control, using ETR inputs of timers
- input capture for timing measurements

The comparator output can be routed simultaneously internally and to the I/O pins.

</tbody>
</table>
29.3.3 COMP reset and clocks

The clock comp_pclk provided by the clock controller is synchronous with the APB clock.

*Note:* *Important: The polarity selection logic and the output redirection to the port works independently from the APB clock. This allows the comparator to work even in Stop mode. The interrupt line, connected to the NVIC of CPU, requires the APB clock (comp_pclk) to work. In absence of the APB clock, the interrupt signal comp_it cannot be generated.*

29.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications with specific functional safety requirements, the comparator configuration can be protected against undesired alteration that could happen, for example, at program counter corruption.

For this purpose, the comparator configuration registers can be write-protected (read-only).

Upon configuring a comparator channel, its LOCK bit is set to 1. This causes the whole register set of the comparator channel, as well as the common COMP_OR register, to become read-only, the LOCK bit inclusive.

The write protection can only be removed through the MCU reset.

The COMP_OR register is locked by the LOCK bit of COMP_CFGR1 OR COMP_CFGR2.

29.3.5 Window comparator

The purpose of the window comparator is to monitor the analog voltage and check that it is comprised within the specified voltage range defined by lower and upper thresholds.

The window comparator requires both COMP channels. The monitored analog voltage is connected to their non-inverting (plus) inputs and the upper and lower threshold voltages are connected to the inverting (minus) input of either comparator, respectively. The non-inverting input of the COMP channel 2 can be connected internally with the non-inverting input of the COMP channel 1 by enabling WINMODE bit. This can save the input pins of COMP channel 2 for other purposes. See *Figure 221: Comparator functional block diagram.*

29.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.
29.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals. The blanking signal gates the internal comparator output such as to clean the comp_out from spurious pulses due to current spikes, as depicted in Figure 223 (the COMP channel number is not represented).

![Figure 223. Comparator output blanking](image-url)
29.3.8 Comparator output on GPIOs

The COMP1_OUT and COMP2_OUT outputs of the comparator channels are mapped to GPIOs through the AFOP field of the COMP_OR register, bits [10:0], and through the GPIO alternate function.

**Table 241. COMP1_OUT assignment to GPIOs**

</tbody>
</table>
The assignment to GPIOs for both comparator channel outputs must be done before locking registers of any channel, because the common COMP_OR register is locked when locking the registers of either comparator channel.

### 29.3.9 Comparator output redirection

The outputs of either COMP channel can be redirected to timer break inputs (TIMx_BKIN or TIMx_BKIN2), as shown in Figure 224. For that end, the COMP channel output is connected to one of GPIOs programmable in alternate function as timer break input. See Table 241 and Table 242. The selected GPIO(s) must be set in open drain mode. The COMP output passes through the GPIO to the timer break input. With a pull-up resistor, the selected GPIO can be used as timer break input logic OR-ed with the comparator output.

#### Figure 224. Output redirection

![Figure 224. Output redirection](MSv38378V1)

### 29.3.10 COMP power and speed modes

The power consumption of the COMP channels versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMP_CFRGx registers can be programmed as follows:

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Very-low speed / ultra-low-power
29.4 COMP low-power modes

Table 243. Comparator behavior in the low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.</td>
</tr>
</tbody>
</table>

Note: The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

29.5 COMP interrupts

There are two ways to use the comparator as interrupt source.

The comparator outputs are internally connected to the Extended interrupt and event controller. Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

The comparators also provide an interrupt line to the NVIC of CPU. This functionality is used when the CPU is active to handle low latency interrupt. It requires APB clock running.

29.5.1 Interrupt through EXTI block

Refer to Interrupt and events section for more details.

Sequence to enable the COMPx interrupt through EXTI block:

1. Configure the EXTI line, receiving the comp_wkup signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

Table 244. Interrupt control bits

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Exit from Sleep mode</th>
<th>Exit from Stop modes</th>
<th>Exit from Standby mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>comp1_wkup</td>
<td>through EXTI</td>
<td>through EXTI</td>
<td>yes</td>

<td>N/A</td>
</tr>
<tr>
<td>comp2_whup</td>
<td>through EXTI</td>
<td>through EXTI</td>
<td>yes</td>
<td>yes</td>
<td>N/A</td>
</tr>
</tbody>
</table>
29.5.2 Interrupt through NVIC of the CPU

Sequence to enable the COMPx interrupt through NVIC of the CPU:
1. Configure and enable the NVIC IRQ channel mapped to the comp_it line.
2. Configure and enable the ITEN in COMP_CFGRx.
3. Enable the COMPx.

Table 245. Interrupt control bits

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Interrupt flag</th>
<th>Enable control bit</th>
<th>Interrupt clear bit</th>
<th>Exit from Sleep mode</th>
<th>Exit from Stop modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>comp_it</td>
<td>C1IF in</td>
<td>ITEN in COMP_CFGR1</td>
<td>CC1IF</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>(With APB clock)</td>
<td></td>
</tr>
<tr>
<td>comp_it</td>
<td>C2IF in</td>
<td>ITEN in COMP_CFGR2</td>
<td>CC2IF</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>(With APB clock)</td>
<td></td>
</tr>
</tbody>
</table>

Note: It is mandatory to enable APB clock to use this interrupt. If clock is not enabled, interrupt is not generated.

29.6 SCALER function

The scaler block is available to provide the different voltage reference levels to the comparator inputs. It is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference.

The amplifier and the resistor bridge can be enabled separately. The amplifier is enabled by the SCALEN bits of the COMP_CFGRx registers. The resistor bridge is enabled by the BRGEN bits of the COMP_CFGRx registers.

When the resistor divided voltage is not used, the resistor bridge can be disconnected in order to reduce the consumption. When it is disconnected, the 1/4 V_REF_COMP, 1/2 V_REF_COMP and 3/4 V_REF_COMP levels are equal to V_REF_COMP.
29.7 **COMP registers**

29.7.1 **Comparator status register (COMP_SR)**

The COMP_SR is the comparator status register.

**Address offset:** 0x00

**System reset value:** 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |
| r   | r   |

Bits 31:18 Reserved, must be kept at reset value.

**Bit 17 C2IF:** COMP channel 2 Interrupt Flag
This bit is set by hardware when the COMP channel 2 output is set
This bit is cleared by software writing 1 the C2IF bit in the COMP_ICFR register.

**Bit 16 C1IF:** COMP channel 1 Interrupt Flag
This bit is set by hardware when the COMP channel 1 output is set
This bit is cleared by software writing 1 the C1IF bit in the COMP_ICFR register.

Bits 15:2 Reserved, must be kept at reset value.

**Bit 1 C2VAL:** COMP channel 2 output status bit
This bit is read-only. It reflects the current COMP channel 2 output taking into account POLARITY and BLANKING bits effect.

**Bit 0 C1VAL:** COMP channel 1 output status bit
This bit is read-only. It reflects the current COMP channel 1 output taking into account POLARITY and BLANKING bits effect.

29.7.2 **Comparator interrupt clear flag register (COMP_ICFR)**

The COMP_ICFR is the Comparator interrupt clear flag register.

**Address offset:** 0x04

**System reset value:** 0x0000 0004

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| rc_w1 | rc_w1 |

1126/3556 RM0399 Rev 4
29.7.3 Comparator option register (COMP_OR)

The COMP_OR is the Comparator option register.

Address offset: 0x08

System reset value: 0x0000 0000

### Bits 31:18
Reserved, must be kept at reset value.

### Bit 17 CC2IF: Clear COMP channel 2 Interrupt Flag
Writing 1 clears the C2IF flag in the COMP_SR register.

### Bit 16 CC1IF: Clear COMP channel 1 Interrupt Flag
Writing 1 clears the C1IF flag in the COMP_SR register.

### Bits 15:0
Reserved, must be kept at reset value.

29.7.4 Comparator configuration register 1 (COMP_CFG1)

The COMP_CFG1 is the COMP channel 1 configuration register.

Address offset: 0x0C

System reset value: 0x0000 0000

### Bits 31:11
Reserved, must be kept at reset value.

### Bits 10:0 AFOP[10:0]: Selection of source for alternate function of output ports
Bits of this field are set and cleared by software (only if LOCK not set).
Output port (GPIO) correspondence:
- bit 10: PK2
- bit 9: PI4
- bit 8: PI1
- bit 7: PG4
- bit 6: PG3
- bit 5: PG2
- bit 4: PE15
- bit 3: PE6
- bit 2: PB12
- bit 1: PA8
- bit 0: PA6
For each bit:
0: COMP1_OUT is selected for the alternate function of the corresponding GPIO
1: COMP2_OUT is selected for the alternate function of the corresponding GPIO
Bit 31  **LOCK**: Lock bit
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 1 configuration register COMP_CFGR1[31:0], and COMP_OR register
0: COMP_CFGR1[31:0] register is read/write
1: COMP_CFGR1[31:0] and COMP_OR registers are read-only

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:24  **BLANKING[3:0]**: COMP channel 1 blanking source selection bits
Bits of this field are set and cleared by software (only if LOCK not set).
The field selects the input source for COMP channel 1 output blanking:
0000: No blanking
0001: comp_blk1
0010: comp_blk2
0011: comp_blk3
0100: comp_blk4
0101: comp_blk5
0110: comp_blk6
All other values: reserved

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **INPSEL**: COMP channel 1 non-inverting input selection bit
This bit is set and cleared by software (only if LOCK not set).
0: COMP1_INP1 (PB0)
1: COMP1_INP2 (PB2)

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  **INMSEL[2:0]**: COMP channel 1 inverting input selection field
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 1.
000 = 1/4 VREF_COMP
001 = 1/2 VREF_COMP
010 = 3/4 VREF_COMP
011 = VREF_COMP
100 = comp_inm1 (DAC channel 1 output)
101 = comp_inm2 (DAC channel 2 output)
110 = COMP1_INM1 (PB1)
111 = COMP1_INM2 (PC4)

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:12  **PWRMODE[1:0]**: Power Mode of the COMP channel 1
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 1.
00: High speed / full power
01: Medium speed / medium power
10: Medium speed / medium power
11: Ultra low power / ultra-low-power

Bits 11:10  Reserved, must be kept at reset value.
Bits 9:8 **HYST[1:0]**: COMP channel 1 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 1.
- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 1 interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 1.
- 0: Interrupt generation disabled for COMP channel 1
- 1: Interrupt generation enabled for COMP channel 1

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **POLARITY**: COMP channel 1 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 1 polarity.
- 0: COMP channel 1 output is not inverted
- 1: COMP channel 1 output is inverted

Bit 2 **SCALEN**: Voltage scaler enable bit
This bit is set and cleared by software (only if LOCK not set). This bit enables the $V_{\text{REFINT}}$ scaler for the COMP channels.
- 0: $V_{\text{REFINT}}$ scaler disabled (if SCALEN bit of COMP_CFRG2 register is also low)
- 1: $V_{\text{REFINT}}$ scaler enabled

Bit 1 **BRGEN**: Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.
- 0: Scaler resistor bridge disabled (if BRGEN bit of COMP_CFRG2 register is also low)
- 1: Scaler resistor bridge enabled

If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level $V_{\text{REF_COMP}}$ (similar to $V_{\text{REFINT}}$).
If SCALEN and BRGEN are set, the four scaler outputs provide $V_{\text{REF_COMP}}$, 3/4 $V_{\text{REF_COMP}}$, 1/2 $V_{\text{REF_COMP}}$ and 1/4 $V_{\text{REF_COMP}}$ levels, respectively.

Bit 0 **EN**: COMP channel 1 enable bit
This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 1.
- 0: Disable
- 1: Enable

### 29.7.5 Comparator configuration register 2 (COMP_CFRG2)
The COMP_CFRG2 is the COMP channel 2 configuration register.

Address offset: 0x10

System reset value: 0x0000 0000

|---|------|------|------|------|-------------|------|------|------|--------|------|-------------|
Bit 31 LOCK: Lock bit
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 2 configuration register COMP_CFGR2[31:0], and COMP_OR register.

0: COMP_CFGR2[31:0] register is read/write
1: COMP_CFGR2[31:0] and COMP_OR registers are read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 BLANKING[3:0]: COMP channel 2 blanking source selection bits
These bits are set and cleared by software (only if LOCK not set). These bits select which timer output controls the COMP channel 2 output blanking.

0000: No blanking
0001: TIM1 OC5 selected as blanking source
0010: TIM2 OC3 selected as blanking source
0011: TIM3 OC3 selected as blanking source
0100: TIM3 OC4 selected as blanking source
0101: TIM8 OC5 selected as blanking source
0110: TIM15 OC1 selected as blanking source
All other values: reserved

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 INPSEL: COMP channel 2 non-inverting input selection bit
This bit is set and cleared by software (only if LOCK not set).
0: COMP2_INP1 (PE9)
1: COMP2_INP2 (PE11)

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 INMSEL[2:0]: COMP channel 2 inverting input selection field
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 2.

000 = 1/4 VREF_COMP
001 = 1/2 VREF_COMP
010 = 3/4 VREF_COMP
011 = VREF_COMP
100 = comp_inm1 (DAC channel 1 output)
101 = comp_inm2 (DAC channel 2 output)
110 = COMP2_INM1 (PE10)
111 = COMP2_INM2 (PE7)

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 PWRRMODE[1:0]: Power Mode of the COMP channel 2
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 2.

00: High speed / full power
01: Medium speed / medium power
10: Medium speed / medium power
11: Ultra low power / ultra-low-power

Bits 11:10 Reserved, must be kept at reset value.
Bits 9:8 **HYST[1:0]:** COMP channel 2 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 2.
- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 **Reserved, must be kept at reset value.**

Bit 6 **ITEN:** COMP channel 2 interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 2.
- 0: Interrupt generation disabled for COMP channel 2
- 1: Interrupt generation enabled for COMP channel 2

Bit 5 **Reserved, must be kept at reset value.**

Bit 4 **WINMODE:** Window comparator mode selection bit
This bit is set and cleared by software (only if LOCK not set). This bit selects the window mode of the comparators. If set, the non-inverting input of COMP channel 2 is connected to the non-inverting input of the COMP channel 1. Depending on the bit value, the non-inverting input of COMP channel 2 is connected to:
- 0: COMP2_INP input selector
- 1: Non-inverting input comp1_inp of COMP channel 1

Bit 3 **POLARITY:** COMP channel 2 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 2 polarity.
- 0: COMP channel 2 output is not inverted
- 1: COMP channel 2 output is inverted

Bit 2 **SCALEN:** Voltage scaler enable bit
This bit is set and cleared by software (only if LOCK not set). This bit enables the VREFINT scaler for the COMP channels.
- 0: VREFINT scaler disabled (if SCALEN bit of COMP_CFGR1 register is also low)
- 1: VREFINT scaler enabled

Bit 1 **BRGEN:** Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.
- 0: Scaler resistor bridge disabled (if BRGEN bit of COMP_CFGR1 register is also low)
- 1: Scaler resistor bridge enabled
If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level \( V_{\text{REF_COMP}} \) (similar to \( V_{\text{REFINT}} \)).
If SCALEN and BRGEN are set, the four scaler outputs provide \( V_{\text{REF_COMP}} \), \( 3/4 V_{\text{REF_COMP}} \), \( 1/2 V_{\text{REF_COMP}} \) and \( 1/4 V_{\text{REF_COMP}} \) levels, respectively.

Bit 0 **EN:** COMP channel 2 enable bit
This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 2.
- 0: Disable
- 1: Enable
29.7.6 COMP register map

The following table summarizes the comparator registers.

Table 246. COMP register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | COMP_SR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x04   | COMP_ICFR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x08   | COMP_OR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0  | 0  |
| (OR_CFG=0) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0  | 0  |
|        | Reset value   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x08   | COMP_OR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0  | 0  |
| (OR_CFG=1) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0  | 0  |
|        | Reset value   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

30 Operational amplifiers (OPAMP)

30.1 Introduction

The devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, thus enabling any type of external interconnections. The operational amplifiers can be configured internally as a follower, as an amplifier with a non-inverting gain ranging from 2 to 16 or with inverting gain ranging from -1 to -15.

Refer to Section 30.3.3: Signal routing for detailed information on OPAMP input and output connection to internal peripherals.

30.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 10 mV with factory calibration)
- 7 MHz gain bandwidth
- High-speed mode to achieve a better slew rate

*Note:* Refer to the product datasheet for detailed OPAMP characteristics.

30.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in Section 30.3.3: Signal routing.

30.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in Section 9.7.45: RCC APB1 clock register (RCC_APB1HENR)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.
30.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three input/outputs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values for its offset calibration. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see Section 30.3.5: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the standard performance. The bit OPAHSM can be set in order to switch the operational amplifier to high-speed mode for a better slew rate. Both normal and high-speed mode characteristics are defined in Section: Electrical characteristics of the datasheet.

As soon as the OPAEN bit in OPAMPx_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 30.3.3: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

30.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMPx_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

</tbody>
</table>

1. Both OPAMP1_VOUT and OPAMP2_VOUT are not available on all packages. In this case, the unused I/O should not be activated since is internally set to a fixed configuration.
30.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

**Note:** The amplifier output pin is directly connected to the output pad to minimize the output impedance. When the amplifier is enabled, it cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the internal channel.

The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

**Standalone mode (external gain setting mode)**

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMPx_CSR, and the default state of GPIOx_MODER, as soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPAHSM can be set to "operational amplifier high-speed" mode in order to have high slew rate.
- USERTRIM can be set to modify the trimming values for input offsets.

**Figure 226. Standalone mode: external gain setting mode**
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure VM_SEL bits as “opamp_out connected to OPAMPx_VINM input”, 11
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00
- As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is buffered to pin OPAMPx_VOUT.

Note: The pin corresponding to OPAMPx_VINM is free for another usage.

The signal on the OPAMP1 output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Figure 227. Follower configuration
**Programmable gain amplifier mode**

The procedure to use the OPAMP as programmable gain amplifier is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16”, 0000 to 0011
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00

As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is amplified by the selected gain and visible on pin OPAMPx_VOUT.

*Note:* To avoid saturation, the input voltage should stay below $V_{DDA}$ divided by the selected gain.

**Figure 228. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used**
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16 with filtering on INM0”, 0100 to 0111
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on INM can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and INM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

1. The gain depends on the cut-off frequency.
Programmable gain amplifier, non-inverting with external bias or inverting mode

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0”, 1000 to 1011
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

**Figure 230. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15)**

**Figure 231. Example configuration**
Programmable gain amplifier, non-inverting with external bias or inverting mode with filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode with filtering

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”,
- configure PGA_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0, INM1 node for filtering”, 1100 to 1111
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on VM1 can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and VM1 for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 232. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15) with filtering

Figure 233. Example configuration
30.3.5 Calibration

The OPAMP interface continuously sends trimmed offset values to the operational amplifiers. At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each operational amplifier can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for high-speed mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the input offset voltage to less than +/-1.5 mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming value needs to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMPx_OTR) and one high-speed mode (OPAMPx_HSOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMPx_CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP option registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 01 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 11 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPAHSM. The software should increment the TRIMOFFSETN bits in the OPAMP control register from 0x00 to the first value that causes the CALOUT bit to change from 1 to 0 in the OPAMP register. If the CALOUT bit is reset, the offset is calibrated correctly and the corresponding trimming value must be stored. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see tOFFTRIMmax delay specification in the electrical characteristics section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

</tbody>
</table>
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set the OPAEN bit in OPAMPx_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMPx_CSR register to 1.
3. Choose a calibration mode (refer to Table 248: Operating modes and calibration). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
   - Normal mode and N differential pair
   The above calibration mode correspond to OPAHSM=0 and CALSEL=11 in the OPAMPx_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 00000b until CALOUT changes to 0 in OPAMPx_CSR.

Note: Between the write to the OPAMPx_OTR register and the read of the CALOUT value, make sure to wait for the tOFFTRIM max delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the is correctly compensated and that the corresponding trim code must be saved in the OPAMPx_OTR register.

Repeat steps 3 to 4 for:
- Normal mode and P differential pair, CALSEL=01
- High-speed mode and N differential pair
- High-speed mode and P differential pair

If a mode is not used, it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 µA.

Table 249. Effect of low-power modes on the OPAMP

30.5 OPAMP PGA gain

When OPAMP is configured as PGA mode, it can select the gain of x2, x4, x8, x16 for non-inverting mode and x-1, x-3, x-7, x-15 for inverting mode.

When OPAMP is configured as non-inverting mode, the Gain error can be refer to the product datasheet. When it is configured as inverting mode, Gain factor is defined not only the on chip feedback resistor but also the signal source output impedance. If signal source output impedance is not negligible compare to the input feedback resistance of PGA, it will create the gain error. Please refer to the PGA resistance value in the product datasheet.

30.6 OPAMP registers

The registers of this peripheral can only be accessed by-word (32-bit).

30.6.1 OPAMP1 control/status register (OPAMP1_CSR)

Address: 0x00
Reset value: 0x0000 0000

 Bit 29  TSTREF: OPAMP calibration reference voltage output control (reserved for test)
  0: INTVREF of OPAMP is not output
  1: INTVREF of OPAMP is output
Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **USERTRIM:** User trimming enable
This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
This bit is active for both mode normal and high-power.
0: ‘factory’ trim code used
1: ‘user’ trim code used

Bits 17:14 **PGA_GAIN:** Operational amplifier Programmable amplifier gain value
0000: Non-inverting internal Gain 2, VREF- referenced
0001: Non-inverting internal Gain 4, VREF- referenced
0010: Non-inverting internal Gain 8, VREF- referenced
0011: Non-inverting internal Gain 16, VREF- referenced
0100: Non-inverting internal Gain 2 with filtering on INM0, VREF- referenced
0101: Non-inverting internal Gain 4 with filtering on INM0, VREF- referenced
0110: Non-inverting internal Gain 8 with filtering on INM0, VREF- referenced
0111: Non-inverting internal Gain 16 with filtering on INM0, VREF- referenced
1000: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias
1001: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias
1010: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias
1011: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias
1100: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias, INM1 node for filtering
1101: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias, INM1 node for filtering
1110: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias, INM1 node for filtering
1111: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias, INM1 node for filtering

Bits 13:12 **CALSEL:** Calibration selection
It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.
00: 0.033*VDDA applied on OPAMP inputs
01: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
10: 0.5*VDDA applied on OPAMP inputs
11: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON:** Calibration mode enabled
0: Normal mode
1: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAHSM:** Operational amplifier high-speed mode
The operational amplifier must be disable to change this configuration.
0: operational amplifier in normal mode
1: operational amplifier in high-speed mode

Bit 7 Reserved, must be kept at reset value.
Bits 6:5 **VM_SEL**: Inverting input selection
- 00: INM0 connected to OPAMP INM input
- 01: INM1 connected to OPAMP NM input
- 10: Feedback resistor is connected to OPAMP INM input (PGA mode), Inverting input selection is depends on the PGA_GAIN setting
- 11: opamp_out connected to OPAMP INM input (Follower mode)

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **VP_SEL**: Non inverting input selection
- 00: GPIO connected to OPAMPx_VINP
- 01: dac_outx connected to OPAMPx_VINP
- 10: Reserved
- 11: Reserved

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
- 0: Normal operating mode. Non-inverting input connected to inputs.
- 1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
- 0: operational amplifier disabled
- 1: operational amplifier enabled

*Note: If OPAMP1 is unconnected in a specific package, it must remain disabled (keep OPAMP1_CSR register default value).*

31 Digital filter for sigma delta modulators (DFSDM)

31.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external Σ∆ modulators. It is featuring up to 8 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from device memory.

An external Σ∆ modulator provides digital data stream of converted analog values from the external Σ∆ modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various Σ∆ modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 8 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 8 internal 16-bit data channels (from internal ADCs or from device memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a Σ∆ modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0’s or 1’s in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.
31.2 DFSDM main features

- Up to 8 multiplexed input digital serial channels:
  - configurable SPI interface to connect various ΣΔ modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for ΣΔ modulator(s)
- Alternative inputs from up to 8 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - Sinc\(x\) filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable Sinc\(x\) digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0’s or 1’s on input data stream
  - monitoring continuously each channel (8 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions
  - “injected” conversions for precise timing and with high conversion priority
31.3 DFSDM implementation

This section describes the configuration implemented in DFSDMx.

31.4.3 DFSDM reset and clocks

DFSDM on-off control

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..7) and digital filters DFSDM_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM_CHyCFGR1 and DFSDM_FLTx enable bit DFEN in DFSDM_FLTxCR1).

Digital filter x DFSDM_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM_FLTxCR1 register. Once DFSDM_FLTx is enabled (DFEN=1), both Sincx digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM_FLTx is put into stop mode. All register settings remain unchanged except DFSDM_FLTxAWSR and DFSDM_FLTxISR (which are reset).

Channel y (y=0..7) is enabled by setting CHEN=1 in the DFSDM_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external ΣΔ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.

Table 254. DFSDM triggers connection (continued)

Table 255. DFSDM break connection
**DFSDM clocks**

The internal DFSDM clock $f_{DFSDMCLK}$, which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK or peripheral clock PCLK2 (see Section 9.7.19: RCC domain 2 kernel clock configuration register (RCC_D2CCIP1R)). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM_FLTx, $x=0..3$).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external $\Sigma\Delta$ modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see Section 9.7.19: RCC domain 2 kernel clock configuration register (RCC_D2CCIP1R)).

**31.4.4 Serial channel transceivers**

There are 8 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external $\Sigma\Delta$ modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM_CHyCFGR1 register).

The channel is enabled for operation by setting CHEN=1 in DFSDM_CHyCFGR1 register.

**Channel inputs selection**

Serial inputs (data and clock signals) from DATINy and CKINy pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).
Configuration of serial channels for PDM microphone input:

- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel y (DATINy, CKOUT) pins.
- Channel y will be configured: CHINSEL = 0 (input from given channel pins: DATINy, CKINy).
- Channel (y-1) (modulo 8) will be configured: CHINSEL = 1 (input from the following channel ((y-1)+1) pins: DATINy, CKINy).
- Channel y: SITP[1:0] = 0 (rising edge to strobe data) => left audio channel on channel y.
- Channel (y-1): SITP[1:0] = 1 (falling edge to strobe data) => right audio channel on channel y-1.
- Two DFSDM filters will be assigned to channel y and channel (y-1) (to filter left and right channels from PDM microphone).

**Figure 235. Input channel pins redirection**
Output clock generation

A clock signal can be provided on CKOUT pin to drive external $\Sigma\Delta$ modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFG1 register) divided by a predivider (see CKOUTDIV bits in DFSDM_CH0CFG1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM_CHyCFG1 register or by DFSDMEN=0 in DFSDM_CH0CFG1 register). The output clock stopping is performed:

- 4 system clocks after DFSDMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSDMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.

SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATINy pin. A clock signal can be provided externally from CKINy pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATINy pin) is sampled on rising or falling clock edge (of CKINy pin) according SITP[1:0] bits setting (in DFSDM_CHyCFG1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM_CHyCFG1 register:

- CKOUT signal:
  - For connection to external $\Sigma\Delta$ modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according SITP[1:0] setting.

- CKOUT/2 signal (generated on CKOUT rising edge):
  - For connection to external $\Sigma\Delta$ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.

- CKOUT/2 signal (generated on CKOUT falling edge):
  - For connection to external $\Sigma\Delta$ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

Note: An internal clock source can only be used when the external $\Sigma\Delta$ modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKINy pin connection (CKINy pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than $f_{DFSDMCLK}/4$.

Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATINy pin only. Decoded data and clock signal are recovered from serial stream after Manchester
decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than f_{DFSDMCLK}/6.

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

\[(\text{CKOUTDIV} + 1) \times T_{SYSCLK} < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{SYSCLK})\]

Recovered clock

Recovered data: 0 0 1 1 0
Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel y by bit CKABEN in DFSDM_CHyCFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock error (see CKABF[7:0] in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit CKABF[y] is set also by hardware when corresponding channel y is disabled (if CHEN[y] = 0 then CKABF[y] is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the CKOUT signal (CKOUTSRC=0 in DFSDM_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by CHEN = 1
- Try to clear the clock absence flag (by CLRCKABF = 1) until the clock absence flag is really cleared (CKABF = 0). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature CKABEN = 1 and the associated interrupt CKABIE = 1 to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (CKOUT signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of CKOUT signal (which is controlled by CKOUTDIV field in DFSDM_CH0CFGR1 register).

Figure 237. Clock absence timing diagram for SPI

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 239 for Manchester synchronization).
The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DATINy pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM_CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal. So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

\[
((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})
\]

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[7:0] in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed.

Figure 238. Clock absence timing diagram for Manchester coding
Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM_CHyCFGR1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM_FLT0ICR, following the software sequence detailed hereafter:

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signalizing that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according the formula below.

\[
(\frac{(CKOUTDIV \times 1)}{T_{SYSCLK}}) < T_{Manchester\ clock} < (2 \times CKOUTDIV \times T_{SYSCLK})
\]

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

Note: When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register).
External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external ΣΔ modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks (fDFSDMCLK) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM_FLTxCNVTIMR register).

In case of parallel data input (Section 31.4.6: Parallel data inputs) the measured frequency is the average input data rate during one conversion.
Note: When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

**injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):**

For Sinc^x filters (x=1..5):

\[ t = \text{CNVCNT}/f_{DFSDMCLK} = \frac{\text{FOSR} \times (\text{IOSR}-1 + \text{FORD}) + \text{FORD}}{f_{CKIN}} \]

For FastSinc filter:

\[ t = \text{CNVCNT}/f_{DFSDMCLK} = \frac{\text{FOSR} \times (\text{IOSR}-1 + 4) + 2}{f_{CKIN}} \]

**regular conversion with FAST = 1 (except first conversion):**

For Sinc^x and FastSinc filters:

\[ t = \text{CNVCNT}/f_{DFSDMCLK} = \frac{\text{FOSR} \times \text{IOSR}}{f_{CKIN}} \]

In case if FOSR = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):

\[ t = \frac{\text{IOSR}}{f_{CKIN}} \text{ (... but CNVCNT=0)} \]

where:

- \( f_{CKIN} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate (in case of parallel data input)
- \( F_{OSR} \) is the filter oversampling ratio: \( F_{OSR} = FOSR[9:0]+1 \) (see DFSDM_FLTxFCR register)
- \( I_{OSR} \) is the integrator oversampling ratio: \( I_{OSR} = IOSR[7:0]+1 \) (see DFSDM_FLTxFCR register)
- \( F_{ORD} \) is the filter order: \( F_{ORD} = FORD[2:0] \) (see DFSDM_FLTxFCR register)

**Channel offset setting**

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM_CHyCFGR2 register.

**Data right bit shift**

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.
31.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable predivider to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM_CH0CFGR1 register.
- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP[1:0] bits in DFSDM_CHyCFGR1 register.
- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM_CHyCFGR1 register.
- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM_CHyCFGR2 register.
- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external Σ∆ modulator). It is defined by OFFSET[23:0] bits in DFSDM_CHyCFGR2 register.
- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM_CHyCFGR1.
- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM_CHyAWSCDR register.

31.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC or direct write by CPU/DMA.

Each channel contains a 32-bit data input register DFSDM_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM_CHyDATINR register is write protected.

**Input from internal ADC**

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM_CHDATIN0R register, ADC2 is filling DFSDM_CHDATIN1R register, ... , ADC8 is filling DFSDM_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

The setting of data packing mode (DATPACK[1:0] in the DFSDM_CHyCFGR1 register) has no effect in case of ADC data input.
Note: Extension of ADC specification: in case the internal ADC is configured in interleaved mode (e.g. ADC1 together with ADC2 - see ADC specification) then each result from ADC1 or from ADC2 will come to the same 16-bit bus - to the bus of ADC1 - which is coming into DFSDM channel 0 (fixed connection). So there will be double input data rate into DFSDM channel 0 (even samples come from ADC1 and odd samples from ADC2). Channel 1 associated with ADC2 will be free.

Input from memory (direct CPU/DMA write)

The direct data write into DFSDM_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM_CHyDATINR register:

1. **CPU data write:**
   
   Input data are written directly by CPU into DFSDM_CHyDATINR register.

2. **DMA data write:**
   
   The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM_CHyDATINR register. The destination memory address is the address of DFSDM_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.
   
   This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

The accesses to DFSDM_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM_CHyCFGR1 register:

1. **Standard mode (DATPACK[1:0]=0):**
   
   Only one sample is stored in field INDAT0[15:0] of DFSDM_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0]) to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM_CHyDATINR register to load one sample per write operation.

2. **Interleaved mode (DATPACK[1:0]=1):**
   
   DFSDM_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital filter must perform two input samplings from channel y to empty DFSDM_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM_CHyDATINR register to load two samples per write operation.

3. **Dual mode (DATPACK[1:0]=2):**
   
   Two samples are written into DFSDM_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register DFSDM_CH[y+1]DATINR). The digital filters must perform two samplings - one from
channel y and one from channel (y+1) - in order to empty DFSDM_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers (y = 0, 2, 4, 6). If odd channel (y = 1, 3, 5, 7) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See Figure 240 for DFSDM_CHyDATINR registers data modes and assignments of data samples to channels.

</table>

The write into DFSDM_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel y) is enabled for data collection (starting conversion for channel y). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM_CHyDATINR before the single conversion is started (any data present in the DFSDM_CHyDATINR before starting a conversion is discarded).

### 31.4.7 Channel selection

There are 8 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 8 channels. JCHG[7:0] in the DFSDM_FLTxJCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel y is selected.

Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[7:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[7:0] if JSCAN=0 resets the channel selection to the lowest selected channel.

Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.
The **regular channel** is a selection of just one of the 8 channels. RCH[2:0] in the DFSDM_FLTxCR1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM_CHyCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM_CHyCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM_FLTxCR1 register.

### 31.4.8 Digital filter configuration

DFSDM contains a Sinc\(x\) type digital filter implementation. This Sinc\(x\) filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sinc\(x\) digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- Filter order/type: (see FORD[2:0] bits in DFSDM_FLTxFCR register):
  - FastSinc
  - Sinc\(^1\)
  - Sinc\(^2\)
  - Sinc\(^3\)
  - Sinc\(^4\)
  - Sinc\(^5\)

- Filter oversampling/decimation ratio (see FOSR[9:0] bits in DFSDM_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sinc\(^x\) filter \(x = F_{ORD} = 1..3\)
  - FOSR = 1-215 - for Sinc\(^x\) filter \(x = F_{ORD} = 4\)
  - FOSR = 1-73 - for Sinc\(^x\) filter \(x = F_{ORD} = 5\)

The filter has the following transfer function (impulse response in H domain):

- **Sinc\(^x\) filter type:**
  \[ H(z) = \left( \frac{1-z^{-FOSR\cdot x}}{1-z^{-1}} \right) \]

- **FastSinc filter type:**
  \[ H(z) = \left( \frac{1-z^{-FOSR\cdot 2}}{1-z^{-1}} \right)^2 \cdot (1+z^{-\left(2\cdot FOSR\right)}) \]
For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

### 31.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM_FLTxFCR register).

</tbody>
</table>
The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).

### 31.4.10 Analog watchdog

The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.
There are 2 options for comparing the threshold registers with the data values:

- **Option1**: in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register)

- **Option2**: in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sinc\(^x\) channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM_CHyAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[7:0] field (DFSDM_FLTxCR2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM_CHyAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWDC[7:0] field of DFSDM_FLTxCR2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHFTF[7:0], AWLTF[7:0] of DFSDM_FLTxAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWDC[7:0] = 0xFF). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.
Analog watchdog filter data for given channel \( y \) is available for reading by firmware on field WDATA[15:0] in DFSDM_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM_CHyCFGR1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the integrator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency \( f_{\text{CKIN}} \)):

- **first conversion:**
  - for Sinc\( x \) filters (\( x=1..5 \)): number of samples = \( [\text{FOSR} \times \text{FORD} + \text{FORD} + 1] \)
  - for FastSinc filter: number of samples = \( [\text{FOSR} \times 4 + 2 + 1] \)

- **next conversions:**
  - for Sinc\( x \) and FastSinc filters: number of samples = \( [\text{FOSR} \times \text{IOSR}] \)

where:

- \( \text{FOSR} \) ....... filter oversampling ratio: \( \text{FOSR} = \text{AWFOSR}[4:0]+1 \) (see DFSDM_CHyAWSCDR register)
- \( \text{FORD} \) ....... the filter order: \( \text{FORD} = \text{AWFORD}[1:0] \) (see DFSDM_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[7:0] field (in DFSDM_FLTxCR2 register).

The status of an analog watchdog event is signalized in DFSDM_FLTxAWSR register where a given event is latched. AWHTF\( y \)=1 flag signalizes crossing AWHT[23:0] value on channel \( y \). AWLTF\( y \)=1 flag signalizes crossing AWLT[23:0] value on channel \( y \). Latched events in DFSDM_FLTxAWSR register are cleared by writing '1' into the corresponding clearing bit CLRAWHTF\( y \) or CLRAWLTF\( y \) in DFSDM_FLTxAWCFR register.

The global status of an analog watchdog is signalized by the AWDF flag bit in DFSDM_FLTxISR register (it is used for the fast detection of an interrupt source). AWDF=1 signals that at least one watchdog occurred (AWHTF\( y \)=1 or AWLTF\( y \)=1 for at least one channel). AWDF bit is cleared when all AWHTF[7:0] and AWLT[7:0] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dfsdm_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM_FLTxAWHTR and DFSDM_FLTxAWLTR register.

### 31.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0’s or 1’s on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM_CHyAWSCDR register), then a short-
circuit event is invoked. Each input channel has its short-circuit detector. Any channel can be selected to be continuously monitored by setting the SCDEN bit (in DFSDM_CHyCFGR1 register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits, status bit SCDF[7:0], status clearing bits CLRSCDF[7:0]). Status flag SCDF[y] is cleared also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal dfsdm_break[3:0]. There are four break outputs to be assigned to a short-circuit detector event. The break signal assignment to a given channel short-circuit detector event is done by BKSCD[3:0] field in DFSDM_CHyAWSCDR register.

Short circuit detector cannot be used in case of parallel input data channel selection (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

### 31.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum register (EXMAX[23:0] bits in DFSDM_FLTxEXMAX register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMAXCH[2:0] bits (in DFSDM_FLTxEXMAX register).

If the output data word is lower than the value stored in the extremes detector minimum register (EXMIN[23:0] bits in DFSDM_FLTxEXMIN register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMINCH[2:0] bits (in DFSDM_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given DFSDM_FLTxEXMAX or DFSDM_FLTxEXMIN register). After refresh, the extremes detector minimum data register DFSDM_FLTxEXMIN is filled with 0x7FFFFF (maximum positive value) and the extremes detector maximum register DFSDM_FLTxEXMAX is filled with 0x800000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data correction. For each extremes detector, the input channels to be considered into computing the extremes value are selected in EXCH[7:0] bits (in DFSDM_FLTxCR2 register).

### 31.4.13 Data unit block

The data unit block is the last block of the whole processing path: External ΣΔ modulators - Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator settings. The maximum output data rate is:

\[
\text{Datarate [samples / s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (1 + \frac{1}{F_{\text{ORD}}}) + (1 + \frac{1}{F_{\text{ORD}}})} \quad \text{...FAST = 0, Sincx filter}
\]

\[
\text{Datarate [samples / s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (1 + 4) + (1 + 4)} \quad \text{...FAST = 0, FastSinc filter}
\]
The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

$$\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( I_{OSR} - 1 + F_{ORD} \right) + \left( F_{ORD} + 1 \right) \leq 2^{31}$$
...FAST = 0, Sincx filter

or

$$\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( I_{OSR} - 1 + 4 \right) + \left( 2 + 1 \right) \leq 2^{31}$$
...FAST = 0, FastSinc filter

or

$$\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( 1 + 4 \right) \leq 2^{31}$$
...FAST = 1 or any filter bypass case (F_{OSR} = 1)

where: \( f_{DATAIN\_RATE} \) --- input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

\[
\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( I_{OSR} - 1 + F_{ORD} \right) + \left( F_{ORD} + 1 \right) \leq 2^{31} \quad \text{...FAST = 0, Sincx filter}
\]

or

\[
\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( I_{OSR} - 1 + 4 \right) + \left( 2 + 1 \right) \leq 2^{31} \quad \text{...FAST = 0, FastSinc filter}
\]

or

\[
\text{fDATAIN\_RATE} FOSR IOSR \cdot \left( 1 + 4 \right) \leq 2^{31} \quad \text{...FAST = 1 or any filter bypass case (F_{OSR} = 1)}
\]

where: \( f_{DATAIN\_RATE} \) --- input data rate from ADC or from CPU/DMA

31.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external σΔ modulator. An external σΔ modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A σΔ modulator output is always assumed in a signed format (a data stream of zeros and ones from a σΔ modulator represents values -1 and +1).
Signed data format in registers: Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two’s complement format).

31.4.15 Launching conversions

Injected conversions can be launched using the following methods:
- Software: writing ‘1’ to JSWSTART in the DFSDM_FLTxCR1 register.
- Trigger: JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM_FLTxCR1 register).
- Synchronous with DFSDM_FLT0 if JSYNC=1: for DFSDM_FLTx (x>0), an injected conversion is automatically launched when in DFSDM_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM_FLT0CR2 register). Each injected conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

Regular conversions can be launched using the following methods:
- Software: by writing ‘1’ to RSWSTART in the DFSDM_FLTxCR1 register.
- Synchronous with DFSDM_FLT0 if RSYNC=1: for DFSDM_FLTx (x>0), a regular conversion is automatically launched when in DFSDM_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM_FLT0CR2 register). Each regular conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signalized by RPEND bit in DFSDM_FLTxRDATAR register.

31.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM_FLTxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after ‘1’ is written to RSWSTART.
The regular conversions executing in continuous mode can be stopped by writing '0' to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM_FLTxCr1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:

- if FAST = 0 (or first conversion if FAST=1):
  - for SincX filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \times (IOSR-1 + FORD) + FORD]}{f_{CKIN}} \]
  - for FastSinc filter:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \times (IOSR-1 + 4) + 2]}{f_{CKIN}} \]

- if FAST = 1 (except first conversion):
  - for SincX and FastSinc filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{FOSR \times IOSR}{f_{CKIN}} \]
    \[ \text{in case } FOSR = FOSR[9:0]+1 = 1 \text{ (filter bypassed, only integrator active):} \]
    \[ t = \frac{IOSR}{f_{CKIN}} \text{ (but CNVCNT=0)} \]

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM_FLTxCr1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM_FLTxCr1 register).

### 31.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is ‘1’ (in the DFSDM_FLTxlISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is ‘1’ (in the DFSDM_FLTxlISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signalized in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When
the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM_FLTxCR1 writes ‘1’ to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

31.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

31.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- End of injected conversion interrupt:
  - enabled by JEOCIE bit in DFSDM_FLTxCR2 register
  - indicated in JEOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACH[2:0] bits in DFSDM_FLTxJDATAR register

- End of regular conversion interrupt:
  - enabled by REOCIE bit in DFSDM_FLTxCR2 register
  - indicated in REOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATAH[2:0] bits in DFSDM_FLTxRDATAR register

- Data overrun interrupt for injected conversions:
  - occurred when injected converted data were not read from DFSDM_FLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM_FLTxCR2 register
  - indicated in JOVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRJOVRF bit in DFSDM_FLTxICR register

- Data overrun interrupt for regular conversions:
  - occurred when regular converted data were not read from DFSDM_FLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM_FLTxCR2 register
  - indicated in ROVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRROVRF bit in DFSDM_FLTxICR register

- Analog watchdog interrupt:
– occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDM_FLTxCR1 register) crosses over/under high/low thresholds in DFSDM_FLTxAWHTR / DFSDM_FLTxAWLTR registers
– enabled by AWDIE bit in DFSDM_FLTxCR2 register (on selected channels AWDCH[7:0])
– indicated in AWDF bit in DFSDM_FLTxISR register
– separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDM_FLTxAWSR register
– cleared by writing ‘1’ into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDM_FLTxAWCFR register

• Short-circuit detector interrupt:
  – occurred when the number of stable data crosses over thresholds in DFSDM_CHyAWSCDR register
  – enabled by SCDIE bit in DFSDM_FLTxCR2 register (on channel selected by SCDEN bit in DFSDM_CHyCFGR1 register)
  – indicated in SCDF[7:0] bits in DFSDM_FLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  – cleared by writing ‘1’ into the corresponding CLRSCDF[7:0] bit in DFSDM_FLTxICR register

• Channel clock absence interrupt:
  – occurred when there is clock absence on CKINy pin (see Clock absence detection in Section 31.4.4: Serial channel transceivers)
  – enabled by CKABIE bit in DFSDM_FLTxCR2 register (on channels selected by CKABEN bit in DFSDM_CHyCFGR1 register)
  – indicated in CKABF[y] bit in DFSDM_FLTxISR register
  – cleared by writing ‘1’ into CLRCKABF[y] bit in DFSDM_FLTxICR register

Table 258. DFSDM interrupt requests
31.6 **DFSDM DMA transfer**

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM_FLTxCRI register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM_FLTxCRI register.

*Note:* With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM_FLTISR register) because DMA is reading DFSDM_FLTxDATAR or DFSDM_FLTxRDATAR register.

31.7 **DFSDM channel y registers (y=0..7)**

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register. Write access to DFSDM_CHyDATINR register can be either word access (32-bit) or half-word access (16-bit).

31.7.1 **DFSDM channel y configuration register (DFSDM_CHyCFGR1)**

This register specifies the parameters used by channel y.

Address offset: 0x000 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

<table>
<thead>

<th>CKOUTSRC: Output serial clock source selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Source for output clock is from system clock</td>
</tr>
<tr>
<td>1</td>
<td>Source for output clock is from audio clock</td>
</tr>
</tbody>
</table>

This value can be modified only when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).

*Note:* **CKOUTSRC is present only in DFSDM_CH0CFGR1 register (channel y=0)**

Bits 29:24 Reserved, must be kept at reset value.
Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider
- 0: Output clock generation is disabled (CKOUT signal is set to low state)
- 1-255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).
CKOUTDIV also defines the threshold for a clock absence detection.
This value can only be modified when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).
If DFSDMEN=0 (in DFSDM_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).
*Note*: **CKOUTDIV is present only in DFSDM_CH0CFGR1 register (channel y=0)**

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM_CHyDATINR register.
- 0: Standard: input data in DFSDM_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM_CHyDATINR register one sample must be read by the DFSDM filter from channel y.
- 1: Interleaved: input data in DFSDM_CHyDATINR register are stored as two samples:
  --first sample in INDAT0[15:0] (assigned to channel y)
  --second sample INDAT1[15:0] (assigned to channel y+1)
To empty DFSDM_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).
- 2: Dual: input data in DFSDM_CHyDATINR register are stored as two samples:
  --first sample INDAT0[15:0] (assigned to channel y)
  --second sample INDAT1[15:0] (assigned to channel y+1)
To empty DFSDM_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.
- 3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y
- 0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM_CHyDATINR register is write protected.
- 1: Data to channel y are taken from internal analog to digital converter ADCy+1 output register update as 16-bit values (if ADCy+1 is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM_CHyDATINR register.
- 2: Data to channel y are taken from internal DFSDM_CHyDATINR register by direct CPU/DMA write.
  There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
- 3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection
- 0: Channel inputs are taken from pins of the same channel y.
- 1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bit 7 **CHEN**: Channel y enable
- 0: Channel y disabled
- 1: Channel y enabled
If channel y is enabled, then serial data receiving is started according to the given channel setting.
Bit 6 **CKABEN**: Clock absence detector enable on channel y
- 0: Clock absence detector disabled on channel y
- 1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y
- 0: Input channel y will not be guarded by the short-circuit detector
- 1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPISEL[1:0]**: SPI clock select for channel y
- 0: Clock coming from external CKIny input - sampling point according SITP[1:0]
- 1: Clock coming from internal CKOUT output - sampling point according SITP[1:0]
- 2: Clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.
  For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
- 3: Clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.
  For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).

This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y
- 00: SPI with rising edge to strobe data
- 01: SPI with falling edge to strobe data
- 10: Manchester coded input on DATIny pin: rising edge = logic 0, falling edge = logic 1
- 11: Manchester coded input on DATIny pin: rising edge = logic 1, falling edge = logic 0

This value can only be modified when CHEN=0 (in DFSDM_CHyCFGR1 register).

### 31.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2)

This register specifies the parameters used by channel y.

Address offset: 0x04 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000
Bits 31:8 **OFFSET[23:0]**: 24-bit calibration offset for channel y  
For channel y, OFFSET is applied to the results of each conversion from this channel.  
This value is set by software.

Bits 7:3 **DTRBS[4:0]**: Data right bit-shift for channel y  
0-31: Defines the shift of the data result coming from the integrator - how many bit shifts to the right  
will be performed to have final results. Bit-shift is performed before offset correction. The data shift is  
rounding the result to nearest integer value. The sign of shifted result is maintained (to have valid  
24-bit signed format of result data).  
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 2:0 Reserved, must be kept at reset value.

### 31.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM_CHyAWSCDR)

Short-circuit detector and analog watchdog settings for channel y.

Address offset: 0x08 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-24</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
| 23-22 | **AWFORD[1:0]**: Analog watchdog Sinc filter order on channel y  
0: FastSinc filter type  
1: Sinc\(^1\) filter type  
2: Sinc\(^2\) filter type  
3: Sinc\(^3\) filter type  
Sinc\(^x\) filter type transfer function: \(H(z) = \left(\frac{1 - z^{-FOSR}}{1 - z^{-1}}\right)^x\)  
FastSinc filter type transfer function: \(H(z) = \left(\frac{1 - z^{-FOSR}}{1 - z^{-1}}\right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})\)  
This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register). |
| 21 | Reserved, must be kept at reset value. |
| 20-16 | **AWFOSR[4:0]**: Analog watchdog filter oversampling ratio (decimation rate) on channel y  
0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.  
This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).  
*Note: If AWFOSR = 0 then the filter has no effect (filter bypass).* |
| 15-0 | Reserved, must be kept at reset value. |
**31.7.4 DFSDM channel y watchdog filter data register (DFSDM_CHyWDATR)**

This register contains the data resulting from the analog watchdog filter associated to the input channel y.

Address offset: 0x0C + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Data converted by the analog watchdog filter for input channel y. This data is continuously converted (no trigger) for this channel, with a limited resolution (OSR=1..32/sinc order = 1..3).</td>
</tr>
</tbody>
</table>
31.8 DFSDM filter x module registers (x=0..3)

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register.

31.8.1 DFSDM filter x control register 1 (DFSDM_FLTxCR1)

Address offset: 0x100 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000
Bit 31  Reserved, must be kept at reset value.

Bit 30  **AWFSEL**: Analog watchdog fast mode select
0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift
1: Analog watchdog on channel transceivers value (after watchdog filter)

Bit 29  **FAST**: Fast conversion mode selection for regular conversions
0: Fast conversion mode disabled
1: Fast conversion mode enabled
When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
if FAST=0 (or first conversion in continuous mode if FAST=1):
\[ t = \frac{[F_{OSR} \times (I_{OSR}-1 + F_{ORD}) + F_{ORD}]}{f_{CKIN}} \text{... for Sinc}\text{x filters} \]
\[ t = \frac{[F_{OSR} \times (I_{OSR}-1 + 4) + 2]}{f_{CKIN}} \text{... for FastSinc filter} \]
if FAST=1 in continuous mode (except first conversion):
\[ t = \frac{[F_{OSR} \times I_{OSR}]}{f_{CKIN}} \]
in case if \( F_{OSR} = F_{OSR}[9:0]+1 = 1 \) (filter bypassed, active only integrator):
\[ t = \frac{I_{OSR}}{f_{CKIN}} \text{... but CNVCNT=0} \]
where, \( f_{CKIN} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.

Bits 28:27  Reserved, must be kept at reset value.

Bits 26:24  **RCH[2:0]**: Regular channel selection
0: Channel 0 is selected as the regular channel
1: Channel 1 is selected as the regular channel
...
7: Channel 7 is selected as the regular channel
Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22  Reserved, must be kept at reset value.

Bit 21  **RDMAEN**: DMA channel enabled to read data for the regular conversion
0: The DMA channel is not enabled to read regular data
1: The DMA channel is enabled to read regular data
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 20  Reserved, must be kept at reset value.

Bit 19  **RSYNC**: Launch regular conversion synchronously with DFSDM_FLT0
0: Do not launch a regular conversion synchronously with DFSDM_FLT0
1: Launch a regular conversion in this DFSDM_FLTx at the very moment when a regular conversion is launched in DFSDM_FLT0
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 18  **RCONT**: Continuous mode selection for regular conversions
0: The regular channel is converted just once for each conversion request
1: The regular channel is converted repeatedly after each conversion request
Writing '0' to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.
Bit 17 **RSWSTART**: Software start of a conversion on the regular channel
0: Writing ‘0’ has no effect
1: Writing ‘1’ makes a request to start a conversion on the regular channel and causes RCIP to become ‘1’. If RCIP=1 already, writing to RSWSTART has no effect. Writing ‘1’ has no effect if RSYNC=1.
This bit is always read as ‘0’.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions
00: Trigger detection is disabled
01: Each rising edge on the selected trigger makes a request to launch an injected conversion
10: Each falling edge on the selected trigger makes a request to launch an injected conversion
11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bits 12:8 **JEXTSEL[4:0]**: Trigger signal selection for launching injected conversions
0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

*Note*: synchronous trigger has latency up to one $f_{DFSDMCLK}$ clock cycle (with deterministic jitter),
asynchronous trigger has latency 2-3 $f_{DFSDMCLK}$ clock cycles (with jitter up to 1 cycle).

```
#define DFSDM_FLTx
0x00 dfsdm_jtrg0
0x01 dfsdm_jtrg1
...
0x1E dfsdm_jtrg30
0x1F dfsdm_jtrg31
```

Refer to Table 254: DFSDM triggers connection.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JDMAEN**: DMA channel enabled to read data for the injected channel group
0: The DMA channel is not enabled to read injected data
1: The DMA channel is enabled to read injected data
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 4 **JSCAN**: Scanning conversion mode for injected conversions
0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.
1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 **JSYNC**: Launch an injected conversion synchronously with the DFSDM_FLT0 JSWSTART trigger
0: Do not launch an injected conversion synchronously with DFSDM_FLT0
1: Launch an injected conversion in this DFSDM_FLTx at the very moment when an injected conversion is launched in DFSDM_FLT0 by its JSWSTART trigger
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
**31.8.2 DFSDM filter x control register 2 (DFSDM_FLTxCR2)**

Address offset: 0x104 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Bits 31:24 **SCDF[7:0]**: short-circuit detector flag

- SCDF[y]=0: No short-circuit detector event occurred on channel y
- SCDF[y]=1: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM_CHyAWSR registers

This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM_FLT0ISR register. SCDF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

*Note: SCDF[7:0] is present only in DFSDM_FLT0ISR register (filter x=0)*

Bits 23:16 **CKABF[7:0]**: Clock absence flag

- CKABF[y]=0: Clock signal on channel y is present.
- CKABF[y]=1: Clock signal on channel y is not present.

Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM_CHyCFGR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM_FLT0ISR register.

*Note: CKABF[7:0] is present only in DFSDM_FLT0ISR register (filter x=0)*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RCIP**: Regular conversion in progress status

- 0: No request to convert the regular channel has been issued
- 1: The conversion of the regular channel is in progress or a request for a regular conversion is pending

A request to start a regular conversion is ignored when RCIP=1.

Bit 13 **JCIP**: Injected conversion in progress status

- 0: No request to convert the injected channel group (neither by software nor by trigger) has been issued
- 1: The conversion of the injected channel group is in progress or a request for a injected conversion is pending, due either to ‘1’ being written to JSWSTART or to a trigger detection

A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **AWDF**: Analog watchdog

- 0: No Analog watchdog event occurred
- 1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM_FLTxAWLTR or DFSDM_FLTxAWHTR registers.

This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM_FLTxAWSR register (by writing ‘1’ into the clear bits in DFSDM_FLTxAWCFR register).

Bit 3 **ROVRF**: Regular conversion overrun flag

- 0: No regular conversion overrun has occurred
- 1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already ‘1’. RDATAR is not affected by overruns

This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM_FLT0ISR register.
Bit 2 **JOVRF**: Injected conversion overrun flag
0: No injected conversion overrun has occurred
1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already ‘1’. JDATAR is not affected by overruns
This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM_FLTxICR register.

Bit 1 **REOCF**: End of regular conversion flag
0: No regular conversion has completed
1: A regular conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxRDATAR.

Bit 0 **JEOCF**: End of injected conversion flag
0: No injected conversion has completed
1: An injected conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxJDATAR.

**Note**: For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM_FLTxISR are automatically reset when DFEN=0.

### 31.8.4 DFSDM filter x interrupt flag clear register (DFSDM_FLTxICR)
Address offset: 0x10C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

**Notes**
- CLRSCDF[7:0]: Clear the short-circuit detector flag
  - CLRSCDF[y]=0: Writing ‘0’ has no effect
  - CLRSCDF[y]=1: Writing ‘1’ to position y clears the corresponding SCDF[y] bit in the DFSDMFLT0ISR register
  - **Note**: CLRSCDF[7:0] is present only in DFSDM_FLT0ICR register (filter x=0)

- CLRCKABF[7:0]: Clear the clock absence flag
  - CLRCKABF[y]=0: Writing ‘0’ has no effect
  - CLRCKABF[y]=1: Writing ‘1’ to position y clears the corresponding CKABF[y] bit in the DFSDMFLT0ISR register. When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y].
  - **Note**: CLRCKABF[7:0] is present only in DFSDM_FLT0ICR register (filter x=0)

- Bits 15:4 Reserved, must be kept at reset value.
**Bit 3** CLRROVRF: Clear the regular conversion overrun flag  
0: Writing '0' has no effect  
1: Writing '1' clears the ROVRF bit in the DFSDM_FLTxISR register  

**Bit 2** CLRJOVRF: Clear the injected conversion overrun flag  
0: Writing '0' has no effect  
1: Writing '1' clears the JOVRF bit in the DFSDM_FLTxISR register  

**Bits 1:0** Reserved, must be kept at reset value.  

*Note:* The bits of DFSDM_FLTxICR are always read as '0'.

Bits 31:8  JDATA[23:0]: Injected group conversion data
When each conversion of a channel in the injected group finishes, its resulting data is stored in this field. The data is valid when JEOCF=1. Reading this register clears the corresponding JEOCF.

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  JDATACH[2:0]: Injected channel most recently converted
When each conversion of a channel in the injected group finishes, JDATACH[2:0] is updated to indicate which channel was converted. Thus, JDATA[23:0] holds the data that corresponds to the channel indicated by JDATACH[2:0].

Note: DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data. Reading this register also clears JEOCF in DFSDM_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.

31.8.8  DFSDM filter x data register for the regular channel (DFSDM_FLTxRDATAR)
Address offset: 0x11C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:8  RDATA[23:0]: Regular channel conversion data
When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  RPEND: Regular channel pending data
Regular data in RDATA[23:0] was delayed due to an injected channel trigger during the conversion

Bit 3  Reserved, must be kept at reset value.

Bits 2:0  RDATACH[2:0]: Regular channel most recently converted
When each regular conversion finishes, RDATACH[2:0] is updated to indicate which channel was converted (because regular channel selection RCH[2:0] in DFSDM_FLTxCR1 register can be updated during regular conversion). Thus RDATA[23:0] holds the data that corresponds to the channel indicated by RDATACH[2:0].

Note:  Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears REOCF in DFSDM_FLTxISR.
### 31.8.9 DFSDM filter x analog watchdog high threshold register (DFSDMFLTxAWHTR)

Address offset: \(0x120 + 0x80 \times x\), \((x = 0\) to \(3)\)
Reset value: \(0x0000\ 0000\)

**Bits 31:8 AWHT[23:0]: Analog watchdog high threshold**

These bits are written by software to define the high threshold for the analog watchdog.

*Note:* In case channel transceivers monitor \((AWFSEL=1)\), the higher 16 bits \((AWHT[23:8])\) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits \(AWHT[7:0]\) are not taken into comparison in this case.

**Bits 7:4:** Reserved, must be kept at reset value.

**Bits 3:0 BKAWH[3:0]: Break signal assignment to analog watchdog high threshold event**

- \(BKAWH[i] = 0\): Break i signal is not assigned to an analog watchdog high threshold event
- \(BKAWH[i] = 1\): Break i signal is assigned to an analog watchdog high threshold event

### 31.8.10 DFSDM filter x analog watchdog low threshold register (DFSDMFLTxAWLTR)

Address offset: \(0x120 + 0x80 \times x\), \((x = 0\) to \(3)\)
Reset value: \(0x0000\ 0000\)

<table>

</tbody>
</table>

**Bits 31:8 AWLT[23:8]: Analog watchdog low threshold**

**Bits 7:0 BKAWL[3:0]: Break signal assignment to analog watchdog low threshold event**

- \(BKAWL[i] = 0\): Break i signal is not assigned to an analog watchdog low threshold event
- \(BKAWL[i] = 1\): Break i signal is assigned to an analog watchdog low threshold event
Bits 31:8  **AWLT[23:0]**: Analog watchdog low threshold
These bits are written by software to define the low threshold for the analog watchdog.

*Note:* In case channel transceivers monitor (AWFSEL=1), only the higher 16 bits (AWLT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWLT[7:0] are not taken into comparison in this case.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **BKAWL[3:0]**: Break signal assignment to analog watchdog low threshold event
- $BKAWL[i] = 0$: Break $i$ signal is not assigned to an analog watchdog low threshold event
- $BKAWL[i] = 1$: Break $i$ signal is assigned to an analog watchdog low threshold event

### 31.8.11  DFSDM filter x analog watchdog status register (DFSDM_FLTxAWSR)
Address offset: $0x128 + 0x80 \times x$, ($x = 0$ to $3$)

Reset value: $0x0000 0000$

</tr>
</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **AWHTF[7:0]**: Analog watchdog high threshold flag
$AWHTF[y]=1$ indicates a high threshold error on channel $y$. It is set by hardware. It can be cleared by software using the corresponding $CLRAWHTF[y]$ bit in the DFSDM_FLTxAWCFR register.

Bits 7:0  **AWLTF[7:0]**: Analog watchdog low threshold flag
$AWLTF[y]=1$ indicates a low threshold error on channel $y$. It is set by hardware. It can be cleared by software using the corresponding $CLRAWLTF[y]$ bit in the DFSDM_FLTxAWCFR register.

*Note:* All the bits of DFSDM_FLTxAWSR are automatically reset when DFEN=0.
31.8.12 **DFSDM filter x analog watchdog clear flag register (DFSDM_FLTxAWCFR)**

Address offset: 0x12C + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **CLRAWHTF[7:0]**: Clear the analog watchdog high threshold flag

- CLRAWHTF[y]=0: Writing ‘0’ has no effect
- CLRAWHTF[y]=1: Writing ‘1’ to position y clears the corresponding AWHTF[y] bit in the DFSDM_FLTxAWSR register

Bits 7:0 **CLRAWLTF[7:0]**: Clear the analog watchdog low threshold flag

- CLRAWLTF[y]=0: Writing ‘0’ has no effect
- CLRAWLTF[y]=1: Writing ‘1’ to position y clears the corresponding AWLTF[y] bit in the DFSDM_FLTxAWSR register

31.8.13 **DFSDM filter x extremes detector maximum register (DFSDM_FLTxEXMAX)**

Address offset: 0x130 + 0x80 * x, (x = 0 to 3)

Reset value: 0x8000 0000

<table>

</tbody>
</table>

Bits 31:8 **EXMAX[23:0]**: Extremes detector maximum value

- These bits are set by hardware and indicate the highest value converted by DFSDM_FLTx.
- EXMAX[23:0] bits are reset to value (0x800000) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMAXCH[2:0]**: Extremes detector maximum data channel.

- These bits contains information about the channel on which the data is stored into EXMAX[23:0].
- Bits are cleared by reading of this register.
31.8.14 DFSDM filter x extremes detector minimum register (DFSDM_FLTxEXMIN)

Address offset: 0x134 + 0x80 * x, (x = 0 to 3)

Reset value: 0x7FFF FF00

<table>

</tr>
</tbody>
</table>

Bits 31:8 **EXMIN[23:0]**: Extremes detector minimum value

These bits are set by hardware and indicate the lowest value converted by DFSDM_FLTx. EXMIN[23:0] bits are reset to value (0x7FFFFF) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMINCH[2:0]**: Extremes detector minimum data channel

These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

31.8.15 DFSDM filter x conversion timer register (DFSDM_FLTxCNVTIMR)

Address offset: 0x138 + 0x80 * x, (x = 0 to 3)

32 Digital camera interface (DCMI)

32.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

32.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

32.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

</tr>
</tbody>
</table>
32.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

32.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

32.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 260.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.

Figure 243. DCMI signal waveforms

Table 260

<table>
<thead>
<tr>
<th>DCMI_PIXCLK</th>
<th>DCMI_D[12:0]</th>
<th>DCMI_HSYNC</th>
<th>DCMI_VSYNC</th>
</tr>
</thead>
</table>

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

### Table 262. Positioning of captured data bytes in 32-bit words (8-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>D_{n+3}[7:0]</td>
<td>D_{n+2}[7:0]</td>
<td>D_{n+1}[7:0]</td>
<td>D_{n}[7:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+7}[7:0]</td>
<td>D_{n+6}[7:0]</td>
<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>

#### 10-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

### Table 263. Positioning of captured data bytes in 32-bit words (10-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:26</th>
<th>25:16</th>
<th>15:10</th>
<th>9:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>D_{n+1}[9:0]</td>
<td>0</td>
<td>D_{n}[9:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[9:0]</td>
<td>0</td>
<td>D_{n+2}[9:0]</td>
</tr>
</tbody>
</table>

#### 12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

### Table 264. Positioning of captured data bytes in 32-bit words (12-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:28</th>
<th>27:16</th>
<th>15:12</th>
<th>11:0</th>
</tr>
</thead>
<tbody>
<tr>

<td>D_{n+1}[11:0]</td>
<td>0</td>
<td>D_{n}[11:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[11:0]</td>
<td>0</td>
<td>D_{n+2}[11:0]</td>
</tr>
</tbody>
</table>

#### 14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.
32.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 244 shows the corresponding timing diagram.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:30</th>
<th>29:16</th>
<th>15:14</th>

<td>D_{n+3}[13:0]</td>
<td>0</td>
<td>D_{n+2}[13:0]</td>
</tr>
</tbody>
</table>

### Table 265. Positioning of captured data bytes in 32-bit words (14-bit width)

#### Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and

---

**Figure 244. Timing diagram**

![Timing diagram](image_url)

Packet dispatching depends on the image content. This results in a variable blanking duration.
capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

**Embedded data synchronization mode**

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are not used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

*Note:* Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- **Mode 2**
  
  Four embedded codes signal the following events
  
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see Section 32.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- **Mode 1**

  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:

  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

  This mode can be supported by programming the following codes:

  - FS ≤ 0xFF
  - FE ≤ 0xFF
  - LS ≤ SAV (active)
  - LE ≤ EAV (active)

  An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

**Example**

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

### 32.3.7 DCMI capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

#### Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

![Figure 245. Frame capture waveforms in snapshot mode](ai15832b)

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

#### Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

### 32.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSIZE and DCMI_CWSTR). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

**Figure 247. Coordinates and size of the window after cropping**

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

**Figure 248. Data capture waveforms**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

### 32.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

### 32.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
### 32.3.11 DCMI data format description

#### Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

#### Figure 249. Pixel raster scan order

![Pixel raster scan order](image)

#### Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

#### Table 266. Data storage in monochrome progressive video format

#### RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGRBGR)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

### Table 267. Data storage in RGB progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>Red n + 4</td>
<td>Green n + 3</td>
<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

### Table 268. Data storage in YCbCr progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Y n + 1</td>
<td>Cr n</td>
<td>Y n</td>
<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in Table 269.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

32.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>

</tbody>
</table>
32.5 **DCMI registers**

Refer to *Section 1.2 on page 106* for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

### 32.5.1 DCMI control register (DCMI_CR)

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20 OELS:** Odd/Even Line Select (Line Select Start)

This bit works in conjunction with the LSM field (LSM = 1).

- 0: Interface captures first line after the frame start, second one being dropped.
- 1: Interface captures second line from the frame start, first one being dropped.

**Bit 19 LSM:** Line Select mode

- 0: Interface captures all received lines.
- 1: Interface captures one line out of two.

**Bit 18 OEBs:** Odd/Even Byte Select (Byte Select Start)

This bit works in conjunction with BSM field (BSM ≠ 00).

- 0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
- 1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

**Bits 17:16 BSM[1:0]: Byte Select mode**

- 00: Interface captures all received data.
- 01: Interface captures every other byte from the received data.
- 10: Interface captures one byte out of four.
- 11: Interface captures two bytes out of four.

*Note:* This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.

**Bit 15** Reserved, must be kept at reset value.

**Bit 14 ENABLE:** DCMI enable

- 0: DCMI disabled
- 1: DCMI enabled

*Note:* The DCMI configuration registers must be programmed correctly before enabling this bit.

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:10 **EDM[1:0]**: Extended data mode
- 00: Interface captures 8-bit data on every pixel clock.
- 01: Interface captures 10-bit data on every pixel clock.
- 10: Interface captures 12-bit data on every pixel clock.
- 11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]**: Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous
grab mode. They are ignored in snapshot mode.
- 00: All frames are captured.
- 01: Every alternate frame captured (50% bandwidth reduction)
- 10: One frame out of four captured (75% bandwidth reduction)
- 11: reserved

Bit 7 **VSPOL**: Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the
parallel interface.
- 0: DCMI_VSYNC active low
- 1: DCMI_VSYNC active high

Bit 6 **HSPOL**: Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the
parallel interface.
- 0: DCMI_HSYNC active low
- 1: DCMI_HSYNC active high

Bit 5 **PCKPOL**: Pixel clock polarity
This bit configures the capture edge of the pixel clock.
- 0: Falling edge active
- 1: Rising edge active

Bit 4 **ESS**: Embedded synchronization select
- 0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the
DCMI_HSYNC/DCMI_VSYNC signals.
- 1: Embedded synchronization data capture is synchronized with synchronization codes
embedded in the data flow.

*Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.*
This bit is disabled in JPEG mode.

Bit 3 **JPEG**: JPEG format
- 0: Uncompressed video format
- 1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable.
The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP**: Crop feature
- 0: The full image is captured. In this case the total number of bytes in an image frame must
be a multiple of four.
- 1: Only the data inside the window specified by the crop register is captured. If the size of the
crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM**: Capture mode
- 0: Continuous grab mode - The received data are transferred into the destination memory
through the DMA. The buffer location and mode (linear or circular buffer) is controlled
through the system DMA.
- 1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame
and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE
bit is automatically reset.
Bit 0  **CAPTURE**: Capture enable
0: Capture disabled
1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.
In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.
In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

*Note: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.*

### 32.5.2  **DCMI status register (DCMI_SR)**

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>HSYNC</td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **FNE**: FIFO not empty
This bit gives the status of the FIFO.
1: FIFO contains valid data.
0: FIFO empty

Bit 1  **VSYNC**: Vertical synchronization
This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active frame
1: synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0  **HSYNC**: Horizontal synchronization
This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active line
1: synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
32.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Bits 31:5 Reserved, must be kept at reset value. |

Bit 4 **LINE_RIS**: Line raw interrupt status
This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.
It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

Bit 3 **VSYNC_RIS**: DCMI_VSYNC raw interrupt status
This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.
It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

Bit 2 **ERR_RIS**: Synchronization error raw interrupt status
0: No synchronization error detected
1: Embedded synchronization characters are not received in the correct order.
This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR_RIS**: Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and the data FIFO is corrupted.
The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

Bit 0 **FRAME_RIS**: Capture complete raw interrupt status
0: No new capture
1: A frame has been captured.
This bit is set when a frame or window has been captured.
In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (for example window cropped outside the frame).
The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.
### 32.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

**Address offset:** 0x0C

**Reset value:** 0x0000 0000

32.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

</table>
Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

33 LCD-TFT display controller (LTDC)

33.1 Introduction

The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

33.2 LTDC main features

- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x64-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer:
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2 bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AXI master interface with burst of 16 double-words
- Up to 4 programmable interrupt events
33.3 LTDC functional description

33.3.1 LTDC block diagram

Figure 250. LTDC block diagram

33.3.2 LTDC pins and internal signals

The table below summarizes the LTDC signal interface.

</tbody>
</table>

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24 bits (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LTDC RGB data lines.

As an example, in the case of an LTDC interfacing with a RGB565 16-bit display, the LTDC display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to the LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3] pins.
The internal signals of the LTDC are given in the table below.

### Table 273. LTDC internal signals

#### 33.3.3 LTDC reset and clocks

The LTDC controller peripheral uses the following clock domains:

- AXI clock domain (ltdc_aclk)
  This domain contains the LTDC AXI master interface for data transfer from the memories to the layer FIFO and the frame-buffer configuration register.
- APB clock domain (ltdc_pclk)
  This domain contains the global configuration registers and the interrupt register.
- Pixel clock domain (LCD_CLK)
  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

The table below summarizes the clock domain for each register.

### Table 274. Clock domain for each register

<table>
<thead>
<tr>
<th>LTDC register</th>

33.4 **LTDC programmable parameters**

The LTDC controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

33.4.1 **LTDC global configuration parameters**

**Synchronous timings**

The figure below presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram *Figure 250*. It generates the horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

**Figure 251. LTDC synchronous timings**

The LTDC programmable synchronous timings are the following:

- HSYNC and VSYNC width: horizontal and vertical synchronization width, configured by programming a value of HSYNC width - 1 and VSYNC width - 1 in the LTDC_SSCR register.
- HBP and VBP: horizontal and vertical synchronization back porch width, configured by programming the accumulated value HSYNC width + HBP - 1 and the accumulated value VSYNC width + VBP - 1 in the LTDC_BPCR register.
- Active width and active height: the active width and active height are configured by programming the accumulated value HSYNC width + HBP + active width - 1 and the
accumulated value VSYNC width + VBP + active height - 1 in the LTDC_AWCR register.

- Total width: the total width is configured by programming the accumulated value HSYNC width + HBP + active width + HFP - 1 in the LTDC_TWCR register. The HFP is the horizontal front porch period.
- Total height: the total height is configured by programming the accumulated value VSYNC height + VBP + active height + VFP - 1 in the LTDC_TWCR register. The VFP is the vertical front porch period.

Note: When the LTDC is enabled, the timings generated start with \( X/Y = 0/0 \) position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch. When the LTDC is disabled, the timing generator block is reset to \( X = \text{total width} - 1, Y = \text{total height} - 1 \) and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

Example of synchronous timings configuration

LTDC timings (must be extracted from panel datasheet):

- horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
- horizontal and vertical back porch: 0x14 pixels and 0x2 lines
- active width and active height: 0x140 pixels, 0xF0 lines (320x240)
- horizontal front porch: 0xA pixels
- vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:

- LTDC_SSCR register to be programmed to 0x00090001 (HSW[11:0] is 0x9 and VSH[10:0] is 0x1)
- LTDC_BPCR register to be programmed to 0x001D0003 (AHBP[11:0] is 0x1D (0xA + 0x13) and AVBP[10:0]A is 0x3 (0x2 + 0x1))
- LTDC_AWCR register to be programmed to 0x015D00F3 (AAW[11:0] is 0x15D (0xA + 0x14 + 0x13F) and AAH[10:0] is 0xF3 (0x2 + 0x2 + 0xEF))
- LTDC_TWCR register to be programmed to 0x00000167 (TOTALW[11:0] is 0x167 (0xA + 0x14 + 0x140 + 0x9))
- LTDC_THCR register to be programmed to 0x000000F7 (TOTALH[10:0]is 0xF7 (0x2 + 0x2 + 0xF0 + 3))

Programmable polarity

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC_GCR register.

Background color

A constant background color (RGB888) can programmed through the LTDC_BCCR register. It is used for blending with the bottom layer.

Dithering

The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in
some cases when displaying a 24-bit data on 18-bit display. Thus the dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is ≥ the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is two bits for each color channel: two bits for red, two bits for green and two bits for blue.

Once the LTDC is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched on and off on the fly through the LTDC_GCR register.

Reload shadow registers

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload must be activated only when all new registers have been written.

The shadow registers must not be modified again before the reload is done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all Layer1 and Layer2 registers except LTDC_LxCLUTWR.

Interrupt generation event

Refer to Section 33.5: LTDC interrupts for the interrupt configuration.

33.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

Windowing

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.

The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame (see Figure 252):

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPO[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPO[10:0] in the LTDC_LxWVPCR register.
Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer.

Up to eight input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions) 43210432 (the three LSBs are filled with the three MSBs of the five bits).

The table below describes the pixel data mapping depending on the selected format.

</tbody>
</table>

The table above describes the pixel data mapping depending on the selected format.
The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:

- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.
• In case of AL44 input pixel format, the CLUT must be loaded by only 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
  – L0 (indexed color 0), at address 0x00
  – L1, at address 0x11
  – L2, at address 0x22
  – ....
  – L15, at address 0xFF

**Color frame buffer address**

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

**Color frame buffer length**

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer:
  • If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
  • If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

**Color frame buffer pitch**

Every layer has a configurable pitch for the color frame buffer, that is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.

**Layer blending**

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to the figure below.

**Figure 253. Blending two layers with background**

[Diagram showing blending two layers with background]
Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

Color keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

Example: if the a mid-yellow color (50 % red + 50 % green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000. Set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.

33.5 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LIPCR register
- Register reload interrupt: generated when the shadow registers reload is performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AXI bus error occurs during data transfer
These interrupt events are connected to the NVIC controller as described in the figure below.

**Figure 254. Interrupt events**

<table>

</tbody>
</table>

**33.6 LTDC programming procedure**

The steps listed below are needed to program the LTDC:

1. Enable the LTDC clock in the RCC register.
2. Configure the required pixel clock following the panel datasheet.
3. Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the [Section 33.4.1](#).
4. Configure the synchronous signals and clock polarity in the LTDC_GCR register.
5. If needed, configure the background color in the LTDC_BCCR register.
6. Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
7. Configure the layer1/2 parameters by:
   - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_WVPCR registers. The layer window must be in the active data area.
   - programming the pixel input format in the LTDC_LxPFCR register
   - programming the color frame buffer start address in the LTDC_LxCFBAR register
   - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
   - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
   - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCFUTWR register
   - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
8. Enable layer 1/2 and if needed the CLUT in the LTDC_LxCR register.
9. If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
10. Reload the shadow registers to active register through the LTDC_SRCR register.
11. Enable the LTDC controller in the LTDC_GCR register.
12. All layer parameters can be modified on the fly except the CLUT. The new configuration must be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

Note: All layer’s registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.

### 33.7 LTDC registers

#### 33.7.1 LTDC synchronization size configuration register (LTDC_SSCR)

Address offset: 0x008  
Reset value: 0x0000 0000  
This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 251 and Section 33.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HSW[11:0]**: Horizontal synchronization width (in units of pixel clock period)
   This bitfield defines the number of Horizontal Synchronization pixel minus 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **VSH[10:0]**: Vertical synchronization height (in units of horizontal scan line)
   This bitfield defines the vertical Synchronization height minus 1. It represents the number of horizontal synchronization lines.

#### 33.7.2 LTDC back porch configuration register (LTDC_BPCR)

Address offset: 0x00C  
Reset value: 0x0000 0000  
This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical
synchronization and back porch lines minus 1 (VSYNC height + VBP - 1).
Refer to Figure 251 and Section 33.4 for an example of configuration.

</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]**: Accumulated horizontal back porch (in units of pixel clock period)
These bits defines the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.
The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AVBP[10:0]**: Accumulated Vertical back porch (in units of horizontal scan line)
These bits define the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.
The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

### 33.7.3 LTDC active width configuration register (LTDC_AWCR)

Address offset: 0x010
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + VBP + active height - 1). Refer to Figure 251 and Section 33.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AAW[11:0]**: Accumulated active width (in units of pixel clock period)
These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.
The active width is the number of pixels in active display area of the panel scan line.
Refer to device datasheet for maximum active width supported following maximum pixel clock.
Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AAH[10:0]**: Accumulated active height (in units of horizontal scan line)

These bits define the accumulated height which includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel.

Refer to device datasheet for maximum active height supported following maximum pixel clock.

### 33.7.4 LTDC total width configuration register (LTDC_TWCR)

Address offset: 0x014

Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + VBP + active height + VFP - 1). Refer to Figure 251 and Section 33.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **TOTALW[11:0]**: Total width (in units of pixel clock period)

These bits define the accumulated total width which includes the horizontal synchronization, horizontal back porch, active width and horizontal front porch pixels minus 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **TOTALH[10:0]**: Total height (in units of horizontal scan line)

These bits define the accumulated height which includes the vertical synchronization, vertical back porch, the active height and vertical front porch height lines minus 1.

### 33.7.5 LTDC global control register (LTDC_GCR)

Address offset: 0x018

Reset value: 0x0000 2220

This register defines the global configuration of the LCD-TFT controller.

Bits 31:28 Reserved, must be kept at reset value.
Bit 31  **HSPOL**: Horizontal synchronization polarity
This bit is set and cleared by software.
0: Horizontal synchronization polarity is active low.
1: Horizontal synchronization polarity is active high.

Bit 30  **VSPOL**: Vertical synchronization polarity
This bit is set and cleared by software.
0: Vertical synchronization is active low.
1: Vertical synchronization is active high.

Bit 29  **DEPOL**: Not data enable polarity
This bit is set and cleared by software.
0: Not data enable polarity is active low.
1: Not data enable polarity is active high.

Bit 28  **PCPOL**: Pixel clock polarity
This bit is set and cleared by software.
0: Pixel clock polarity is active low.
1: Pixel clock is active high.

Bits 27:17  Reserved, must be kept at reset value.

Bit 16  **DEN**: Dither enable
This bit is set and cleared by software.
0: Dither disabled
1: Dither enabled

Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **DRW[2:0]**: Dither red width
These bits return the dither red bits.

Bit 11  Reserved, must be kept at reset value.

Bits 10:8  **DGW[2:0]**: Dither green width
These bits return the dither green bits.

Bit 7  Reserved, must be kept at reset value.

Bits 6:4  **DBW[2:0]**: Dither blue width
These bits return the dither blue bits.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **LTDCEN**: LCD-TFT controller enable
This bit is set and cleared by software.
0: LTDC disabled
1: LTDC enabled
33.7.6 LTDC shadow reload configuration register (LTDC_SRCR)

Address offset: 0x024
Reset value: 0x0000 0000

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC_L1CLUTWR and the LTDC_L2CLUTWR.

The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 VBR: Vertical blanking reload
This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).
0: No effect
1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 IMR: Immediate reload
This bit is set by software and cleared only by hardware after reload.
0: No effect
1: The shadow registers are reloaded immediately.

33.7.7 LTDC background color configuration register (LTDC_BCCR)

Address offset: 0x02C
Reset value: 0x0000 0000

This register defines the background color (RGB888).

These bits configure the background green value.

Bits 7:0 **BCBLUE[7:0]**: Background color blue value
These bits configure the background blue value.

### 33.7.8 LTDC interrupt enable register (LTDC_IER)

Address offset: 0x034
Reset value: 0x0000 0000

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

<table>

### 33.7.13 LTDC current display status register (LTDC_CDSR)

Address offset: 0x048

Reset value: 0x0000 000F

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNC bit is active high.

The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

33.7.15 **LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)**

Address offset: 0x088 + 0x80 \* (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window. The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

**Example:** The LTDC_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:

- layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5).
- layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

</tbody>
</table>

**WHSPPOS[11:0]**

- Bits 31:28 Reserved, must be kept at reset value.
- Bits 27:16 **WHSPPOS[11:0]:** Window horizontal stop position
  
  These bits configure the last visible pixel of a line of the layer window. WHSPPOS[11:0] must be ≥ AHBP[11:0] bits + 1 (programmed in LTDC_BPCR register).
33.7.16 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)

Address offset: 0x08C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.

The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

Example:
The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:
- layer window first line, WVSTPOS[10:0], must be programmed to 0xE (0x5 + 1 + 0x8).
- layer window last line, WVSPPOS[10:0] must be programmed to 0x1DA.

| Bits 31:27 | Reserved, must be kept at reset value. |
| Bits 26:16 | WVSPPOS[10:0]: Window vertical stop position |
| These bits configure the last visible line of the layer window. |

| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | WVSTPOS[10:0]: Window vertical start position |
| These bits configure the first visible line of the layer window. |
| WVSTPOS[10:0] must be ≤ AAH[10:0] bits (programmed in LTDC_AWCR register). |
33.7.17  **LTDC layer x color keying configuration register (LTDC_LxCKCR)**

Address offset: 0x090 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color key value (RGB), that is used by the color keying.

<table>

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **CKRED[7:0]**: Color key red value

Bits 15:8  **CKGREEN[7:0]**: Color key green value

Bits 7:0  **CKBLUE[7:0]**: Color key blue value

33.7.18  **LTDC layer x pixel format configuration register (LTDC_LxPFCR)**

Address offset: 0x094 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

<table>

</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **PF[2:0]**: Pixel format

These bits configure the pixel format
000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
101: L8 (8-bit luminance)
110: AL44 (4-bit alpha, 4-bit luminance)
111: AL88 (8-bit alpha, 8-bit luminance)
### 33.7.19 LTDC layer x constant alpha configuration register (LTDC_LxCACR)

Address offset: 0x098 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 00FF

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC_LxBFCR register.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>

<td>rw</td>
</tr>
</tbody>
</table>

**Bits 31:8** Reserved, must be kept at reset value.

**Bits 7:0** **CONSTA[7:0]:** Constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is \(255 / 255 = 1\).

### 33.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR)

Address offset: 0x09C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

<table>
<thead>
<tr>
<th>31</th>

</tbody>
</table>

**Bits 31:24** **DCALPHA[7:0]:** Default color alpha

These bits configure the default alpha value.

**Bits 23:16** **DCRED[7:0]:** Default color red

These bits configure the default red value.

**Bits 15:8** **DCGREEN[7:0]:** Default color green

These bits configure the default green value.

**Bits 7:0** **DCBLUE[7:0]:** Default color blue

These bits configure the default blue value.
33.7.21  **LTDC layer x blending factors configuration register (LTDC_LxBFCR)**

Address offset: 0x0A0 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0607

This register defines the blending factors F1 and F2.

The general blending formula is: \( BC = BF1 \times C + BF2 \times Cs \)

- \( BC \) = blended color
- \( BF1 \) = blend factor 1
- \( C \) = current layer color
- \( BF2 \) = blend factor 2
- \( Cs \) = subjacent layers blended color

The constant alpha value, is the programmed value in LTDC_LxCACR divided by 255 by hardware.

*Example:* Only layer 1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128.

\( Cs \): background color is 48. Layer 1 is blended with the background color.

\[ BC = constant \ alpha \times C + (1 - Constant \ Alpha) \times Cs = 0.94 \times 128 + (1 - 0.94) \times 48 = 123. \]

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:8  **BF1[2:0]:** Blending factor 1

These bits select the blending factor F1.

100: constant alpha  
110: pixel alpha x constant alpha  
Others: Reserved

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  **BF2[2:0]:** blending factor 2

These bits select the blending factor F2.

101: 1 - constant alpha  
111: 1 - (pixel alpha x constant alpha)  
Others: Reserved
33.7.22  **LTDC layer x color frame buffer address register (LTDC_LxCFBAR)**

Address offset: 0x0AC + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Bits 31:0  **CFBADD[31:0]**: Color frame buffer start address  
These bits define the color frame buffer start address.

33.7.23  **LTDC layer x color frame buffer length register (LTDC_LxCFBLR)**

Address offset: 0x0B0 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer line length and pitch.

**Example:**

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.

</tbody>
</table>

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:16  **CFBP[12:0]**: Color frame buffer pitch in bytes  
These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13  Reserved, must be kept at reset value.
33.7.24  **LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR)**

- **Address offset**: 0x0B4 + 0x80 * (x - 1), (x = 1 to 2)
- **Reset value**: 0x0000 0000

This register defines the number of lines in the color frame buffer.

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.

<table>
<thead>
<tr>
<th>Bits 12:0 CFBL[12:0]: Color frame buffer line length</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits define the length of one line of pixels in bytes + 7.</td>
</tr>
<tr>
<td>The line length is computed as follows:</td>
</tr>
<tr>
<td>active high width * number of bytes per pixel + 7.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 31:11 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 10:0 CFBLNBR[10:0]: Frame buffer line number</td>
</tr>
<tr>
<td>These bits define the number of lines in the frame buffer that corresponds to the active high width.</td>
</tr>
</tbody>
</table>

33.7.25  **LTDC layer x CLUT write register (LTDC_LxCLUTWR)**

- **Address offset**: 0x0C4 + 0x80 * (x - 1), (x = 1 to 2)
- **Reset value**: 0x0000 0000

This register defines the CLUT address and the RGB value.

The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register.

The CLUT is only meaningful for L8, AL44 and AL88 pixel format.
Bits 31:24 **CLUTADD[7:0]**: CLUT address
These bits configure the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 **RED[7:0]**: Red value
These bits configure the red value.

Bits 15:8 **GREEN[7:0]**: Green value
These bits configure the green value.

Bits 7:0 **BLUE[7:0]**: Blue value
These bits configure the blue value.

34 DSI Host (DSI)

34.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The display serial interface (DSI) is part of a group of communication protocols defined by the MIPI® Alliance.

The MIPI® DSI Host controller is a digital core that implements all protocol functions defined in the MIPI® DSI specification. It provides an interface between the system and the MIPI® D-PHY, allowing the user to communicate with a DSI-compliant display.

34.2 Standard and references

- MIPI® Alliance Specification for Display Serial interface (DSI)  
  v1.1 - 22 November 2011

- MIPI® Alliance Specification for Display Command set (DCS)  
  v1.1 - 22 November 2011
- MIPI® Alliance Specification for Display Pixel interface (DPI-2)  
  v2.00 - 15 September 2005
- MIPI® Alliance Specification for Stereoscopic Display Formats (SDF)  
  v1.0 - 22 November 2011
- MIPI® Alliance Specification for D-PHY  
  v1.1 - 7 November 2011
34.3 DSI Host main features

- Compliant with MIPI® Alliance standards (see Section 34.2: Standard and references)
- Interface with MIPI® D-PHY
- Supports all commands defined in the MIPI® Alliance specification for DCS:
  - Transmission of all command mode packets through the APB interface
  - Transmission of commands in low-power and high-speed during video mode
- Supports up to two D-PHY data lanes
- Bidirectional communication and escape mode support through data lane 0
- Supports non continuous clock in D-PHY clock lane for additional power saving
- Supports ultra low-power mode with PLL disabled
- ECC and checksum capabilities
- Support for end of transmission packet (EoTp)
- Fault recovery schemes
- Configurable selection of system interfaces:
  - AMBA APB for control and optional support for generic and DCS commands
  - Video mode interface through LTDC
  - Adapted command mode interface through LTDC
  - Independently programmable virtual channel ID in video mode, adapted command mode, and APB slave
- Video mode interfaces features:
  - LTDC interface color coding mappings into 24-bit interface:
    • 16-bit RGB, configurations 1, 2, and 3
    • 18-bit RGB, configurations 1 and 2
    • 24-bit RGB
  - Programmable polarity of all LTDC interface signals
  - Extended resolutions beyond the DPI standard maximum resolution of 800x480 pixels
  - Maximum resolution is limited by available DSI physical link bandwidth:
    • Number of lanes: 2
    • Maximum speed per lane: 1 Gbit/s
    • See examples in Section 34.4.3: Supported resolutions and frame rates
- Adapted interface features:
  - Support for sending large amounts of data through the memory_write_start (WMS) and memory_write_continue (WMC) DCS commands
  - LTDC interface color coding mappings into 24-bit interface:
    • 16-bit RGB, configurations 1, 2, and 3
    • 18-bit RGB, configurations 1 and 2
    • 24-bit RGB
- Video mode pattern generator:
  - Vertical and horizontal color bar generation without LTDC stimuli
  - BER pattern without LTDC stimuli
34.4 DSI Host functional description

34.4.1 General description

The MIPI® DSI Host includes dedicated video interfaces internally connected to the LTDC and a generic APB interface that can be used to transmit information to the display. More in detail:

- **LTDC interface**:
  - Used to transmit information in video mode, in which the transfers from the host processor to the peripheral take the form of a real-time pixel stream (DPI).
  - Through a customized mode, this interface can be used to transmit information in full bandwidth in the adapted command mode (DBI).

- **APB slave interface**: allows the transmission of generic information in command mode, and follows a proprietary register interface. This interface can operate concurrently with either LTDC interface in either video mode or adapted command mode.

- **Video mode pattern generator**: allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

The block diagram is shown in Figure 255.

34.4.2 DSI Host pins and internal signals

*Table 279 and Table 280 list, respectively, the DSI pins (alternate functions) and the internal input/output signals.*
34.4.3 Supported resolutions and frame rates

The DSI specification does not define supported standard resolutions or frame rates. Display resolution, blanking periods, synchronization events duration, frame rates, and pixel color depth play a fundamental role in the required bandwidth. In addition, other link related attributes can influence the ability of the link to support a DSI-specific device, namely display input buffering capabilities, video transmission mode (burst or non-burst), bus turn-around (BTA) time, concurrent command mode traffic in a video mode transmission, or display device specifics. All these variables make it difficult to define a standard procedure to estimate the minimum lane rate and the minimum number of lanes that support a specific display device.

The basic assumptions for estimates are:
- clock lane frequency is 500 MHz, resulting in a bandwidth of 1 Gbit/s for each data lane
- the display must be capable of buffering the pixel data at the speed at which it is delivered in the DSI link
- no significant control traffic is present on the link when the pixel data is being transmitted.

34.4.4 System level architecture

Figure 256 shows the architecture of the DSI Host
The different parts have the following functions:

- The DSI Wrapper ensures the interfacing between the LTDC and the DSI Host kernel. It can adapt the color mode, the signal polarity and manages the tearing effect (TE) management for automatic frame buffer update in adapted command mode. The DSI Wrapper also controls the DSI regulator, the DSI PLL and specific functions of the MIPI® D-PHY.

- The LTDC interface captures the data and control signals from the LTDC and conveys them to a FIFO for video control signals and another one for the pixel data. This data is then used to build one of the following:
  - Video packets, when in video mode (see Section 34.5)
  - The `memory_write_start` and `memory_write_continue` DCS commands, when in adapted command mode (see Section 34.6)

- The register bank is accessible through a standard AMBA-APB slave interface, providing access to the DSI Host registers for configuration and control. There is also a fully programmable interrupt generator to inform the system about certain events.

- The PHY interface control is responsible for managing the D-PHY interface. It acknowledges the current operation and enables low-power transmission/reception or a high-speed transmission. It also performs data splitting between available D-PHY lanes for high-speed transmission.

- The packet handler schedules the activities inside the link. It performs several functions based on the interfaces that are currently operational and the video transmission mode that is used (burst mode or non-burst mode with sync pulses or sync events). It builds
long or short packet generating correspondent ECC and CRC codes. This block also performs the following functions:

- packet reception
- validation of packet header by checking the ECC
- header correction and notification for single-bit errors
- termination of reception
- multiple header error notification
- depending on the virtual channel of the incoming packet, the handler routes the output data to the respective port.

- The APB-to-generic block bridges the APB operations into FIFOs holding the generic commands. The block interfaces with the following FIFOs:
  - Command FIFO
  - Write payload FIFO
  - Read payload FIFO

- The error management notifies and monitors the error conditions on the DSI link. It controls the timers used to determine if a timeout condition occurred, performing an internal soft reset and triggering an interruption notification.
### 34.5 Functional description: video mode on LTDC interface

The LTDC interface captures the data and control signals and conveys them to the FIFO interfaces that transmit them to the DSI link.

Two different streams of data are present at the interface, namely video control signals and pixel data. Depending on the interface color coding, the pixel data is disposed differently throughout the LTDC bus.

Interface pixel color coding is summarized in Table 281.

<table>

</tr>
</tbody>
</table>
The LTDC interface can be configured to increase flexibility and promote correct use of this interface for several systems. The following configuration options are available:

- **Polarity control**: all the control signals are programmable to change the polarity depending on the LTDC configuration.
- After the core reset, DSI Host waits for the first VSYNC active transition to start signal sampling, including pixel data, thus avoiding starting the transmission of the image data in the middle of a frame.
- If interface pixel color coding is 18 bits and the 18-bit loosely packed stream is disabled, the number of pixels programmed in the VPSIZE field must be a multiple of four. This means that in this mode, the two LSBs in the configuration are always inferred as zero. The specification states that in this mode, the pixel line size must be a multiple of four.
- To avoid FIFO underflows and overflows, the configured number of pixels is assumed to be received from the LTDC at all times.
- To keep the memory organized with respect to the packet scheduling, the number of pixels per packet parameter is used to separate the memory space of different video packets.

For SHTDN and COLM sampling and transmission, the video streaming from the LTDC must be active. This means that if the LTDC is not actively generating the video signals like VSYNC and HSYNC, these signals are not transmitted through the DSI link. Because of such constraints and for commands to be correctly transmitted, the first VSYNC active pulse must occur for the command sampling and transmission. When shutting down the display, it is necessary for the LTDC to be kept active for one frame after the command being issued. This ensures that the commands are correctly transmitted before actually disabling the video generation at the LTDC interface.

The SHTDN and COLM values can be programmed in the DSI Wrapper control register (DSI_WCR).

For all of the data types, one entire pixel is received per each clock cycle. The number of pixels of payload is restricted to a multiple of a value, as shown in Table 282.

### 34.5.1 Video transmission mode

There are different video transmission modes, namely:

- **Burst mode**
- **Non-burst mode**
  - Non-burst mode with sync pulse
  - Non-burst mode with sync event
Burst mode
In this mode, the entire active pixel line is buffered into a FIFO and transmitted in a single packet with no interruptions. This transmission mode requires that the DPI pixel FIFO has the capacity to store a full line of active pixel data inside it. This mode is optimally used when the difference between the pixel required bandwidth and DSI link bandwidth is significant, it enables the DSI Host to quickly dispatch the entire active video line in a single burst of data and then return to low-power mode.

Non-burst mode
In this mode, the processor uses the partitioning properties of the DSI Host to divide the video line transmission into several DSI packets. This is done to match the pixel required bandwidth with the DSI link bandwidth. With this mode, the controller configuration does not require a full line of pixel data to be stored inside the LTDC interface pixel FIFO. It requires only the content of one video packet.

Guidelines for selecting the burst or non-burst mode
Selecting the burst and non-burst mode is mainly dependent on the system configuration and the device requirements. Choose the video transmission mode that suits the application scenario. The burst mode is more beneficial because it increases the probability of the link spending more time in the low-power mode, decreasing power consumption. The following conditions must be met to get the maximum benefits from the burst mode of operation:

- The DSI Host core must have sufficient pixel memory to store an entire pixel line to avoid the overflow of the internal FIFOs.
- The display device must support receiving a full pixel line in a single packet burst to avoid the overflow on the reception buffer.
- The DSI output bandwidth must be higher than the LTDC interface input bandwidth in a relation that enables the link to go to low-power once per line.

If the system cannot meet these requirements, it is likely that the pixel data is lost causing the malfunctioning of the display device while using the burst mode. These errors are related to the capabilities of the system to store the temporary pixel data.

If all the conditions for using the burst mode cannot be met, use the non-burst mode to avoid errors. The non-burst mode provides a better matching of rates for pixel transmission, enabling:

- only a certain number of pixels to be stored in the memory, and not requiring a full pixel line (lesser LTDC interface RAM requirements in the DSI Host)
- operation with devices that support only a small amount of pixel buffering (less than a full pixel line).

The DSI non-burst mode must be configured so that the DSI output pixel ratio matches with the LTDC interface input pixel ratio, reducing the memory requirements on both host and/or device side. This is achieved by dividing a pixel line into several chunks of pixels and optionally interleaving them with null packets.

The following equations show how the DSI Host core transmission parameters must be programmed in non-burst mode to match the DSI link pixel output ratio (left hand side of the “=” sign) and LTDC interface pixel input (right hand side of the “=” sign).
When the null packets are enabled:
\[
\text{lanebyteclkperiod} \times \text{NUMC} \times (\text{VPSIZE} \times \text{bytes_per_pixel} + 12 + \text{NPSIZE}) / \text{number_of_lanes} \\
= \text{pixels_per_line} \times \text{LTDC_Clock_period}
\]

When the null packets are disabled:
\[
\text{lanebyteclkperiod} \times \text{NUMC} \times (\text{VPSIZE} \times \text{bytes_per_pixel} + 6) / \text{number_of_lanes} \\
= \text{pixels_per_line} \times \text{LTDC_Clock_period}
\]

### 34.5.2 Updating the LTDC interface configuration in video mode

It is possible to update the LTDC interface configuration on the fly without impacting the current frame. It is done with the help of shadow registers. This feature is controlled by the DSI Host video shadow control register (DSI_VSCR).

The new configuration is only used when the system requests for it. To update the video configuration during the transmission of a video frame, the configuration of that frame needs to be stored in the auxiliary registers. This way, the new frame configurations can be set through the APB interface without corrupting the current frame.

By default, this feature is disabled. To enable this feature, set the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) to 1.

When this feature is enabled, the system supplies the configuration stored in the auxiliary registers.

*Figure 257* shows the necessary steps to update the LTDC interface configuration.

### Immediate update

When the shadow register feature is active, the auxiliary registers require the LTDC configuration before the video engine starts. This means that, after a reset, update register (UR) bit is immediately granted.
When it is required to immediately update the active registers without the reset (as in Figure 258), ensure that the enable (EN) and update register (UR) bits of the DSI Host video shadow control register (DSI_VSCR) are set to 0.

**Figure 258. Immediate update procedure**

Updating the configuration during the transmission of a frame using APB

To update the LTDC interface configuration, follow the steps shown in Figure 259:

1. Ensure that the enable (EN) bit of the DSI Host video shadow control register (DSI_VSCR) register is set to 1.
2. Set the update register (UR) bit of DSI Host video shadow control register (DSI_VSCR) to 1.
3. Monitor the update register (UR) bit. This bit is set to 0 when the update is complete.

**Figure 259. Configuration update during the transmission of a frame**

Requesting a configuration update

It is possible to request for the LTDC interface configuration update at any part of the frame. DSI Host waits until the end of the frame to change the configuration. However, avoid sending the update request during the first line of the frame because the data must propagate between clock domains.
34.6 **Functional description: adapted command mode on LTDC interface**

The adapted command mode, enables the system to input a stream of pixel from the LTDC that is conveyed by DSI Host using the command mode transmission (using the DCS packets). The adapted command mode also supports pixel input control rate signaling and tearing effect report mechanism.

The adapted command mode makes it possible to send large amounts of data through the `memory_write_start` (WMS) and `memory_write_continue` (WMC) DCS commands. It helps in delivering a wider data bandwidth for the memory write operations sent in command mode to MIPI® displays and to refresh large areas of pixels in high resolution displays. If additional commands such as display configuration commands, read back commands, and tearing effect initialization are to be transferred, then the APB slave generic interface must be used to complement the adapted command mode functionality.

Adapted command mode of operation supports 16 bpp, 18 bpp, and 24 bpp RGB.

To transmit the image data in adapted command mode:

- Set command mode (CMDM) bit of the DSI Host mode configuration register (DSI_MCR) to 1.
- Set DSI mode (DSIM) bit in the DSI Wrapper configuration register (DSI_WCFGR) to 1.

To transmit the image data, follow these steps:

- Define the image area to be refreshed, by using the `set_column_address` and `set_page_address` DCS commands. The image area needs to be defined only once and remains effective until different values are defined.
- Define the pixel color coding to be used by using the color coding (COLC) field in the DSI Host LTDC color coding register (DSI_LCOLCR).
- Define the virtual channel ID of the LTDC interface generated packets using the virtual channel ID (VCID) field in the DSI Host LTDC VCID register (DSI_LVCIDR). These also need to be defined only once.
- Start transmitting the data from the LTDC setting the LTDC enable (LTDCEN) bit of the DSI_WCR register.

*Figure 260* shows the adapted command mode usage flow.
When the command mode (CMDM) bit of the DSI Host mode configuration register (DSI_CFGR) is set to 1, the LTDC interface assumes the behavior corresponding to the adapted command mode.

In this mode, the host processor can use the LTDC interface to transmit a continuous stream of pixels to be written in the local frame buffer of the peripheral. It uses a pixel input bus to receive the pixels and controls the flow automatically to limit the stream of continuous pixels. When the first pixel is received, the current value of the command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR), is shadowed to the internal interface function. The interface increments a counter on every valid pixel that is input through the interface. When this pixel counter reaches command size (CMDSIZE), a command is written into the command FIFO, and the packet can be transmitted through the DSI link.

If the last pixel arrives before the counter reaches the value of shadowed command size (CMDSIZE), a WMS command is issued to the command FIFO with word count (WC) set to the number of bytes corresponding to the counter value. If more than CMDSIZE pixels are received (shadowed value), a WMS command is sent to the command FIFO with WC set to the number of bytes corresponding to the command size (CMDSIZE) and the counter is restarted.

After the first WMS command has been written to the FIFO, the circuit behaves in a similar way, but issues WMC commands instead of WMS commands. The process is repeated until the last pixel of the image is received. The core automatically starts sending a new packet.
when the last pixel of the image is received, falls, or command size (CMDSIZE) limit is reached.

**Synchronization with the LTDC**

The DSI Wrapper performs the synchronization of the transfer process by:
- controlling the start/halt of the LTDC
- making the data flow control between LTDC and DSI Host.

The transfer to refresh the display frame buffer can be triggered
- manually, setting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR)
- automatically when a tearing effect (TEIF) event occurs, and automatic refresh (AR) is enabled.

The selection between manual and automatic mode is done through the automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR).

Once the transfer of one frame is done whatever in manual or automatic refresh mode, the DSI Wrapper halts the TFT display controller (LTDC), resetting the LTDC enable (LTDCEN) bit of the DSI Wrapper control register (DSI_WCR), and setting the end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR). If the end of refresh interrupt enable (ERIE) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, an interrupt is generated.

The end of refresh interrupt flag (ERIF) flag of the DSI Wrapper status register (DSI_WSR) can be reset setting the clear end of refresh interrupt flag (CERIF) bit of the DSI Wrapper clear interrupt flag register (DSI_WCIFR).

The halting of the TFT display controller (LTDC) by the DSI Wrapper is done synchronously on a rising edge or a falling edge of VSync according to the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

**Support of tearing effect**

The DSI specification supports tearing effect function in command mode displays. It enables the Host processor to receive timing accurate information about where the display peripheral is in the process of reading the content of its frame buffer.

The tearing effect can be managed through:
- a separate pin, which is not covered in the DSI specification
- the DSI tearing effect functionality: a set_tear_on DCS command must be issued through the APB interface using the generic interface registers.

**Tearing effect through a GPIO**

When the tearing effect source (TESRC) bit of the DSI Wrapper configuration register (DSI_WCFGR) is set, the tearing effect is signaled through a GPIO.

The polarity of the input signal can be configured by the tearing effect polarity (TEPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).

When the programmed edge is detected, the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR) is set.

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.
**Tearing effect through DSI link**

When the TESRC bit of the DSI Wrapper configuration register (DSI_WCFGR) is reset, the tearing effect is managed through the DSI link:

The DSI Host performs a double bus turn-around (BTA) after sending the `set_tear_on` command granting the ownership of the link to the DSI display. The display holds the ownership of the bus until the tear event occurs, which is indicated to the DSI Host by a D-PHY trigger event. The DSI Host then decodes the trigger and reports the event setting the tearing effect interrupt flag (TEIF) bit of the DSI Wrapper interrupt and status register (DSI_WISR).

If the tearing effect interrupt enable (TEIE) bit of the DSI Wrapper interrupt enable register (DSI_WIER) is set, an interrupt is generated.

To use this function, it is necessary to issue a `set_tear_on` command after the update of the display using the WMS and WMC DCS commands. This procedure halts the DSI link until the display is ready to receive a new frame update.

The DSI Host does not automatically generate the tearing effect request (double BTA) after a WMS/WMC sequence for flexibility purposes, so several regions of the display can be updated improving DSI bandwidth usage. Tearing effect request must always be triggered by a `set_tear_on` command in the DSI Host implementation.

Configure the following registers to activate the tearing effect:

- **DSI Host command mode configuration register (DSI_CMCR): TEARE**
- **DSI Host protocol configuration register (DSI_PCR): BTAE.**
34.7 **Functional description: APB slave generic interface**

The APB slave interface allows the transmission of generic information in command mode, and follows a proprietary register interface. Commands sent through this interface are not constrained to comply with the DCS specification, and can include generic commands described in the DSI specification as manufacturer-specific.

The DSI Host supports the transmission of write and read command mode packets as described in the DSI specification. These packets are built using the APB register access. The DSI Host generic payload data register (DSI_GPDR) has two distinct functions based on the operation. Writing to this register sends the data as payload when sending a command mode packet. Reading this register returns the payload of a read back operation.

The DSI Host generic header configuration register (DSI_GHCR) contains the command mode packet header type and header data. Writing to this register triggers the transmission of the packet implying that for a long command mode packet, the packet payload needs to be written in advance in the DSI Host generic payload data register (DSI_GPDR).

The valid packets that can be transmitted through the generic interface are the following:

- Generic write short packet 0 parameters
- Generic write short packet 1 parameters
- Generic write short packet 2 parameters
- Generic read short packet 0 parameters
- Generic read short packet 1 parameters
- Generic read short packet 2 parameters
- Maximum read packet configuration
- Generic long write packet
- DCS write short packet 0 parameters
- DCS write short packet 1 parameters
- DCS read short packet 0 parameters
- DCS write long packet.

A set of bits in the DSI Host generic packet status register (DSI_GPSR) reports the status of the FIFO associated with APB interface support.

Generic interface packets are always transported using one of the DSI transmission modes, that is, video mode or command mode. If neither of these modes is selected, the packets are not transmitted through the link, and the related FIFO eventually becomes overflown.

### 34.7.1 Packet transmission using the generic interface

The transfer of packets through the APB bus is based on the following conditions:

- The APB protocol defines that the write and read procedure takes two clock cycles each to be executed. This means that the maximum input data rate through the APB interface is always half the speed of the APB clock.
- The data input bus has a maximum width of 32 bits. This allows for a relation to be defined between the input APB clock frequency and the maximum bit rate achievable by the APB interface.
- The DSI link pixel bit rate when using solely APB is \((\text{APB clock frequency}) \times \frac{16}{2} \text{ Mbit/s}\).
- When using only the APB interface, the theoretical DSI link maximum bit rate can be expressed as \(\text{DSI link maximum bit rate} = \text{APB clock frequency (in MHz)} \times \frac{32}{2} \text{ Mbit/s}\).
In this formula, the number 32 represents the APB data bus width, and the division by two is present because each APB write procedure takes two clock cycles to be executed.

- The bandwidth is dependent on the APB clock frequency; the available bandwidth increases with the clock frequency.

To drive the APB interface to achieve high bandwidth command mode traffic transported by the DSI link, the DSI Host must operate only in the command mode, and the APB interface must be the only data source in use. Thus, the APB interface has the entire bandwidth of the DSI link and does not share it with any another input interface source.

The memory write commands require maximum throughput from the APB interface, because they contain the most amount of data conveyed by the DSI link. While writing the packet information, first write the payload of a given packet into the payload FIFO using the DSI Host generic payload data register (DSI_GPDR). When the payload data is for the command parameters, place the first byte to be transmitted in the least significant byte position of the APB data bus.

After writing the payload, write the packet header into the command FIFO. For more information about the packet header organization on the 32-bit APB data bus, so that it is correctly stored inside the command FIFO.

When the payload data is for a memory write command, it contains pixel information and it must follow the pixel to byte conversion organization referred in the Annex A of the DCS specification.

Figures 261 to 265 show how the pixel data must be organized in the APB data write bus.

The memory write commands are conveyed in DCS long packets, encapsulated in a DSI packet. The DSI specifies that the DCS command must be present in the first payload byte of the packet. This is also included in the diagrams. In figures 261 to 265, the write memory command can be replaced by the DCS command write memory Start and write memory Continue.

**Figure 261. 24 bpp APB pixel to byte organization**

Figure 265. 8 bpp APB pixel to byte organization
34.8  **Functional description: timeout counters**

The DSI Host includes counters to manage timeout during the various communication phases. The duration of each timeout can be configured by the six timeout counter configuration registers (DSI_TCCR0...5).

There are two types of counters:
- contention error detection timeout counters (*Section 34.8.1*)
- peripheral response timeout counters (*Section 34.8.2*).

34.8.1  **Contention error detection timeout counters**

The DSI Host implements a set of counters and conditions to notify the errors. It features a set of registers to control the timers used to determine if a timeout has occurred, and also contains a set of interruption status registers that are cleared upon a read operation (detailed in *Table 283*). Optionally, these registers also trigger an interrupt signal that can be used by the system to be activated when an error occurs within the DSI connection.

**Table 283. Contention detection timeout counters configuration**

<table>
<thead>
<tr>
<th>Timeout counter</th>
<th>Value register</th>
<th>Value field</th>
<th>Flag register</th>
<th>Flag field</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-speed transmission</td>
<td>DSI_TCCR0</td>

<td>DSI_ISR1</td>
<td>TOHSTX</td>
</tr>
<tr>
<td>Low-power reception</td>
<td>DSI_TCCR0</td>
<td>TOLPRX</td>
<td>DSI_ISR1</td>
<td>TOLPRX</td>
</tr>
</tbody>
</table>

Time units for these 16-bit counters are configured in cycles defined in the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR).

The value written to the timeout clock division (TOCKDIV) field in the DSI Host clock control register (DSI_CCR) defines the time unit for the timeout limits using the lane byte clock as input.

This mechanism increases the range to define these limits.

**High-speed transmission contention detection**

The timeout duration is configured in the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0). A 16-bit counter measures the time during which the high-speed mode is active.

If that counter reaches the value defined by the high-speed transmission timeout count (HSTX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout high-speed transmission (TOHSTX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout high-speed transmission interrupt enable (TOHSTXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated.

**Low-power reception contention detection**

The timeout is configured in the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR1). A 16-bit counter measures the time during which the low-power reception is active.
If that counter reaches the value defined by the low-power reception timeout counter (LPRX_TOCNT) field of the DSI Host timeout counter configuration register 1 (DSI_TCCR0), the timeout low-power reception (TOLPRX) bit in the DSI Host interrupt and status register 1 (DSI_ISR1) is asserted and an internal soft reset is generated to the DSI Host.

If the timeout low-power reception interrupt enable (TOLPRXIE) bit of the DSI Host interrupt enable register 1 (DSI_IER1) is set, an interrupt is generated. Once the software gets notified by the interrupt, it must reset the D-PHY by deasserting and asserting the digital enable (DEN) bit of the DSI Host PHY control register (DSI_PCTLR).

### 34.8.2 Peripheral response timeout counters

A peripheral may not immediately respond correctly to some received packets. For example, a peripheral receives a read request, but due to its architecture cannot access the RAM for a while (for example, the panel is being refreshed and takes some time to respond). In this case, set a timeout to ensure that the host waits long enough so that the device is able to process the previous data before receiving the new data or responding correctly to new requests.

*Table 284* lists the events belonging to various categories having an associated timeout for peripheral response.

**Table 284. List of events of different categories of the PRESP_TO counter**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The DSI Host ensures that, on sending an event that triggers a timeout, the D-PHY switches to the Stop state and a counter starts running until it reaches the value of that timeout. The link remains in the LP-11 state and unused until the timeout ends, even if there are other events ready to be transmitted.

Figures 266 to 268 illustrate the flow of counting in the PRESP_TO counter for the three categories listed in *Table 284*.

The values in these registers are measured in number of cycles of the lane byte clock. These registers are only used in command mode because in video mode, there is a rigid timing schedule to be met to keep the display properly refreshed and it must not be broken by these or any other timeouts. Setting a given timeout to 0 disables going into LP-11 state and timeout for events of that category.

The read and the write requests in high-speed mode are distinct from those in low-power mode. For example, if HSRD_TOCNT is set to 0 and LPRD_TOCNT is set to a non-0 value, a generic read with no parameters does not activate the PRESP_TO counter in high-speed, but activates the PRESP_TO in low-power.

The DSI Host timeout counter configuration register 4 (DSI_TCCR3) includes a special Presp mode (PM) bit to change the normal behavior of PRESP_TO in Adaptive command.
mode for high-speed write operation timeout. When set to 1, this bit allows the PRESP_TO from HSWR_TOCTNT to be used only once, when both of the following conditions are met:

- the LTDC VSYNC signal rises and falls
- the packets originated from the LTDC interface in adapted command mode are transmitted and its FIFO is empty again.

In this scenario, non-adapted command mode requests are not sent to the D-PHY, even if there is traffic from the generic interface ready to be sent, returning them to the Stop state. When it happens, the PRESP_TO counter is activated and only when it is completed, the DSI Host sends any other traffic that is ready, as illustrated in Figure 269.

**Figure 269. Effect of prep mode at 1**

![Diagram showing the effect of prep mode at 1](diagram.png)
34.9 Functional description: transmission of commands

34.9.1 Transmission of commands in video mode

The DSI Host supports the transmission of commands, both in high-speed and low-power, while in video mode. The DSI Host uses blanking or low-power (BLLP) periods to transmit commands inserted through the APB generic interface. Those periods correspond to the gray areas of Figure 270.

Figure 270. Command transmission periods within the image area

Commands are transmitted in the blanking periods after the following packets/states:
- Vertical Sync Start (VSS) packets, if the video sync pulses are not enabled
- Horizontal sync end (HSE) packets, in the VSA, VBP, and VFP regions
- Horizontal sync Start (HSS) packets, if the video sync pulses are not enabled in the VSA, VBP, and VFP regions
- Horizontal active (HACT) state

Besides the areas corresponding to BLLP, large commands can also be sent during the last line of a frame. In that case, the line time for the video mode is violated and the edpihalt signal is set to request the DPI video timing signals to remain inactive. Only if a command does not fit into any BLLP area, it is postponed to the last line, causing the violation of the line time for the video mode, as illustrated in Figure 271.
Figure 271. Transmission of commands on the last line of a frame

Only one command is transmitted per line, even in the case of the last line of a frame but one command is possible for each line.

There can be only one command sent in low-power per line. However, one low-power command is possible for each line. In high-speed, the DSI Host can send more than one command, as many as it determines to fit in the available time.

The DSI Host avoids sending commands in the last line because it is possible that the last line is shorter than the other ones. For instance, the line time \(t_L\) can be half a cycle longer than the \(t_L\) on the LTDC interface, that is, each line in the frame taking half a cycle from time for the last line. This results in the last line being \(\frac{1}{2} \) cycle \(x\) (number of lines -1) shorter than \(t_L\).

The COLM and SHTDN bits of the DSI Wrapper control register (DSI_WCR) are also able to trigger the sending of command packets. The commands are:

- Color mode ON
- Color mode OFF
- Shut down peripheral
- Turn on peripheral

These commands are not sent in the VACT region. If the low-power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) is set, these commands are sent in low-power mode.

In low-power mode, the largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) is used to determine if these commands can be transmitted. It is assumed that largest packet size (LPSIZE) is greater than or equal to four bytes (number of bytes in a short packet), because the DSI Host does not transmit these commands on the last line.

If the frame bus-turn-around acknowledge enable (FBTAAE) bit is set in the DSI Host low-power mode configuration register (DSI_LPMCR), a BTA is generated by DSI Host after the last line of a frame. This may coincide with a write command or a read command. In either case, the LTDC interface is halted until an acknowledge is received (control of the DSI bus is returned to the host).
34.9.2 Transmission of commands in low-power mode

DSI Host can be configured to send the low-power commands during the high-speed video mode transmission.

To enable this feature, set the Low Power command enable (LPCE) bit of the DSI Host video mode configuration register (DSI_VMCR) to 1. In this case, it is necessary to calculate the time available, in bytes, to transmit a command in low-power mode to horizontal front-porch (HFP), vertical sync active (VSA), vertical back-porch (VBP), and vertical front-porch (VFP) regions.

Bits 8 to 13 of the video mode configuration register (DSI_VMCR) indicate if DSI Host can go to LP when idle. If the low-power command enable (LPCE) bit is set and non-video packets are in queue, DSI Host ignores the low-power configuration and transmits low-power commands, even if it is not allowed to enter low-power mode in a specific region. After the low-power commands transmission, DSI Host remains in low-power until a sync event occurs.

For example, consider that the VFP is selected as high-speed region (LPVFPE = 1'b0) with LPCE set as a command to transmit in low-power in the VPF region. This command is transmitted in low-power, and the line stays in low-power mode until a new HSS arrives.

Calculating the time to transmit commands in LP mode in the VSA, VBP, and VFP regions

The largest packet size (LPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in low-power mode (based on the escape clock) on a line during the VSA, VBP, and the VFP regions.

Calculation of largest packet size (LPSIZE) depends on the used video mode. Figure 272 illustrates the timing intervals for the video mode in non-burst with sync pulses, while Figure 273 refers to video mode in burst and non-burst with sync events.
This time is calculated as follows:

\[
\text{LPSIZE} = \left( t_L - (t_{H_1} + t_{HS->LP} + t_{LPDT} + 2 \times t_{ESCCLK}) \right) / (2 \times 8 \times t_{ESCCLK}),
\]

- \( t_L \) = line time
- \( t_{H_1} \) = time of the HSA pulse for sync pulses mode (Figure 272) or time to send the HSS packet, including EoTp (Figure 273)
- \( t_{HS->LP} \) = time to enter the low-power mode
- \( t_{LP->HS} \) = time to leave the low-power mode
- \( t_{LPDT} \) = D-PHY timing related with escape mode entry, LPDT command, and escape exit. According to the D-PHY specification, this value is always 11 bits in LP (or 22 TX escape clock cycles)
- \( t_{ESCCLK} \) = escape clock period as programmed in the TXECKDIV field of the DSI_CCR register
- \( t_{ESCCLK} \) = delay imposed by the DSI Host implementation.

In the above equation, division by eight is done to convert the available time to bytes. Division by two is done because one bit is transmitted every two escape clock cycles. The largest packet size (LPSIZE) field can be compared directly with the size of the command to be transmitted to determine if there is enough time to transmit the command. The maximum size of a command that can be transmitted in low-power mode is limited to 255 bytes by this field. Program this register to a value greater than or equal to 4 bytes for the transmission of the DCTRL commands, such as shutdown and color in low-power mode.

Consider an example of a frame with 12.4 \( \mu \text{s} \) per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbit/s. In this case, it is possible to send 124 bits in escape mode (that is, 124 bit = 12.4 \( \mu \text{s} \) * 20 MHz / 2). Still, you need to consider the D-PHY protocol and PHY timings.

The following assumptions are made:
- lane byte clock period is 10 ns (800 Mbit/s per lane)
- escape clock period is 50 ns (DSI_CCR.TXECKDIV = 5)
- video is transmitted in non-burst mode with sync pulses bounded by HSS and HSE packets
- DSI is configured for two lanes
- D-PHY takes 180 ns to transit from low-power to high-speed mode (DSI_DLTCR.LS2HS_TIME = 18)
- D-PHY takes 200 ns to transit from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- \( t_{HSA} \) = 420 ns.

In this example, a 13-byte command can be transmitted as follows:

\[
\text{LPSIZE} = \left( 12.4 \mu \text{s} - (420 \text{ ns} + 180 \text{ ns} + 200 \text{ ns} + (22 \times 50 \text{ ns} + 2 \times 50 \text{ ns})) \right) / (2 \times 8 \times 50 \text{ ns}) = 13 \text{ bytes}.
\]

**Calculating the time to transmit commands in low-power mode in HFP region**

The VACT largest packet size (VLPSIZE) field of the DSI Host low-power mode configuration register (DSI_LPMCR) indicates the time available (in bytes) to transmit a command in low-power mode (based on the escape clock) in the vertical active (VACT) region.
To calculate the value of VACT largest packet size (VLPSIZE), consider the video mode being used. Figure 274 shows the timing intervals for video mode in non-burst with sync pulses, Figure 275 those for video mode in non-burst with sync events, and Figure 276 refers to the burst video mode.

Figure 274. VLPSIZE for non-burst with sync pulses

Figure 275. VLPSIZE for non-burst with sync events

Figure 276. VLPSIZE for burst mode

This time is calculated as follows:

\[
VLPSIZE = \frac{t_L - (t_{HSA} + t_{HBP} + t_{HACT} + t_{HS->LP} + t_{LP->HS} + t_{LPDT} + 2 \times t_{ESCCLK})}{2 \times 8 \times t_{ESCCLK}}
\]

where

- \( t_L \) = line time
- \( t_{HSA} \) = time of the HSA pulse (DSI_VHSAHCR.HSA)
- \( t_{HBP} \) = time of horizontal back-porch (DSI_VHBPCR.HBP)
- \( t_{HACT} \) = time of video active. For burst mode, the video active is time compressed and is calculated as \( t_{HACT} = \text{VPSIZE} \times \text{Bytes per Pixel} / \text{Number Lanes} \times t_{\text{lane byte clk}} \)
- \( t_{ESCCLK} \) = escape clock period as programmed in TXECKDIV field of the DSI_CCR register.
The VLPSIZE field can be compared directly with the size of the command to be transmitted to determine if there is time to transmit the command.

Consider an example of a frame with 16.4 µs per line and assume an escape clock frequency of 20 MHz and a lane bit rate of 800 Mbits/s. In this case, it is possible to send 420 bits in escape mode (that is, 164 bits = 16.4 µs * 20 MHz / 2). Still, since it is the vertical active region of the frame, consider the HSA, HBP, and HACT timings apart from the D-PHY protocol and PHY timings. The following assumptions are made:

- number of active lanes is four
- Lane byte clock period (lanebyteclkperiod) is 10 ns (800 Mbit/s per lane)
- escape clock period is 50 ns (DSI_CCR.TXECCKDIV = 5)
- D-PHY takes 180 ns to pass from low-power to high-speed mode (DSI_DLTCR.LP2HS_TIME = 18)
- D-PHY takes 200 ns to pass from high-speed to low-power mode (DSI_DLTCR.HS2LP_TIME = 20)
- \( t_{\text{HSA}} = 420 \) ns
- \( t_{\text{HBP}} = 800 \) ns
- \( t_{\text{HACT}} = 12800 \) ns to send 1280 pixel at 24 bpp
- video is transmitted in non-burst mode
- DSI is configured for four lanes.

In this example, consider that video is sent in non-burst mode. The VLPSIZE is calculated as follows:

\[
\text{VLPSIZE} = \frac{(16.4 \, \mu s - (420 \, ns + 800 \, ns + 12.8 \, \mu s + 180 \, ns + 200 \, ns + (22 \times 50 \, ns + 2 \times 50 \, ns))}{(2 \times 8 \times 50 \, ns)} = 1 \, \text{byte}
\]

Only one byte can be transmitted in this period. A short packet (for example, generic short write) requires a minimum of four bytes. Therefore, in this example, commands are not sent in the VACT region.

If burst mode is enabled, more time is available to transmit the commands in the VACT region, because HACT is time compressed.

\[
\text{VLPSIZE} = \frac{(16.4 \, \mu s - (420 \, ns + 800 \, ns + (1280 \times 3 / 4 \times 10 \, ns) + 180 \, ns + 200 \, ns + (22 \times 50 \, ns + 2 \times 50 \, ns))}{(2 \times 8 \times 50 \, ns)} = 5 \, \text{bytes}
\]

For burst mode, the VLPSIZE is 5 bytes and then a 4-byte short packet can be sent.

**Transmission of commands in different periods**

The LPSIZE and VLPSIZE fields allow a simple comparison to determine if a command can be transmitted in any of the BLLP periods.

*Figure 277* illustrates the meaning of VLPSIZE and LPSIZE, matching them with the shaded areas and the VACT region.
34.9.3 Transmission of commands in high-speed

If the LPCE bit of the DSI_VMCR register is 0, the commands are sent in high-speed in video mode. In this case, the DSI Host automatically determines the area where each command can be sent and no programming or calculation is required.

34.9.4 Read command transmission

The MRD_TIME field of the DSI_DLTCR register configures the maximum amount of time required to perform a read command in lane byte clock cycles, it is calculated as:

\[
\text{MRD\_TIME} = \frac{(t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{read}} + 2 \times t_{\text{BTA}})}{\text{lanebyteclkperiod}}
\]

The time to return the read data packet from the peripheral depends on the number of bytes read and the escape clock frequency of the peripheral, not the escape clock of the host. The MRD_TIME field is used in both high-speed and low-power mode to determine if there is time to complete a read command in a BLLP period.

In high-speed mode (LPCE = 0), MRD_TIME is calculated as follows:

\[
\text{MRD\_TIME} = \frac{(t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{read}} + 2 \times t_{\text{BTA}})}{\text{lanebyteclkperiod}}
\]

In low-power mode (LPCE = 1), MRD_TIME is calculated as follows:

\[
\text{MRD\_TIME} = \frac{(t_{\text{HS->LP}} + t_{\text{LP->HS}} + t_{\text{LPDT}} + t_{\text{lprd}} + t_{\text{read}} + 2 \times t_{\text{BTA}})}{\text{lanebyteclkperiod}}
\]

where:

- \( t_{\text{HS->LP}} \) = time to enter the low-power mode
- \( t_{\text{LP->HS}} \) = time to leave the low-power mode
- \( t_{\text{LPDT}} \) = D-PHY timing related to escape mode entry, LPDT command, and escape mode exit (according to the D-PHY specification, this value is always 11 bits in LP, or 22 TX escape clock cycles)
- \( t_{\text{lprd}} \) = read command time in low-power mode (64 * TX esc clock)
- \( t_{\text{read}} \) = time to return the read data packet from the peripheral
- \( t_{\text{BTA}} \) = time to perform a bus-turn-around (D-PHY dependent).
Keep the maximum number of bytes read from the peripheral to a minimum, to issue the read commands in a line time. Ensure that MRD_TIME x lane byte clock period is less than LPSIZE x 16 x escape clock period of the host, otherwise, the read commands are dispatched on the last line of a frame. If it is necessary to read a large number of parameters (> 16), increase the MRD_TIME while the read command is executed. When the read has completed, decrease the MRD_TIME to a lower value.

If a read command is issued on the last line of a frame, the LTDC interface is halted and stays halted until the read command is in progress. The video transmission must be stopped during this period.

34.9.5 Clock lane in low-power mode

To reduce the power consumption of the D-PHY, the DSI Host, when not transmitting in the high-speed mode, allows the clock lane to enter into the low-power mode. The controller automatically handles the transition of the clock lane from HS (clock lane active sending clock) to LP state without direct intervention by the software. This feature can be enabled by configuring the DPCC and the ACR bits of the DSI_CLCR register.

In the command mode, the DSI Host can place the clock lane in the low-power mode when it does not have any HS packets to transmit.

In the video mode (LTDC interface), the DSI Host controller uses its internal video and PHY timing configurations to determine if there is time available for the clock line to enter the low-power mode and not compromise the video data transmission of pixel data and sync events.

Along with a correct configuration of the video mode (see Section 34.5: Functional description: video mode on LTDC interface), the DSI Host needs to know the time required by the clock lane to go from high-speed to low-power mode and vice-versa. The values required can be obtained from the D-PHY specification: program the DSI_CLTCR register with the following values:

- HS2LP_TIME = time from HS to LP in clock lane / byte clock period in HS (lanebyteclk)
- LP2HS_TIME = time from LP to HS in clock lane / byte clock period in HS (lanebyteclk)

Based on the programmed values, the DSI Host calculates if there is enough time for the clock lane to enter the low-power mode during inactive regions of the video frame.

The DSI Host decides the best approach to follow regarding power saving out of the three possible scenarios:

- there is no enough time to go to the low-power mode. Therefore, blanking period is added as shown in Figure 278.
- there is enough time for the data lanes to go to the low-power mode but not enough time for the clock lane to enter the low-power mode, see Figure 279.
- there is enough time for both data lanes and clock lane to go to the low-power mode, as in Figure 280.

![Figure 278. Clock lane and data lane in HS](image)
Figure 279. Clock lane in HS and data lanes in LP

Figure 280. Clock lane and data lane in LP
34.10 Functional description: virtual channels

The DSI Host supports choosing the virtual channel (VC) for use for each interface. Using multiple virtual channels, the system can address multiple displays at the same time, when each display has a different virtual channel identifier.

When the LTDC interface is configured for a particular virtual channel, it is possible to use the APB slave generic interface to issue the commands while the video stream is being transmitted. With this, it is possible to send the commands through the ongoing video stream, addressing different virtual channels and thus enable the interface with multiple displays. During the video mode, the video stream transmission has the maximum priority. Therefore, the transmission of sideband packets such as the ones from the generic interface are only transported when there is time available within the video stream transmission. The DSI Host identifies the available time periods and uses them to transport the generic interface packets. Figure 281 illustrates where the DSI Host inserts the packets from the APB generic interface within the video stream transmitted by the LTDC interface.

![Figure 281. Command transmission by the generic interface](image)

It is also possible to address the multiple displays with only the generic interface using different virtual channels. Because the generic interface is not restricted to any particular virtual channel through configuration, it is possible to issue the packets with different virtual channels. This enables the interface to time multiplex the packets to be provided to the displays with different virtual channels.

You can use the following configuration registers to select the virtual channel ID associated with transmissions over the LTDC and APB slave generic interfaces:

- **DSI_LVCIDR.VCID** field configures the virtual channel ID that is indexed to the video mode packets using the LTDC interface.
- **DSI_GHCR** register configures the packet header (which includes the virtual channel ID to be used) for transmissions using APB slave generic interface.
- **DSI_GVCIDR** register configures the virtual channel ID of the read responses to store and return to the generic interface.
34.11 Functional description: video mode pattern generator

The video mode pattern generator allows the transmission of horizontal/vertical color bar and D-PHY BER testing pattern without any stimuli.

The frame requirements must be defined in video registers that are listed in Table 286.

34.11.1 Color bar pattern

The color bar pattern comprises eight bars for white, yellow, cyan, green, magenta, red, blue, and black colors.

Each color width is calculated by dividing the line pixel size (vertical pattern) or the number of lines (horizontal pattern) by eight. In the vertical color bar mode (Figure 282), each single color bar has a width of the number of pixels in a line divided by eight. In case the number of pixels in a line is not divisible by eight, the last color (black) contains the remaining.

In the horizontal color bar mode (Figure 283), each color line has a color width of the number of lines in a frame divided by eight. In case the number of lines in a frame is not divisible by eight, the last color (black) contains the remaining lines.

34.11.3 BER testing pattern

The BER testing pattern simplifies conformance testing. This pattern tests the RX D-PHY capability to receive the data correctly. The following data patterns are required:

- X bytes of 0xAA (high-frequency pattern, inverted)
- X bytes of 0x33 (mid-frequency pattern)
- X bytes of 0xF0 (low-frequency pattern, inverted)
- X bytes of 0x7F (lone 0 pattern)
- X bytes of 0x55 (high-frequency pattern)
- X bytes of 0xCC (mid-frequency pattern, inverted)
- X bytes of 0x0F (low-frequency pattern)
- Y bytes of 0x80 (lone 1 pattern).

In most cases, Y is equal to X. However, depending on line length and the color coding used, Y may be different from X. With RGB888 color coding and horizontal resolution in multiples of eight, the pattern shown in Figure 284 appears on the DSI display.
34.11.4 Video mode pattern generator resolution

Depending on the orientation, BER mode, and color coding, the smallest resolutions accepted by the video mode pattern generator are:

- BER mode: 8x8
- horizontal color bar mode: 8x8
- vertical color bar mode: 8x8.

**Vertical pattern**

The width of each color bar is determined by the division of horizontal resolution (pixels) for eight test pattern colors. If the horizontal resolution is not divisible by eight, the last color (black) is extended to fill the resolution.

In the example in *Figure 285*, the horizontal resolution is 103.

*Figure 285. Vertical pattern (103x15)*

**Horizontal pattern**

The width of each color bar is determined by the division of the number of vertical resolution (lines) for eight test pattern colors. If the vertical resolution is not divisible by eight, the last color (black) is extended to fill the resolution, as shown in *Figure 286*.

*Figure 286. Horizontal pattern (103x15)*
34.12 Functional description: D-PHY management

The embedded MIPI® D-PHY is controlled directly by the DSI Host and is configured through the DSI Wrapper.

A dedicated PLL and a dedicated 1.2 V regulator are also embedded to supply the clock and the power supply to the DSI and D-PHY.

34.12.1 D-PHY configuration

The D-PHY configuration is carried out through the DSI Wrapper thanks to the DSI_WPCRx registers.

Timing definition

The MIPI® D-PHY manages all the communication timing with dedicated timers. As all the timings are specified in nanoseconds, it is mandatory to configure the unit interval field to ensure the good duration of the timings.

Unit interval is configured through the DSI_WPCR0.UIX4 field. This value defines the bit period in high-speed mode in units of 0.25 ns. If this period is not a multiple of 0.25 ns, the value driven must be rounded down.

As an example, for a 300 Mbit/s link, the unit interval is 3.33 ns, so UIX4 is 13.33. In this case a value of 13 (0x0D) must be written.

Slew-rate and delay tuning on pins

To fine tune DSI communication, slew-rates and delay can be adjusted:
- slew-rate in high-speed transmission on data lane and clock lane
- slew-rate in low-power transmission on data lane and clock lane
- transmission delay in high-speed transmission on data lane and clock lane

<table>
<thead>
<tr>
<th>Function</th>

</tr>
</tbody>
</table>

The default value for all these parameters is 2’h00. All these values can be programmed only when the DSI is stopped (DSI_WCR.DSIEN = 0 and CR.EN = 0).

Low-power reception filter tuning

The cut-off frequency of the low-pass on low-power receiver can be fine tuned through the LPRXFT field of the DSI_WPCR1 register. The default value is 2’h00 and it can be programmed only when the DSI is stopped (CR.DSIEN = 0 and CR.EN = 0).
**Special Sdd control**

An additional current path can be activated on both clock lane and data lane to meet the Sdd_{TX} parameter defined in the MIPI® D-PHY Specification.

This activation is done setting the SDDC bit of the DSI_WPCR1 register.

**Custom lane configuration**

To ease DSI integration, lane pins can be swapped and/or high-speed signals can be inverted on a lane as described in Table 289.

<table>

All these values can be programmed only when the DSI is stopped (CR.DSIEN = 0 and CR.EN = 0).
34.12.2 D-PHY HS2LP and LP2HS durations

The DSI system is able to switch to LP mode during blanking period if there is enough time between two HS transmission.

To be able to make the scheduling and estimate if it is possible or not to make the switch, the duration of the transitions from HS to LP and from LP to HS must be programmed in the DSI Host in the DSI_CLTCR register for the clock lane and in the DSI_DLTCR register for the data lanes.

Table 291 gives an estimation of the values to be programmed for these timings, expressed in lane byte clock cycles.

Table 291. HS2LP and LP2HS values

</tr>
</tbody>
</table>

34.12.3 Special D-PHY operations

The DSI Wrapper features some control bits to force the D-PHY in some particular state and/or behavior.

Forcing lane state

It is possible to force the data lane and/or the clock lane in TX Stop mode through the bits FTXSMDL and FTXSMCL of the DSI_WPCR0 register. Setting these bits causes the respective lane module to immediately jump in transmit control mode and to begin transmitting a stop state (LP-11).

This feature can be used to go back in TX mode after a wrong BTA sequence.

Forcing low-power receiver in low-power mode

The FLPRXLPERM bit of the DSI_WPCR1 register enables the low-power mode of the low power receiver (LPRX). When set, the LPRX operates in low-power mode all the time. When not set, the LPRX operates in low-power mode during ULPS only.

Disabling turn of data lane

When set, the TDDL bit of the DSI_WPCR0 register forces the data lane to remain in reception mode even if a bus-turn-around request (BTA) is received from the other side.

34.12.4 Special low-power D-PHY functions

The embedded D-PHY offers specific features to optimize consumption.

Pull-down on lanes

The D-PHY embeds a pull-down on each lane to prevent floating states when the lanes are unused.
When set, the PDEN bit of the DSI_WPCR0 register enables the pull-down on the lanes.

**Disabling contention detection on data lanes**

The contention detector on the data lane can be turned off to lower the overall D-PHY consumption.

When set, the CDOFFDL bit of the DSI_WPCR0 register disables the contention detection on data lanes.

This can be used in forward escape mode to reduce the static power consumption.

### 34.12.5 DSI PLL control

The dedicated DSI PLL is controlled through the DSI Wrapper, as shown in Figure 287 (analog blocks and signals in gray, digital signals in black, digital blocks in light blue).

**Figure 287. PLL block diagram**

The PLL output frequency is configured through the DSI_WRPCR register fields. The VCO frequency and the PLL output frequency are calculated as follows:

\[
F_{VCO} = \frac{\text{CLKIN}}{\text{IDF}} \times 2 \times \text{NDIV},
\]

\[
\text{PHI} = \frac{F_{VCO}}{2 \times \text{ODF}}
\]
where:
- $\text{CLKIN}$ is in the 8 to 200 MHz range
- $\text{DSI\_WRPCR.NDIV}$ is in the 10 to 125 range
- $\text{DSI\_WRPCR.IDF}$ is in the 1 to 7 range
- $\text{INFIN}$ is in the 8 to 50 MHz range
- $\text{FVCO}$ is in the 1 to 2 GHz range
- $\text{DSI\_WRPCR.ODF}$ can be 1, 2, 4 or 8
- $\text{PHI}$ is in the 62.5 MHz to 1 GHz range

The PLL is enabled by setting the PLLEN bit in the DSI\_WRPCR register.

Once the PLL is locked, the PLLLIF bit is set in the DSI\_WISR. If the PLLLIE bit is set in the DSI\_WIER, an interrupt is generated.

The PLL status (lock or unlock) can be monitored with the PLLLS flag in the DSI\_WISR register.

If the PLL gets unlocked, the PLLUIF bit of the DSI\_WISR is set. If the PLLUIE bit of the DSI\_WIER register is set, an interrupt is generated.

The DSI PLL settings can be changed only when the PLL is disabled.

### 34.12.6 Regulator control

The DSI regulator providing the 1.2 V is controlled through the DSI Wrapper.

The regulator is enabled setting the REGEN bit of the DSI\_WRPCR register.

Once the regulator is ready, the RRIF bit of the DSI\_WISR register is set. If the RRIE bit of the DSI\_WIER register is set, an interrupt is generated.

The regulator status (ready or not) can be monitored with the RRS flag in the DSI\_WISR register.

Note that the D-PHY has no separated Power ON control bit. The power ON/OFF of the D-PHY is done directly enabling the 1.2 V regulator.

When the 1.2 V regulator is disabled, the 3.3 V part of the D-PHY is automatically powered OFF.

### 34.13 Functional description: interrupts and errors

The interrupts can be generated either by the DSI Host or by the DSI Wrapper.

All the interrupts are merged in one interrupt lane going to the interrupt controller.

#### 34.13.1 DSI Wrapper interrupts

An interrupt can be produced on the following events:
- tearing effect event
- end of refresh
- PLL locked
- PLL unlocked
- regulator ready
Separate interrupt enable bits are available for flexibility.

### 34.13.2 DSI Host interrupts and errors

The DSI_ISR0 and DSI_ISR1 registers are associated with error condition reporting. These registers can trigger an interrupt to inform the system about the occurrence of errors.

The DSI Host has one interrupt line that is set high when an error occurs in either the DSI_ISR0 or the DSI_ISR1 register.

The triggering of the interrupt can be masked by programming the mask registers DSI_IER0 and DSI_IER1. By default all errors are masked. When any bit of these registers is set to 1, it enables the interrupt for a specific error. The error bit is always set in the respective DSI_ISR register. The DSI_ISR0 and DSI_ISR1 registers are always cleared after a read operation. The interrupt line is cleared if all registers that caused the interrupt are read.

The interrupt force registers (DSI_FIR0 and DSI_FIR1) are used for test purposes: they allow triggering the interrupt events individually without the need to activate the conditions that trigger the interrupt sources (it is extremely complex to generate the stimuli for that purpose). This feature also facilitates the development and testing of the software associated with the interrupt events. Setting any bit of these registers to 1 triggers the corresponding interrupt.
The light yellow boxes in Figure 288 illustrate the location of some of the errors.

**Table 293** explains the reasons that set off these interrupts and also explains how to recover from these interrupts.

<td>The acknowledge with error packet contains this error. The device detects the false control error. The device detects one of the following: – The LP-10 (LP request) is not followed by the remainder of a valid escape or turnaround sequence. – The LP-01 (HS request) is not followed by a bridge state (LP-00). The D-PHY communications are corrupted. This error is unrecoverable. Reset the DSI Host and the D-PHY. Refer to the section 7.1.6 of the DSI Specification 1.1.</td>
</tr>
</tbody>
</table>
The acknowledge with error packet contains this error. The display timeout counters for a HS reception and LP transmission expire.

It is possible that the Host and device timeout counters are not correctly configured. The device HS_TX timeout must be shorter than the Host HS_RX timeout. Host LP_RX timeout must be longer than the device LP_TX timeout. Check and confirm that the Host configuration is consistent with the device specifications. This error is automatically recovered, although there is no guarantee that all the packets in the transmission or reception are complete. For additional information about this error, see section 7.2.2 of the DSI Specification 1.1.

The device reports that the LPDT is not aligned in an 8-bit boundary.

There is no guarantee that the device properly receives the packets. Transmit the packets again. For additional information about this error, see section 7.1.5 of the DSI Specification.

The device does not recognize the escape mode entry command. The device does not recognize the escape mode entry code.

Check the device capability. For additional information about this error, see section 7.1.4 of the DSI Specification.

The device detects the HS transmission did not end in an 8-bit boundary when the EoT sequence is detected.

There is no guarantee that the device properly received the packets. Re-transmission must be performed. Transmit the packets again. For additional information about this error, see section 7.1.3 of the DSI Specification 1.1.

The device detects that the SoT leader sequence is corrupted.

The device discards the incoming transmission. Re-transmission must be performed by the Host. For additional information about this error, see section 7.1.2 of the DSI Specification 1.1.

The device is tolerant to single bit and some multi-bit errors in the SoT sequence but the packet correctness is compromised. If the packet content was important, transmit the packets again. For additional information about this error, see section 7.1.1 of the DSI Specification 1.1.

34.14  **Programing procedure**

To operate the DSI Host the user must be familiar with the MIPI® DSI specification. Every software programmable register is accessible through the APB interface.

34.14.1  **Programing procedure overview**

The procedure for video mode or adapted command mode must respect the following order:

1. Configure the RCC (refer to the RCC section)
   a) Enable clock for DSI and LTDC
   b) Configure LTDC PLL, turn it ON and wait for its lock
2. Optionally, configure the GPIO (if tearing effect requires GPIO usage, for example)
3. Optionally, validate the ISR
4. Configure the LTDC (refer to the LTDC section)
   a) Program the panel timings
   b) Enable the relevant layers
5. Turn on the DSI regulator and wait for the regulator to be ready, as described in Section 34.12.6
6. Configure the DSI PLL, turn it ON and wait for its lock as described in Section 34.12.5
7. Configure the D-PHY parameters in the DSI Host and the DSI Wrapper to define D-PHY configuration and timing as detailed in Section 34.14.2
8. Configure the DSI Host timings as detailed in Section 34.14.3
9. Configure the DSI Host flow control and DBI interface as detailed in Section 34.14.4
10. Configure the DSI Host LTDC interface as detailed in Section 34.14.5
11. Configure the DSI Host for video mode as detailed in Section 34.14.6 or adapted command mode as detailed in Section 34.14.7
12. Enable the D-PHY setting the DEN bit of the DSI_PCTLR
13. Enable the D-PHY clock lane setting the CKEN bit of the DSI_PCTLR
14. Enable the DSI Host setting the EN bit of the DSI_CR
15. Enable the DSI Wrapper setting the DSIEN bit of the DSI_WCR
16. Optionally, send DCS commands through the APB generic interface to configure the display
17. Enable the LTDC in the LTDC
18. Start the LTDC flow through the DSI Wrapper (DSI_WCR.LTDCEN = 1)
   a) In video mode, the data streaming starts as soon as the LTDC is enabled
   b) In adapted command mode, the frame buffer update is launched as soon as bit DSI_WCR.LTDCEN is set

34.14.2  **Configuring the D-PHY parameters**

The D-PHY requires a specific configuration prior starting any communications. The configuration parameters are stored either in the DSI Host or the DSI Wrapper.
Configuring the D-PHY parameters in the DSI Wrapper

The DSI Wrapper can be used to fine tunes either timing or physical parameters of the D-PHY. This operation is not required for a standard usage of the D-PHY. All the fields and parameters are detailed in the register description of the DSI Wrapper.

Only one field is mandatory to properly start the D-PHY: the unit interval multiplied by 4 (UIX4) field of the DSI Wrapper PHY configuration register 1 (DSI_WPCR0).

This field defines the bit period in high-speed mode in unit of 0.25 ns, and is used as a timebase for all the timings managed by the D-PHY.

If the link is working at 600 Mbit/s, the unit interval shall be 1.667 ns, that becomes 6.667 ns when multiplied by four. When rounded down, a value of 6 must be written in the UIX4 field of the DSI_WPCR0 register.

Configuring the D-PHY parameters in the DSI Host

The DSI Host stores the configuration of D-PHY timing parameters and number of lanes.

The following fields must be configured prior to any startup:

- Number of data lanes in the DSI_PCONFR register
- Automatic clock lane control (ACR) in the DSI_CLCR register
- Clock control (DPCC) in the DSI_CLCR register
- Time for LP/HS and HS/LP transitions for both clock lane and data lanes in DSI_CLTCR and DSI_DLTCR registers
- Stop wait time in the DSI_PCONFR register

34.14.3 Configuring the DSI Host timing

All the protocol timing must be configured in the DSI Host.

Clock divider configuration

Two clocks are generated internally, namely the timeout clock and the TX escape clock.

The timeout clock is used as the timing unit in the configuration of HS to LP and LP to HS transition error. Its division factor is configured by the timeout clock division (TOCKDIV) field of the DSI Host clock control register (DSI_CCR).

The TX escape clock is used in low-power transmission. Its division factor is configured by the TX escape clock division (TXECKDIV) field of the DSI Host clock control register (DSI_CCR) relatively to the lanebyteclock. Its typical value must be around 20 MHz.

Timeout configuration

The timings for timeout management as described in Section 34.8 are configured in the DSI Host timeout counter configuration registers (DSI_TCCR0 to DSI_TCCR5).
34.14.4 Configuring flow control and DBI interface

The flow control is configured thanks to the DSI Host protocol configuration register (DSI_PCR). The configuration parameters are the following:

- CRC reception enable (CRCRXE bit)
- ECC reception enable (ECCRXE bit)
- BTA enable (BTAE bit)
- EoTp reception enable (ETRXE bit)
- EoTp transmission enable (ETTXE bit)

Their values depend upon the protocol to be used for the communication with the DSI display.

The virtual channel ID used for the generic DBI interface must be configured by the virtual channel ID (VCID) field of the DSI Host generic VCID register (DSI_GVCIDR).

All the DCS command, depending on their type, can be transmitted or received either in high-speed or low-power. For each of them, a dedicated configuration bit must be programmed in the DSI Host command mode configuration register (DSI_CMCR).

Acknowledge request for packet or tearing effect event must also be configured in the DSI Host command mode configuration register (DSI_CMCR).

34.14.5 Configuring the DSI Host LTDC interface

As the DSI Host is interface to the system through the LTDC for video mode or adapted command mode, the DSI Wrapper performs a low level interfacing in between.

The parameter programmed into the DSI Wrapper must be aligned with the parameters programmed into the LTDC and the DSI Host.

The following fields must be configured:

- Virtual channel ID in the virtual channel ID (VCID) field of the DSI Host LTDC VCID register (DSI_LVCIDR).
- Color coding (COLC) field of the DSI Host LTDC color coding register (DSI_LCOLCR) and the color multiplexing (COLMUX) in the DSI Wrapper configuration register (DSI_WCFGR).
- If loose packets are used for 18-bit mode, the loosely packet enable (LPE) bit of the DSI Host LTDC color coding register (DSI_LCOLCR) must be set.
- The HSYNC polarity in the HSync polarity (HSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).
- The VSYNC polarity in the VSync polarity (VSP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR) and in the VSync polarity (VSPOL) bit of the DSI Wrapper configuration register (DSI_WCFGR).
- The DATA ENABLE polarity data enable polarity (DEP) bit of the DSI Host LTDC polarity configuration register (DSI_LPCR).
34.14.6 Configuring the video mode

The video mode configuration defines the behavior of the controller in low-power for command transmission, the type of video transmission (burst or non-burst mode) and the panel horizontal and vertical timing:

- Select the video transmission mode to define how the processor requires the video line to be transported through the DSI link.
  - Configure the low-power transitions in the DSI_VMCR to define the video periods, which are permitted to go to low-power if there is time available to do so.
  - Configure if the controller must request the peripheral acknowledge message at the end of frames (DSI_VMCR.FBTAAE).
  - Configure if commands are to be transmitted in low-power (DSI_VMCR.LPE).
- Select the video mode type
  - Burst mode:
    Configure the video mode type (DSI_VMCR.VMT) with value 2'b1x.
    Configure the video packet size (DSI_VPCR.VPSIZE) with the size of the active line period, measured in pixels.
    The registers DSI_VCCR and DSI_VNPCR are ignored by the DSI Host.
  - Non-burst mode:
    Configure the video mode type (DSI_VMCR.VMT) with 2'b00 to enable the transmission of sync pulses or with 2'b01 to enable the transmission of sync events.
    Configure the video packet size (DSI_VPCR.VPSIZE) with the number of pixels to be transmitted in a single packet. Selecting this value depends on the available memory of the attached peripheral, if the data is first stored, or on the memory you want to select for the FIFO in DSI Host.
    Configure the number of chunks (DSI_VCCR.NUMC) with the number of packets to be transmitted per video line. The value of VPSIZE * NUMC is the number of pixels per line of video, except if NUMC is 0, which disables the multi-packets. If you set it to 1, there is still only one packet per line, but it can be part of a chunk, followed by a null packet.
    Configure the null packet size (DSI_VNPCR.NPSIZE) with the size of null packets to be inserted as part of the chunks. Setting it to 0 disables null packets.
- Define the video horizontal timing configuration as follows:
  - Configure the horizontal line time (DSI_VLCR.HLINE) with the time taken by an LTDC video line measured in cycles of lane byte clock (for a clock lane at 500 MHz the lane byte clock period is 8 ns). When the periods of LTDC clock and lane byte clock are not multiples, the value to program the DSI_VLCR.HLINE needs to be rounded. A timing mismatch is introduced between the lines due to the rounding of configuration values. If the DSI Host is configured not to go to low-power, this timing divergence accumulates on every line, introducing a significant amount of mismatch towards the end of the frame. The reason for this is that the DSI Host cannot resynchronize on every new line because it transmits the blanking packets when the horizontal sync event occurs on the LTDC interface. However, the accumulated mismatch must become extinct on the last line of a frame, where, according to the DSI specification, the link must always return to low-power regaining synchronization, when a new frame starts on a vertical sync event. If the accumulated timing mismatch is greater than the time in low-power on the last
line, a malfunction occurs. This phenomenon can be avoided by configuring the DSI Host to go to low-power once per line.

- Configure the horizontal sync duration (DSI_VHSACR.HSA) with the time taken by an LTDC horizontal sync active period measured in cycles of lane byte clock (normally a period of 8 ns).
- Configure the horizontal back-porch duration (DSI_VHBPCR.HBP) with the time taken by the LTDC horizontal back-porch period measured in cycles of lane byte clock (normally a period of 8 ns). Special attention must be given to the calculation of this parameter.

- Define the vertical line configuration:
  - Configure the vertical sync duration (DSI_VVSACR.VSA) with the number of lines existing in the LTDC vertical sync active period.
  - Configure the vertical back-porch duration (DSI_VVBPCR.VBP) with the number of lines existing in the LTDC vertical back-porch period.
  - Configure the vertical front-porch duration (DSI_VVFPCR.VFP) with the number of lines existing in the LTDC vertical front-porch period.
  - Configure the vertical active duration (DSI_VVACR.VA) with the number of lines existing in the LTDC vertical active period.
Figure 289 illustrates the steps for configuring the DPI packet transmission.

**Figure 289. Video packet transmission configuration flow diagram**

- **Global configuration**
  Configure the DPI I/F
- **Burst Mode**
  - **NO**
  - **YES**
    - Determine the DSI link to pixel ratio
    - Enable multiple packets
      - **YES**
        - Calculate the number of chunks
          - Determine the chunk overhead (needs to be $\geq 12$ or $= 6$)
      - **NO**
        - Determine number of pixel per packet
          - Enable null packets
            - **YES**
              - Calculate:
                - $Hline\_time - Hsa\_time - Hbp\_time$
              - Configure:
                - $VSA\_lines - VBP\_lines - Vact\_lines - VFP\_lines$
            - **NO**
              - If the DSI chunk overhead is $\geq 12$
- **If the DSI link to pixel ratio is $> 1$**
  - **Configure video\_packet\_size**
    - Determine number of pixel per packet
      - Enable null packets
        - **YES**
          - Null packet size
Example of video configuration

The following is an example of video packet transmission configuration:

Video resolution:
- PCLK period = 50 ns
- HSA = 8 PCLK
- HBP = 8 PCLK
- HACT = 480 PCLK
- HFP = 24 PCLK
- VSA = 2 lines
- VBP = 2 lines
- VACT = 640 lines
- VFP = 4 lines

Configuration steps:
- Video transmission mode configuration:
  a) Configure the low-power transitions:
     DSI_VMCR[13:8] = 6'b111111, to enable LP in all video period.
  b) DSI_VMCR.FBTAAE = 1, for the DSI Host to request an acknowledge response message from the peripheral at the end of each frame.
- To use the burst mode, follow these steps:
  DSI_VMCR.VMT = 2'b1x
  DSI_VPCR.VPSIZE = 480
- Horizontal timing configuration:
  - DSI_VLCR.HLINE =
    (HSA + HBP + HACT + HFP) * (PCLK period / Clk lane byte period) =
    (8 + 8 + 480 + 24) * (50 / 8) = 3250
  - DSI_VHSACR.HSA = HSA * (PCLK period/Clk lane byte period) =
    8 * (50 / 8) = 50
  - DSI_VHBPCR.HBP = HBP * (PCLK period / Clk lane byte period) =
    8 * (50 / 8) = 50
- Vertical line configuration:
  - DSI_VVSACR.VSA = 2
  - DSI_VVBPCR.VBP = 2
  - DSI_VVFPCR.VFP = 4
  - DSI_VVACR.VA = 640
34.14.7 Configuring the adapted command mode

The adapted command mode requires the following parameters to be configured:

- Command size (CMDSIZE) field of the DSI Host LTDC command configuration register (DSI_LCCR) to define the maximum allowed size for a write memory command.
- The tearing effect source (TESRC) and optionally tearing effect polarity (TEPOL) bits of the DSI Wrapper configuration register (DSI_WCFGR).
- The automatic refresh (AR) bit of the DSI Wrapper configuration register (DSI_WCFGR) if the display needs to be updated automatically each time a tearing effect event is received.

34.14.8 Configuring the video mode pattern generator

DSI Host can transmit a color bar pattern without horizontal/vertical color bar and D-PHY BER testing pattern without any kind of stimuli.

Figure 290 shows the programming sequence to send a test pattern:

1. Configure the DSI_MCR register to enable video mode. Configure the video mode type using DSI_VMCR.VMT.
2. Configure the DSI_LCOLCR register.
3. Configure the frame using registers shown in Figure 291 (where the gray area indicates the transferred pixels).
4. Configure the pattern generation mode (DSI_VMCR.PGM) and the pattern orientation (DSI_VMCR.PGO), and enable them (DSI_VMCR.PGE).

Figure 290. Programming sequence to send a test pattern
34.14.9 Managing ULPM

There are two ways to configure the software to enter and exit the ULPM:
- enter and exit the ULPM with the D-PHY PLL running (a faster process)
- enter and exit the ULPM with the D-PHY PLL turned off (a more efficient process in terms of power consumption).

Clock management for ULPM sequence

The ULPM management state machine is working on the lanebyteclock provided by the D-PHY.

Because the D-PHY is providing the lanebyteclock only when the clock lane is not in ULPM state, it is mandatory to switch the lanebyteclock source of the DSI Host before starting the ULPM mode entry sequence.

The lanebyteclock source is controlled by the RCC. It can be
- the lanebyteclock provided by the D-PHY (for all modes except ULPM)
- a clock generated by the system PLL (for ULPM)
Process flow to enter the ULPM

Implement the process described in detail in the following procedure to enter the ULPM on both clock lane and data lanes:

1. Verify the initial status of the DSI Host:
   - DSI_PCTL[2:1] = 2’h3
   - DSI_WRPCR.PLLLEN = 1’h1 and DSI_WRPCR.REGEN = 1’h1
   - DSI_PUCR[3:0] = 4’h0
   - DSI_PTCR[3:0] = 4’h0
   - Verify that all active lanes are in Stop state and the D-PHY PLL is locked:
     One-lane configuration: DSI_PSR[6:4] = 3’h3 and DSI_PSR[1] = 1’h0 and DSI_WISR.PLLS = 1’h1
     Two-lanes configuration: DSI_PSR[8:4] = 5’h1B and DSI_PSR[1] = 1’h0 and DSI_WISR.PLLS = 1’h1

2. Switch the lanebyteclock source in the RCC from D-PHY to system PLL

3. Set DSI_PUCR[3:0] = 4’h5 to enter ULPM in the data and the clock lanes.

4. Wait until the D-PHY active lanes enter into ULPM:
   - One-lane configuration: DSI_PSR[6:1] = 6’h00
   - Two-lanes configuration: DSI_PSR[8:1] = 8’h00
   The DSI Host is now in ULPM.

5. Turn off the D-PHY PLL by setting DSI_WRPCR.PLLLEN = 1’b0
Process flow to exit the ULPM

Implement the process flow described in the following procedure to exit the ULPM on both clock lane and data lanes:

1. Verify that all active lanes are in ULPM:
   - One-lane configuration: DSI_PSR[6:1] = 6'h00
   - Two-lanes configuration: DSI_PSR[8:1] = 8'h00
2. Turn on the D-PHY PLL by setting DSI_WRPCR.PLLEN = 1'b1.
3. Wait until D-PHY PLL locked
   - DSI_WISR.PLLS = 1'b1
4. Without de-asserting the ULPM request bits, assert the exit ULPM bits by setting DSI_PUCR[3:0] = 4'hF.
5. Wait until all active lanes exit ULPM:
   - One-lane configuration:
     DSI_PSR[5] = 1'b1
     DSI_PSR[3] = 1'b1
   - Two-lanes configuration:
     DSI_PSR[8] = 1'b1
     DSI_PSR[5] = 1'b1
     DSI_PSR[3] = 1'b1
6. Wait for 1 ms.
7. De-assert the ULPM requests and the ULPM exit bits by setting DSI_PUCR [3:0] = 4'h0.
8. Switch the lanbyteclock source in the RCC from system PLL to D-PHY
9. The DSI Host is now in Stop state and the D-PHY PLL is locked:
   - One-lane configuration:
     DSI_PSR[6:4] = 3'h3
     DSI_PSR[1] = 1'h0
     DSI_WRPCR.PLLEN = 1'b1
   - Two-lanes configuration:
     DSI_PSR[8:4] = 5'h1B
     DSI_PSR[1] = 1'h0
     DSI_WRPCR.PLLEN = 1'b1
### 34.15 DSI Host registers

This bit enables the loosely packed variant to 18-bit configuration  
0: Loosely packet variant disabled  
1: Loosely packet variant enabled

Bits 7:4 Reserved, must be kept at reset value.
34.15.6  DSI Host LTDC polarity configuration register (DSI_LPCR)

Address offset: 0x0014
Reset value: 0x0000 0000

Bits 3:0  **COLC[3:0]:** Color coding
This field configures the DPI color coding.
0000: 16-bit configuration 1
0001: 16-bit configuration 2
0010: 16-bit configuration 3
0011: 18-bit configuration 1
0100: 18-bit configuration 2
0101: 24-bit
Others: Reserved

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **HSP:** HSYNC polarity
This bit configures the polarity of HSYNC pin.
0: HSYNC pin active high (default)
1: VSYNC pin active low

Bit 1  **VSP:** VSYNC polarity
This bit configures the polarity of VSYNC pin.
0: Shutdown pin active high (default)
1: Shutdown pin active low

Bit 0  **DEP:** Data enable polarity
This bit configures the polarity of data enable pin.
0: Data enable pin active high (default)
1: Data enable pin active low

34.15.7  DSI Host low-power mode configuration register (DSI_LPMCR)

Address offset: 0x0018
Reset value: 0x0000 0000

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **HSP:** HSYNC polarity
This bit configures the polarity of HSYNC pin.
0: HSYNC pin active high (default)
1: VSYNC pin active low

Bit 1  **VSP:** VSYNC polarity
This bit configures the polarity of VSYNC pin.
0: Shutdown pin active high (default)
1: Shutdown pin active low

Bit 0  **DEP:** Data enable polarity
This bit configures the polarity of data enable pin.
0: Data enable pin active high (default)
1: Data enable pin active low
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **LPSIZE[7:0]:** Largest packet size
            This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VSA, VBP and VFP regions.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **VLPSIZE[7:0]:** VACT largest packet size
            This field is used for the transmission of commands in low-power mode. It defines the size, in bytes, of the largest packet that can fit in a line during VACT regions.

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **PGO**: Pattern generator orientation
   This bit configures the color bar orientation.
   0: Vertical color bars.
   1: Horizontal color bars.

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **PGM**: Pattern generator mode
   This bit configures the pattern generator mode.
   0: Color bars (horizontal or vertical).
   1: BER pattern (vertical only).

Bits 19:17  Reserved, must be kept at reset value.

Bit 16  **PGE**: Pattern generator enable
   This bit enables the video mode pattern generator.
   0: Pattern generator is disabled.
   1: Pattern generator is enabled.

Bit 15  **LPCE**: Low-power command enable
   This bit enables the command transmission only in low-power mode.
   0: Command transmission in low-power mode is disabled.
   1: Command transmission in low-power mode is enabled.

Bit 14  **FBTAAE**: Frame bus-turn-around acknowledge enable
   This bit enables the request for an acknowledge response at the end of a frame.
   0: Acknowledge response at the end of a frame is disabled.
   1: Acknowledge response at the end of a frame is enabled.

Bit 13  **LPHFPE**: Low-power horizontal front-porch enable
   This bit enables the return to low-power inside the horizontal front-porch (HFP) period when timing allows.
   0: Return to low-power inside the HFP period is disabled.
   1: Return to low-power inside the HFP period is enabled.

Bit 12  **LPHBPE**: Low-power horizontal back-porch enable
   This bit enables the return to low-power inside the horizontal back-porch (HBP) period when timing allows.
   0: Return to low-power inside the HBP period is disabled.
   1: Return to low-power inside the HBP period is enabled.

Bit 11  **LPVAE**: Low-power vertical active enable
   This bit enables to return to low-power inside the vertical active (VACT) period when timing allows.
   0: Return to low-power inside the VACT is disabled.
   1: Return to low-power inside the VACT is enabled.

Bit 10  **LPVFPE**: Low-power vertical front-porch enable
   This bit enables to return to low-power inside the vertical front-porch (VFP) period when timing allows.
   0: Return to low-power inside the VFP is disabled.
   1: Return to low-power inside the VFP is enabled.
Bit 9  **LPVBPE**: Low-power vertical back-porch enable
- This bit enables to return to low-power inside the vertical back-porch (VBP) period when timing allows.
  - 0: Return to low-power inside the VBP is disabled.
  - 1: Return to low-power inside the VBP is enabled.

Bit 8  **LPVSAS**: Low-power vertical sync active enable
- This bit enables to return to low-power inside the vertical sync time (VSA) period when timing allows.
  - 0: Return to low-power inside the VSA is disabled.
  - 1: Return to low-power inside the VSA is enabled

Bits 7:2  Reserved, must be kept at reset value.

Bits 1:0  **VMT[1:0]**: Video mode type
- This field configures the video mode transmission type:
  - 00: Non-burst with sync pulses.
  - 01: Non-burst with sync events.
  - 1x: Burst mode

### 34.15.12 DSI Host video packet configuration register (DSI_VPCR)

</table>

Bits 31:14  Reserved, must be kept at reset value.

Bits 13:0  **VPSIZE[13:0]**: Video packet size
- This field configures the number of pixels in a single video packet.
  - For 18-bit not loosely packed data types, this number must be a multiple of 4.
  - For YCbCr data types, it must be a multiple of 2 as described in the DSI specification.

1332/3556  RM0399 Rev 4
34.15.14  DSI Host video null packet configuration register (DSI_VNPCR)

Address offset: 0x0044
Reset value: 0x0000 0000

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **NUMC[12:0]: Number of chunks**
This register configures the number of chunks to be transmitted during a line period (a chunk consists of a video packet and a null packet).
If set to 0 or 1, the video line is transmitted in a single packet.
If set to 1, the packet is part of a chunk, so a null packet follows it if NPSIZE > 0. Otherwise, multiple chunks are used to transmit each video line.

</tbody>
</table>

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **NPSIZE[12:0]: Null packet size**
This field configures the number of bytes inside a null packet.
Setting to 0 disables the null packets.

34.15.15  DSI Host video HSA configuration register (DSI_VHSACR)

Address offset: 0x0048
Reset value: 0x0000 0000

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **HSA[11:0]: Horizontal synchronism active duration**
This field configures the horizontal synchronism active period in lane byte clock cycles.
### 34.15.16 DSI Host video HBP configuration register (DSI_VHBPCR)

Address offset: 0x004C  
Reset value: 0x0000 0000

Bits 31:10  Reserved, must be kept at reset value.
### 34.15.19 DSI Host video VBP configuration register (DSI_VVBPCR)

Address offset: 0x0058  
Reset value: 0x0000 0000

| Bits 31:10 Reserved, must be kept at reset value. |
| Bits 9:0 **VBP[9:0]**: Vertical back-porch duration |
| This field configures the vertical back-porch period measured in number of horizontal lines. |

![VBP configuration register table]

### 34.15.20 DSI Host video VFP configuration register (DSI_VVFPCR)

Address offset: 0x005C  
Reset value: 0x0000 0000

| Bits 31:10 Reserved, must be kept at reset value. |
| Bits 9:0 **VFP[9:0]**: Vertical front-porch duration |
| This field configures the vertical front-porch period measured in number of horizontal lines. |

![VFP configuration register table]

### 34.15.21 DSI Host video VA configuration register (DSI_VVACR)

Address offset: 0x0060  
Reset value: 0x0000 0000

| Bits 13:0 **VA[13:0]** |
| This field configures the vertical active period measured in number of horizontal lines. |
34.15.22 DSI Host LTDC command configuration register (DSI_LCCR)

Address offset: 0x0064
Reset value: 0x0000 0000

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **VA[13:0]**: Vertical active duration
This field configures the vertical active period measured in number of horizontal lines.

34.15.23 DSI Host command mode configuration register (DSI_CMCR)

Address offset: 0x0068
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMDSIZE[15:0]**: Command size
This field configures the maximum allowed size for an LTDC write memory command, measured in pixels. Automatic partitioning of data obtained from LTDC is permanently enabled.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **MRDPS**: Maximum read packet size
This bit configures the maximum read packet size command transmission type:
0: High-speed
1: Low-power

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **DLWTX**: DCS long write transmission
This bit configures the DCS long write packet command transmission type:
0: High-speed
1: Low-power
Bit 18 **DSR0TX**: DCS short read zero parameter transmission
This bit configures the DCS short read packet with zero parameter command transmission type:
- 0: High-speed
- 1: Low-power

Bit 17 **DSW1TX**: DCS short write one parameter transmission
This bit configures the DCS short write packet with one parameter command transmission type:
- 0: High-speed
- 1: Low-power

Bit 16 **DSW0TX**: DCS short write zero parameter transmission
This bit configures the DCS short write packet with zero parameter command transmission type:
- 0: High-speed
- 1: Low-power

Bit 15 Reserved, must be kept at reset value.

Bit 14 **GLWTX**: Generic long write transmission
This bit configures the generic long write packet command transmission type:
- 0: High-speed
- 1: Low-power

Bit 13 **GSR2TX**: Generic short read two parameters transmission
This bit configures the generic short read packet with two parameters command transmission type:
- 0: High-speed
- 1: Low-power

Bit 12 **GSR1TX**: Generic short read one parameters transmission
This bit configures the generic short read packet with one parameters command transmission type:
- 0: High-speed
- 1: Low-power

Bit 11 **GSR0TX**: Generic short read zero parameters transmission
This bit configures the generic short read packet with zero parameters command transmission type:
- 0: High-speed
- 1: Low-power

Bit 10 **GSW2TX**: Generic short write two parameters transmission
This bit configures the generic short write packet with two parameters command transmission type:
- 0: High-speed
- 1: Low-power

Bit 9 **GSW1TX**: Generic short write one parameters transmission
This bit configures the generic short write packet with one parameters command transmission type:
- 0: High-speed
- 1: Low-power
Bit 8 **GSW0TX**: Generic short write zero parameters transmission
This bit configures the generic short write packet with zero parameters command transmission type:
0: High-speed
1: Low-power

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **ARE**: Acknowledge request enable
This bit enables the acknowledge request after each packet transmission:
0: Acknowledge request is disabled.
1: Acknowledge request is enabled.

Bit 0 **TEARE**: Tearing effect acknowledge request enable
This bit enables the tearing effect acknowledge request:
0: Tearing effect acknowledge request is disabled.
1: Tearing effect acknowledge request is enabled.

### 34.15.24 DSI Host generic header configuration register (DSI_GHCR)

Address offset: 0x006C

</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WCMSB[7:0]**: WordCount MSB
This field configures the most significant byte of the header packet’s word count for long packets, or data 1 for short packets.

Bits 15:8 **WCLSB[7:0]**: WordCount LSB
This field configures the less significant byte of the header packet word count for long packets, or data 0 for short packets.

Bits 7:6 **VCID[1:0]**: Channel
This field configures the virtual channel ID of the header packet.

Bits 5:0 **DT[5:0]**: Type
This field configures the packet data type of the header packet.
34.15.25  DSI Host generic payload data register (DSI_GPDR)

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:16 **HSTX_TOCNT[15:0]**: High-speed transmission timeout counter  
This field configures the timeout counter that triggers a high-speed transmission timeout contention detection (measured in TOCKDIV cycles).  
If using the non-burst mode and there is no enough time to switch from high-speed to low-power and back in the period from one line data finishing to the next line sync start, the DSI link returns the low-power state once per frame, then configure the TOCKDIV and HSTX_TOCNT to be in accordance with:  
\[
\text{HSTX\_TOCNT} \times \text{lanebyteclkperiod} \times \text{TOCKDIV} \geq \text{the time of one FRAME data transmission} \times (1 + 10\%) 
\]
In burst mode, RGB pixel packets are time-compressed, leaving more time during a scan line. Therefore, if in burst mode and there is enough time to switch from high-speed to low-power and back in the period from one line data finishing to the next line sync start, the DSI link can return low-power mode and back in this time interval to save power. For this, configure the TOCKDIV and HSTX_TOCNT to be in accordance with:  
\[
\text{HSTX\_TOCNT} \times \text{lanebyteclkperiod} \times \text{TOCKDIV} \geq \text{the time of one LINE data transmission} \times (1 + 10\%) 
\]

Bits 15:0 **LPRX_TOCNT[15:0]**: Low-power reception timeout counter  
This field configures the timeout counter that triggers a low-power reception timeout contention detection (measured in TOCKDIV cycles).
34.15.28 DSI Host timeout counter configuration register 1 (DSI_TCCR1)

</tr>
</tbody>
</table>
Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **PM**: Presp mode
When set to 1, this bit ensures that the peripheral response timeout caused by HSWR_TOCNT is used only once per LTDC frame in command mode, when both the following conditions are met:
- dpivsync_edpiwms has risen and fallen.
- Packets originated from LTDC in command mode have been transmitted and its FIFO is empty again.

In this scenario no non-LTDC command requests are sent to the D-PHY, even if there is traffic from generic interface ready to be sent, making it return to stop state. When it does so, PRESP_TO counter is activated and only when it finishes does the controller send any other traffic that is ready.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **HSWR_TOCNT[15:0]**: High-speed write timeout counter
This field sets a period for which the DSI Host keeps the link inactive after sending a high-speed write operation. This period is measured in cycles of lanebyteclk. The counting starts when the D-PHY enters the Stop state and causes no interrupts.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ACR**: Automatic clock lane control
This bit enables the automatic mechanism to stop providing clock in the clock lane when time allows.
0: Automatic clock lane control disabled
1: Automatic clock lane control enabled

Bit 0 **DPCC**: D-PHY clock control
This bit controls the D-PHY clock state:
0: Clock lane is in low-power mode.
1: Clock lane runs in high-speed mode.

Bits 31:24 **HS2LP_TIME[7:0]**: High-speed to low-power time
This field configures the maximum time that the D-PHY data lanes take to go from high-speed to low-power transmission measured in lane byte clock cycles.

Bits 23:16 **LP2HS_TIME[7:0]**: Low-power to high-speed time
This field configures the maximum time that the D-PHY data lanes take to go from low-power to high-speed transmission measured in lane byte clock cycles.

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **MRD_TIME[14:0]**: Maximum read time
This field configures the maximum time required to perform a read command in lane byte clock cycles. This register can only be modified when no read command is in progress.
Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 CKE: Clock enable**
This bit enables the D-PHY clock lane module:
0: D-PHY clock lane module is disabled.
1: D-PHY clock lane module is enabled.

**Bit 1 DEN: Digital enable**
When set to 0, this bit places the digital section of the D-PHY in the reset state
0: The digital section of the D-PHY is in the reset state.
1: The digital section of the D-PHY is enabled.

**Bit 0** Reserved, must be kept at reset value.

34.15.39 DSI Host PHY TX triggers configuration register (DSI_PTTCR)

Address offset: 0x00AC
Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **UEDL**: ULPS exit on data lane
ULPS mode exit on all active data lanes.
0: No exit request
1: Exit ULPS mode on all active data lane URDL

Bit 2 **URDL**: ULPS request on data lane
ULPS mode request on all active data lanes.
0: No ULPS request
1: Request ULPS mode on all active data lane UECL

Bit 1 **UECL**: ULPS exit on clock lane
ULPS mode exit on clock lane.
0: No exit request
1: Exit ULPS mode on clock lane

Bit 0 **URCL**: ULPS request on clock lane
ULPS mode request on clock lane.
0: No ULPS request
1: Request ULPS mode on clock lane

34.15.40 DSI Host PHY status register (DSI_PSR)

Address offset: 0x00B0
Reset value: 0x0000 1528

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **TX_TRIG[3:0]**: Transmission trigger
Escape mode transmit trigger 0-3.
Only one bit of TX_TRIG is asserted at any given time.
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **UAN1**: ULPS active not lane 1  
This bit indicates the status of ulpsactivenot1lane D-PHY signal.

Bit 7  **PSS1**: PHY stop state lane 1  
This bit indicates the status of phystopstate1lane D-PHY signal.

Bit 6  **RUE0**: RX ULPS escape lane 0  
This bit indicates the status of rxulpsesc0lane D-PHY signal.

Bit 5  **UAN0**: ULPS active not lane 1  
This bit indicates the status of ulpsactivenot0lane D-PHY signal.

Bit 4  **PSS0**: PHY stop state lane 0  
This bit indicates the status of phystopstate0lane D-PHY signal.

Bit 3  **UANC**: ULPS active not clock lane  
This bit indicates the status of ulpsactivenotclklane D-PHY signal.

Bit 2  **PSSC**: PHY stop state clock lane  
This bit indicates the status of phystopstateclklane D-PHY signal.

Bit 1  **PD**: PHY direction  
This bit indicates the status of phydirection D-PHY signal.

Bit 0  Reserved, must be kept at reset value.

Bits 31:21  Reserved, must be kept at reset value.

Bit 20  **PE4**: PHY error 4  
This bit indicates the LP1 contention error ErrContentionLP1 from lane 0.

Bit 19  **PE3**: PHY error 3  
This bit indicates the LP0 contention error ErrContentionLP0 from lane 0.

Bit 18  **PE2**: PHY error 2  
This bit indicates the ErrControl error from lane 0.

Bit 17  **PE1**: PHY error 1  
This bit indicates the ErrSyncEsc low-power transmission synchronization error from lane 0.

Bit 16  **PE0**: PHY error 0  
This bit indicates the ErrEsc escape entry error from lane 0.
### Bit 15: AE15 - Acknowledge error 15
This bit retrieves the DSI protocol violation from the acknowledge error report.

### Bit 14: AE14 - Acknowledge error 14
This bit retrieves the reserved (specific to the device) from the acknowledge error report.

### Bit 13: AE13 - Acknowledge error 13
This bit retrieves the invalid transmission length from the acknowledge error report.

### Bit 12: AE12 - Acknowledge error 12
This bit retrieves the DSI VC ID Invalid from the acknowledge error report.

### Bit 11: AE11 - Acknowledge error 11
This bit retrieves the not recognized DSI data type from the acknowledge error report.

### Bit 10: AE10 - Acknowledge error 10
This bit retrieves the checksum error (long packet only) from the acknowledge error report.

### Bit 9: AE9 - Acknowledge error 9
This bit retrieves the ECC error, multi-bit (detected, not corrected) from the acknowledge error report.

### Bit 8: AE8 - Acknowledge error 8
This bit retrieves the ECC error, single-bit (detected and corrected) from the acknowledge error report.

### Bit 7: AE7 - Acknowledge error 7
This bit retrieves the reserved (specific to the device) from the acknowledge error report.

### Bit 6: AE6 - Acknowledge error 6
This bit retrieves the false control error from the acknowledge error report.

### Bit 5: AE5 - Acknowledge error 5
This bit retrieves the peripheral timeout error from the acknowledge error report.

### Bit 4: AE4 - Acknowledge error 4
This bit retrieves the LP transmit sync error from the acknowledge error report.

### Bit 3: AE3 - Acknowledge error 3
This bit retrieves the escape mode entry command error from the acknowledge error report.

### Bit 2: AE2 - Acknowledge error 2
This bit retrieves the EoT sync error from the acknowledge error report.

### Bit 1: AE1 - Acknowledge error 1
This bit retrieves the SoT sync error from the acknowledge error report.

### Bit 0: AE0 - Acknowledge error 0
This bit retrieves the SoT error from the acknowledge error report.

Bits 31:13  Reserved, must be kept at reset value.

Bit 12  GPRXE: Generic payload receive error
This bit indicates that during a generic interface packet read back, the payload FIFO becomes full and the received data is corrupted.

Bit 11  GPRDE: Generic payload read error
This bit indicates that during a DCS read data, the payload FIFO becomes empty and the data sent to the interface is corrupted.

Bit 10  GPTXE: Generic payload transmit error
This bit indicates that during a generic interface packet build, the payload FIFO becomes empty and corrupt data is sent.

Bit 9  GPWRE: Generic payload write error
This bit indicates that the system tried to write a payload data through the generic interface and the FIFO is full. Therefore, the payload is not written.

Bit 8  GCWRE: Generic command write error
This bit indicates that the system tried to write a command through the generic interface and the FIFO is full. Therefore, the command is not written.

Bit 7  LPWRE: LTDC payload write error
This bit indicates that during a DPI pixel line storage, the payload FIFO becomes full and the data stored is corrupted.

Bit 6  EOTPE: EoTp error
This bit indicates that the EoTp packet is not received at the end of the incoming peripheral transmission.

Bit 5  PSE: Packet size error
This bit indicates that the packet size error is detected during the packet reception.

Bit 4  CRCE: CRC error
This bit indicates that the CRC error is detected in the received packet payload.

Bit 3  ECCME: ECC multi-bit error
This bit indicates that the ECC multiple error is detected in a received packet.
Bit 2 **ECCSE**: ECC single-bit error
This bit indicates that the ECC single error is detected and corrected in a received packet.

Bit 1 **TOLPRX**: Timeout low-power reception
This bit indicates that the low-power reception timeout counter reached the end and contention is detected.

Bit 0 **TOHSTX**: Timeout high-speed transmission
This bit indicates that the high-speed transmission timeout counter reached the end and contention is detected.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **PE4IE**: PHY error 4 interrupt enable
This bit enables the interrupt generation on PHY error 4.
0: Interrupt on PHY error 4 disabled
1: Interrupt on PHY error 4 enabled

Bit 19 **PE3IE**: PHY error 3 interrupt enable
This bit enables the interrupt generation on PHY error 4.
0: Interrupt on PHY error 3 disabled
1: Interrupt on PHY error 3 enabled

Bit 18 **PE2IE**: PHY error 2 interrupt enable
This bit enables the interrupt generation on PHY error 2.
0: Interrupt on PHY error 2 disabled
1: Interrupt on PHY error 2 enabled

Bit 17 **PE1IE**: PHY error 1 interrupt enable
This bit enables the interrupt generation on PHY error 1.
0: Interrupt on PHY error 1 disabled
1: Interrupt on PHY error 1 enabled

Bit 16 **PE0IE**: PHY error 0 interrupt enable
This bit enables the interrupt generation on PHY error 0.
0: Interrupt on PHY error 0 disabled
1: Interrupt on PHY error 0 enabled

Bit 15 **AE15IE**: Acknowledge error 15 interrupt enable
This bit enables the interrupt generation on acknowledge error 15.
0: Interrupt on acknowledge error 15 disabled
1: Interrupt on acknowledge error 15 enabled
Bit 14 **AE14IE**: Acknowledge error 14 interrupt enable  
This bit enables the interrupt generation on acknowledge error 14.  
0: Interrupt on acknowledge error 14 disabled  
1: Interrupt on acknowledge error 14 enabled

Bit 13 **AE13IE**: Acknowledge error 13 interrupt enable  
This bit enables the interrupt generation on acknowledge error 13.  
0: Interrupt on acknowledge error 13 disabled  
1: Interrupt on acknowledge error 13 enabled

Bit 12 **AE12IE**: Acknowledge error 12 interrupt enable  
This bit enables the interrupt generation on acknowledge error 12.  
0: Interrupt on acknowledge error 12 disabled  
1: Interrupt on acknowledge error 12 enabled

Bit 11 **AE11IE**: Acknowledge error 11 interrupt enable  
This bit enables the interrupt generation on acknowledge error 11.  
0: Interrupt on acknowledge error 11 disabled  
1: Interrupt on acknowledge error 11 enabled

Bit 10 **AE10IE**: Acknowledge error 10 interrupt enable  
This bit enables the interrupt generation on acknowledge error 10.  
0: Interrupt on acknowledge error 10 disabled  
1: Interrupt on acknowledge error 10 enabled

Bit 9 **AE9IE**: Acknowledge error 9 interrupt enable  
This bit enables the interrupt generation on acknowledge error 9.  
0: Interrupt on acknowledge error 9 disabled  
1: Interrupt on acknowledge error 9 enabled

Bit 8 **AE8IE**: Acknowledge error 8 interrupt enable  
This bit enables the interrupt generation on acknowledge error 8.  
0: Interrupt on acknowledge error 8 disabled  
1: Interrupt on acknowledge error 8 enabled

Bit 7 **AE7IE**: Acknowledge error 7 interrupt enable  
This bit enables the interrupt generation on acknowledge error 7.  
0: Interrupt on acknowledge error 7 disabled  
1: Interrupt on acknowledge error 7 enabled

Bit 6 **AE6IE**: Acknowledge error 6 interrupt enable  
This bit enables the interrupt generation on acknowledge error 6.  
0: Interrupt on acknowledge error 6 disabled  
1: Interrupt on acknowledge error 6 enabled

Bit 5 **AE5IE**: Acknowledge error 5 interrupt enable  
This bit enables the interrupt generation on acknowledge error 5.  
0: Interrupt on acknowledge error 5 disabled  
1: Interrupt on acknowledge error 5 enabled

Bit 4 **AE4IE**: Acknowledge error 4 interrupt enable  
This bit enables the interrupt generation on acknowledge error 4.  
0: Interrupt on acknowledge error 4 disabled  
1: Interrupt on acknowledge error 4 enabled

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **FGPRXE**: Force generic payload receive error
Writing one to this bit forces a generic payload receive error.

Bit 11 **FGPRDE**: Force generic payload read error
Writing one to this bit forces a generic payload read error.

Bit 10 **FGPTXE**: Force generic payload transmit error
Writing one to this bit forces a generic payload transmit error.

Bit 9 **FGPWRE**: Force generic payload write error
Writing one to this bit forces a generic payload write error.

Bit 8 **FGCWRE**: Force generic command write error
Writing one to this bit forces a generic command write error.

Bit 7 **FLPWRE**: Force LTDC payload write error
Writing one to this bit forces a LTDC payload write error.

Bit 6 **FEOTPE**: Force EoTp error
Writing one to this bit forces a EoTp error.

Bit 5 **FPSE**: Force packet size error
Writing one to this bit forces a packet size error.
Bit 4 **FCRCE**: Force CRC error
Writing one to this bit forces a CRC error.

Bit 3 **FECCME**: Force ECC multi-bit error
Writing one to this bit forces a ECC multi-bit error.

Bit 2 **FECCSE**: Force ECC single-bit error
Writing one to this bit forces a ECC single-bit error.

Bit 1 **FTOLPRX**: Force timeout low-power reception
Writing one to this bit forces a timeout low-power reception.

Bit 0 **FTOHSTX**: Force timeout high-speed transmission
Writing one to this bit forces a timeout high-speed transmission.

</table>

Bits 31:10  Reserved, must be kept at reset value.

Bit 9  LPEC: Low-power command enable
This bit returns the current command transmission state in low-power mode.
0: Command transmission in low-power mode is disabled.
1: Command transmission in low-power mode is enabled.

Bit 8  FBTAAE: Frame BTA acknowledge enable
This bit returns the current state of request for an acknowledge response at the end of a frame.
0: Acknowledge response at the end of a frame is disabled.
1: Acknowledge response at the end of a frame is enabled.
Bit 7 **LPHFE**: Low-power horizontal front-porch enable
This bit returns the current state of return to low-power inside the horizontal front-porch (HFP) period when timing allows.
0: Return to low-power inside the HFP period is disabled.
1: Return to low-power inside the HFP period is enabled.

Bit 6 **LPHBPE**: Low-power horizontal back-porch enable
This bit returns the current state of return to low-power inside the horizontal back-porch (HBP) period when timing allows.
0: Return to low-power inside the HBP period is disabled.
1: Return to low-power inside the HBP period is enabled.

Bit 5 **LPVAE**: Low-power vertical active enable
This bit returns the current state of return to low-power inside the vertical active (VACT) period when timing allows.
0: Return to low-power inside the VACT is disabled.
1: Return to low-power inside the VACT is enabled.

Bit 4 **LPVFE**: Low-power vertical front-porch enable
This bit returns the current state of return to low-power inside the vertical front-porch (VFP) period when timing allows.
0: Return to low-power inside the VFP is disabled.
1: Return to low-power inside the VFP is enabled.

Bit 3 **LPVBPE**: Low-power vertical back-porch enable
This bit returns the current state of return to low-power inside the vertical back-porch (VBP) period when timing allows.
0: Return to low-power inside the VBP is disabled.
1: Return to low-power inside the VBP is enabled.

Bit 2 **LPVSAE**: Low-power vertical sync time enable
This bit returns the current state of return to low-power inside the vertical sync time (VSA) period when timing allows.
0: Return to low-power inside the VSA is disabled.
1: Return to low-power inside the VSA is enabled

Bits 1:0 **VMT[1:0]**: Video mode type
This field returns the current video mode transmission type:
00: Non-burst with sync pulses
01: Non-burst with sync events
1x: Burst mode

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 VSPOL: VSync polarity
This bit selects the VSync edge on which the LTDC is halted.
0: LTDC halted on a falling edge
1: LTDC halted on a rising edge
This bit must only be changed when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).

Bit 6 AR: Automatic refresh
This bit selects the refresh mode in DBI mode.
0: automatic refresh mode disabled
1: automatic refresh mode enabled
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bit 5 TEPOL: TE polarity
This bit selects the polarity of the external pin tearing effect (TE) source.
0: rising edge.
1: falling edge.
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bit 4 TESRC: TE source
This bit selects the tearing effect (TE) source.
0: DSI Link
1: External pin
This bit must only be changed when DSI Host is stopped (DSI_CR.EN = 0).

Bits 3:1 COLMUX[2:0]: Color multiplexing
This bit selects the color multiplexing used by DSI Host.
000: 16-bit configuration 1
001: 16-bit configuration 2
010: 16-bit configuration 3
011: 18-bit configuration 1
100: 18-bit configuration 2
101: 24-bit
This field must only be changed when DSI is stopped (DSI_WCR.DSIEN = 0 and DSI_CR.EN = 0).

34.16.4 DSI Wrapper interrupt and status register (DSI_WISR)

Address offset: 0x040C
Reset value: 0x0000 0000

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **RRIE**: Regulator ready interrupt enable
This bit enables the regulator ready interrupt.
0: Regulator ready interrupt disabled
1: Regulator ready interrupt enabled

Bit 12:11 Reserved, must be kept at reset value.

Bit 10 **PLLUIE**: PLL unlock interrupt enable
This bit enables the PLL unlock interrupt.
0: PLL unlock interrupt disabled
1: PLL unlock interrupt enabled

Bit 9 **PLLLIE**: PLL lock interrupt enable
This bit enables the PLL lock interrupt.
0: PLL lock interrupt disabled
1: PLL lock interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **ERIE**: End of refresh interrupt enable
This bit enables the end of refresh interrupt.
0: End of refresh interrupt disabled
1: End of refresh interrupt enabled

Bit 0 **TEIE**: Tearing effect interrupt enable
This bit enables the tearing effect interrupt.
0: Tearing effect interrupt disabled
1: Tearing effect interrupt enabled

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **RRIF**: Regulator ready interrupt flag
This bit is set when the regulator becomes ready.
0: No regulator ready event occurred
1: Regulator ready event occurred

Bit 12 **RRS**: Regulator ready status
This bit gives the status of the regulator.
0: Regulator is not ready.
1: Regulator is ready.
Bit 11 Reserved, must be kept at reset value.

Bit 10 **PLLUIF**: PLL unlock interrupt flag
   This bit is set when the PLL becomes unlocked.
   0: No PLL unlock event occurred
   1: PLL unlock event occurred

Bit 9 **PLLLIF**: PLL lock interrupt flag
   This bit is set when the PLL becomes locked.
   0: No PLL lock event occurred
   1: PLL lock event occurred

Bit 8 **PLLLS**: PLL lock status
   This bit is set when the PLL is locked and cleared when it is unlocked.
   0: PLL is unlocked.
   1: PLL is locked.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BUSY**: Busy flag
   This bit is set when the transfer of a frame in adapted command mode is ongoing.
   0: No transfer on going
   1: Transfer on going

Bit 1 **ERIF**: End of refresh interrupt flag
   This bit is set when the transfer of a frame in adapted command mode is finished.
   0: No end of refresh event occurred
   1: End of refresh event occurred

Bit 0 **TEIF**: Tearing effect interrupt flag
   This bit is set when a tearing effect event occurs.
   0: No tearing effect event occurred
   1: Tearing effect event occurred

### 34.16.5 DSI Wrapper interrupt flag clear register (DSI_WIFCR)

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **CRRIF**: Clear regulator ready interrupt flag
   Write 1 clears the RRIF flag in the DSI_WSR register.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **CPLLUIF**: Clear PLL unlock interrupt flag
   Write 1 clears the PLLUIF flag in the DSI_WSR register.
Bit 9  **CPLLIF**: Clear PLL lock interrupt flag  
Write 1 clears the PLLLIF flag in the DSI_WSR register.

Bits 8:2  Reserved, must be kept at reset value.

Bit 1  **CERIF**: Clear end of refresh interrupt flag  
Write 1 clears the ERIF flag in the DSI_WSR register.

Bit 0  **CTEIF**: Clear tearing effect interrupt flag  
Write 1 clears the TEIF flag in the DSI_WSR register.

### 34.16.6  DSI Wrapper PHY configuration register 0 (DSI_WPCR0)

Bits 31:28  Reserved, must be kept at reset value.

- **TCLKPOSTEN**: Custom time for tCLK-POST enable  
  This bit enables the manual programming of tCLK-POST duration in the D-PHY. The desired value must be programmed in the TCLKPOST field of the DSI_WPCR4 register.  
  0: Default value is used for tCLKPOST.  
  1: Programmable value is used for tCLKPOST.

- **TLPXCEN**: Custom time for tLPX for clock lane enable  
  This bit enables the manual programming of tLPX duration for the clock lane in the D-PHY. The desired value must be programmed in the TLPXC field of the DSI_WPCR3 register.  
  0: Default value is used for tLPX for the clock lane.  
  1: Programmable value is used for tLPX for the clock lane.

- **THSEXITEN**: Custom time for tHS-EXIT enable  
  This bit enables the manual programming of tHS-EXIT duration in the D-PHY. The desired value must be programmed in the THSEXIT field of the DSI_WPCR3 register.  
  0: Default value is used for tHS-EXIT.  
  1: Programmable value is used for tHS-EXIT.

- **TLPXDEN**: Custom time for tLPX for data lanes enable  
  This bit enables the manual programming of tLPX duration for the data lanes in the D-PHY. The desired value must be programmed in the TLPXD field of the DSI_WPCR3 register.  
  0: Default value is used for tLPX for the data lanes.  
  1: Programmable value is used for tLPX for the data lanes.
Bit 23 **THSZEROEN**: Custom time for $t_{HS-ZERO}$ enable
This bit enables the manual programming of $t_{HS-ZERO}$ duration in the D-PHY. The desired value must be programmed in the THSZERO field of the DSI_WPCR3 register.
0: Default value is used for $t_{HS-ZERO}$
1: Programmable value is used for $t_{HS-ZERO}$

Bit 22 **THSTRAILEN**: Custom time for $t_{HS-TRAIL}$ enable
This bit enables the manual programming of $T_{HS-TRAIL}$ duration in the D-PHY. The desired value must be programmed in the THSRAIL field of the DSI_WPCR2 register.
0: Default value is used for $T_{HS-TRAIL}$
1: Programmable value is used for $T_{HS-TRAIL}$

Bit 21 **THSPREPEN**: Custom time for $t_{HS-PREPARE}$ enable
This bit enables the manual programming of $t_{HS-PREPARE}$ duration in the D-PHY. The desired value must be programmed in the THSPREP field of the DSI_WPCR2 register.
0: Default value is used for $t_{HS-PREPARE}$
1: Programmable value is used for $t_{HS-PREPARE}$

Bit 20 **TCLKZEROEN**: Custom time for $t_{CLK-ZERO}$ enable
This bit enables the manual programming of $t_{CLK-ZERO}$ duration in the D-PHY. The desired value must be programmed in the TCLKZERO field of the DSI_WPCR2 register.
0: Default value is used for $t_{CLK-ZERO}$
1: Programmable value is used for $t_{CLK-ZERO}$

Bit 19 **TCLKPREPEN**: Custom time for $t_{CLK-PREPARE}$ enable
This bit enables the manual programming of $t_{CLK-PREPARE}$ duration in the D-PHY. The desired value must be programmed in the TCLKPREP field of the DSI_WPCR2 register.
0: Default value is used for $t_{CLK-PREPARE}$
1: Programmable value is used for $t_{CLK-PREPARE}$

Bit 18 **PDEN**: Pull-down enable
This bit enables a pull-down on the lane to prevent from floating states when unused.
0: Pull-down on lanes disabled
1: Pull-down on lanes enabled

Bit 17 Reserved, must be kept at reset value.

Bit 16 **TDDL**: Turn disable data lanes
This bit forces the data lane to remain in RX event if it receives a bus-turn-around request from the other side.
0: No effect
1: Force data lanes in RX mode after a BTA

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CDOFFDL**: Contention detection OFF on data lanes
When only forward escape mode is used, this signal can be made high to switch off the contention detector and reduce static power consumption.
0: Contention detection on data lane ON
1: Contention detection on data lane OFF

Bit 13 **FTXSMDL**: Force in TX Stop mode the data lanes
This bit forces the data lanes in TX stop mode. It is used to initialize a lane module in transmit mode. It causes the lane module to immediately jump to transmit control mode and to begin transmitting a stop state (LP-11). It can be used to go back in TX mode after a wrong BTA sequence.
0: No effect
1: Force the data lanes in TX Stop mode
Bit 12  **FTXSMCL**: Force in TX Stop mode the clock lane
This bit forces the clock lane in TX stop mode. It is used to initialize a lane module in transmit mode. It causes the lane module to immediately jump to transmit control mode and to begin transmitting a stop state (LP-11). It can be used to go back in TX mode after a wrong BTA sequence.
0: No effect
1: Force the clock lane in TX Stop mode

Bit 11  **HSIDL1**: Invert the high-speed data signal on data lane 1
This bit inverts the high-speed data signal on data lane 1.
0: Normal data signal configuration
1: Inverted data signal configuration

Bit 10  **HSIDL0**: Invert the high-speed data signal on data lane 0
This bit inverts the high-speed data signal on clock lane.
0: Normal data signal configuration
1: Inverted data signal configuration

Bit 9  **HSICL**: Invert high-speed data signal on clock lane
This bit inverts the high-speed data signal on clock lane.
0: Normal data configuration
1: Inverted data configuration

Bit 8  **SWDL1**: Swap data lane 1 pins
This bit swaps the pins on clock lane.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bit 7  **SWDL0**: Swap data lane 0 pins
This bit swaps the pins on data lane 0.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bit 6  **SWCL**: Swap clock lane pins
This bit swaps the pins on clock lane.
0: Regular clock lane pin configuration
1: Swapped clock lane pin

Bits 5:0  **UIX4[5:0]**: Unit interval multiplied by 4
This field defines the bit period in high-speed mode in unit of 0.25 ns.
As an example, if the unit interval is 3 ns, a value of twelve (0x0C) must be driven to this input. This value is used to generate delays. If the period is not a multiple of 0.25 ns, the value driven must be rounded down. For example, a 600 Mbit/s link uses a unit interval of 1.667 ns, which, multiplied by four gives 6.667 ns. In this case a value of 6 (not 7) must be driven onto the ui_x4 input.

### 34.16.7  **DSI Wrapper PHY configuration register 1 (DSI_WPCR1)**

Address offset: 0x041C
Reset value: 0x0000 0000

*Note:*  This register must be programmed only when DSI is stopped (CR. DSIEN=0 and CR.EN = 0).
Bits 31:27  Reserved, must be kept at reset value.

Bits 26:25  **LPRXFT[1:0]**: Low-power RX low-pass filtering tuning
This signal can be used to tune the cutoff frequency of low-pass filter at the input of LPRX.

Bits 24:23  Reserved, must be kept at reset value.

Bit 22  **FLPRXLP**: Forces LP receiver in low-power mode
This bit enables the low-power mode of LP receiver (LPRX). When set, the LPRX operates in low-power mode all the time (when this is not activated, LPRX operates in low-power mode during ULPS only).
0: No effect
1: LPRX is forced in low-power mode.

Bits 21:20  Reserved, must be kept at reset value.

Bits 19:18  **HSTXSRCDL[1:0]**: High-speed transmission slew-rate control on data lanes
Slew-rate control for high-speed transmitter output. It can be used to change slew-rate of data lane HS transitions.
Default value = 00.

Bits 17:16  **HSTXSRCCL[1:0]**: High-speed transmission slew-rate control on clock lane
Slew-rate control for high-speed transmitter output. It can be used to change slew-rate of clock lane HS transitions.
Default value = 00.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **SDDC**: SDD control
This bit switches on the additional current path to meet the SDDTx parameter defined by MIPI® D-PHY Specification on both clock and data lanes.
0: No effect
1: Activate additional current path on all lanes

Bits 11:10  Reserved, must be kept at reset value.

Bits 9:8  **LPSRCDL[1:0]**: Low-power transmission slew-rate compensation on data lanes
Can be used to change slew-rate of data lane LP transitions.
Default value = 00.

Bits 7:6  **LPSRCCCL[1:0]**: Low-power transmission slew-rate compensation on clock lane
Can be used to change slew-rate of clock lane LP transitions.
Default value = 00.
Bits 5:4  Reserved, must be kept at reset value.

Bits 3:2  **HSTXDDL[1:0]**: High-speed transmission delay on data lanes
          Delay tuner control to change delay (up to DP/DN) in data path. Can be used to change data
          edge transition positions with respect to clock edge on DP/DN.
          Default value = 00.

Bits 1:0  **HSTXDCL[1:0]**: High-speed transmission delay on clock lane
          Delay tuner control to change delay (up to DP/DN) in clock path. Can be used to change
          clock edge position with respect to data bit transitions on DP/DN.
          Default value = 00.

### 34.16.8  **DSI Wrapper PHY configuration register 2 (DSI_WPCR2)**

Address offset: 0x0420

Reset value: 0x0000 0000

**Note:**  This register must be programmed only when DSI is stopped (CR. DSIEN=0 and
           CR.EN = 0).

Bits 31:24  **THSTRAIL[7:0]**: t\textsubscript{HSTRAIL}

This field defines the t\textsubscript{HSTRAIL} has specified in the MIPI\textsuperscript{®} D-PHY specification. This value is
used by the D-PHY when the THSTRAILEN bit of the DSI_WPCR0 is set.

THSTRAIL = 2 x t\textsubscript{HSTRAIL} expressed in ns. The default value used by the D-PHY when

THSTRAILEN bit of the DSI_WPCR0 is reset is 140 (70 ns + 8 * UI).

Bits 23:16  **THSPREP[7:0]**: t\textsubscript{HS-PREPARE}

This field defines the t\textsubscript{HS-PREPARE} has specified in the MIPI\textsuperscript{®} D-PHY specification. This value is
used by the D-PHY when the THSPREPEN bit of the DSI_WPCR0 is set.

THSPREP = 2 x t\textsubscript{HS-PREPARE} expressed in ns. The default value used by the D-PHY when

THSPREPEN bit of the DSI_WPCR0 is reset is 126 (63 ns + 12 * UI).

Bits 15:8  **TCLKZERO[7:0]**: t\textsubscript{CLK-ZERO}

This field defines the t\textsubscript{CLK-ZERO} has specified in the MIPI\textsuperscript{®} D-PHY specification. This value is
used by the D-PHY when the TCLKZEROEN bit of the DSI_WPCR0 is set.

TCLKZERO = t\textsubscript{CLK-ZERO} / 2 expressed in ns. The default value used by the D-PHY when

TCLKZEROEN bit of the DSI_WPCR0 is reset is 195 (390 ns).

Bits 7:0  **TCLKPREP[7:0]**: t\textsubscript{CLK-PREPARE}

This field defines the t\textsubscript{CLK-PREPARE} has specified in the MIPI\textsuperscript{®} D-PHY specification. This value is
used by the D-PHY when the TCLKPREPEN bit of the DSI_WPCR0 is set.

TCLKPREP = 2 x t\textsubscript{CLK-PREPARE} expressed in ns. The default value used by the D-PHY when

TCLKPREPEN bit of the DSI_WPCR0 is reset is 120 (60 ns + 20 * UI).
34.16.9 DSI Wrapper PHY configuration register 3 (DSI_WPCR3)

Address offset: 0x0424
Reset value: 0x0000 0000

Note: This register shall be programmed only when DSI is stopped (CR. DSIEN=0 and DSI_CR.EN = 0).

<table>
<thead>

Bits 31:24 TLPXC[7:0]: tLPXC for clock lane
This field defines the tLPX has specified in the MIPI® D-PHY specification for the clock lane.
This value is used by the D-PHY when the TLPXCN bit of the DSI_WPCR1 is set.
TLPXC = 2 x tLPX expressed in ns. The default value used by the D-PHY when TLPXCN bit of the DSI_WPCR1 is reset is 100 (50 ns).

Bits 23:16 THSEXIT[7:0]: tHS-EXIT
This field defines the tHS-EXIT has specified in the MIPI® D-PHY specification. This value is used by the D-PHY when the THSEXITEN bit of the DSI_WPCR1 is set.
THSEXIT = tHS-ZERO expressed in ns. The default value used by the D-PHY when THSEXITEN bit of the DSI_WPCR1 is reset is 100 (100 ns).

Bits 15:8 TLPXD[7:0]: tLPX for data lanes
This field defines the tLPX has specified in the MIPI® D-PHY specification for the data lanes.
This value is used by the D-PHY when the TLPXDEN bit of the DSI_WPCR1 is set.
TLPXD = 2 x tLPX expressed in ns. The default value used by the D-PHY when TLPXDEN bit of the DSI_WPCR1 is reset is 100 (50 ns).

Bits 7:0 THSZERO[7:0]: tHS-ZERO
This field defines the tHS-ZERO has specified in the MIPI® D-PHY specification. This value is used by the D-PHY when the THSZEROEN bit of the DSI_WPCR1 is set.
THSZERO = tHS-ZERO expressed in ns. The default value used by the D-PHY when THSZEROEN bit of the DSI_WPCR1 is reset is 175 (175 ns).

34.16.10 DSI Wrapper PHY configuration register 4 (DSI_WPCR4)

Address offset: 0x0428
Reset value: 0x0000 0000

Note: This register shall be programmed only when DSI is stopped (CR. DSIEN=0 and DSI_CR.EN = 0).

**Table 294. DSI register map and reset values**

- **Offset**: The offset of the register in the memory.
- **Register**: The name of the register.
- **31 to 0**: The reset values for each bit position.
- **DSI_VR**: Version register.
- **DSI_CR**: Control register.
- **DSI_CCR**: Clock control register.
- **DSI_LVCIDR**: Local video control register.
- **DSI_LCOLCR**: Local color control register.
- **DSI_LPCR**: Local pixel control register.
- **DSI_LPMCR**: Local pixel mapping control register.
- **DSI_PCR**: Pixel control register.
- **DSI_GVCIDR**: Global video control register.
- **DSI_MCR**: Memory control register.

The table shows the reset values for each bit position in the registers.

35 JPEG codec (JPEG)

35.1 Introduction
The hardware 8-bit JPEG codec encodes uncompressed image data stream or decodes JPEG-compressed image data stream. It also fully manages JPEG headers.

35.2 JPEG codec main features
- High-speed fully-synchronous operation
- Configurable as encoder or decoder
- Single-clock-per-pixel encode/decode
- RGB, YCbCr, YCMK and BW (grayscale) image color space support
- 8-bit depth per image component at encode/decode
- JPEG header generator/parser with enable/disable
- Four programmable quantization tables
- Single-clock Huffman coding and decoding
- Fully-programmable Huffman tables (two AC and two DC)
- Fully-programmable minimum coded unit (MCU)
- Concurrent input and output data stream interfaces
35.3 JPEG codec block functional description

35.3.1 General description
The block diagram of the JPEG codec is shown in Figure 292.

![Figure 292. JPEG codec block diagram](image)

35.3.2 JPEG internal signals

</tbody>
</table>
35.3.3 JPEG decoding procedure

The JPEG codec can decode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally parse the JPEG header and update accordingly the JPEG codec registers, the quantization tables and the Huffman tables.

The JPEG codec is configured in decode mode setting the DE bit (decode enable) of the JPEG_CONFR1 register.

The JPEG decode starts by setting the START bit of the JPEG_CONFR0 register.

The JPEG codec requests data for its input FIFO through generating one of:
- MDMA trigger
- interrupts

**Interrupt or MDMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or MDMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or an interrupt request / MDMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (Input FIFO Flush) of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

**Header parsing**

The header parsing can be activated setting the HDR bit of the JPEG_CONFR1 register.

The JPEG header parser supports all markers relevant to the JPEG baseline algorithm indicated in Annex B of the ISO/IEC 10918-1.
When parsing a supported marker, the JPEG header parser extracts the required parameters and stores them in shadow registers. At the end of the parsing the JPEG codec registers are updated.

If a DQT marker segment is located, quantization data associated with it is written into the quantization table memory.

If a DHT marker segment is located, the Huffman table data associated with it is converted into three different table formats (HuffMin, HuffBase and HuffSymb) and stored in their respective memories.

Once the parsing operation is completed, the HPDF (header parsing done flag) bit of the JPEG_SR register is set. An interrupt is generated if the EHPIE (end of header parsing interrupt enable) bit of the JPEG_CR register is set.

**JPEG decoding**

Once the JPEG header is parsed or JPEG codec registers and memories are properly programmed, the incoming data stream is decoded and the resulting MCUs are sent to the output FIFO.

When decoding two images successively, the START bit of the JPEG_CONFR0 register must be set again (even if already 1) after the header processing of the second image is completed.

**Interrupt or MDMA trigger generation for output FIFO**

The output FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO Threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. If the FIFO needs to be flushed, it must be done by software setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

### 35.3.4 JPEG encoding procedure

The JPEG codec can encode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally generate the JPEG Header.

The JPEG codec is configured in encode mode resetting the DE bit (decode enable) of the JPEG_CONFR1 register.
The configuration used for encoding the JPEG must be loaded in the JPEG codec:
- JPEG codec configuration registers
- quantization tables
- Huffman tables

The JPEG codec is started setting the START bit of the JPEG_CONFR0 register.

Once the JPEG codec has been started, it request data for its input FIFO generating one of:
- MDMA trigger
- interrupts

**Interrupt or MDMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:
- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or MDMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or an interrupt request / MDMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:
- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.

**JPEG encoding**

Once the JPEG header generated, the incoming MCUs are encoded and the resulting data stream sent to the output FIFO.

**Interrupt or MDMA trigger generation for output FIFO**

Output FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:
- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the FF bit (FIFO flush) of the JPEG_CR register.
Prior to flushing the FIFO:
- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

The EOCF bit (end of conversion flag) of the JPEG_SR register can only be cleared when the output FIFO is empty.

Clearing either of the HDR bit (header processing) of the JPEG_CONFR1 register and the JCEN bit (JPEG codec enable) of the JPEG_CR register is allowed only when the EOCF bit of the JPEG_SR register is cleared.

### 35.4 JPEG codec interrupts

An interrupt can be produced on the following events:
- input FIFO threshold reached
- input FIFO not full
- output FIFO threshold reached
- output FIFO not empty
- end of conversion
- header parsing done

Separate interrupt enable bits are available for flexibility.

</tbody>
</table>

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:0  **NMCU[25:0]:** Number of MCUs
For encoding: this field defines the number of MCU units minus 1 to encode.
For decoding: this field indicates the number of complete MCU units minus 1 to be decoded
(this field is updated after the JPEG header parsing). If the decoded image size has not a X or
Y size multiple of 8 or 16 (depending on the sub-sampling process), the resulting incomplete
or empty MCU must be added to this value to get the total number of MCUs generated.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **OFF**: Output FIFO flush  
This bit flushes the output FIFO.  
0: No effect  
1: Output FIFO is flushed  
*Note: Reads always return 0.*

Bit 13  **IFF**: Input FIFO flush  
This bit flushes the input FIFO.  
0: No effect  
1: Input FIFO is flushed  
*Note: Reads always return 0.*

Bits 12:7  Reserved, must be kept at reset value.

Bit 6  **HPDIE**: Header parsing done interrupt enable  
This bit enables interrupt generation upon the completion of the header parsing operation.  
0: Disabled  
1: Enabled

Bit 5  **EOCIE**: End of conversion interrupt enable  
This bit enables interrupt generation at the end of conversion.  
0: Disabled  
1: Enabled

Bit 4  **OFNEIE**: Output FIFO not empty interrupt enable  
This bit enables interrupt generation when the output FIFO is not empty.  
0: Disabled  
1: Enabled
Bit 3 **OFTIE**: Output FIFO threshold interrupt enable
This bit enables interrupt generation when the output FIFO reaches a threshold.
0: Disabled
1: Enabled

Bit 2 **IFNIE**: Input FIFO not full interrupt enable
This bit enables interrupt generation when the input FIFO is not empty.
0: Disabled
1: Enabled

Bit 1 **IFTIE**: Input FIFO threshold interrupt enable
This bit enables interrupt generation when the input FIFO reaches a threshold.
0: Disabled
1: Enabled

Bit 0 **JCEN**: JPEG core enable
This bit enables the JPEG codec core.
0: Disabled (internal registers are reset).
1: Enabled (internal registers are accessible).

### 35.5.7 JPEG status register (JPEG_SR)

**Address offset**: 0x034

**Reset value**: 0x0000 0006

**Bits 31:8** Reserved, must be kept at reset value.

**Bit 7** **COF**: Codec operation flag
This bit flags code/decode operation in progress.
0: Not in progress
1: In progress

**Bit 6** **HPDF**: Header parsing done flag
In decode mode, this bit flags the completion of header parsing and updating internal registers.
0: Not completed
1: Completed

**Bit 5** **EOCF**: End of conversion flag
This bit flags the completion of encode/decode process and data transfer to the output FIFO.
0: Not completed
1: Completed
Bit 4 **OFNEF**: Output FIFO not empty flag
This bit flags that data is available in the output FIFO.
- 0: Empty (data not available)
- 1: Not empty (data available)

Bit 3 **OFTF**: Output FIFO threshold flag
This bit flags that the amount of data in the output FIFO reaches or exceeds a threshold.
- 0: Below threshold
- 1: At or above threshold

Bit 2 **IFNFF**: Input FIFO not full flag
This bit flags that the input FIFO is not full (data can be written).
- 0: Full
- 1: Not full

Bit 1 **IFTF**: Input FIFO threshold flag
This bit flags that the amount of data in the input FIFO is below a threshold.
- 0: At or above threshold
- 1: Below threshold

Bit 0 **Reserved**: Reserved, must be kept at reset value.

### 35.5.8 JPEG clear flag register (JPEG_CFR)

Address offset: 0x038
Reset value: 0x0000 0000

Bits 31:7 **Reserved**: Reserved, must be kept at reset value.

Bit 6 **CHPDF**: Clear header parsing done flag
Writing 1 clears the HPDF bit of the JPEG_SR register.
- 0: No effect
- 1: Clear

Bit 5 **CEOCF**: Clear end of conversion flag
Writing 1 clears the ECF bit of the JPEG_SR register.
- 0: No effect
- 1: Clear

Bits 4:0 **Reserved**: Reserved, must be kept at reset value.
35.5.9 JPEG data input register (JPEG_DIR)

Address offset: 0x040
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16 DATAIN[31:16]</th>

Bits 31:0 DATAOUT[31:0]: Data output FIFO
Output FIFO data register.
35.5.11 JPEG quantization memory x (JPEG_QMEMx_y)

Address offset: 0x050 + 0x40 * x + 0x4 * y, (x = 0 to 3; y = 0 to 15)
Reset value: 0xXXXX XXXX

Four quantization tables as specified by ISO documentation.

For decoding with header parsing, no quantization table programming is required, the coefficients are directly written in the quantization memories by header parser.

For decoding without header parsing or for encoding, the quantization table must be written by software in zig zag order.

Bits 31:24 QCOEF(4*y+3)[7:0]: Quantization coefficient {4*y+3}
8-bit quantization coefficient.

Bits 23:16 QCOEF(4*y+2)[7:0]: Quantization coefficient {4*y+2}
8-bit quantization coefficient.

Bits 15:8 QCOEF(4*y+1)[7:0]: Quantization coefficient {4*y+1}
8-bit quantization coefficient.

Bits 7:0 QCOEF(4*y)[7:0]: Quantization coefficient {4*y}
8-bit quantization coefficient.

35.5.12 JPEG Huffman min (JPEG_HUFFMINx_y)

Address offset: 0x150 + 0x10 * x + 0x4 * y, (x = 0 to 3; y = 0 to 2)
Reset value: 0xXXXX XXXX

This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.

- DATA0: Min AC0 value
- DATA1: Min DC0 value
- DATA2: Min AC1 value
- DATA3: Min DC1 value

**35.5.14 JPEG Huffman base (JPEG_HUFFBASEx)**

Address offset: 0x190 + 0x4*x, (x = 0 to 31)

Reset value: 0xXXXX XXXX

This memory stores the base Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA15: Base AC0 value
- DATA16 to DATA31: Base DC0 value
- DATA32 to DATA47: Base AC1 value
- DATA48 to DATA63: Base DC1 value

<table>

35.5.15  JPEG Huffman symbol (JPEG_HUFFSYMBx)

Address offset: 0x210 + 0x4 * x, (x = 0 to 83)
Reset value: 0xXXXX XXXX

This memory stores the Huffman symbols used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:
- DATA0 to DATA161: AC0 symbols
- DATA162 to DATA173: DC0 and DC1 symbols
- DATA174 to DATA335: AC1 symbols

Bits 31:25  DATA{4*x+3}[7:0]: Data {4*x+3}
Huffman symbol.

Bits 23:16  DATA{4*x+2}[7:0]: Data {4*x+2}
Huffman symbol.

Bits 15:8  DATA{4*x+1}[7:0]: Data {4*x+1}
Huffman symbol.

Bits 7:0  DATA{4*x}[7:0]: Data {4*x}
Huffman symbol.
35.5.16 JPEG DHT memory (JPEG_DHTMEMx)

Address offset: 0x360 + 0x4 * x, (x = 0 to 102)

Reset value: 0xXXXX XXXX

For encoding process with header generation, this memory stores the DHT marker segment AC and DC Huffman tables in the ISO/IEC specification format:
- DATA0 to DATA27: DC Huffman table0
- DATA28 to DATA205: AC Huffman table0
- DATA206 to DATA233: DC Huffman table1
- DATA234 to DATA411: AC Huffman table1

<table>

</tr>
</tbody>
</table>

Bits 31:24 DATA[4*x+3][7:0]: Huffman table data {4*x+3}
Huffman table data for DHT marker segment generation.

Bits 23:16 DATA[4*x+2][7:0]: Huffman table data {4*x+2}
Huffman table data for DHT marker segment generation.

Bits 15:8 DATA[4*x+1][7:0]: Huffman table data {4*x+1}
Huffman table data for DHT marker segment generation.

Bits 7:0 DATA[4*x][7:0]: Huffman table data {4*x}
Huffman table data for DHT marker segment generation.

35.5.17 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx_y)

Address offset: 0x500 + 0x160 * x + 0x4 * y, (x = 0 to 1; y = 0 to 87)

Reset value: 0xXXXX XXXX

This memory defines the Huffman codes used during the encoding process of AC components.

<table>
<thead>
<tr>

</table>

Bits 31:28 Reserved, must be kept at reset value.
35.5.18 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx_y)

Address offset: 0x7C0 + 0x20*x + 0x4*y, (x = 0 to 1; y = 0 to 7)
Reset value: 0xXXXX XXXX

This memory defines the Huffman codes used during the encoding process of DC components.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:24 | HLEN(2*y+1)[3:0]: Huffman length (2*y+1) |
|            | Number of bits in the Huffman code HCODE(2*y+1) minus 1. |
| Bits 23:16 | HCODE(2*y+1)[7:0]: Huffman code (2*y+1) |
|            | 8 least significant bits of the Huffman code. |
|            | If the Huffman code is less than 8 bits long, the unused bits must be 0. |
| Bits 15:12 | Reserved, must be kept at reset value. |
| Bits 11:8  | HLEN(2*y)[3:0]: Huffman length (2*y) |
|            | Number of bits in the Huffman code HCODE(2*y) minus 1. |
| Bits 7:0   | HCODE(2*y)[7:0]: Huffman code (2*y) |
|            | 8 least significant bits of the Huffman code. |
|            | If the Huffman code is less than 8 bits long, the unused bits must be 0. |
The following table summarizes the JPEG codec registers. Refer to the register boundary addresses table for the JPEG codec register base address.

Refer to Section 2.3 for the register boundary addresses.
36 True random number generator (RNG)

36.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG can be used to construct a NIST compliant deterministic random bit generator (DRBG), acting as a live entropy source.

The RNG true random number generator has been tested using the German BSI statistical tests of AIS-31 (T0 to T8).

36.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source processed by a high quality conditioning stage.
- In the NIST configuration, it produces four 32-bit random samples every $16 \times \frac{f_{\text{AHB}}}{f_{\text{RNG}}}$ AHB clock cycles, if value is higher than 213 cycles (213 cycles otherwise).
- It allows embedded continuous basic health tests with associated error management:
  - Includes too low sampling clock detection and repetition count tests.
- It can be disabled to reduce power consumption.
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
36.3 RNG functional description

36.3.1 RNG block diagram

36.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals. Within its boundary the RNG implements the entropy source model pictured on Figure 294.

It includes an analog noise source, a digitization stage with post-processing, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

Figure 294. Entropy source model

The components pictured above are detailed hereafter.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. It is composed of:

- Two analog noise sources, each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 36.3.8: RNG low-power use.
- A sampling stage of these outputs clocked by a dedicated clock input (rng_clk), delivering a 2-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk).

Note: In Section 36.6: RNG entropy source validation the recommended RNG clock frequencies are given.
Post processing

The sample values obtained from a true random noise source consist of 2-bit bitstrings. Because this noise source output is biased, the RNG implements a post-processing component that reduces that bias to a tolerable level.

More specifically, for each of the two noise source bits the RNG takes half of the bits from the sampled noise source, and half of the bits from the inverted sampled noise source. Thus, if the source generates more ‘1’ than ‘0’ (or the opposite), it is filtered.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit).

Also note that post-processing computations are triggered when at least 32 bits of raw datum is received and when output FIFO needs a refill. Thus, the RNG output entropy is maximum when the RNG 128-bit FIFO is emptied by application after 64 RNG clock cycles.

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 36.5: RNG processing time.

The conditioning component is clocked by the faster AHB clock.

Output buffer

A data output buffer can store up to four 32-bit words, which have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register 213 AHB clock cycles later.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features.

1. Continuous health tests, running indefinitely on the output of the noise source
   - Repetition count test, flagging an error when:
     a) One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bits patterns ("01" or "10")
     b) Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bits patterns ("01" or "10")

2. Vendor specific continuous test
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle is smaller than AHB clock cycle divided by 32.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 36.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

36.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 295.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and logic immediately starts sampling the analog output, filling the 128-bit conditioning shift register.
2. The conditioning logic is enabled and the post-processing context is initialized using two 128 noise source bits.
3. The conditioning stage internal input data buffer is filled again with 128-bit and one conditioning round is performed. The output buffer is then filled with the post processing result.
4. The output buffer is refilled automatically according to the RNG usage.
The associated initialization time can be found in Section 36.5: RNG processing time.

Figure 295. RNG initialization overview

36.3.5 RNG operation

Normal operations

To run the RNG using interrupts, the following steps are recommended:
1. Enable the interrupts by setting the IE bit in the RNG_CR register. At the same time, enable the RNG by setting the bit RNGEN=1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 36.3.7 must be used.
To run the RNG in polling mode following steps are recommended:
1. Enable the random number generation by setting the RNGEN bit to “1” in the RNG_CR register.
2. Read the RNG_SR register and check that:
   – No error occurred (the SEIS and CEIS bits must be set to 0)
   – A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 36.3.7 must be used.

**Note:** When data is not ready (DRDY = 0) RNG_DR returns zero. It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

**Low-power operations**

If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 36.3.8: RNG low-power use.

**Software post-processing**

If a NIST approved DRBG with 128 bits of security strength is required an approved random generator software must be built around the RNG true random number generator.

Built-in health check functions are described in Section 36.3.3: Random number generation.

### 36.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock is used for noise source sampling. Recommended clock configurations are detailed in Section 36.6: RNG entropy source validation.

**Note:** When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency the must be higher than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 36.3.1: RNG block diagram for details (AHB and RNG clock domains).

### 36.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

**Clock error detection**

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see
Section 36.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.

CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy. If the error was detected during the initialization phase the whole initialization sequence is automatically restarted by the RNG.

The following sequence must be used to fully recover from a seed error after the RNG initialization:
1. Clear the SEIS bit by writing it to “0”.
2. Read out 12 words from the RNG_DR register, and discard each of them in order to clean the pipeline.
3. Confirm that SEIS is still cleared. Random number generation is back to normal.

36.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

• If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
• If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case the RNG must be re-enabled by the application until at least 32 new bits are collected from the noise source and a complete conditioning round is done. It corresponds to 16 RNG clock cycles to sample new bits, and 216 AHB clock cycles to run a conditioning round.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1.
36.4 **RNG interrupts**

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 36.3.7: Error management
- Clock error, see Section 36.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 299.

Dedicated interrupt enable control bits are available as shown in Table 299.

**Table 299. RNG interrupt requests**

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>

<td>IE</td>
<td>Write 0 to SEIS</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

*Note:* Interrupts are generated only when RNG is enabled.

36.5 **RNG processing time**

The conditioning stage can produce four 32-bit random numbers every $16 \times \frac{f_{AHB}}{f_{RNG}}$ clock cycles, if the value is higher than 213 cycles (213 cycles otherwise). More time is needed for the first set of random numbers after the device exits reset (see Section 36.3.4: RNG initialization). Indeed, after enabling the RNG for the first time, random data is first available after either:

- 128 RNG clock cycles + 426 AHB cycles, if $f_{AHB} < f_{\text{threshold}}$
- 192 RNG clock cycles + 213 AHB cycles, if $f_{AHB} \geq f_{\text{threshold}}$

With $f_{\text{threshold}} = \left(\frac{213 \times f_{RNG}}{64}\right)$

36.6 **RNG entropy source validation**

36.6.1 **Introduction**

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8). The results can be provided on demand or the customer can reproduce the tests.

36.6.2 **Validation conditions**

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk= 48 MHz (CED bit = ‘0’ in RNG_CR register) and rng_clk = 400 kHz (CED bit = ‘1’ in RNG_CR register).
36.6.3 Data collection
In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. Contact STMicroelectronics if the above samples need to be retrieved for the product.

36.7 RNG registers
The RNG is associated with a control register, a data register and a status register.

36.7.1 RNG control register (RNG_CR)

| 6   | **SEIS:** Seed error interrupt status |       | This bit is set at the same time as SECS. It is cleared by writing 0. Writing 1 has no effect.  
0: No faulty sequence detected  
1: At least one faulty sequence is detected. See SECS bit description for details.  
An interrupt is pending if IE = 1 in the RNG_CR register. |
| 5   | **CEIS:** Clock error interrupt status |       | This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.  
0: The RNG clock is correct (fRNGCLK > fHCLK/32)  
1: The RNG is detected too slow (fRNGCLK < fHCLK/32)  
An interrupt is pending if IE = 1 in the RNG_CR register. |
| 4-3 | Reserved, must be kept at reset value. |       |                                            |
| 2   | **SECS:** Seed error current status |       | 0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.  
1: At least one of the following faulty sequences has been detected:  
- One of the noise sources has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bit patterns ("01" or "10")  
- Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bit patterns ("01" or "10") |
| 1   | **CECS:** Clock error current status |       | 0: The RNG clock is correct (fRNGCLK > fHCLK/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.  
1: The RNG clock is too slow (fRNGCLK < fHCLK/32).  
*Note:* CECS bit is valid only if the CED bit in the RNG_CR register is set to 0. |
| 0   | **DRDY:** Data ready |       | 0: The RNG_DR register is not yet valid, no random data is available.  
1: The RNG_DR register contains valid random data.  
Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.  
*Note:* The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).  
If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1. |
36.7.3 RNG data register (RNG_DR)

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. After being read, this register delivers a new random value after 216 periods of AHB clock if the output FIFO is empty.

The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

<table>
<thead>
<tr>
<th>Address (Hex)</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x008</td>

37 Cryptographic processor (CRYP)

37.1 Introduction

The cryptographic processor (CRYP) can be used both to encrypt and decrypt data using the DES, Triple-DES or AES algorithms. It is a fully compliant implementation of the following standards:

- The data encryption standard (DES) and Triple-DES (TDES) as defined by Federal Information Processing Standards Publication (FIPS PUB 46-3, Oct 1999), and the American National Standards Institute (ANSI X9.52)
- The advanced encryption standard (AES) as defined by Federal Information Processing Standards Publication (FIPS PUB 197, Nov 2001)

Multiple key sizes and chaining modes are supported:

- DES/TDES chaining modes ECB and CBC, supporting standard 56-bit keys with 8-bit parity per key
- AES chaining modes ECB, CBC, CTR, GCM, GMAC, CCM for key sizes of 128, 192 or 256 bits

The CRYP processor is a 32-bit AHB peripheral. It supports DMA transfers for incoming and outgoing data (two DMA channels are required). The peripheral also includes input and output FIFOs (each 8 words deep) for better performance.

37.2 CRYP main features

- Compliant implementation of the following standards:
  - NIST FIPS publication 46-3, Data Encryption Standard (DES)
  - ANSI X9.52, Triple Data Encryption Algorithm Modes of Operation
  - NIST FIPS publication 197, Advanced Encryption Standard (AES)
- AES symmetric block cipher implementation
  - 128-bit data block processing
  - Support for 128-, 192- and 256-bit cipher key lengths
  - Encryption and decryption with multiple chaining modes: Electronic Code Book (ECB), Cipher Block Chaining (CBC), Counter mode (CTR), Galois Counter Mode (GCM), Galois Message Authentication Code mode (GMAC) and Counter with CBC-MAC (CCM)
  - 14 (respectively 18) clock cycles for processing one 128-bit block of data with a 128-bit (respectively 256-bit) key in AES-ECB mode
  - Integrated key scheduler with its key derivation stage (ECB or CBC decryption only)
- DES/TDES encryption/decryption implementation
  - 64-bit data block processing
  - Support for 64-, 128- and 192-bit cipher key lengths (including parity)
  - Encryption and decryption with support of ECB and CBC chaining modes
  - Direct implementation of simple DES algorithms (a single key K1 is used)
- 16 (respectively 48) clock cycles for processing one 64-bit block of data in DES (respectively TDES) ECB mode
- Software implementation of ciphertext stealing

- Features common to DES/TDES and AES
  - AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
  - 256-bit register for storing the cryptographic key (8x 32-bit registers)
  - 128-bit registers for storing initialization vectors (4x 32-bit)
  - 1x32-bit INPUT buffer associated with an internal IN FIFO of eight 32-bit words, corresponding to four incoming DES blocks or two AES blocks
  - 1x32-bit OUTPUT buffer associated with an internal OUT FIFO of eight 32-bit words, corresponding to four processed DES blocks or two AES blocks
  - Automatic data flow control supporting direct memory access (DMA) using two channels (one for incoming data, one for processed data). The OUT FIFO supports both single and burst transfers, while the IN FIFO supports only burst transfers.
  - Data swapping logic to support 1-, 8-, 16- or 32-bit data
  - Possibility for software to suspend a message if the cryptographic processor needs to process another message with higher priority (suspend/resume operation)

37.3 CRYP implementation
This device has one CRYP instance.
37.4 **CRYP functional description**

37.4.1 **CRYP block diagram**

The figure below shows the block diagram of the cryptographic processor.

37.4.3 CRYP DES/TDES cryptographic core

Overview

The DES/Triple-DES cryptographic core consists of three components:
- The DES Algorithm (DEA core)
- Multiple keys (one for the DES algorithm, one to three for the TDES algorithm)
- The initialization vector, which is used only in CBC mode

The DES/Triple-DES cryptographic core provides two operating modes:
- **ALGODIR = 0:** Plaintext encryption using the key stored in the CRYP_Kx registers.
- **ALGODIR = 1:** Ciphertext decryption using the key stored in the CRYP_Kx registers.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

Typical data processing

Typical usage of the cryptographic processor in DES modes can be found in Section 37.4.10: CRYP DES/TDES basic chaining modes (ECB, CBC).

Note: The outputs of the intermediate DEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IV registers in CBC mode.

DES/TDES keying and chaining modes

The DES/TDES allows three different keying options:
- **Three independent keys**
  The first option specifies that all the keys are independent, that is, K1, K2 and K3 are independent. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 1 and, to the TDES as 3-key TDES.
- **Two independent keys**
  The second option specifies that K1 and K2 are independent and K3 is equal to K1, that is, K1 and K2 are independent, K3 = K1. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 2 and, to the TDES as 2-key TDES.
Three equal keys
The third option specifies that K1, K2 and K3 are equal, that is:

\[ K1 = K2 = K3 \]

FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to the third option as the Keying Option 3. This “1-key” TDES is equivalent to single DES.

The following chaining algorithms are supported by the DES hardware and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)

These modes are described in details in Section 37.4.10: CRYP DES/TDES basic chaining modes (ECB, CBC).

37.4.4 CRYP AES cryptographic core

Overview

The AES cryptographic core consists of the following components:

- The AES algorithm (AEA core)
- The Multiplier over a binary Galois field (GF2mul)
- The key information
- The initialization vector (IV) or Nonce information
- Chaining algorithms logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks of (four words) with 128-, 192- or 256-bit key lengths. Depending on the chaining mode, the peripheral requires zero or one 128-bit initialization vector (IV).

The cryptographic peripheral features two operating modes:

- **ALGODIR = 0**: Plaintext encryption using the key stored in the CRYP_Kx registers.
- **ALGODIR = 1**: Ciphertext decryption using the key stored in the CRYP_Kx registers. When ECB and CBC chaining modes are selected, an initial key derivation process is automatically performed by the cryptographic peripheral.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

Typical data processing

A description of cryptographic processor typical usage in AES mode can be found in Section 37.4.11: CRYP AES basic chaining modes (ECB, CBC).

**Note:** The outputs of the intermediate AEA stages is never revealed outside the cryptographic boundary, with the exclusion of the IV registers.
AES chaining modes

The following chaining algorithms are supported by the cryptographic processor and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)
- Counter Mode (CTR)
- Galois/Counter Mode (GCM)
- Galois Message Authentication Code mode (GMAC)
- Counter with CBC-MAC (CCM)

A quick introduction on these chaining modes can be found in the following subsections.

For detailed instructions, refer to Section 37.4.11: CRYP AES basic chaining modes (ECB, CBC) and onward.

key scheduling

ECB is the simplest operating mode. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

Note: For decryption, a special key scheduling is required before processing the first block.
AES Cipher block chaining (CBC)

Figure 298. AES-CBC mode overview

CBC operating mode chains the output of each block with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

**Note:** For decryption, a special key scheduling is required before processing the first block.
AES Counter mode (CTR)

The CTR mode uses the AES core to generate a key stream; these keys are then XORed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

Note: Unlike ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the counter blocks.
AES Galois/Counter mode (GCM)

In Galois/Counter mode (GCM), the plaintext message is encrypted, while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

AES Galois message authentication code (GMAC)

In Galois/Counter mode (GCM), the plaintext message is encrypted, while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.
Galois Message Authentication Code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GMAC is similar to Galois/Counter mode (GCM), except that it is applied on a message composed only by clear-text authenticated data (i.e. only header, no payload).

**AES Counter with CBC-MAC (CCM)**

In Counter with Cipher Block Chaining-Message Authentication Code (CCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM CCM chaining mode, AES-CCM mode can be applied on a message composed only by cleartext authenticated data (i.e. only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its usage is not recommended by NIST.
37.4.5  **CRYP procedure to perform a cipher operation**

**Introduction**

To understand how the cryptographic peripheral operates, a typical cipher operation is described below. For the detailed peripheral usage according to the cipher mode, refer to the specific section, for example *Section 37.4.11: CRYP AES basic chaining modes (ECB, CBC)*.

**CRYP initialization**

To initialize the cryptographic processor, first disable it by clearing the CRYPEN bit in the CRYP_CR register. Then execute the following steps:

1. Configure the algorithm and the chaining mode through the ALGOMODE and ALGODIR bits in the CRYP_CR register. Configure also the key size with the KEYSIZE bits.
   - When ALGODIR is set to 1 (decryption) and the selected algorithm/chaining mode is AES-ECB or AES-CBC, an initial key derivation of the encryption key must be performed as described in *Section 37.4.7: Preparing the CRYP AES key for decryption*.
2. When the previous step is complete, and when applicable, write the symmetric key into the CRYP_KxL/R registers. The way to write key registers is defined in *Section 37.4.17: CRYP key registers*
3. Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits of the CRYP_CR register.
4. When it is required (for example for CBC or CTR chaining modes), write the initialization vectors into the CRYP_IVx(L/R)R register.
5. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.

**Preliminary warning for all cases**

If the ECB or CBC mode is selected and data are not a multiple of 64 bits (for DES) or 128 bits (for AES), the second and the last block management is more complex than the sequences below. Refer to *Section 37.4.8: CRYP stealing and data padding* for more details.
Appending data using the CPU in Polling mode

1. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR register.
2. Write data in the IN FIFO (one block or until the FIFO is full).
3. Repeat the following sequence until the second last block of data has been processed:
   a) Wait until the not-empty-flag OFNE is set to 1, then read the OUT FIFO (one block or until the FIFO is empty).
   b) Wait until the not-full-flag IFNF is set to 1, then write the IN FIFO (one block or until the FIFO is full) except if it is the last block.
4. The BUSY bit is set automatically by the cryptographic processor. At the end of the processing, the BUSY bit returns to 0 and both FIFOs are empty (IN FIFO empty flag IFEM = 1 and OUT FIFO not empty flag OFNE = 0).
5. If the next processing block is the last block, the CPU must pad (when applicable) the data with zeroes to obtain a complete block and specify the number of non-valid bytes using NPBLB bits in CRYP_CR register in case of AES GCM payload encryption or AES CCM payload decryption (otherwise the tag computation will be wrong). This operation must be performed after checking that the BUSY bit in the CRYP_CR register is set to 0.

Note: **NPBLB bits are not used in the header phase of AES GCM, GMAC and CCM modes.**
6. When the operation is complete, the cryptographic processor can be disabled by clearing the CRYPEN bit in CRYP_CR register.

Appending data using the CPU in Interrupt mode

1. Enable the interrupts by setting the INIM and OUTIM bits in the CRYP_IMSCR register.
2. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR register.
3. In the interrupt service routine that manages the input data:
   a) If the last block is being loaded, the CPU must pad (when applicable) the data with zeroes to have a complete block and specify the number of non-valid bytes using NPBLB bits in CRYP_CR register in case of AES GCM payload encryption or AES CCM payload decryption (otherwise the tag computation will be wrong). This operation must be performed after checking that the BUSY bit in the CRYP_CR register is set to 0. Then load the block into the IN FIFO.
   b) If it is not the last block, load the data into the IN FIFO. You can load only one block (2 words for DES, 4 words for AES), or load data until the FIFO is full.
   c) In all cases, after the last word of data has been written, disable the interrupt by clearing the INIM interrupt mask.
4. In the interrupt service routine that manages the input data:
   a) Read the output data from the OUT FIFO. You can read only one block (2 words for DES, 4 words for AES), or read data until the FIFO is empty.
   b) When the last word has been read, INIM and BUSY bits are set to 0 and both FIFOs are empty (IFEM = 1 and OFNE = 0). You can disable the interrupt by clearing the OUTIM bit, and disable the peripheral by clearing the CRYPEN bit.
   c) If you read the last block of cleartext data (i.e. decryption), optionally discard the data that is not part of message/payload.
Appending data using the DMA

1. Prepare the last block of data by optionally padding it with zeroes to have a complete block.

2. Configure the DMA controller to transfer the input data from the memory and transfer the output data from the peripheral to the memory, as described in Section 37.4.19: CRYP DMA interface. The DMA should be configured to set an interrupt on transfer completion to indicate that the processing is complete. In case of AES GCM payload encryption or AES CCM payload decryption, DMA transfers must not include the last block. The sequence using the CPU described above must be used instead for this last block, because NPBLB bits needs to be setup before processing the block (otherwise the tag computation will be wrong).

Note: NPBLB bits are not used in the header phase of AES GCM, GMAC and CCM.

3. Enable the cryptographic processor by setting to 1 the CRYPEN bit in CRYP_CR register, then enable the DMA IN and OUT requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

4. All the transfers and processing are managed by the DMA and the cryptographic processor. The DMA interrupt indicates that the processing is complete. Both FIFOs are normally empty and BUSY flag is set 0.

Caution: It is important that DMA controller empties the cryptographic processor output FIFO before filling up the cryptographic processor input FIFO. To achieve this, the DMA controller should be configured so that the transfer from the cryptographic peripheral to the memory has a higher priority than the transfer from the memory to the cryptographic peripheral.

37.4.6 CRYP busy state

The cryptographic processor is busy and processing data (BUSY set to 1 in CRYP_SR register) when all the conditions below are met:

- CRYPEN = 1 in CRYP_CR register.
- There are enough data in the input FIFO (at least two words for the DES or TDES algorithm mode, four words for the AES algorithm mode).
- There is enough free-space in the output FIFO (at least two word locations for DES, four for AES).

Write operations to the CRYP_Kx(L/R)R key registers, to the CRYP_IVx(L/R)R initialization registers, or to bits [9:2] of the CRYP_CR register, are ignored when cryptographic processor is busy (i.e. the registers are not modified). It is thus not possible to modify the configuration of the cryptographic processor while it is processing a data block.

It is possible to clear the CRYPEN bit while BUSY bit is set to 1. In this case the ongoing DES/TDES or AES processing first completes (i.e. the word results are written to the output FIFO) before the BUSY bit is cleared by hardware.

Note: If the application needs to suspend a message to process another one with a higher priority, refer to Section 37.4.9: CRYP suspend/resume operations

When a block is being processed in DES or TDES mode, if the output FIFO becomes full and the input FIFO contains at least one new block, then the new block is popped off the input FIFO and the BUSY bit remains high until there is enough space to store this new block into the output FIFO.
37.4.7 Preparing the CRYP AES key for decryption

When performing an AES ECB or CBC decryption, the AES key has to be prepared. Indeed, in AES encryption the round 0 key is the one stored in the key registers, and AES decryption must start using the last round key. Hence, as the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key. This preparation is not required in any other AES modes than ECB or CBC decryption.

When the cryptographic processor is disabled (CRYPEN = 0), the CRYP key preparation process is performed as follows:

1. Program ALGOMODE bits to 0x7 and ALGODIR to 0x0 in CRYP_CR. In addition, configure the key length with the KEYSIZE bits.
2. Write the symmetric key to the CRYP_KxL/R registers, as described in Section 37.4.17: CRYP key registers.
3. Enable the cryptographic processor by setting the CRYPEN bit in the CRYP_CR register. It immediately starts an AES round for key preparation (BUSY = 1).
4. Wait until the BUSY bit is cleared in the CRYP_SR register. Then update ALGOMODE bits in the CRYP_CR register to select the correct chaining mode, that is 0x4 for ECB or 0x5 for CBC.
5. The AES key is available in the CRYP key registers, ready to use for decryption.

Note: As the CRYPEN bitfield is reset by hardware at the end of the key preparation, the application software must set it again for the next operation.

The latency of the key preparation operation is 14, 16 or 18 clock cycles depending on the key size (128, 192 or 256 bits).

37.4.8 CRYP stealing and data padding

When using DES or AES algorithm in ECB or CBC modes to manage messages that are not multiple of the block size (64 bits for DES, 128 bits for AES), use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the cryptographic processor does not implement such techniques, the last two blocks must be handled in a special way by the application.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when the AES algorithm is used in other modes than ECB or CBC, incomplete input data blocks (i.e. block shorter than 128 bits) have to be padded with zeroes by the application prior to encryption (i.e. extra bits should be appended to the trailing end of the data string). After decryption, the extra bits have to be discarded. The cryptographic processor does not implement automatic data padding operation to the last block, so the application should follow the recommendation given in Section 37.4.5: CRYP procedure to perform a cipher operation to manage messages that are not multiple of 128 bits.

Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE field in CRYP_CR register (see Section 37.4.16: CRYP data registers and data swapping for details).
37.4.9 **CRYP suspend/resume operations**

A message can be suspended if another message with a higher priority has to be processed. When this highest priority message has been sent, the suspended message can be resumed in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can be resumed as soon as cryptographic processor is enabled again to receive the next data block.

*Figure 303* gives an example of suspend.resume operation: message 1 is suspended in order to send a higher priority message (message 2), which is shorter than message 1 (AES algorithm).

*Figure 303. Example of suspend mode management*

A detailed description of suspend/resume operations can be found in each AES mode section.
37.4.10 **CRYP DES/TDES basic chaining modes (ECB, CBC)**

**Overview**

FIPS PUB 46-3 – 1999 (and ANSI X9.52-1998) provides a thorough explanation of the processing involved in the four operation modes supplied by the DES computing core: TDES-ECB encryption, TDES-ECB decryption, TDES-CBC encryption and TDES-CBC decryption. This section only gives a brief explanation of each mode.

**DES/TDES-ECB encryption**

*Figure 304* illustrates the encryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE 0x0 and ALGODIR to 0 in CRYP_CR.

*Figure 304. DES/TDES-ECB mode encryption*

A 64-bit plaintext data block (P) is used after bit/byte/half-word as the input block (I). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA where the DES is performed in the decrypt state using K2. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K3. The resultant 64-bit output block (O) is used, after bit/byte/half-word swapping, as ciphertext (C) and it is pushed into the OUT FIFO.

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

Note: For more information on data swapping, refer to Section 37.4.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 37.4.5: CRYP procedure to perform a cipher operation.
DES/TDES-ECB mode decryption

*Figure 305* illustrates the decryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE to 0x0 and ALGODIR to 1 in CRYP_CR.

**Figure 305. DES/TDES-ECB mode decryption**

A 64-bit ciphertext block (C) is used, after bit/byte/half-word swapping, as the input block (I). The keying sequence is reversed compared to that used in the encryption process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K2. The new result is directly fed to the input of the DEA where the DES is performed in the decrypt state using K1. The resultant 64-bit output block (O), after bit/byte/half-word swapping, produces the plaintext (P).

**Note:** For more information on data swapping refer to *Section 37.4.16: CRYP data registers and data swapping.*

Detailed DES/TDES encryption sequence can be found in *Section 37.4.5: CRYP procedure to perform a cipher operation.*
DES/TDES-CBC encryption

Figure 306 illustrates the encryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE to 0x1 and ALGODIR to 0 in CRYP_CR.

Figure 306. DES/TDES-CBC mode encryption

K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

This mode begins by dividing a plaintext message into 64-bit data blocks. In TCBC encryption, the first input block \( I_1 \), obtained after bit/byte/half-word swapping, is formed by exclusive-ORing the first plaintext data block \( P_1 \) with a 64-bit initialization vector IV \( I_1 = IV \oplus P_1 \). The input block is processed through the DEA in the encrypt state using \( K_1 \). The output of this process is fed back directly to the input of the DEA, which performs the DES in the decrypt state using \( K_2 \). The output of this process is fed directly to the input of the DEA, which performs the DES in the encrypt state using \( K_3 \). The resultant 64-bit output block \( O_1 \) is used directly as the ciphertext \( C_1 \), that is, \( C_1 = O_1 \).

This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, \( I_2 = (C_1 \oplus P_2) \). Note that \( I_2 \) and \( P_2 \) now refer to the second block. The second input block is processed through the TDEA to produce the second ciphertext block.

This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.
Note: For more information on data swapping refer to Section 37.4.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 37.4.5: CRYP procedure to perform a cipher operation.

DES/TDES-CBC decryption

Figure 306 illustrates the decryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0x1 and ALGODIR to 1 in CRYP_CR.

Figure 307. DES/TDES-CBC mode decryption

![Diagram of DES/TDES-CBC decryption]

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

In this mode the first ciphertext block (C1) is used directly as the input block (I1). The keying sequence is reversed compared to that used for the encrypt process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed directly to the input of the DEA where the DES is processed in the encrypt state using K2. This resulting value is directly fed to the input of the DEA where the DES is processed in the decrypt state using K1. The resulting output block is exclusive-ORed with the IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the TDEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data.
The DES/TDES-CBC decryption process continues in this manner until the last complete
ciphertext block has been decrypted.

Ciphertext representing a partial data block must be decrypted in a manner specified for the
application.

Note: For more information on data swapping refer to Section 37.4.16: CRYP data registers and
data swapping.

Detailed DES/TDES encryption sequence can be found in Section 37.4.5: CRYP procedure
to perform a cipher operation.

DES/TDES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following steps:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in
   the CRYP_DMACR register.

2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the
   CRYP_SR) and the BUSY bit is cleared. Alternatively, as the input FIFO can contain up
to four unprocessed DES blocks, the application could decide for real-time reason to
interrupt the cryptographic processing without waiting for the IN FIFO to be empty. In
this case, the alternative is:
   a) Wait until OUT FIFO is empty (OFNE = 0).
   b) Read back the data loaded in the IN FIFO that have not been processed and save
      them in the memory until the IN FIFO is empty.

3. If DMA is used stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN
   bit in the CRYP_DMACR register.

4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then
   save the current configuration (bits [9:2] in the CRYP_CR register). If CBC mode is
   selected, save the initialization vector registers, since CRYP_IVx(L/R)R registers have
   changed from initial values during the data processing.

   Note: Key registers do not need to be saved as the original key value is known by the application.

5. If DMA is used, save the DMA controller status (such as the pointers to IN and OUT
   data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and
   FIFO OUT transfers.

2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in
   CRYP_CR (it must be 0).

3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as
   well as the key registers using the saved configuration.

4. If the CBC mode is selected, restore CRYP_IVx(L/R)R registers using the saved
   configuration.

5. Optionally, write the data that were saved during context saving into the IN FIFO.

6. Enable the cryptographic processor by setting the CRYPEN bit to 1.

7. If DMA is used, enable again DMA requests for the cryptographic processor, by setting
   to 1 the DIEN and DOEN bits in the CRYP_DMACR register.
37.4.11 CRYP AES basic chaining modes (ECB, CBC)

Overview

FIPS PUB 197 (November 26, 2001) provides a thorough explanation of the processing involved in the four basic operation modes supplied by the AES computing core: AES-ECB encryption, AES-ECB decryption, AES-CBC encryption and AES-CBC decryption. This section only gives a brief explanation of each mode.

AES ECB encryption

*Figure 308* illustrates the AES Electronic codebook (AES-ECB) mode encryption. This mode is selected by writing ALGOMODE to 0x4 and ALGODIR to 0 in CRYP_CR.

*Figure 308. AES-ECB mode encryption*

![Figure 308. AES-ECB mode encryption](image)

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

2. If Key size = 128: Key = \([K_3 \ K_2]\)
   
   If Key size = 192: Key = \([K_3 \ K_2 \ K_1]\)
   
   If Key size = 256: Key = \([K_3 \ K_2 \ K_1 \ K_0]\).

In this mode a 128- bit plaintext data block (P) is used after bit/byte/half-word swapping as the input block (I). The input block is processed through the AEA in the encrypt state using the 128, 192 or 256-bit key. The resultant 128-bit output block (O) is used after bit/byte/half-word swapping as ciphertext (C). It is then pushed into the OUT FIFO.

For more information on data swapping refer to *Section 37.4.16: CRYP data registers and data swapping.*
AES ECB decryption

*Figure 309* illustrates the AES Electronic codebook (AES-ECB) mode decryption. This mode is selected by programming ALGOMODE to 0x4 and ALGODIR to 1 in CRYP_CR.

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.
2. If Key size = 128 => Key = \([K_3 \ K_2]\).
   If Key size = 192 => Key = \([K_3 \ K_2 \ K_1]\).
   If Key size = 256 => Key = \([K_3 \ K_2 \ K_1 \ K_0]\).

To perform an AES decryption in ECB mode, the secret key has to be prepared (it is necessary to execute the complete key schedule for encryption) by collecting the last round key, and using it as the first round key for the decryption of the ciphertext. This preparation phase is computed by the AES core. Refer to *Section 37.4.7: Preparing the CRYP AES key for decryption* for more details on how to prepare the key.

When the key preparation is complete, the decryption proceed as follows: a 128-bit ciphertext block (C) is used after bit/byte/half-word swapping as the input block (I). The keying sequence is reversed compared to that of the encryption process. The resultant 128-bit output block (O), after bit/byte or half-word swapping, produces the plaintext (P). The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

For more information on data swapping refer to *Section 37.4.16: CRYP data registers and data swapping.*
AES CBC encryption

*Figure 310* illustrates the AES Cipher block chaining (AES-CBC) mode encryption. This mode is selected by writing ALGOMODE to 0x5 and ALGODIR to 0 in CRYP_CR.

**Figure 310. AES-CBC mode encryption**

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.
2. IVx = [IVxR IVxL], R = right, L = left.
3. If Key size = 128 => Key = [K3 K2].
   If Key size = 192 => Key = [K3 K2 K1]
   If Key size = 256 => Key = [K3 K2 K1 K0].

In this mode the first input block (I1) obtained after bit/byte/half-word swapping is formed by exclusive-ORing the first plaintext data block (P1) with a 128-bit initialization vector IV (I1 = IV ⊕ P1). The input block is processed through the AEA in the encrypt state using the 128-, 192- or 256-bit key (K0...K3). The resultant 128-bit output block (O1) is used directly as ciphertext (C1), that is, C1 = O1. This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, (I2) = (C1 ⊕ P2). Note that I2 and P2 now refer to the second block. The second input block is processed through the AEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application, as explained in Section 37.4.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 37.4.16: CRYP data registers and data swapping.
AES CBC decryption

*Figure 311* illustrates the AES Cipher block chaining (AES-CBC) mode decryption. This mode is selected by writing ALGOMODE to 0x5 and ALGODIR to 1 in CRYP.CR.

**Figure 311. AES-CBC mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.

2. IVx = [IVxR IVxL], R = right, L = left.

3. If Key size = 128 => Key = [K3 K2].
   If Key size = 192 => Key = [K3 K2 K1].
   If Key size = 256 => Key = [K3 K2 K1 K0].

In CBC mode, like in ECB mode, the secret key must be prepared to perform an AES decryption. Refer to Section 37.4.7: Preparing the CRYP AES key for decryption for more details on how to prepare the key.

When the key preparation process is complete, the decryption proceeds as follows: the first 128-bit ciphertext block (C1) is used directly as the input block (I1). The input block is processed through the AEA in the decrypt state using the 128-, 192- or 256-bit key. The resulting output block is exclusive-ORed with the 128-bit initialization vector IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the AEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data. The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.
Ciphertext representing a partial data block must be decrypted in a manner specified for the application, as explained in Section 37.4.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 37.4.16: CRYP data registers and data swapping.

AES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the CRYP by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2] in the CRYP_CR register). If ECB mode is not selected, save the initialization vector registers, because CRYP_IVx(L/R)R registers have changed from initial values during the data processing.

Note: Key registers do not need to be saved as the original key value is known by the application.
5. If DMA is used, save the DMA controller status (such as pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be set to 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. For AES-ECB or AES-CBC decryption, the key must be prepared again, as described in Section 37.4.7: Preparing the CRYP AES key for decryption.
5. If ECB mode is not selected, restore CRYP_IVx(L/R)R registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again the DMA requests from the cryptographic processor, by setting DIEN and DOEN bits to 1 in the CRYP_DMACR register.
37.4.12 CRYP AES counter mode (AES-CTR)

Overview

The AES counter mode (CTR) uses the AES block as a key stream generator. The generated keys are then XORed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation. A typical message construction in CTR mode is given in Figure 312.

Figure 312. Message construction for the Counter mode

The structure of this message is as below:

- A 16-byte Initial Counter Block (ICB), composed of three distinct fields:
  - A nonce: a 32-bit, single-use value (i.e. a new nonce should be assigned to each new communication).
  - The initialization vector (IV): a 64-bit value that must be unique for each execution of the mode under a given key.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. The initial value of the counter should be set to 1.
- The plaintext (P) is both authenticated and encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.
AES CTR processing

*Figure 313* (respectively *Figure 314*) describes the AES-CTR encryption (respectively decryption) process implemented within this peripheral. This mode is selected by programming ALGOMODE bitfield to 0x6 in CRYP_CR.

*Figure 313. AES-CTR mode encryption*

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.
Figure 314. AES-CTR mode decryption

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.

In CTR mode, the output block is XORed with the subsequent input block before it is input to the algorithm. Initialization vectors in the peripheral must be initialized as shown on Table 302.

Table 302. Counter mode initialization vector

<table>
<thead>

<th>CRYP_IV0LR[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit counter = 0x1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Unlike in CBC mode, which uses the CRYP_IVx(L/R)R registers only once when processing the first data block, in CTR mode IV registers are used for processing each data block, and the peripheral increments the least significant 32 bits (leaving the other most significant 96 bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that will be XORed with the plaintext or cipher as input. Thus when ALGOMODE is set to 0x6, ALGODIR is don’t care.

Note: In this mode the key must NOT be prepared for decryption.
The following sequence must be used to perform an encryption or a decryption in CTR chaining mode:

1. Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
2. Configure CRYP_CR as follows:
   a) Program ALGOMODE bits to 0x6 to select CTR mode. ALGODIR can be set to any value.
   b) Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits.
   c) Define the key length using KEYSIZE bits.
3. Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as described in Table 302.
4. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.
5. If it is the last block, optionally pad the data with zeros to have a complete block.
6. Append data in the cryptographic processor and read the result. The three possible scenarios are described in Section 37.4.5: CRYP procedure to perform a cipher operation.
7. Repeat the previous step until the second last block is processed. For the last block, execute the two previous steps. For this last block, the driver must discard the data that is not part of the data when the last block size is less than 16 bytes.

**Suspend/resume operations in CTR mode**

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message which was interrupted. Detailed CBC sequence can be found in Section 37.4.11: CRYP AES basic chaining modes (ECB, CBC).

**Note:** Like for CBC mode, IV registers must be reloaded during the resume operation.
37.4.13 CRYP AES Galois/counter mode (GCM)

Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 315.

Figure 315. Message construction for the Galois/counter mode

The structure of this message is defined as below:

- A 16-byte Initial Counter Block (ICB), composed of two distinct fields:
  - The initialization vector (IV): a 96-bit value that must be unique for each execution of the mode under a given key. Note that the GCM standard supports IV that are shorter than 96-bit, but in this case strict rules apply.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- The authenticated header A (also knows as Additional Authentication Data) has a known length \( \text{Len}(A) \) that can be non-multiple of 16 bytes and cannot exceed \( 2^{64} - 1 \) bits. This part of the message is only authenticated, not encrypted.
- The plaintext message (P) is both authenticated and encrypted as ciphertext C, with a known length \( \text{Len}(P) \) that can be non-multiple of 16 bytes, and cannot exceed \( 2^{32} - 2 \) blocks of 128-bits.

Note: GCM standard specifies that ciphertext C has same bit length as the plaintext P.

- When a part of the message (AAD or P) has a length which is non-multiple of 16 bytes, a special padding scheme is required.
- The last block is composed of the length of A (on 64 bits) and the length of ciphertext C (on 64 bits) as shown in Table 303.
AES GCM processing

This mode is selected by writing ALGOMODE bitfield to 0x6 in CRYP_CR.

The mechanism for the confidentiality of the plaintext in GCM mode is a variation of the Counter mode, with a particular 32-bit incrementing function that generates the necessary sequence of counter blocks.

CRYP_IVx(L/R)R registers are used for processing each data block. The cryptographic processor automatically increments the 32 least signification bits of the counter block. The first counter block (CB1) written by the application is equal to the Initial Counter Block incremented by one (see Table 304).

<td>0x0</td>
<td>Payload length[31:0]</td>
</tr>
</tbody>
</table>

Table 303. GCM last block definition

Note: In this mode the key must NOT be prepared for decryption.

The authentication mechanism in GCM mode is based on a hash function, called GF2mul, that performs multiplication by a fixed parameter, called the hash subkey (H), within a binary Galois field.

To process a GCM message, the driver must go through four phases, which are described in the following subsections.

- The Init phase: the peripheral prepares the GCM hash subkey (H) and performs the IV processing.
- The Header phase: the peripheral processes the Additional Authenticated Data (AAD), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P) with hash computation, keystream encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the authenticated tag (T) using the data last block.

Table 304. GCM mode IV registers initialization

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>32-bit counter = 0x2</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
1. **GCM initialization phase**
   During this first step, the GCM hash subkey (H) is calculated and saved internally to be used for processing all the blocks. It is recommended to follow the sequence below:
   a) Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
   b) Select the GCM chaining mode by programming ALGOMODE bits to 0x8 in CRYP_CR. In the same register define the key length using KEYSIZE bits and the data type using DATATYPE bits.
   c) Configure GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that the initialization phase is ongoing.
   d) Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as defined in Table 304.
   e) Set CRYPEN bit to 1 to start the calculation of the hash key.
   f) Wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor, before moving on to the next phase.

2. **GCM header phase**
   The below sequence shall be performed after the GCM initialization phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption.
   g) Set the GCM_CCMPH bits to 0b01 in CRYP_CR to indicate that the header phase is ongoing.
   h) Set the CRYPEN bit to 1 to start accepting data.
   i) If it is the last block of additional authenticated data, optionally pad the data with zeros to have a complete block.
   j) Append additional authenticated data in the cryptographic processor. The three possible scenarios are described in Section 37.4.5: CRYP procedure to perform a cipher operation.
   k) Repeat the previous step until the second last additional authenticated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared before moving on to the next phase.

*Note:* This phase can be skipped if there is no additional authenticated data, i.e. Len(A) = 0.

In header and payload phases, CRYPEN bit is not automatically cleared by the cryptographic processor.
3. **GCM payload phase (encryption or decryption)**

When the payload size is not null, this sequence must be executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.

l) Set the CRYPEN bit to 0.

m) Configure GCM_CCMPH to 0b10 in the CRYP_CR register to indicate that the payload phase is ongoing.

n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.

o) Set the CRYPEN bit to 1 to start accepting data.

p) If it is the last block of cleartext or plaintext, optionally pad the data with zeros to have a complete block. For encryption, refer to *Section 37.4.8: CRYP stealing and data padding* for more details.

q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in *Section 37.4.5: CRYP procedure to perform a cipher operation*.

r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, the driver must discard the bits that are not part of the cleartext or the ciphertext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

Note: *This phase can be skipped if there is no payload data, i.e. Len(C) = 0 (see GMAC mode).*

4. **GCM final phase**

In this last step, the cryptographic processor generates the GCM authentication tag and stores it in CRYP_DOUT register.

s) Configure GCM_CCMPH[1:0] to 0b11 in CRYP_CR to indicate that the Final phase is ongoing. Set the ALGODIR bit to 0 in the same register.

t) Write the input to the CRYP_DIN register four times. The input must be composed of the length in bits of the additional authenticated data (coded on 64 bits) concatenated with the length in bits of the payload (coded of 64 bits), as show in *Table 303*.

Note: *In this final phase, data have to be inserted normally (no swapping).*

u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.

v) Read the CRYP_DOUT register four times: the output corresponds to the authentication tag.

w) Disable the cryptographic processor (CRYPEN bit = 0 in CRYP_CR)

x) If an authenticated decryption is being performed, compare the generated tag with the expected tag passed with the message.
Suspend/resume operations in GCM mode

Before interrupting the current message in header or payload phase, the user application must respect the following sequence:

1. If DMA is used, stop DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 of the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx(L/R)R registers have changed from their initial values during data processing.

Note: Key registers do not need to be saved as original their key value is known by the application.
5. Save context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
6. If DMA is used, save the DMA controller status (pointers to IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
5. Restore CRYP_IVx(L/R)R registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

Note: In Header phase, DMA OUT FIFO transfer is not used.
37.4.14 CRYP AES Galois message authentication code (GMAC)

Overview

The Galois message authentication code (GMAC) allows authenticating a plaintext and generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

A typical message construction in GMAC mode is given in Figure 316.

**Figure 316. Message construction for the Galois Message Authentication Code mode**

![Message construction diagram]

**AES GMAC processing**

This mode is selected by writing ALGOMODE bitfield to 0x6 in CRYP_CR.

GMAC algorithm corresponds to the GCM algorithm applied on a message composed only of an header. As a consequence, all steps and settings are the same as in GCM mode, except that the payload phase (3) is not used.

**Suspend/resume operations in GMAC**

GMAC is exactly the same as GCM algorithm except that only header phase (2) can be interrupted.
37.4.15 CRYP AES Counter with CBC-MAC (CCM)

Overview

The AES Counter with Cipher Block Chaining-Message Authentication Code (CCM) algorithm allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, CCM algorithm is based on AES counter mode. It uses Cipher Block Chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside of the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction in CCM mode is given in Figure 317.

Figure 317. Message construction for the Counter with CBC-MAC mode

The structure of this message is as below:

- One 16-byte first authentication block (called B0 by the standard), composed of three distinct fields:
  - Q: a bit string representation of the byte length of P (Plen)
  - A nonce (N): single-use value (i.e. a new nonce should be assigned to each new communication). Size of nonce Nlen + size of Plen shall be equal to 15 bytes.
  - Flags: most significant byte containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and q (plaintext length such as Plen<2^8q bytes). Note that the counter blocks range associated to q is equal to 2^{8q-4}, i.e. if q maximum value is 8, the counter blocks used in cipher shall be on 60 bits.
- 16-bytes blocks (B) associated to the Associated Data (A).
  This part of the message is only authenticated, not encrypted. This section has a
  known length, \textit{A\text{len}}, that can be a non-multiple of 16 bytes (see \textit{Figure 317}). The
  standard also states that, on the MSB bits of the first message block (B1), the
  associated data length expressed in bytes (\textit{a}) must be encoded as defined below:
  - If \(0 < \textit{a} < 2^{16} - 2^8\), then it is encoded as \([\textit{a}]_{16}\), i.e. two bytes.
  - If \(2^{16} - 2^8 < \textit{a} < 2^{32}\), then it is encoded as \(0xff \| 0xfe \| [\textit{a}]_{32}\), i.e. six bytes.
  - If \(2^{32} < \textit{a} < 2^{64}\), then it is encoded as \(0xff \| 0xff \| [\textit{a}]_{64}\), i.e. ten bytes.

- 16-byte blocks (B) associated to the plaintext message (P), which is both authenticated
  and encrypted as ciphertext C, with a known length of \textit{Pl\text{en}}. This length can be a non-
  multiple of 16 bytes (see \textit{Figure 317}).

- The encrypted MAC (T) of length \textit{T\text{len}} appended to the ciphertext C of overall length
  \textit{C\text{len}}.

- When a part of the message (A or P) has a length which is a non-multiple of 16 bytes, a
  special padding scheme is required.

\textit{Note:} \textit{CCM chaining mode can also be used with associated data only (i.e. no payload).}

As an example, the C.1 section in \textit{NIST Special Publication 800-38C} gives the following:

\textit{N}: \texttt{10111213 141516} \ (N\text{len} = 56 bits or 0x7 bytes)
\textit{A}: \texttt{00010203 04050607} \ (A\text{len} = 64 bits or 0x8 bytes)
\textit{P}: \texttt{20212223} \ (P\text{len} = 32 bits i.e. Q = 0x4 bytes)
\textit{T}: \texttt{6084341b} \ (T\text{len} = 32 bits or t = 4)
\textit{B0}: \texttt{4f101112 13141516} \ 00000000 \ 00000004
\textit{B1}: \texttt{00080001 02030405 06070000} \ 00000000
\textit{B2}: \texttt{20212223} \ 00000000 \ 00000000 \ 00000000
\textit{CTR0}: \texttt{0710111213 141516} \ 00000000 \ 00000000
\textit{CTR1}: \texttt{0710111213 141516} \ 00000000 \ 00000001

The usage of control blocks CTRx is explained in the following section. The generation of
CTR0 from the first block (B0) must be managed by software.
AES CCM processing

This mode is selected by writing ALGOMODE bitfield to 0x9 in CRYP_CR.

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted data to generate a MAC, whose length is known. Counter mode encryption, which requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting data, called the ciphertext C, is the output of the generation-encryption process on plaintext P.

CRYP_IVx(L/R)R registers are used for processing each data block. The cryptographic processor automatically increments the CTR counter with a bit length defined by the first block (B0). The first counter written by application, CTR1, is equal to B0 with the first 5 bits zeroed and the most significant bits containing P byte length also zeroed, then incremented by one (see Table 305).

<td>B0[31:0], where Q length bits are set to 0, except for bit 0 that is set to 1</td>
</tr>
</tbody>
</table>

Note: *In this mode, the key must NOT be prepared for decryption.*

To process a CCM message, the driver must go through four phases, which are described below.

- **The Initialization phase**: the peripheral processes the first block and prepares the first counter block.
- **The Header phase**: the peripheral processes the Associated data (A), with hash computation only.
- **The Payload phase**: the peripheral processes the plaintext (P), with hash computation, counter block encryption and data XORing. It operates in a similar way for ciphertext (C).
- **The Final phase**: the peripheral generates the message authentication code (MAC).
1. **CCM initialization phase**

   In this first step, the first block (B0) of the CCM message is programmed into the CRYP_DIN register. During this phase, the CRYP_DOUT register does not contain any output data. It is recommended to follow the sequence below:

   a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
   
   b) Select the CCM chaining mode by programming the ALGOMODE bits to 0x9 in the CRYP_CR register. In the same register define the key length using KEYSIZE bits and the data type using DATATYPE bits.
   
   c) Configure the GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that we are in the initialization phase.
   
   d) Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) with CTR1 information, as defined in Table 305.
   
   e) Set the CRYPEN bit to 1 in CRYP_CR to start accepting data.
   
   f) Write the B0 packet into CRYP_DIN register, then wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor before moving on to the next phase.

   **Note:** In this initialization phase, data have to be inserted normally (no swapping).

2. **CCM header phase**

   The below sequence shall be performed after the CCM initialization phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption. During this phase, the CRYP_DOUT register does not contain any output data.

   g) Set the GCM_CCMPH bit to 0b01 in CRYP_CR to indicate that the header phase is ongoing.
   
   h) Set the CRYPEN bit to 1 to start accepting data.
   
   i) If it is the last block of associated data, optionally pad the data with zeros to have a complete block.
   
   j) Append the associated data in the cryptographic processor. The three possible scenarios are described in Section 37.4.5: CRYP procedure to perform a cipher operation.
   
   k) Repeat the previous step until the second last associated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared.

   **Note:** This phase can be skipped if there is no associated data (Alen = 0).

   The first block of the associated data B1 must be formatted with the associated data length. This task must be managed by the driver.
3. **CCM payload phase (encryption or decryption)**

When the payload size is not null, this sequence must be performed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.

- l) Set the CRYPEN bit to 0.
- m) Configure GCM_CCMPH bits to 0b10 in CRYP_CR to indicate that the payload phase is ongoing.
- n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.
- o) Set the CRYPEN bit to 1 to start accepting data.
- p) If it is the last block of cleartext, optionally pad the data with zeros to have a complete block (encryption only). For decryption, refer to *Section 37.4.8: CRYP stealing and data padding* for more details.
- q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in *Section 37.4.5: CRYP procedure to perform a cipher operation*.
- r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block of ciphertext (decryption only), the driver must discard the data that is not part of the cleartext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

*Note:* This phase can be skipped if there is no payload data, i.e. Plen = 0 or Clen = Tlen

*Note:* Do not forget to remove LSB\textsubscript{Tlen}(C) encrypted tag information when decrypting ciphertext C.

4. **CCM final phase**

In this last step, the cryptographic processor generates the CCM authentication tag and stores it in the CRYP_DOUT register.

- s) Configure GCM_CCMPH[1:0] bits to 0b11 in CRYP_CR to indicate that the final phase is ongoing and set the ALGODIR bit to 0 in the same register.
- t) Load in CRYP_DIN, the CTR0 information which is described in Table 305 with bit[0] set to 0.

*Note:* In this final phase, data have to be inserted normally (no swapping).

- u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.
- v) Read the CRYP_DOUT register four times: the output corresponds to the encrypted CCM tag.
- w) Disable the cryptographic processor (CRYPEN bit set to 0 in CRYP_CR).
- x) If an authenticated decryption is being performed, compare the generated encrypted tag with the encrypted tag padded in the ciphertext, i.e. \( \text{LSB}_{\text{Tlen}}(C) = \text{MSB}_{\text{Tlen}}(\text{CRYP\_DOUT data}) \).
Suspend/resume operations in CCM mode

Before interrupting the current message in payload phase, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 in the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx(L/R)R registers have changed from their initial values during the data processing.

Note: Key registers do not need to be saved as their original key value is known by the application.
5. Save context swap registers: CRYP_CSGCMCCM0..7R
6. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (must be 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR and key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R
5. Restore CRYP_IVx(L/R)R registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

Note: In Header phase DMA OUT FIFO transfer is not used.

37.4.16 CRYP data registers and data swapping

The CRYP_DIN register is the 32-bit wide data input register of the peripheral. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

The four adjacent (respectively two) words of the AES (respectively DES/TDES) data block are organized in big-endian order, with the most significant byte of a word on the lowest address.

The cryptographic accelerator can be configured to perform a bit, byte, half-word, or no swapping on the input data word in the CRYP_DINR register, before loading it to the CRYP processing core, and on the data output from the CRYP processing core, before sending it
to the CRYP_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES_CR register. The selection applies both to the input and the output of the CRYP processing core.

Note: The CRYP Key registers (CRYP_Kx(L/R)) and initialization registers (CRYP_IVx(L/R)) are not sensitive to the swap mode selected.

More information on data input and data swapping can be found in the next subsections.

**DES/TDES data input and output**

A 64-bit data block is entered into the cryptographic processor with two successive 32-bit word write operations to the CRYP_DINR register (DIN[31:0] bitfield), the most significant word (bits [64:33]) first, the least significant word (bits [32:1]) last.

A 64-bit data block is retrieved from the cryptographic processor with two successive 32-bit word read operations from the CRYP_DOUTR register (DOUT[31:0] bitfield), the most significant word (bits [64:33]) first, the least significant word (bits [32:1]) last.

**DES/TDES data swapping feature**

The cryptographic processor data swapping feature for DES/TDES is summarized in Table 306 and Figure 318.

AES data input and output

A 128-bit data block is entered into the cryptographic processor with four successive 32-bit word writes into the CRYP_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the cryptographic processor with four successive 32-bit word reads from the CRYP_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

AES data swapping feature

The cryptographic processor data swapping feature for AES is summarized in Table 307 and Figure 319.

**Note:** Data swapping does not apply to GCM and CCM final phases. Data can be inserted normally by the application.

Note: In memory and in CRYP key registers, AES and DES/TDES keys are stored in big-endian format, with most significant byte on the lowest address.

37.4.17 CRYP key registers

The CRYP_Kx registers are write-only registers used to store the encryption or decryption keys. They are organized as four 64-bit registers, as shown in Table 308 and Table 309.

Legend:
- Dx: input/output data bit 'x'
- Data swap
- Zero padding (example)
- Order of write to CRYP_DINR / read from CRYP_DOUTR

Table 308. Key endianness in CRYP_KxR/LR registers (AES 128/192/256-bit keys)

<td>-</td>
<td>k[127:96]</td>
<td>k[95:64]</td>
<td>k[63:32]</td>
<td>k[31:0]</td>
</tr>
</tbody>
</table>
As shown on Table 309, when TDES is selected (ALGOMODE[2:0] = 000 or 001) a 3-key vector (K1, K2, and K3) is used. When DES is selected (ALGOMODE[2:0] = 010 or 011) only 1-key vector (K1) is used.

Note: DES/TDES keys include 8-bit parity information that are not used by the cryptographic processor. In other words, bits 8, 16, 24, 32, 40, 48, 56 and 64 of each 64-bit key value Kx[1:64] are not used.

Write operations to the CRYP_Kx(L/R) registers when the BUSY bit is set to 1 in the CRYP_SR register are ignored (which means that the register content is not modified). The application must thus check that the BUSY bit is cleared to 0 before modifying key registers.

Key registers are not affected by the data swapping controlled by DATATYPE value in CRYP_CR register.

Refer to Section 37.7: CRYP registers for a detailed description of CRYP_Kx(L/R) registers.

### 37.4.18 CRYP initialization vector registers

The CRYP_IVxL/IVxR registers are used to store the initialization vector or the nonce, depending on the chaining mode selected. When used, these registers are updated by the core after each computation round of the TDES or AES core.

They are organized as four 64-bit registers, as shown in shown in Table 310 and Table 311. In DES/TDES mode only CRYP_IV0x are used.

Note: In memory and in CRYP IV registers, AES and DES/TDES initialization vectors are stored in big-endian format, with most significant byte on the lowest address.

#### Table 310. Initialization vector endianness in CRYP_IVx(L/R)R registers (AES)

<table>
<thead>
<tr>
<th>CRYP_IV0LR[31:0]</th>
<th>CRYP_IV0RR[31:0]</th>
<th>CRYP_IV1LR[31:0]</th>
<th>CRYP_IV1RR[31:0]</th>
</tr>
</thead>
</table>

#### Table 311. Initialization vector endianness in CRYP_IVx(L/R)R registers (DES/TDES)

<table>
<thead>
<tr>
<th>CRYP_IV0LR[31:0]</th>
<th>CRYP_IV0RR[31:0]</th>
<th>CRYP_IV1LR[31:0]</th>
<th>CRYP_IV1RR[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>IVI[64:32]</td>
<td>IVI[31:0]</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Any write operation to the CRYP_IV0...1(L/R)R registers when the BUSY bit is set to 1 in the CRYP_SR register is disregarded (which means that register content not modified). The
software must thus check that the BUSY bit is cleared to 0 in the CRYP_SR register before modifying initialization vectors.

Reading the CRYP_IV0...1(L/R)R register returns the latest counter value (useful for managing suspend mode) except for CCM/GCM.

The initialization vector registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP_CR register.

Refer to [Section 37.7: CRYP registers](#) for a detailed description of CRYP_IVxL/IVxR registers.

### 37.4.19 CRYP DMA interface

The cryptographic processor provides an interface to connect to the DMA (Direct Memory Access) controller. The DMA operation is controlled through the CRYP DMA control register (CRYP_DMACR).

#### Data input using DMA

DMA can be enabled for writing data into the cryptographic peripheral by setting the DIEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the INPUT phase each time it requires a word to be written to the CRYP_DIN register.

(Table 312) shows the recommended configuration to transfer data from memory to cryptographic processor through the DMA controller.

<table>
<thead>
<tr>

<td>CRYP FIFO_size /2 = 16 bytes</td>
</tr>
<tr>
<td>Source transfer width (memory)</td>
<td>32-bit words</td>
</tr>
<tr>
<td>Destination transfer width (peripheral)</td>
<td>32-bit words</td>
</tr>
</tbody>
</table>
Data output using DMA

To enable the DMA for reading data from CRYP processor, set the DOEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the OUTPUT phase each time it requires a word to be read from the CRYP_DOUT register.

*Table 313* shows the recommended configuration to transfer data from cryptographic processor to memory through the DMA controller.

  (FIFO_size = 8x32-bit, transfer_width = 32-bit) |
| Destination burst size (memory) | CRYP FIFO_size /2 /transfer_width = 4 |
| DMA FIFO size | CRYP FIFO_size /2 = 16 bytes |
| Source transfer width (peripheral) | 32-bit words |
| memory transfer width (memory) | 32-bit words |
| Source address increment (peripheral) | Fixed address of CRYP_DOUT shall be used (no increment). |
| Destination address increment (memory) | Yes, after each 32-bit transfer. |
DMA mode

When AES is used, the cryptographic processor manages two DMA transfer requests through cryp_in_dma and cryp_out_dma internal input/output signals, which are asserted:

- for IN FIFO: every time a block has been read from FIFO by CRYP,
- for OUT FIFO: every time a block has been written into the FIFO by the cryptographic processor.

When DES/TDES is used, the cryptographic processor manages two DMA transfer requests through cryp_in_dma and cryp_out_dma internal input/output signals, which are asserted:

- for IN FIFO: every time two blocks have been read from FIFO by the cryptographic processor
- for OUT FIFO: every time a word has been written into the FIFO by the cryptographic processor (single transfer). Note that a burst transfer is also triggered when two blocks have been written into the FIFO.

All request signals are deasserted if the cryptographic peripheral is disabled or the DMA enable bit is cleared (DIEN bit for the IN FIFO and DOEN bit for the OUT FIFO in the CRYP_DMACR register).

Caution: It is important that DMA controller empties the cryptographic peripheral output FIFO before filling up the CRYP input FIFO. To achieve it, the DMA controller should be configured so that the transfer from the peripheral to the memory has a higher priority than the transfer from the memory to the peripheral.

For more detailed information on DMA operations, refer to Section 37.4.5: CRYP procedure to perform a cipher operation.

37.4.20 CRYP error management

No error flags are generated by the cryptographic processor.

37.5 CRYP interrupts

Overview

There are two individual maskable interrupt sources generated by the cryptographic processor to signal the following events:

- Input FIFO empty or not full
- Output FIFO full or not empty

These two sources are combined into a single interrupt signal which is the only interrupt signal from the CRYP processor that drives the Cortex® CPU interrupt controller. You can enable or disable CRYP interrupt sources individually by changing the mask bits in the CRYP_IMSCR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual maskable interrupt sources can be read either from the CRYP_RISR register, for raw interrupt status, or from the CRYP_MISR register for masked
interrupt status. The status of the individual source of event flags can be read from the CRYP_SR register.

*Table 314* gives a summary of the available features.

### Table 314. CRYP interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag in CRYP_xISR(1)</th>
<th>Event flag in CRYP_SR</th>
<th>Enable bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRYP</td>
<td>Output FIFO full</td>
<td>OUTFIS (not masked)</td>
<td>OFFU</td>
<td>OUTIM(2) and CRYPEN</td>
<td>Read one data from output FIFO</td>
</tr>
<tr>
<td></td>
<td>Output FIFO not empty</td>
<td>OUTFM (masked)</td>
<td>OFNE</td>
<td></td>
<td>Read all data from output FIFO</td>
</tr>
<tr>
<td></td>
<td>Input FIFO not full</td>

</tr>
<tr>
<td></td>
<td>Input FIFO empty</td>
<td>INFM (masked)</td>
<td>IFEM</td>
<td></td>
<td>Write at least one word in input FIFO</td>
</tr>
</tbody>
</table>

1. The flags belong to CRYP_RISR registers (unmasked or raw) or CRYP_MISR registers (masked).
2. The flags belong to CRYP_IMSCR register.

**Output FIFO service interrupt - OUTMIS**

The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is when the interrupt follows the state of the output FIFO not empty flag OFNE).

The output FIFO service interrupt OUTMIS is NOT enabled with the CRYP processor enable bit. Consequently, disabling the CRYP processor does not force the OUTMIS signal low if the output FIFO is not empty.

**Input FIFO service interrupt - INMIS**

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is enabled with the CRYP enable bit. Consequently, when CRYP is disabled, the INMIS signal is low even if the input FIFO is empty.

### 37.6 CRYP processing time

The time required to process a block for each mode of operation is summarized below. The block size is 128 bits for AES and 64 bits for DES/TDES.
The cryptographic core is associated with several control and status registers, eight key registers and four initialization vectors registers.

### 37.7 CRYP registers

The cryptographic core is associated with several control and status registers, eight key registers and four initialization vectors registers.

#### 37.7.1 CRYP control register (CRYP_CR)

</tr>
</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.
Bits 23:20 **NPBLB[3:0]**: Number of Padding Bytes in Last Block of payload.
This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.
- 0000: All bytes are valid (no padding)
- 0001: Padding for the last LSB byte
- ...
- 1111: Padding for the 15 LSB bytes of last block.
Writing NPBLB bits while BUSY = 1 has no effect.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **GCM_CCMPH[1:0]**: GCM or CCM Phase selection
This bitfield has no effect if GCM, GMAC or CCM algorithm is not selected in ALGOMODE field.
- 00: Initialization phase
- 01: Header phase
- 10: Payload phase
- 11: Final phase
Writing to GCM_CCMPH bits while BUSY = 1 has no effect.

Bit 15 **CRYPEN**: CRYP processor Enable
- 0: Cryptographic processor peripheral is disabled
- 1: Cryptographic processor peripheral is enabled
This bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE = 0111) or after GCM/GMAC or CCM Initialization phase.

Bit 14 **FFLUSH**: CRYP FIFO Flush
- 0: No FIFO flush
- 1: FIFO flush enabled
When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (that is read and write pointers of the FIFOs are reset). Writing this bit to 0 has no effect. When CRYPEN = 1, writing this bit to 0 or 1 has no effect.
Reading this bit always returns 0.
FFLUSH bit has to be set only when BUSY = 0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a non-empty FIFO condition.

Bits 13:10 Reserved, must be kept at reset value.

Bits 9:8 **KEYSIZE[1:0]**: Key size selection (AES mode only)
This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is ‘don’t care’ in the DES or TDES modes.
- 00: 128-bit key length
- 01: 192-bit key length
- 10: 256-bit key length
- 11: Reserved, do not use this value
Writing KEYSIZE bits while BUSY = 1 has no effect.
37.7.2  CRYP status register (CRYP_SR)

Address offset: 0x04

Reset value: 0x0000 0003

<table>
<thead>
<tr>

</tr>
<tr>
<td>Reserved</td>
<td>IFEM</td>
</tr>
</tbody>
</table>

Bits 31:5  Reserved, must be kept at reset value.

Bits 7:6  DATATYPE[1:0]: Data Type selection

This bitfield defines the format of data written in CRYP_DIN or read from CRYP_DOUT registers. For more details refer to Section 37.4.16: CRYP data registers and data swapping.  
00: 32-bit data. No swapping for each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64 etc.  
01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.  
10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.  
11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.  
Writing DATATYPE bits while BUSY = 1 has no effect.

Bits 19, 5:3  ALGOMODE[3:0]: Algorithm mode

Below definition includes the bit 19:
0000: TDES-ECB (triple-DES Electronic Codebook).  
0001: TDES-CBC (triple-DES Cipher Block Chaining).  
0010: DES-ECB (simple DES Electronic Codebook).  
0011: DES-CBC (simple DES Cipher Block Chaining).  
0100: AES-ECB (AES Electronic Codebook).  
0101: AES-CBC (AES Cipher Block Chaining).  
0110: AES-CTR (AES Counter mode).  
0111: AES key preparation for ECB or CBC decryption.  
1000: AES-GCM (Galois Counter mode) and AES-GMAC (Galois Message Authentication Code mode).  
1001: AES-CCM (Counter with CBC-MAC).  
Writing ALGOMODE bits while BUSY = 1 has no effect.

Others: Reserved, must not be used

Bit 2  ALGODIR: Algorithm Direction

0: Encrypt
1: Decrypt

Writing ALGODIR bit while BUSY = 1 has no effect.

Bits 1:0  Reserved, must be kept at reset value.
37.7.3 CRYP data input register (CRYP_DIN)

Address offset: 0x08

Reset value: 0x0000 0000

The CRYP_DIN register is the data input register. It is 32-bit wide. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to Section 37.4.16: CRYP data registers and data swapping for more details.

When CRYP_DIN register is written to the data are pushed into the input FIFO.
- If CRYPEN = 1, when at least four 32-bit words in the AES mode have been pushed into the input FIFO (two words in the DES/TDES mode), and when at least four words are free in the output FIFO (two words in the DES/TDES mode), the CRYP engine starts an encrypting or decrypting process.

When CRYP_DIN register is read:
- If CRYPEN = 0, the FIFO is popped, and then the data present in the Input FIFO are returned, from the oldest one (first reading) to the newest one (last reading). The IFEM flag must be checked before each read operation to make sure that the FIFO is not empty.
- If CRYPEN = 1, an undefined value is returned.

Bit 4 BUSY: Busy bit
  0: The CRYP core is not processing any data. The reason is:
    - either that the CRYP core is disabled (CRYPEN = 0 in the CRYP_CR register) and the last processing has completed,
    - or the CRYP core is waiting for enough data in the input FIFO or enough free space in the output FIFO (that is in each case at least 2 words in the DES, 4 words in the AES).
  1: The CRYP core is currently processing a block of data or a key preparation is ongoing (AES ECB or CBC decryption only).

Bit 3 OFFU: Output FIFO full flag
  0: Output FIFO is not full
  1: Output FIFO is full

Bit 2 OFNE: Output FIFO not empty flag
  0: Output FIFO is empty
  1: Output FIFO is not empty

Bit 1 IFNF: Input FIFO not full flag
  0: Input FIFO is full
  1: Input FIFO is not full

Bit 0 IFEM: Input FIFO empty flag
  0: Input FIFO is not empty
  1: Input FIFO is empty
Note: After the CRYP_DIN register has been read once or several times, the FIFO must be flushed by setting the FFLUSH bit prior to processing new data.

37.7.4 CRYP data output register (CRYP_DOUT)

Address offset: 0x0C
Reset value: 0x0000 0000

The CRYP_DOUT register is the data output register. It is read-only and 32-bit wide. It is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to Section 37.4.16: CRYP data registers and data swapping for more details.

When CRYP_DOUT register is read, the last data entered into the output FIFO (pointed to by the read pointer) is returned.

Bits 31:0 DATAOUT[31:0]: Data output
On read returns output FIFO content (pointed to by read pointer), else returns an undefined value.
On write, no effect.
37.7.5 CRYP DMA control register (CRYP_DMACR)

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
<tr>
<td>DOEN DIEN</td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DOEN**: DMA output enable
- When this bit is set, DMA requests are automatically generated by the peripheral during the output data phase.
  - 0: Outgoing data transfer from CRYP via DMA is disabled
  - 1: Outgoing data transfer from CRYP via DMA is enabled

Bit 0 **DIEN**: DMA input enable
- When this bit is set, DMA requests are automatically generated by the peripheral during the input data phase.
  - 0: Incoming data transfer to CRYP via DMA is disabled
  - 1: Incoming data transfer to CRYP via DMA is enabled

37.7.6 CRYP interrupt mask set/clear register (CRYP_IMSCR)

Address offset: 0x14
Reset value: 0x0000 0000

The CRYP_IMSCR register is the interrupt mask set or clear register. It is a read/write register. When a read operation is performed, this register gives the current value of the mask applied to the relevant interrupt. Writing 1 to the particular bit sets the mask, thus enabling the interrupt to be read. Writing 0 to this bit clears the corresponding mask. All the bits are cleared to 0 when the peripheral is reset.

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
<tr>
<td>OUTIM INIM</td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OUTIM**: Output FIFO service interrupt mask
- 0: Output FIFO service interrupt is masked
- 1: Output FIFO service interrupt is not masked
Bit 0 **INIM**: Input FIFO service interrupt mask
   0: Input FIFO service interrupt is masked
   1: Input FIFO service interrupt is not masked

### 37.7.7 CRYP raw interrupt status register (CRYP_RISR)

Address offset: 0x18

Reset value: 0x0000 0001

The CRYP_RISR register is the raw interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current raw status of the corresponding interrupt, i.e. the interrupt information without taking CRYP_IMSCR mask into account. Write operations have no effect.

<table>
<thead>
<tr>
<th>Bit 31:2 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 1 <strong>OUTRIS</strong>: Output FIFO service raw interrupt status</td>
</tr>
<tr>
<td>This bit gives the output FIFO interrupt information without taking CRYP_IMSCR corresponding mask into account.</td>
</tr>
<tr>
<td>0: Raw interrupt not pending</td>
</tr>
<tr>
<td>1: Raw interrupt pending</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 0 <strong>INRIS</strong>: Input FIFO service raw interrupt status</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit gives the input FIFO interrupt information without taking CRYP_IMSCR corresponding mask into account.</td>
</tr>
<tr>
<td>0: Raw interrupt not pending</td>
</tr>
<tr>
<td>1: Raw interrupt pending</td>
</tr>
</tbody>
</table>
37.7.8 CRYP masked interrupt status register (CRYP_MISR)

Address offset: 0x1C
Reset value: 0x0000 0000

The CRYP_MISR register is the masked interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current masked status of the corresponding interrupt, i.e., the interrupt information taking CRYP_IMSCR mask into account. Write operations have no effect.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 OUTMIS: Output FIFO service masked interrupt status
This bit gives the output FIFO interrupt information taking into account the corresponding CRYP_IMSCR mask.
0: Output FIFO interrupt not pending
1: Output FIFO interrupt pending

Bit 0 INMIS: Input FIFO service masked interrupt status
This bit gives the input FIFO interrupt information taking into account the corresponding CRYP_IMSCR mask.
0: Input FIFO interrupt not pending
1: Input FIFO interrupt pending when CRYPEN = 1

37.7.9 CRYP key register 0L (CRYP_K0LR)

Address offset: 0x20
Reset value: 0x0000 0000

CRYP key registers contain the cryptographic keys.
For more information refer to Section 37.4.17: CRYP key registers.

Note: Write accesses to these registers are disregarded when the cryptographic processor is busy (bit BUSY = 1 in the CRYP_SR register).

Bits 31:0  **K[191:176]**: Key bit x (x = 191 to 160)

This write-only bitfield contains the bits [191:160] of the AES encryption or decryption key, depending on the operating mode. In DES/TDES mode this bitfield contains the bits [64:33] of the key K1, with parity bits unused.
### 37.7.12 CRYP key register 1R (CRYP_K1RR)

Address offset: 0x2C  
Reset value: 0x0000 0000  
Refer to *Section 37.7.9: CRYP key register 0L (CRYP_K0LR)* for details.

Bits 31:0 \[K_{31:0}]\: Key bit \(x\) (\(x = 31\) to 0)
This write-only bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode. In DES/TDES mode this bitfield contains the bits [32:1] of the key K3, with parity bits unused.

37.7.17 CRYP initialization vector register 0L (CRYP_IV0LR)

Address offset: 0x40
Reset value: 0x0000 0000

The CRYP_IVx(L/R)R registers store the initialization vector or the nonce, depending on the chaining mode selected. The size of the IV data is 64 bits for DES/TDES and 128 bits for AES. For more information refer to Section 37.4.18: CRYP initialization vector registers.

Note: Write accesses to these registers are disregarded when the cryptographic processor is busy (BUSY = 1 in the CRYP_SR register).

Bits 31:0 \[IV_{127:96}\]: Initialization vector bit \(x\) (\(x = 127\) to 96)
This bitfield stores the initialization vector bits [127:96] for AES chaining modes other than ECB. In DES/TDES mode it corresponds to IVI bits [63:32].
IV registers are updated by the core after each computation round of the DES/TDES or AES core.
37.7.18 CRYP initialization vector register 0R (CRYP_IV0RR)

Address offset: 0x44
Reset value: 0x0000 0000
Refer to Section 37.7.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.

Bits 31:0 IV[31:0]: Initialization vector bit x (x = 31 to 0)  
This bitfield stores the initialization vector bits [31:0] for AES chaining modes other than ECB.  
This register is not used in DES mode.  
IV registers are updated by the core after each computation round of the AES core.

37.7.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR)

Address offset: 0x050 + x* 0x4 (x = 0 to 7)  
Reset value: 0x0000 0000  
These registers contain the complete internal register states of the CRYP processor when the GCM/GMAC or CCM algorithm is selected. They are useful when a context swap has to be performed because a high-priority task needs the cryptographic processor while it is already in use by another task.

When such an event occurs, the CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R (in GCM/GMAC mode) or CRYP_CSGCMCCM0..7R (in CCM mode) registers have to be read and the values retrieved have to be saved in the system memory space. The cryptographic processor can then be used by the preemptive task. Then when the cryptographic computation is complete, the saved context can be read from memory and written back into the corresponding context swap registers.

38 Hash processor (HASH)

38.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA2-224, SHA2-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to \((2^{64} - 1)\) bits. It also computes 128-bit digests for the MD5 algorithm.

38.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321, MD5 Message-Digest Algorithm
- Fast computation of SHA-1, SHA2-224, SHA2-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA2-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits (16 × 32 bits)
- Single 32-bit input register associated to an internal input FIFO, corresponding to one block size
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- 8 × 32-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel.
- Single or fixed DMA burst transfers of four words
- Interruptible message digest computation, on a per-block basis
  - Re-loadable digest registers
  - Hashing computation suspend/resume mechanism, including DMA

### 38.3 HASH implementation

The devices have a single instance of HASH peripheral.

38.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below $2^{64}$ bits is provided on input, the HASH processing core produces respectively a fixed-length output string called a message digest, defined as follows:

- For MD5 digest size is 128-bit
- For SHA-1 digest size is 160-bit
- For SHA2-224 and SHA2-256, the digest size is 224 bits and 256 bits, respectively

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit, with very high probability, results in a different message digest, and the signature fails to verify.

38.4.4 Message data feeding

The message (or data file) to be processed by the HASH is considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word `0x00363261`, and 8-bit words `0x61626300`.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).
In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. Figure 321 shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 321. Message data swapping feature
38.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. For MD5, SHA1 and SHA2, the block size is 512 bits.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in Section 38.4.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO.

In order to perform the hash computation on this data below sequence must be used by the application:

1. Initialize the hash processor using the HASH_CR register:
   a) Select the right algorithm using the ALGO bitfield. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH_CR.
   b) When the HMAC mode is required, set the MODE bit, as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (else keep LKEY cleared). Refer to Section 38.4.7: HMAC operation for details.
   c) Update NBLW[4:0] to define the number of valid bits in last word of the message if it is different from 32 bits. NBLW[4:0] information are used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting to 1 the INIT bit in HASH_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

Caution: When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW[4:0]).

3. Start filling data by writing to HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   a) When data are filled by software:
      – Partial digest computation are triggered each time the application writes the first word of the next block. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
      – The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of the block size, the NBLW[4:0] bitfield in HASH_STR register must be written prior to writing DCAL bit (see Section 38.4.6 for details).
   b) When data are filled by DMA as a single DMA transfer (MDMAT bit = 0):
      – Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of the block size, the NBLW[4:0] field
c) When data are filled by DMA using multiple DMA transfers (MDMAT bit = 1):
   - Partial digest computations are triggered as for single DMA transfers. However the
     final digest computation is not triggered automatically when the last block has
     been transferred by DMA to the HASH_DIN register (DCAL bit is not set to 1 by
     hardware). It allows the hash processor to receive a new DMA transfer as part of
     this digest computation. To launch the final digest computation, the software must
     set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest
     computation as it is done for single DMA transfers (see description before).

4. Once the digest computation is complete (DCIS = 1), the resulting digest can be read
   from the output registers as described in Table 319.

operation.

38.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data
into the hash processor (with automatic partial digest computation every block transfer)
loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written
to the hash processor may have a valid number of bits between 1 and 32. This number of
valid bits in the last word, NBLW[4:0], has to be written to the HASH_STR register, so that
message padding is correctly performed before the final message digest computation.

Padding processing

Detailed padding sequences with DMA enabled or disabled are described in Section 38.4.5:
Message digest computing.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, the message
padding consists in appending a “1” followed by \( k \) “0”s, itself followed by a 64-bit integer that
is equal to the length \( L \) in bits of the message. These three padding operations generate a
padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at
the bit position defined by the NBLW[4:0] bitfield, and the remaining upper bits are cleared
(“0”s).
Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24:

```
byte 0  byte 1  byte 2  byte 3
01100001 01100010 01100011  UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW[4:0] has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

The message length value, L, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 0000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered by following the below sequence:

1. **0xUU636261** is written to the HASH_DIN register (where ‘U’ means don’t care).
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits).
3. **0x10** is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0...4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_HR0 = 0xA9993E36
HASH_HR1 = 0x4706816A
HASH_HR2 = 0xBA3E2571
HASH_HR3 = 0x7850C26C
HASH_HR4 = 0x9CD0D89D
```
38.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC(message)} = \text{Hash}((\text{Key} | \text{pad}) \ XOR \ opad | \\
\text{Hash}((\text{Key} | \text{pad}) \ XOR \ ipad | \text{message}))
\]

where:

- \( \text{opad} = [0x5C]_n \) (outer pad) and \( \text{ipad} = [0x36]_n \) (inner pad)
- \([X]_n\) represents a repetition of \( X \) \( n \) times, where \( n \) equal to the size of the underlying hash function data block \( (n = 64 \) for 512-bit blocks).
- \( \text{pad} \) is a sequence of zeroes needed to extend the key to the length \( n \) defined above. If the key length is greater than \( n \), the application must first hash the key using \( \text{Hash}() \) function and then use the resultant byte string as the actual key to HMAC.
- \( | \) represents the concatenation operator.

Note: HMAC mode of the hash processor can be used with all supported algorithms.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software writes the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.

2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register.

Note: Endianness details can be found in Section 38.4.4: Message data feeding.

3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software writes DCAL bit to 1 in HASH_STR register, the NBLW[4:0] bitfield must be written at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 38.4.4: Message data feeding.

4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set to 1.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 38.6: HASH processing time.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST.
Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen = blocklen", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is no padding), specified by NIST. As key length = 64, LKEY bit is set to 0 in HASH_CR register
   
   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F

2. **Message** input (length = 34, that is padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don't care)
   
   53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
   6E36262C 6F636B6C 656EUUUU

3. **Outer hash key** input (length = 64, that is no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers (x = 0 to 4), as shown below:

   - HASH_HR0 = 0x5FD596EE
   - HASH_HR1 = 0x78D5553C
   - HASH_HR2 = 0x8FF4E72D
   - HASH_HR3 = 0x266DFD19
   - HASH_HR4 = 0x2366DA29
38.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 322.

Figure 322. HASH suspend/resume mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing 16 words 32-bit (plus one if it is the first block):
1. In Polling mode, wait for BUSY = 0, then poll if the DINIS status bit is set to 1.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:
1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR and HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Note: To optimize the resume process when NBW[3:0] = 0x0, HASH_CSR22 to HASH_CSR37 registers do not need to be saved then restored as the FIFO is empty.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing is described below.

To suspend the processing of a message using DMA, proceed as follows:
1. In Polling mode, wait for BUSY = 0. If DCIS is set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 2.
2. In Polling mode, wait for BUSY = 1.
3. Disable the DMA channel. Then clear DMAE bit in HASH_CR register.
4. In Polling mode, wait for BUSY = 0. If DCIS is set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR, HASH_CR, and HASH_CSR0 to HASH_CSR37 registers. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again. Do not forget to take into account the words that have been already pushed into the FIFO if NBW[3:0] is higher than 0x0.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

Note: To optimize the resume process when NBW[3:0] = 0x0, HASH_CSR22 to HASH_CSR37 registers do not need to be saved then restored as the FIFO is empty.

38.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to Section 38.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[
NBLW[4:0] = \text{Len}(\text{Message}) \mod 32
\]

where “\(x \mod 32\)” gives the remainder of \(x\) divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

38.4.10 HASH error management

No error flags are generated by the hash processor.

38.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the NVIC (nested vectored interrupt controller). Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.
The status of each maskable interrupt source can be read from the HASH_SR register. Table 320 gives a summary of the available features.

### Table 320. HASH interrupt requests

1. Add the time required to load the block into the processor.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- 1 to 2.5 for a hash message
- ~2.5 for an HMAC input-key
- 1 to 2.5 for an HMAC message
- ~2.5 for an HMAC output key in case of a short key
- 3.5 to 5 for an HMAC output key in case of a long key
38.7 HASH registers

The HASH core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

38.7.1 HASH control register (HASH_CR)

Address offset: 0x00
Reset value: 0x0000 0000

| Bit 31-19 | Reserved, must be kept at reset value. |
| Bit 17   | Reserved, must be kept at reset value. |
| Bit 16   | LKEY: Long key selection  
|          | This bit selects between short key (≤ 64 bytes) or long key (> 64 bytes) in HMAC mode.  
|          | 0: the HMAC key is shorter or equal to 64 bytes. The actual key value written to HASH_DIN is used during the HMAC computation.  
|          | 1: the HMAC key is longer than 64 bytes. The hash of the key is used instead of the real key during the HMAC computation.  
|          | This selection is only taken into account when the INIT and MODE bits are both set. Changing this bit during a computation has no effect. |
| Bit 15   | Reserved, must be kept at reset value. |
| Bit 14   | Reserved, must be kept at reset value. |
| Bit 13   | MDMAT: Multiple DMA transfers  
|          | This bit is set when hashing large files when multiple DMA transfers are needed.  
|          | 0: DCAL is automatically set at the end of a DMA transfer.  
|          | 1: DCAL is not automatically set at the end of a DMA transfer. |
| Bit 12   | DINNE: DIN not empty  
|          | This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.  
|          | 0: No data are present in the data input buffer  
|          | 1: The input buffer contains at least one word of data  
|          | This bit is read-only. |
Bits 11:8  **NBW[3:0]:** Number of words already pushed  

This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO. NBW is incremented by one when a write access to the HASH_DIN register is performed (except if DINNE = 0 and the DMA is not used, see below description). NBW goes to zero when the INIT bit is written to 1.  
This bitfield is read-only.  

**If the DMA is not used**  
0000: if DINNE = 0, no word has been pushed into the DIN buffer (both HASH_DIN register and IN FIFO are empty), otherwise one word has been pushed into the DIN buffer (HASH_DIN register contains one word and IN FIFO is empty)  
0001: two words have been pushed into the DIN buffer (that is HASH_DIN register and the IN FIFO contain one word each)  
...  
1111: 16 words have been pushed into the DIN buffer.  

**If the DMA is used**  
NBW contains the exact number of words that have been pushed into the IN FIFO by the DMA.  

Bits 18, 7  **ALGO[1:0]:** Algorithm selection  

These bits select the hash algorithm.  
00: SHA-1  
01: MD5  
10: SHA2-224  
11: SHA2-256  

This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.  

Bit 6  **MODE:** Mode selection  

This bit selects the HASH or HMAC mode for the selected algorithm:  
0: Hash mode selected  
1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.  
This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.  

Bits 5:4  **DATATYPE[1:0]:** Data type selection  

Defines the format of the data entered into the HASH_DIN register:  
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.  
01: 16-bit data, or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.  
10: 8-bit data, or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.  
11: bit data, or bit-string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).
Bit 3 **DMAE**: DMA enable
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the HASH core is ready to receive data.
After this bit is set it is cleared by hardware while the last data of the message is written into the hash processor.
Setting this bit to 0 while a DMA transfer is ongoing is not aborting this current transfer.
Instead, the DMA interface of the IP remains internally enabled until the transfer is completed or INIT is written to 1.
Setting INIT bit to 1 does not clear DMAE bit.

Bit 2 **INIT**: Initialize message digest calculation
Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0 Reserved, must be kept at reset value.

### 38.7.2 HASH data input register (HASH_DIN)

Address offset: 0x04
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks. When the HASH_DIN register is programmed, the value presented on the AHB databus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:
- by writing new data into the HASH_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by writing the DCAL bit to 1 in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is set to 0.

Reading the HASH_DIN register returns the last word written to this location (zero after reset).

**Note:** When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.
38.7.3 HASH start register (HASH_STR)

Address offset: 0x08
Reset value: 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register).
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1.

</tbody>
</table>
38.7.4 HASH digest registers

These registers contain the message digest result named as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0, HASH_HR1, HASH_HR2 and HASH_HR3 registers return A, B, C and D (respectively), as defined by MD5.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256 digest result.

In all cases, the digest most significant bit is stored in HASH_H0[31] and unused HASH_HRx registers are read as zeros.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation is stalled until the hash calculation has completed.

**Note:** When starting a digest computation for a new message (by writing the INIT bit to 1), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses.

**HASH aliased digest register x (HASH_HRAx)**

Address offset: 0x0C + 0x4 * x, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

**HASH digest register x (HASH_HRx)**

Address offset: 0x310 + 0x4 * x, (x = 0 to 4)

Reset value: 0x0000 0000

Refer to Section 38.7.4: HASH digest registers introduction.
### HASH supplementary digest register x (HASH_HRx)

Address offset: 0x310 + 0x4 * x, (x = 5 to 7)

Reset value: 0x0000 0000

</tr>
<tr>
<td></td>
<td>1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.</td>
</tr>
<tr>
<td></td>
<td>When DINIS=0, HASH_CSRx registers reads as zero.</td>
</tr>
</tbody>
</table>

38.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.
HASH context swap register x (HASH_CSRx)
Address offset: 0x0F8 + x * 0x4, (x = 0 to 53)
Reset value: 0x0000 0002 (HASH_CSR0)

Refer to Section 2.3 on page 134 for the register boundary addresses.
39 High-resolution timer (HRTIM)

39.1 Introduction

The high-resolution timer can generate up to 10 digital signals with highly accurate timings. It is primarily intended to drive power conversion systems such as switch mode power supplies or lighting systems, but can be of general purpose usage, whenever a very fine timing resolution is expected.

Its modular architecture allows to generate either independent or coupled waveforms. The wave-shape is defined by self-contained timings (using counters and compare units) and a broad range of external events, such as analog or digital feedbacks and synchronization signals. This allows to produce a large variety of control signal (PWM, phase-shifted, constant Ton,...) and address most of conversion topologies.

For control and monitoring purposes, the timer has also timing measure capabilities and links to built-in ADC and DAC converters. Last, it features light-load management mode and is able to handle various fault schemes for safe shut-down purposes.
39.2 Main features

- Multiple timing units
  - Full-resolution available on all outputs, possibility to adjust duty-cycle, frequency and pulse width in triggered one-pulse mode
  - 6 16-bit timing units (each one with an independent counter and 4 compare units)
  - 10 outputs that can be controlled by any timing unit, up to 32 set/reset sources per channel
  - Modular architecture to address either multiple independent converters with 1 or 2 switches or few large multi-switch topologies
- Up to 10 external events, available for any timing unit
  - Programmable polarity and edge sensitivity
  - 5 events with a fast asynchronous mode
  - 5 events with a programmable digital filter
  - Spurious events filtering with blanking and windowing modes
- Multiple links to built-in analog peripherals
  - 4 triggers to ADC converters
  - 3 triggers to DAC converters
  - 3 comparators for analog signal conditioning
- Versatile protection scheme
  - 5 fault inputs can be combined and associated to any timing unit
  - Programmable polarity, edge sensitivity, and programmable digital filter
  - dedicated delayed protections for resonant converters
- Multiple HRTIM instances can be synchronized with external synchronization inputs/outputs
- Versatile output stage
  - Full-resolution Deadtime insertion
  - Programmable output polarity
  - Chopper mode
- Burst mode controller to handle light-load operation synchronously on multiple converters
- 7 interrupt vectors, each one with up to 14 sources
- 6 DMA requests with up to 14 sources, with a burst mode for multiple registers update
39.3 Functional description

39.3.1 General description

The HRTIM can be partitioned into several sub entities:

- The master timer
- The timing units (Timer A to Timer E)
- The output stage
- The burst mode controller
- An external event and fault signal conditioning logic that is shared by all timers
- The system interface

The master timer is based on a 16-bit up counter. It can set/reset any of the 10 outputs via 4 compare units and it provides synchronization signals to the 5 timer units. Its main purpose is to have the timer units controlled by a unique source. An interleaved buck converter is a typical application example where the master timer manages the phase-shifts between the multiple units.

The timer units are working either independently or coupled with the other timers including the master timer. Each timer contains the controls for two outputs. The outputs set/reset events are triggered either by the timing units compare registers or by events coming from the master timer, from the other timers or from external events.

The output stage has several duties

- Addition of deadtime when the 2 outputs are configured in complementary PWM mode
- Addition of a carrier frequency on top of the modulating signal
- Management of fault events, by asynchronously asserting the outputs to a predefined safe level

The burst mode controller can take over the control of one or multiple timers in case of light-load operation. The burst length and period can be programmed, as well as the idle state of the outputs.

The external event and fault signal conditioning logic includes:

- The input selection MUXes (for instance for selecting a digital input or an on-chip source for a given external event channel)
- Polarity and edge-sensitivity programming
- Digital filtering (for 5 channels out of 10)

The system interface allows the HRTIM to interact with the rest of the MCU:

- Interrupt requests to the CPU
- DMA controller for automatic accesses to/from the memories, including an HRTIM specific burst mode
- Triggers for the ADC and DAC converters

The HRTIM registers are split into 7 groups:

- Master timer registers
- Timer A to Timer E registers
- Common registers for features shared by all timer units
Note: As a writing convention, references to the 5 timing units in the text and in registers are generalized using the “x” letter, where x can be any value from A to E.

The block diagram of the timer is shown in Figure 323.

Figure 323. High-resolution timer block diagram
### 39.3.2 HRTIM pins and internal signals

The table here below summarizes the HRTIM inputs and outputs, both on-chip and off-chip.

The HRTIM must be supplied by the tHRTIM system clock to offer a full resolution. All clocks present in the HRTIM are derived from this reference clock.

**Definition of terms**

- \( f_{\text{HRTIM}} \): main HRTIM clock (hrtim_ker_ck). All subsequent clocks are derived and synchronous with this source.
- \( f_{\text{DTG}} \): deadtime generator clock. For convenience, only the \( t_{\text{DTG}} \) period (\( t_{\text{DTG}} = 1/f_{\text{DTG}} \)) is used in this document.
- \( f_{\text{CHPFRQ}} \): chopper stage clock source.
- \( f_{\text{1STPW}} \): clock source defining the length of the initial pulse in chopper mode. For convenience, only the \( t_{\text{1STPW}} \) period (\( t_{\text{1STPW}} = 1/f_{\text{1STPW}} \)) is used in this document.
- \( f_{\text{BRST}} \): burst mode controller counter clock.
- \( f_{\text{SAMPLING}} \): clock needed to sample the fault or the external events inputs.
- \( f_{\text{FLTS}} \): clock derived from \( f_{\text{HRTIM}} \) which is used as a source for \( f_{\text{SAMPLING}} \) to filter fault events.
- \( f_{\text{EEVS}} \): clock derived from \( f_{\text{HRTIM}} \) which is used as a source for \( f_{\text{SAMPLING}} \) to filter external events.
- \( f_{\text{pclk}} \) (hrtim_pclk): APB bus clock, needed for register read/write accesses.

**Timer clock and prescaler**

Each timer in the HRTIM has its own individual clock prescaler, which allows you to adjust the timer resolution. (See Table 324).

**Initialization**

At start-up, it is mandatory to initialize first the prescaler bitfields before writing the compare and period registers. Once the timer is enabled (MCEN or TxCEN bit set in the HRTIM_MCR register), the prescaler cannot be modified.

When multiple timers are enabled, the prescalers are synchronized with the prescaler of the timer that was started first.

---

**Warning:** It is possible to have different prescaling ratios in the master and TIMA..E timers only if the counter and output behavior does not depend on other timers’ information and signals. It is mandatory to configure identical prescaling ratios in these timers when one of the following events is propagated from one timing unit (or master timer) to another: output set/reset event, counter reset event, update event, external event filter or capture triggers. Prescaler factors not equal will yield to unpredictable results.

---

**Deadtime generator clock**

The deadtime prescaler is supplied by $f_{\text{HRTIM}} / 8 / 2^{(\text{DTPRSC}[2:0])}$, programmed with DTPRSC[2:0] bits in the HRTIM_DTxR register.

$t_{\text{DTG}}$ ranges from 2.5 ns to 20 ns for $f_{\text{HRTIM}} = 400$ MHz.

1. CKPSC[2:0] values from 000 to 100 are reserved.
Chopper stage clock

The chopper stage clock source $f_{CHPFRQ}$ is derived from $f_{HRTIM}$ with a division factor ranging from 16 to 256, so that $1.56\text{ MHz} \leq f_{CHPFRQ} \leq 25\text{ MHz}$ for $f_{HRTIM} = 400\text{ MHz}$.

$t_{1STPW}$ is the length of the initial pulse in chopper mode, programmed with the STRPW[3:0] bits in the HRTIM_CHPxR register, as follows:

$$t_{1STPW} = (\text{STRPW}[3:0]+1) \times 16 \times t_{HRTIM}.$$  

It uses $f_{HRTIM} / 16$ as clock source (25 MHz for $f_{HRTIM} = 400\text{ MHz}$).

Burst Mode Prescaler

The burst mode controller counter clock $f_{BRST}$ can be supplied by several sources, among which one is derived from $f_{HRTIM}$.

In this case, $f_{BRST}$ ranges from $f_{HRTIM}$ to $f_{HRTIM} / 32768$ (12.2 kHz for $f_{HRTIM} = 400\text{ MHz}$).

Fault input sampling clock

The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either $f_{HRTIM}$ or $f_{FLTS}$.

$f_{FLTS}$ is derived from $f_{HRTIM}$ and ranges from 400 MHz to 50 MHz for $f_{HRTIM} = 400\text{ MHz}$.

External Event input sampling clock

The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either $f_{HRTIM}$ or $f_{EEVS}$.

$f_{EEVS}$ is derived from $f_{HRTIM}$ and ranges from 400 MHz to 50 MHz for $f_{HRTIM} = 400\text{ MHz}$.
39.3.4 Timer A..E timing units

The HRTIM embeds 5 identical timing units made of a 16-bit up-counter with an auto-reload mechanism to define the counting period, 4 compare and 2 capture units, as per Figure 324. Each unit includes all control features for 2 outputs, so that it can operate as a standalone timer.

Figure 324. Timer A..E overview

The period and compare values must be within a lower and an upper limit related to the high-resolution implementation and listed in Table 325:

- The minimum value must be greater than or equal to 3 periods of the $f_{\text{HRTIM}}$ clock
- The maximum value must be less than or equal to 0xFFFF - 1 periods of the $f_{\text{HRTIM}}$ clock

Note: A compare value greater than the period register value will not generate a compare match event.

Counter operating mode

Timer A..E can operate in continuous (free-running) mode or in single-shot manner where counting is started by a reset event, using the CONT bit in the HRTIM_TIMxCR control register. An additional RETRIG bit allows you to select whether the single-shot operation is retriggerable or non-retriggerable. Details of operation are summarized on Table 326 and on Figure 325 and Figure 326.

<td></td>
</tr>
</tbody>
</table>

The TxEN bit can be cleared at any time to disable the timer and stop the counting.

Figure 325. Continuous timer operation
A counter roll-over event is generated when the counter goes back to 0 after having reached the period value set in the HRTIM_PERxR register in continuous mode.

This event is used for multiple purposes in the HRTIM:
- To set/reset the outputs
- To trigger the register content update (transfer from preload to active)
- To trigger an IRQ or a DMA request
- To serve as a burst mode clock source or a burst start trigger
- as an ADC trigger
- To decrement the repetition counter

If the initial counter value is above the period value when the timer is started, or if a new period is set while the counter is already above this value, the counter is not reset: it will overflow at the maximum period value and the repetition counter will not decrement.
Timer reset

The reset of the timing unit counter can be triggered by up to 30 events that can be selected simultaneously in the HRTIM_RSTxR register, among the following sources:

- The timing unit: Compare 2, Compare 4 and Update (3 events)
- The master timer: Reset and Compare 1..4 (5 events)
- The external events EXTEVNT1..10 (10 events)
- All other timing units (e.g. Timer B..E for timer A): Compare 1, 2 and 4 (12 events)

Several events can be selected simultaneously to handle multiple reset sources. In this case, the multiple reset requests are ORed. When 2 counter reset events are generated within the same \( f_{\text{HRTIM}} \) clock cycle, the last counter reset is taken into account.

Additionally, it is possible to do a software reset of the counter using the TxRST bits in the HRTIM_CR2 register. These control bits are grouped into a single register to allow the simultaneous reset of several counters.

The reset requests are taken into account only once the related counters are enabled (TxCEN bit set).

When the \( f_{\text{HRTIM}} \) clock prescaling ratio is above 1, the counter reset event is delayed to the next active edge of the prescaled clock. This allows to maintain a jitterless waveform generation when an output transition is synchronized to the reset event (typically a constant \( T_{\text{on}} \) time converter).

*Figure 327* shows how the reset is handled for a clock prescaling ratio of 4 (\( f_{\text{HRTIM}} \) divided by 4).

*Figure 327. Timer reset resynchronization (prescaling ratio above 32)*
Repetition counter

A common software practice is to have an interrupt generated when the period value is reached, so that the maximum amount of time is left for processing before the next period begins. The main purpose of the repetition counter is to adjust the period interrupt rate and off-load the CPU by decoupling the switching frequency and the interrupt frequency.

The timing units have a repetition counter. This counter cannot be read, but solely programmed with an auto-reload value in the HRTIM_REPxR register.

The repetition counter is initialized with the content of the HRTIM_REPxR register when the timer is enabled (TXCEN bit set). Once the timer has been enabled, any time the counter is cleared, either due to a reset event or due to a counter roll-over, the repetition counter is decreased. When it reaches zero, a REP interrupt or a DMA request is issued if enabled (REPIE and REPDE bits in the HRTIM_DIER register).

If the HRTIM_REPxR register is set to 0, an interrupt is generated for each and every period. For any value above 0, a REP interrupt is generated after \((HRTIM_REPxR + 1)\) periods. \(Figure\ 328\) presents the repetition counter operation for various values, in continuous mode.

\(Figure\ 328.\ \text{Repetition rate vs HRTIM\_REPxR content in continuous mode}\)

![Diagram](MS32262V1)

* denotes repetition counter internal values (not readable, for explanation purpose only)

The repetition counter can also be used when the counter is reset before reaching the period value (variable frequency operation) either in continuous or in single-shot mode (\(Figure\ 329\) here-below). The reset causes the repetition counter to be decremented, at the exception of the very first start following counter enable (TxCE bit set).
A reset or start event from the hrtim_in_sync[3:1] source causes the repetition to be decremented as any other reset. However, in SYNCSTRTx bit set in the HRTIM_TIMxCR register, the repetition counter will be decremented only on the 1st reset event following the period. Any subsequent reset will not alter the repetition counter until the counter is re-started by a new request on hrtim_in_sync[3:1] inputs.

**Set / reset crossbar**

A “set” event correspond to a transition to the output active state, while a “reset” event corresponds to a transition to the output inactive state. The polarity of the waveform is defined in the output stage to accommodate positive or negative logic external components: an active level corresponds to a logic level 1 for a positive polarity (POLx = 0), and to a logic level 0 for a negative polarity (POLx = 1).

Each of the timing units handles the set/reset crossbar for two outputs. These 2 outputs can be set, reset or toggled by up to 32 events that can be selected among the following sources:

- The timing unit: Period, Compare 1..4, register update (6 events)
- The master timer: Period, Compare 1..4, HRTIM synchronization (6 events)
- All other timing units (e.g. Timer B..E for timer A): TIMEVNT1..9 (9 events described in Table 327)
- The external events EXTEVNT1..10 (10 events)
- A software forcing (1 event)

The event sources are ORed and multiple events can be simultaneously selected.

Each output is controlled by two 32-bit registers, one coding for the set (HRTIM_SETxyR) and another one for the reset (HRTIM_RSTxyR), where x stands for the timing unit: A..E and y stands for the output 1 or 2 (e.g. HRTIM_SETA1R, HRTIM_RSTC2R,...).

If the same event is selected for both set and reset, it will toggle the output. It is not possible to toggle the output state more than one time per \( t_{\text{HRTIM}} \) period: in case of two consecutive toggling events within the same cycle, only the first one is considered.

The set and reset requests are taken into account only once the counter is enabled (TxCEN bit set), except if the software is forcing a request to allow the prepositioning of the outputs at timer start-up.
Table 327 summarizes the events from other timing units that can be used to set and reset the outputs. The number corresponds to the timer events (such as TIMEVNTx) listed in the register, and empty locations are indicating non-available events.

For instance, Timer A outputs can be set or reset by the following events: Timer B Compare1, 2 and 4, Timer C Compare 2 and 3,... and Timer E Compare 3 will be listed as TIMEVNT8 in HRTIM_SETA1R.

Figure 330 represents how a PWM signal is generated using two compare events.

Figure 330. Compare events action on outputs: set on compare 1, reset on compare 2

Register setting: HRTIM_SETA1R = 0x0000 0008, HRTIM_RSTA1R = 0x0000 0010
Set/Reset on Update events

Half mode

This mode aims at generating square signal with fixed 50% duty cycle and variable frequency (typically for converters using resonant topologies). It allows to have the duty cycle automatically forced to half of the period value when a new period is programmed.

This mode is enabled by writing HALF bit to 1 in the HRTIM_TIMxCR register. When the HRTIM_PERxR register is written, it causes an automatic update of the Compare 1 value with HRTIM_PERxR/2 value.

The output on which a square wave is generated must be programmed to have one transition on CMP1 event, and one transition on the period event, as follows:

- \( \text{HRTIM}\_\text{SETxyR} = 0x0000\ 0008, \text{HRTIM}\_\text{RSTxyR} = 0x0000\ 0004, \) or
- \( \text{HRTIM}\_\text{SETxyR} = 0x0000\ 0004, \text{HRTIM}\_\text{RSTxyR} = 0x0000\ 0008 \)

The HALF mode overrides the content of the HRTIM_CMP1xR register. The access to the HRTIM_PERxR register only causes Compare 1 internal register to be updated. The user-accessible HRTIM_CMP1xR register is not updated with the HRTIM_PERxR / 2 value.

When the preload is enabled (PREEN = 1, MUDIS, TxUDIS), Compare 1 active register is refreshed on the Update event. If the preload is disabled (PREEN= 0), Compare 1 active register is updated as soon as HRTIM_PERxR is written.

The period must be greater than or equal to 6 periods of the \( f_{\text{HRTIM}} \) clock when the HALF mode is enabled.

Capture

The timing unit has the capability to capture the counter value, triggered by internal and external events. The purpose is to:

- measure events arrival timings or occurrence intervals
- update Compare 2 and Compare 4 values in auto-delayed mode (see Auto-delayed mode).

The capture is done with \( f_{\text{HRTIM}} \) resolution.

The timer has 2 capture registers: HRTIM_CPT1xR and HRTIM_CPT2xR. The capture triggers are programmed in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers.

The capture of the timing unit counter can be triggered by up to 28 events that can be selected simultaneously in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers, among the following sources:

- The external events, EXTEVNT1..10 (10 events)
- All other timing units (e.g. Timer B..E for timer A): Compare 1, 2 and output 1 set/reset events (16 events)
- The timing unit: Update (1 event)
- A software capture (1 event)

Several events can be selected simultaneously to handle multiple capture triggers. In this case, the concurrent trigger requests are ORed. The capture can generate an interrupt or a DMA request when CPTxIE and CPTxDE bits are set in the HRTIM_TIMxDIER register.

Over-capture is not prevented by the circuitry: a new capture is triggered even if the previous value was not read, or if the capture flag was not cleared.
Auto-delayed mode

This mode allows to have compare events generated relatively to capture events, so that for instance an output change can happen with a programmed timing following a capture. In this case, the compare match occurs independently from the timer counter value. It enables the generation of waveforms with timings synchronized to external events without the need of software computation and interrupt servicing.

As long as no capture is triggered, the content of the HRTIM_CMPxR register is ignored (no compare event is generated when the counter value matches the Compare value. Once the capture is triggered, the compare value programmed in HRTIM_CMPxR is summed with the captured counter value in HRTIM_CPTxyR, and it updates the internal auto-delayed compare register, as seen on Figure 332. The auto-delayed compare register is internal to the timing unit and cannot be read. The HRTIM_CMPxR preload register is not modified after the calculation.

This feature is available only for Compare 2 and Compare 4 registers. Compare 2 is associated with capture 1, while Compare 4 is associated with capture 2. HRTIM_CMP2xR and HRTIM_CMP4xR Compares cannot be programmed with a value below 3 \( f_{\text{HRTIM}} \) clock periods, as in the regular mode.
The auto-delayed Compare is only valid from the capture up to the period event: once the counter has reached the period value, the system is re-armed with Compare disabled until a capture occurs.

DELCMP2[1:0] and DELCMP4[1:0] bits in HRTIM_TIMxCR register allow to configure the auto-delayed mode as follows:

- **00**
  Regular compare mode: HRTIM_CMP2xR and HRTIM_CMP4xR register contents are directly compared with the counter value.

- **01**
  Auto-delayed mode: Compare 2 and Compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event.

---

**Figure 332. Auto-delayed overview (Compare 2 only)**
• 1X

Auto-delayed mode with timeout: Compare 2 and Compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event or after a Compare 1 match (DELCMPx[1:0]= 10) or a Compare 3 match (DELCMPx[1:0]= 11) to have a timeout function if capture 1/2 event is missing.

When the capture occurs, the comparison is done with the (HRTIM_CMP2/4xR + HRTIM_CPT1/2xR) value. If no capture is triggered within the period, the behavior depends on the DELCMPx[1:0] value:

• DELCMPx[1:0] = 01: the compare event is not generated
• DELCMPx[1:0] = 10 or 11: the comparison is done with the sum of the 2 compares (for instance HRTIM_CMP2xR + HRTIM_CMP1xR). The captures are not taken into account if they are triggered after CMPx + CMP1 (resp. CMPx + CMP3).

The captures are enabled again at the beginning of the next PWM period.

If the result of the auto-delayed summation is above 0xFFFF (overflow), the value is ignored and no compare event will be generated until a new period is started.

**Note:** DELCMPx[1:0] bitfield must be reset when reprogrammed from one value to the other to re-initialize properly the auto-delayed mechanism, for instance:

• DELCMPx[1:0] = 10
• DELCMPx[1:0] = 00
• DELCMPx[1:0] = 11

As an example, **Figure 333** shows how the following signal can be generated:

• Output set when the counter is equal to Compare 1 value
• Output reset 4 cycles after a falling edge on a given external event

**Note:** To simplify the figure, the external event signal is shown without any resynchronization delay; practically, there is a delay of 1 to 2 \( f_{HRTIM} \) clock periods between the falling edge and the capture event due to an internal resynchronization stage which is necessary to process external input signals.

![Figure 333. Auto-delayed compare](image_url)

A regular compare channel (e.g. Compare 1) is used for the output set: as soon as the counter matches the content of the compare register, the output goes to its active state.
A delayed compare is used for the output reset: the compare event can be generated only if a capture event has occurred. No event is generated when the counter matches the delayed compare value (counter = 4). Once the capture event has been triggered by the external event, the content of the capture register is summed to the delayed compare value to have the new compare value. In the example, the auto-delayed value 4 is summed to the capture equal to 7 to give a value of 12 in the auto-delayed compare register. From this time on, the compare event can be generated and will happen when the counter is equal to 12, causing the output to be reset.

**Overcapture management in auto-delayed mode**

Overcapture is prevented when the auto-delayed mode is enabled (DELCMPx[1:0] = 01, 10, 11).

When multiple capture requests occur within the same counting period, only the first capture is taken into account to compute the auto-delayed compare value. A new capture is possible only:

- Once the auto-delayed compare has matched the counter value (compare event)
- Once the counter has rolled over (period)
- Once the timer has been reset

**Changing auto-delayed compare values**

When the auto-delayed compare value is preloaded (PREEN bit set), the new compare value is taken into account on the next coming update event (for instance on the period event), regardless of when the compare register was written and if the capture occurred (see Figure 333, where the delay is changed when the counter rolls over).

When the preload is disabled (PREEN bit reset), the new compare value is taken into account immediately, even if it is modified after the capture event has occurred, as per the example below:

1. At t1, DELCMP2 = 1.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, a capture event occurs capturing the value CPTR1 = 0x20. => comparison enabled, compare value = 0x60
4. At t4, CMP2_act = 0x100 (before the counter reached value CPTR1 + 0x40) => comparison still enabled, new compare value = 0x120
5. At t5, the counter reaches the period value => comparison disabled, cmp2_act = 0x100

Similarly, if the CMP1(CMP3) value changes while DELCMPx = 10 or 11, and preload is disabled:

1. At t1, DELCMP2 = 2.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, CMP3 event occurs - CMP3_act = 0x50 before capture 1 event occurs => comparison enabled, compare value = 0x90
4. At t4, CMP3_act = 0x100 (before the counter reached value 0x90) => comparison still enabled, Compare 2 event will occur at = 0x140
**Push-pull mode**

This mode primarily aims at driving converters using push-pull topologies. It also needs to be enabled when the delayed idle protection is required, typically for resonant converters (refer to Section 39.3.9: Delayed Protection).

The push-pull mode is enabled by setting PSHPLL bit in the HRTIM_TIMxCR register.

It applies the signals generated by the crossbar to output 1 and output 2 alternatively, on the period basis, maintaining the other output to its inactive state. The redirection rate (push-pull frequency) is defined by the timer’s period event, as shown on Figure 334. The push-pull period is twice the timer counting period.

**Figure 334. Push-pull mode block diagram**

![Push-pull mode block diagram](image)

The push-pull mode is only available when the timer operates in continuous mode: the counter must not be reset once it has been enabled (TxCEN bit set). It is necessary to disable the timer to stop a push-pull operation and to reset the counter before re-enabling it. The signal shape is defined using HRTIM_SETxyR and HRTIM_RSTxyR for both outputs. It is necessary to have HRTIM_SETx1R = HRTIM_SETx2R and HRTIM_RSTx1R = HRTIM_RSTx2R to have both outputs with identical waveforms and to achieve a balanced operation. Still, it is possible to have different programming on both outputs for other uses.

**Note:** The push-pull operation cannot be used when a deadtime is enabled (mutually exclusive functions).

The CPPSAT status bit in HRTIM_TIMxISR indicates on which output the signal is currently active. CPPSTAT is reset when the push-pull mode is disabled.

In the example given on Figure 335, the timer internal waveform is defined as follows:

- Output set on period event
- Output reset on Compare 1 match event
Deadtime

A deadtime insertion unit allows to generate a couple of complementary signals from a single reference waveform, with programmable delays between active state transitions. This is commonly used for topologies using half-bridges or full bridges. It simplifies the software: only 1 waveform is programmed and controlled to drive two outputs.

The Dead time insertion is enabled by setting DTEN bit in HRTIM_OUTxR register. The complementary signals are built based on the reference waveform defined for output 1, using HRTIM_SETx1R and HRTIM_RSTx1R registers: HRTIM_SETx2R and HRTIM_RSTx2R registers are not significant when DTEN bit is set.

Note: The deadtime cannot be used simultaneously with the push-pull mode.

Two deadtimes can be defined in relationship with the rising edge and the falling edge of the reference waveform, as in Figure 336.
Negative deadtime values can be defined when some control overlap is required. This is done using the deadtime sign bits (SDTFx and SDTRx bits in HRTIM_DTxR register).

*Figure 337* shows complementary signal waveforms depending on respective signs.

The deadtime values are defined with DTFx[8:0] and DTRx[8:0] bitfields and based on a specific clock prescaled according to DTPRSC[2:0] bits, as follows:

\[ t_{DTX} = \pm x \times t_{DTG} \]

where \( x \) is either R or F and \( t_{DTG} = (2^{\text{DTPRSC}[2:0]}) \times t_{HRTIM} \).

*Table 328* gives the resolution and maximum absolute values depending on the prescaler value.

</table>

1. DTPRSC[2:0] values 000, 001, 010 are reserved.
**Figure 338** to **Figure 341** present how the deadtime generator behaves for reference waveforms with pulsewidth below the deadtime values, for all deadtime configurations.

**Figure 338.** Complementary outputs for low pulse width (SDTRx = SDTFx = 0)

**Figure 339.** Complementary outputs for low pulse width (SDTRx = SDTFx = 1)

**Figure 340.** Complementary outputs for low pulse width (SDTRx = 0, SDTFx = 1)
For safety purposes, it is possible to prevent any spurious write into the deadtime registers by locking the sign and/or the value of the deadtime using DTFLKx, DTRLKx, DTFSLKx and DTRSLKx. Once these bits are set, the related bits and bitfields are becoming read only until the next system reset.

**Caution:** DTEN bit must not be changed in the following cases:
- When the timer is enabled (TxEN bit set)
- When the timer outputs are set/reset by another timer (while TxEN is reset)

Otherwise, an unpredictable behavior would result.

It is therefore necessary to disable the timer (TxCEN bit reset) and have the corresponding outputs disabled.

For the particular case where DTEN must be set while the burst mode is enabled with a deadtime upon entry (BME = 1, DIDL = 1, IDLEM = 1), it is necessary to force the two outputs in their IDLES state by software commands (SST, RST bits) before setting DTEN bit. This is to avoid any side effect resulting from a burst mode entry that would happen immediately before a deadtime enable.
39.3.5 Master timer

The main purpose of the master timer is to provide common signals to the 5 timing units, either for synchronization purpose or to set/reset outputs. It does not have direct control over any outputs, but still can be used indirectly by the set/reset crossbars.

*Figure 342* provides an overview of the master timer.

![Figure 342. Master timer overview](MS32276V1)

The master timer is based on the very same architecture as the timing units, with the following differences:
- It does not have outputs associated with, nor output related control
- It does not have its own crossbar unit, nor push-pull or deadtime mode
- It can only be reset by the external synchronization circuitry
- It does not have a capture unit, nor the auto-delayed mode
- It does not include external event blanking and windowing circuitry
- It has a limited set of interrupt / DMA requests: Compare 1..4, repetition, register update and external synchronization event.

The master timer control register includes all the timer enable bits, for the master and Timer A..E timing units. This allows to have all timer synchronously started with a single write access.

It also handles the external synchronization for the whole HRTIM timer (see *Section 39.3.17: Synchronizing the HRTIM with other timers or HRTIM instances*), with both MCU internal and external (inputs/outputs) resources.
Master timer control registers are mapped with the same offset as the timing units’ registers.

### 39.3.6 Set/reset events priorities and narrow pulses management

This section describes how the output waveform is generated when several set and/or reset requests are occurring within 3 consecutive \( t_{\text{HRTIM}} \) periods.

An arbitration is performed during each \( t_{\text{HRTIM}} \) period, in 2 steps:

1. For each active event, the desired output transition is determined (set, reset or toggle).
2. A predefined arbitration is performed among the active events (from highest to lowest priority): \( \text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \rightarrow \text{PER} \), see *Concurrent set request / Concurrent reset requests*.

When set and reset requests from two different sources are simultaneous, the reset action has the highest priority.

*Concurrent set request / Concurrent reset requests*

When multiple sources are selected for a set event, an arbitration is performed when the set requests occur within the same \( f_{\text{HRTIM}} \) clock period.

In case of multiple requests from adjacent timers (TIMEVNT1..9), the request which occurs first is taken into account. The arbitration is done in 2 steps, depending on the source (from the highest to the lowest priority): \( \text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \).

If multiple requests from the master timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and a single request will be taken into account (from the highest to the lowest priority):

\[
\text{MSTCMP4} \rightarrow \text{MSTCMP3} \rightarrow \text{MSTCMP2} \rightarrow \text{MSTCMP1} \rightarrow \text{MSTCMPER}
\]

When multiple requests internal to the timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and the requests are taken with the following priority, whatever the effective timing (from highest to lowest):

\[
\text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \rightarrow \text{PER}
\]

*Note:* Practically, this is of a primary importance only when using auto-delayed Compare 2 and Compare 4 simultaneously (i.e. when the effective set/reset cannot be determined a priori because it is related to an external event). In this case, the highest priority signal must be affected to the CMP4 event.

Last, the highest priority is given to non timing-related: EXTEVNT1..10, RESYNC (coming from SYNC event if SYNCRSTx or SYNCSTRTx is set or from a software reset), update and software set (SST).

As a summary, in case of simultaneous events, the effective set (reset) event will be arbitrated between:

- Any TIMEVNT1..9 event
- A single source from the master (as per the fixed arbitration given above)
- A single source from the timer
- The “non timing-related events”.

The same arbitration principle applies for concurrent reset requests. In this case, the reset request has the highest priority.
A set or reset event occurring within the prescaler clock cycle is delayed to the next active edge of the prescaled clock (as for a counter reset), even if the arbitration is still performed every $t_{\text{HRTIM}}$ cycle.

If a reset event is followed by a set event within the same prescaler clock cycle, the latest event will be considered.

### 39.3.7 External events global conditioning

The HRTIM timer can handle events not generated within the timer, referred to as “external event”. These external events come from multiple sources, either on-chip or off-chip:

- built-in comparators,
- digital input pins (typically connected to off-chip comparators and zero-crossing detectors),
- on-chip events for other peripheral (ADC’s analog watchdogs and general purpose timer trigger outputs).

The external events conditioning circuitry allows to select the signal source for a given channel (with a 4:1 multiplexer) and to convert it into an information that can be processed by the crossbar unit (for instance, to have an output reset triggered by a falling edge detection on an external event channel).

Up to 10 external event channels can be conditioned and are available simultaneously for any of the 5 timers. This conditioning is common to all timers, since this is usually dictated by external components (such as a zero-crossing detector) and environmental conditions (typically the filter set-up will be related to the applications noise level and signature). *Figure 343* presents an overview of the conditioning logic for a single channel.
The 10 external events are initialized using the HRTIM_EECR1 and HRTIM EECR2 registers:
- to select up to 4 sources with the EExSRC[1:0] bits,
- to select the sensitivity with EExSNS[1:0] bits, to be either level-sensitive or edge-sensitive (rising, falling or both),
- to select the polarity, in case of a level sensitivity, with EExPOL bit,
- to have a low latency mode, with EExFAST bits (see *Latency to external events*), for external events 1 to 5.

*Note:* The external events used as triggers for reset, capture, burst mode, ADC triggers and delayed protection are edge-sensitive even if EESNS bit is reset (level-sensitive selection): if POL = 0 the trigger is active on external event rising edge, while if POL = 1 the trigger is active on external event falling edge.

The external events are discarded as long as the counters are disabled (TxCEN bit reset) to prevent any output state change and counter reset, except if they are used as ADC triggers.

Additionally, it is possible to enable digital noise filters, for external events 6 to 10, using EExF[3:0] bits in the HRTIM_EECR3 register.

A digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has
reached the value \( N \), the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches \( N \), the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected).

The sampling clock is either the \( f_{\text{HRTIM}} \) clock or a specific prescaled clock \( f_{\text{EEVS}} \) derived from \( f_{\text{HRTIM}} \), defined with \( \text{EEVSD}[1:0] \) bits in HRTIM_EECR3 register.

Table 329 summarizes the available sources and features associated with each of the 10 external events channels.

1. OPAMP1_VOUT can be used as High-resolution timer internal event source. In this case, OPAMP1_VOUT (PC4) pin must be configured in input mode. The data from the GPIO pin is redirected to the HRTIM external events through the pin Schmitt trigger. If OPAMP1 is disabled, PC4 pin, configured in input mode, can be used as HRTIM external events.

### Latency to external events

The external event conditioning gives the possibility to adjust the external event processing time (and associated latency) depending on performance expectations:

- A regular operating mode, in which the external event is resampled with the clock before acting on the output crossbar. This adds some latency but gives access to all crossbar functionalities. It enables the generation of an externally triggered high-resolution pulse.

- A fast operating mode, in which the latency between the external event and the action on the output is minimized. This mode is convenient for ultra-fast over-current protections, for instance.

EEExFAST bits in the HRTIM_EECR1 register allow to define the operating for channels 1 to 5. This influences the latency and the jitter present on the output pulses, as summarized in the table below.
The EExFAST mode is only available with level-sensitive programming (EExSNS[1:0] = 00); the edge-sensitivity cannot be programmed.

It is possible to apply event filtering to external events (both blanking and windowing with EExFLTR[3:0] != 0000, see Section 39.3.8). In this case, EExLTCHx bit must be reset: the postponed mode is not supported, neither the windowing timeout feature.

### Note:

*The external event configuration (source and polarity) must not be modified once the related EExFAST bit is set.*

A fast external event cannot be used to toggle an output: if must be enabled either in HRTIM_SETxyR or HRTIM_RSTxyR registers, not in both.

When a set and a reset event - from 2 independent fast external events - occur simultaneously, the reset has the highest priority in the crossbar and the output becomes inactive.

When EExFAST bit is set, the output cannot be changed during the 11 f_HRTIM clock periods following the external event.

*Figure 344 and Figure 345* give practical examples of the reaction time to external events, for output set/reset and counter reset.
Figure 344. Latency to external events falling edge (counter reset and output set)

Figure 345. Latency to external events (output reset on external event)
39.3.8 External event filtering in timing units

Once conditioned, the 10 external events are available for all timing units. They can be used directly and are active as soon as the timing unit counter is enabled (TxCEN bit set).

They can also be filtered to have an action limited in time, usually related to the counting period. Two operations can be performed:
- blanking, to mask external events during a defined time period,
- windowing, to enable external events only during a defined time period.

These modes are enabled using HRTIM_EExFLTR[3:0] bits in the HRTIM_EEFxR1 and HRTIM_EEFxR2 registers. Each of the 5 TimerA..E timing units has its own programmable filter settings for the 10 external events.

Blanking mode

In event blanking mode (see Figure 346), the external event is ignored if it happens during a given blanking period. This is convenient, for instance, to avoid a current limit to trip on switching noise at the beginning of a PWM period. This mode is active for EExFLTR[3:0] bitfield values ranging from 0001 to 1100.

![Figure 346. Event blanking mode](image)

In event postpone mode, the external event is not taken into account immediately but is memorized (latched) and generated as soon as the blanking period is completed, as shown on Figure 347. This mode is enabled by setting EExLTCH bit in HRTIM_EEFxR1 and HRTIM_EEFxR2 registers.

![Figure 347. Event postpone mode](image)
The blanking signal comes from several sources:

- the timer itself: the blanking lasts from the counter reset to the compare match
  \( (\text{EExFLTR}[3:0] = 0001 \text{ to } 0100 \text{ for Compare 1 to Compare 4}) \)
- from other timing units \( (\text{EExFLTR}[3:0] = 0101 \text{ to } 1100) \): the blanking lasts from the
  selected timing unit counter reset to one of its compare match, or can be fully
  programmed as a waveform on Tx2 output. In this case, events are masked as long as
  the Tx2 signal is inactive (it is not necessary to have the output enabled, the signal
  is taken prior to the output stage).

The \text{EExFLTR}[3:0] configurations from 0101 to 1100 are referred to as \text{TIMFLTR1} to
\text{TIMFLTR8} in the bit description, and differ from one timing unit to the other. \textit{Table 331} gives
the 8 available options per timer: \text{CMPx} refers to blanking from counter reset to compare
match, \text{Tx2} refers to the timing unit \text{TIMx} output 2 waveform defined with \text{HRTIM_SETx2}
and \text{HRTIM_RSTx2} registers. For instance, Timer B (\text{TIMFLTR6}) is Timer C output 2
waveform.

\textit{Figure 348} and \textit{Figure 349} give an example of external event blanking for all edge and level
sensitivities, in regular and postponed modes.
Figure 348. External trigger blanking with edge-sensitive trigger

Figure 349. External trigger blanking, level sensitive triggering

* A high level denotes a continuous event generation after blanking
Windowing mode

In event windowing mode, the event is taken into account only if it occurs within a given time window, otherwise it is ignored. This mode is active for EEFLTR[3:0] ranging from 1101 to 1111.

**Figure 350. Event windowing mode**

EExLTCH bit in EEFxR1 and EEFxR2 registers allows to latch the signal, if set to 1: in this case, an event is accepted if it occurs during the window but is delayed at the end of it.

- If EExLTCH bit is reset and the signal occurs during the window, it is passed through directly.
- If EExLTCH bit is reset and no signal occurs, a timeout event is generated at the end of the window.

A use case of the windowing mode is to filter synchronization signals. The timeout generation allows to force a default synchronization event, when the expected synchronization event is lacking (for instance during a converter start-up).

There are 3 sources for each external event windowing, coded as follows:
- 1101 and 1110: the windowing lasts from the counter reset to the compare match (respectively Compare 2 and Compare 3)
- 1111: the windowing is related to another timing unit and lasts from its counter reset to its Compare 2 match. The source is described as TIMWIN in the bit description and is given in Table 332. As an example, the external events in timer B can be filtered by a window starting from timer A counter reset to timer A Compare 2.

**Table 332. Windowing signals mapping per timer (EEFLTR[3:0] = 1111)**

* A high level denotes continuous event generation after windowing.
### 39.3.9 Delayed Protection

The HRTIM features specific protection schemes, typically for resonant converters when it is necessary to shut down the PWM outputs in a delayed manner, either once the active pulse is completed or once a push-pull period is completed. These features are enabled with DLYPRTEN bit in the HRTIM_OUTxR register, and are using specific external event channels.

#### Delayed Idle

In this mode, the active pulse is completed before the protection is activated. The selected external event causes the output to enter in idle mode at the end of the active pulse (defined by an output reset event in HRTIM_RSTx1R or HRTIM_RSTx2R).

Once the protection is triggered, the idle mode is permanently maintained but the counter continues to run, until the output is re-enabled. Tx1OEN and Tx2OEN bits are not affected by the delayed idle entry. To exit from delayed idle and resume operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1. The output state will change on the first transition to an active state following the output enable command.

*Note:* The delayed idle mode cannot be exited immediately after having been entered, before the active pulse is completed: it is mandatory to make sure that the outputs are in idle state before resuming the run mode. This can be done by waiting up to the next period, for instance, or by polling the O1CPY and/or O2CPY status bits in the TIMxISR register.

The delayed idle mode can be applied to a single output (DLYPRT[2:0] = x00 or x01) or to both outputs (DLYPRT[2:0] = x10).

An interrupt or a DMA request can be generated in response to a Delayed Idle mode entry. The DLYPRT flag in HRTIM_TIMxISR is set as soon as the external event arrives, independently from the end of the active pulse on output.

When the Delayed Idle mode is triggered, the output states can be determined using O1STAT and O2STAT in HRTIM_TIMxISR. Both status bits are updated even if the delayed idle is applied to a single output. When the push-pull mode is enabled, the IPPSTAT flag in HRTIM_TIMxISR indicates during which period the delayed protection request occurred.

This mode is available whatever the timer operating mode (regular, push-pull, deadtime). It is available with 2 external events only:

- hrtim_evt6 and hrtim_evt7 for Timer A, B and C
- hrtim_evt8 and hrtim_evt9 for Timer D and E

The delayed protection mode can be triggered only when the counter is enabled (TxCEN bit set). It remains active even if the TxEN bit is reset, until the TxyOEN bits are set.
The delayed idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the delayed idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode will be resumed normally and the output will be maintained in the idle state until the burst mode exits. Figure 354 gives an overview of these different scenarios.
The same priorities are applied when the delayed burst mode entry is enabled (DIDL bit set), as shown on Figure 355 below.
**Figure 355. Burst mode and delayed protection priorities (DIDL = 1)**

**Balanced Idle**

Only available in push-pull mode, it allows to have balanced pulsewidth on the two outputs when one of the active pulse is shortened due to a protection. The pulsewidth, which was terminated earlier than programmed, is copied on the alternate output and the two outputs are then put in idle state, until the normal operation is resumed by software. This mode is enabled by writing x11 in DLYPRT[2:0] bitfield in HRTIM_OUTxR.

This mode is available with 2 external events only:

- hrtim_evt6 and hrtim_evt7 for Timer A, B and C
- hrtim_evt8 and hrtim_evt9 for Timer D and E
When the balanced Idle mode is enabled, the selected external event triggers a capture of the counter value into the Compare 4 active register (this value is not user-accessible). The push-pull is maintained for one additional period so that the shorten pulse can be repeated: a new output reset event is generated while the regular output set event is maintained.
The Idle mode is then entered and the output takes the level defined by IDLESx bits in the HRTIM_OUTxR register. The balanced idle mode entry is indicated by the DLYPRT flag, while the IPPSTAT flag indicates during which period the external event occurred, to determine the sequence of shorten pulses (HRTIM_CHA1 then HRTIM_CHA2 or vice versa).

The timer operation is not interrupted (the counter continues to run).

To enable the balanced idle mode, it is necessary to have the following initialization:
- timer operating in continuous mode (CONT = 1)
- Push-pull mode enabled
- HRTIM_CMP4xR must be set to 0 and the content transferred into the active register (for instance by forcing a software update)
- DELCMP4[1:0] bit field must be set to 00 (auto-delayed mode disabled)
- DLYPRT[2:0] = x11 (delayed protection enable)

Note: The HRTIM_CMP4xR register must not be written during a balanced idle operation. The CMP4 event is reserved and cannot be used for another purpose.

In balanced idle mode, it is recommended to avoid multiple external events or software-based reset events causing an output reset. If such an event arrives before a balanced idle request within the same period, it will cause the output pulses to be unbalanced (1st pulse length defined by the external event or software reset, while the 2nd pulse is defined by the balanced idle mode entry).

The minimum pulsewidth that can be handled in balanced idle mode is 4 \( f_{\text{HRTIM}} \) clock periods.

If the capture occurs before the counter has reached this minimum value, the current pulse is extended up to 4 \( f_{\text{HRTIM}} \) clock periods before being copied into the secondary output. In any case, the pulsewidths are always balanced.

Tx1OEN and Tx2OEN bits are not affected by the balanced idle entry. To exit from balanced idle and resume the operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1 simultaneously. The output state will change on the first active transition following the output enable.

It is possible to resume operation similarly to the delayed idle entry. For instance, if the external event arrives while output 1 is active (delayed idle effective after output 2 pulse), the re-start sequence can be initiated for output 1 first. To do so, it is necessary to poll CPPSTAT bit in the HRTIM_TIMxISR register. Using the above example (IPPSTAT flag equal to 0), the operation will be resumed when CPPSTAT bit is 0.

In order to have a specific re-start sequence, it is possible to poll the CPPSTAT to know which output will be active first. This allows, for instance, to re-start with the same sequence as the idle entry sequence: if EEV arrives during output 1 active, the re-start sequence will be initiated when the output 1 is active (CPPSTAT = 0).

Note: The balanced idle mode must not be disabled while a pulse balancing sequence is ongoing. It is necessary to wait until the CMP4 flag is set, thus indicating that the sequence is completed, to reset the DLYPRTEN bit.

The balanced idle protection mode can be triggered only when the counter is enabled (TxCNT bit set). It remains active even if the TxCNT bit is reset, until TxYN bits are set.
Balanced idle can be used together with the burst mode under the following conditions:

- TxBM bit must be reset (counter clock maintained during the burst, see Section 39.3.13),
- No balanced idle protection must be triggered while the outputs are in a burst idle state.

The balanced idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the balanced idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode will be resumed normally.

Note: Although the output state is frozen in idle mode, a number of events are still generated on the auxiliary outputs (see Section 39.3.16) during the idle period following the delayed protection:
- Output set/reset interrupt or DMA requests
- External event filtering based on output signal
- Capture events triggered by set/reset

39.3.10 Register preload and update management

Most of HRTIM registers are buffered and can be preloaded if needed. Typically, this allows to prevent the waveforms from being altered by a register update not synchronized with the active events (set/reset).

When the preload mode is enabled, accessed registers are shadow registers. Their content is transferred into the active register after an update request, either software or synchronized with an event.

By default, PREEN bits in HRTIM_MCR and HRTIM_TIMxCR registers are reset and the registers are not preloaded: any write directly updates the active registers. If PREEN bit is reset while the timer is running and preload was enabled, the content of the preload registers is directly transferred into the active registers.

Each timing unit and the master timer have their own PREEN bit. If PRREN is set, the preload registers are enabled and transferred to the active register only upon an update event.

There are two options to initialize the timer when the preload feature is needed:
- Enable PREEN bit at the very end of the timer initialization to have the preload registers transferred into the active registers before the timer is enabled (by setting MCEN and TxCEN bits).
- enable PREEN bit at any time during the initialization and force a software update immediately before starting.

Table 333 lists the registers which can be preloaded, together with a summary of available update events.
The master timer has 4 update options:

1. Software: writing 1 into MSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is cancelled.
2. Update done when the master counter rolls over and the master repetition counter is equal to 0. This is enabled when MREPU bit is set in HRTIM_MCR.
3. Update done once Burst DMA is completed (see Section 39.3.21 for details). This is enabled when BRSTDMA[1:0] = 01 in HRTIM_MCR. It is possible to have both MREPU=1 and BRSTDMA=01. 
   
   Note: The update can take place immediately after the end of the burst sequence if SWU bit is set (i.e. forced update mode). If SWU bit is reset, the update will be done on the next update event following the end of the burst sequence.
4. Update done when the master counter rolls over following a Burst DMA completion. This is enabled when BRSTDMA[1:0] = 10 in HRTIM_MCR.

An interrupt or a DMA request can be generated by the master update event.

</tr>
</tbody>
</table>
Each timer (TIMA..E) can also have the update done as follows:

- By software: writing 1 into TxSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is canceled.
- Update done when the counter rolls over and the repetition counter is equal to 0. This is enabled when TxREPU bit is set in HRTIM_TIMxCR.
- Update done when the counter is reset or rolls over in continuous mode. This is enabled when TxRSTU bit is set in HRTIM_TIMxCR. This is used for a timer operating in single-shot mode, for instance.
- Update done once a Burst DMA is completed. This is enabled when UPDGAT[3:0] = 0001 in HRTIM_TIMxCR.
- Update done on the update event following a Burst DMA completion (the event can be enabled with TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0010 in HRTIM_TIMxCR.
- Update done when receiving a request on the update enable input 1..3. This is enabled when UPDGAT[3:0] = 0011, 0100, 0101 in HRTIM_TIMxCR.
- Update done on the update event following a request on the update enable input 1..3 (the event can be enabled with TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0110, 0111, 1000 in HRTIM_TIMxCR.
- Update done synchronously with any other timer or master update (for instance TIMA can be updated simultaneously with TIMB). This is used for converters requiring several timers, and is enabled by setting bits MSTU and TxU in HRTIM_TIMxCR register.

The update enable inputs 1..3 allow to have an update event synchronized with on-chip events coming from the general-purpose timers. These inputs are rising-edge sensitive. The update events are synchronized to the prescaler clock when CKPSC[2:0] > 5.

An interrupt or a DMA request can be generated by the Timx update event.

MUDIS and TxUDIS bits in the HRTIM_CR1 register allow to temporarily disable the transfer from preload to active registers, whatever the selected update event. This allows to modify several registers in multiple timers. The regular update event takes place once these bits are reset.

MUDIS and TxUDIS bits are all grouped in the same register. This allows the update of multiple timers (not necessarily synchronized) to be disabled and resumed simultaneously.
The following example is a practical use case. A first power converter is controlled with the master, TIMB and TIMC. TIMB and TIMC must be updated simultaneously with the master timer repetition event. A second converter works in parallel with TIMA, TIMD and TIME, and TIMD, TIME must be updated with TIMA repetition event.

**First converter**

In HRTIM_MCR, MREPU bit is set: the update will occur at the end of the master timer counter repetition period. In HRTIM_TIMBCR and HRTIM_TIMCCR, MSTU bits are set to have TIMB and TIMC timers updated simultaneously with the master timer.

When the power converter set-point has to be adjusted by software, MUDIS, TBUDIS and TCUDIS bits of the HRTIM_CR register must be set prior to write accessing registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, MUDIS, TBUDIS and TCUDIS bits must be reset. The transfer from preload to active registers will be done as soon as the master repetition event occurs.

**Second converter**

In HRTIM_TIMACR, TAREPU bit is set: the update will occur at the end of the Timer A counter repetition period. In HRTIM_TIMDCR and HRTIM_TIMECR, TAU bits are set to have TIMD and TIME timers updated simultaneously with Timer A.

When the power converter set-point has to be adjusted by software, TAUDIS, TDUDIS and TEUDIS bits of the HRTIM_CR register must be set prior to write accessing the registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, TAUDIS, TDUDIS and TEUDIS bits can be reset: the transfer from preload to active registers will be done as soon as the Timer A repetition event occurs.

### 39.3.11 Events propagation within or across multiple timers

The HRTIM offers many possibilities for cascading events or sharing them across multiple timing units, including the master timer, to get full benefits from its modular architecture. These are key features for converters requiring multiple synchronized outputs.

This section summarizes the various options and specifies whether and how an event is propagated within the HRTIM.

**TIMx update triggered by the Master timer update**

The sources listed in Table 335 are generating a master timer update. The table indicates if the source event can be used to trigger a simultaneous update in any of TIMx timing units.

Operating condition: MSTU bit is set in HRTIM_TIMxCR register.
The sources listed in Table 336 are generating a TIMy update. The table indicates if the given event can be used to trigger a simultaneous update in another or multiple TIMx timers.

Operating condition: TyU bit set in HRTIM_TIMxCR register (source = TIMy and destination = TIMx).

39.3.12 Output management

Each timing unit controls a pair of outputs. The outputs have three operating states:

- **RUN**: this is the main operating mode, where the output can take the active or inactive level as programmed in the crossbar unit.
- **IDLE**: this state is the default operating state after an HRTIM reset, when the outputs are disabled by software or during a burst mode operation (where outputs are temporary disabled during a normal operating mode; refer to Section 39.3.13 for more details). It is either permanently active or inactive.
- **FAULT**: this is the safety state, entered in case of a shut-down request on FAULTx inputs. It can be permanently active, inactive or Hi-Z.

The output status is indicated by TxyOEN bit in HRTIM_OENR register and TxyODS bit in HRTIM_ODSR register, as in Table 339.

### Table 339. Output state programming, x= A..E, y = 1 or 2

<table>
<thead>
<tr>
<th>TxyOEN (control/status)</th>
<th>TxyODS (status)</th>
<th>Output operating state</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>RUN</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>IDLE</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>FAULT</td>
</tr>
</tbody>
</table>

TxyOEN bit is both a control and a status bit: it must be set by software to have the output in RUN mode. It is cleared by hardware when the output goes back in IDLE or FAULT mode. When TxyOEN bit is cleared, TxyODS bit indicates whether the output is in the IDLE or FAULT state. A third bit in the HRTIM_ODISR register allows to disable the output by software.
Figure 357. Output management overview

Figure 358 summarizes the bit values for the three states and how the transitions are triggered. Faults can be triggered by any external or internal fault source, as listed in Section 39.3.15, while the Idle state can be entered when the burst mode or delayed protections are active.

Figure 358. HRTIM output states and transitions

The FAULT and IDLE levels are defined as active or inactive. Active (or inactive) refers to the level on the timer output that causes a power switch to be closed (or opened for an inactive state).

The IDLE state has the highest priority: the transition FAULT → IDLE is possible even if the FAULT condition is still valid, triggered by ODIS bit set.

The FAULT state has priority over the RUN state: if TxyOEN bit is set simultaneously with a Fault event, the FAULT state will be entered. The condition is given on the transition IDLE →
FAULT, as in Figure 358: fault protection needs to be enabled (FAULTx[1:0] bits = 01, 10, 11) and the Txy OEN bit set with a fault active (or during a breakpoint if DBG_HRTIM_STOP = 1).

The output polarity is programmed using POLx bits in HRTIM_OUTxR. When POLx = 0, the polarity is positive (output active high), while it is active low in case of a negative polarity (POLx = 1). Practically, the polarity is defined depending on the power switch to be driven (PMOS vs. NMOS) or on a gate driver polarity.

The output level in the FAULT state is configured using FAULTx[1:0] bits in HRTIM_OUTxR, for each output, as follows:
- 00: output never enters the fault state and stays in RUN or IDLE state
- 01: output at active level when in FAULT
- 10: output at inactive level when in FAULT
- 11: output is tri-stated when in FAULT. The safe state must be forced externally with pull-up or pull-down resistors, for instance.

Note: FAULTx[1:0] bits must not be changed as long as the outputs are in FAULT state.

The level of the output in IDLE state is configured using IDLESx bit in HRTIM_OUTxR, as follows:
- 0: output at inactive level when in IDLE
- 1: output at active level when in IDLE

When TxyOEN bit is set to enter the RUN state, the output is immediately connected to the crossbar output. If the timer clock is stopped, the level will either be inactive (after an HRTIM reset) or correspond to the RUN level (when the timer was stopped and the output disabled).

During the HRTIM initialization, the output level can be prepositioned prior to have it in RUN mode, using the software forced output set and reset in the HRTIM_SETx1R and HRTIM_RSTx1R registers.

39.3.13 Burst mode controller

The burst mode controller allows to have the outputs alternatively in IDLE and RUN state, by hardware, so as to skip some switching periods with a programmable periodicity and duty cycle.

Burst mode operation is of common use in power converters when operating under light loads. It can significantly increase the efficiency of the converter by reducing the number of transitions on the outputs and the associated switching losses.

When operating in burst mode, one or a few pulses are outputs followed by an idle period equal to several counting periods, typically, where no output pulses are produced, as shown in the example on Figure 359.
The burst mode controller consists of:
- A counter that can be clocked by various sources, either within or outside the HRTIM (typically the end of a PWM period).
- A compare register to define the number of idle periods: HRTIM_BMCMP.
- A period register to define the burst repetition rate (corresponding to the sum of the idle and run periods): HRTIM_BMPER.

The burst mode controller is able to take over the control of any of the 10 PWM outputs. The state of each output during a burst mode operation is programmed using IDLESx and IDLEMx bits in the HRTIM_OUTxR register, as in Table 340.

### Table 340. Timer output programming for burst mode

<table>
<thead>
<tr>
<th>IDLEMx</th>
<th>IDLESx</th>
<th>Output state during burst mode</th>

<td>0</td>
<td>Output inactive during the burst</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Output active during the burst</td>
</tr>
</tbody>
</table>

**Note:** *IDLEMx bit must not be changed while the burst mode is active.*

The burst mode controller only acts on the output stage. A number of events are still generated during the idle period:
- Output set/reset interrupt or DMA requests
- External event filtering based on Tx2 output signal
- Capture events triggered by output set/reset

During the burst mode, neither start not reset events are generated on the HRTIM_SCOUT output, even if TxBM bit is set.
High-resolution timer (HRTIM)  

Operating mode

It is necessary to have the counter enabled (TxCEN bit set) before using the burst mode on a given timing unit. The burst mode is enabled with BME bit in the HRTIM_BMCR register.

It can operate in continuous or single-shot mode, using BMOM bit in the HRTIM_BMCR register. The continuous mode is enabled when BMOM = 1. The Burst operation is maintained until BMSTAT bit in HRTIM_BMCR is reset to terminate it.

In single-shot mode (BMOM = 0), the idle sequence is executed once, following the burst mode trigger, and the normal timer operation is resumed immediately after.

The duration of the idle and run periods is defined with a burst mode counter and 2 registers. The HRTIM_BMCMPR register defines the number of counts during which the selected timer(s) are in an idle state (idle period). HRTIM_BMPER defines the overall burst mode period (sum of the idle and run periods). Once the initial burst mode trigger has occurred, the idle period length is HRTIM_BMCMPR+1, the overall burst period is HRTIM_BMPER+1.

Note: The burst mode period must not be less than or equal to the deadtime duration defined with DTRx[8:0] and DTFx[8:0] bitfields.

The counters of the timing units and the master timer can be stopped and reset during the burst mode operation. HRTIM_BMCR holds 6 control bits for this purpose: MTBM (master) and TABM..TEBM for Timer A..E.

When MTBM or TxBM bit is reset, the counter clock is maintained. This allows to keep a phase relationship with other timers in multiphase systems, for instance.

When MTBM or TxBM bit is set, the corresponding counter is stopped and maintained in reset state during the burst idle period. This allows to have the timer restarting a full period when exiting from idle. If SYNCSRC[1:0] = 00 or 10 (synchronization output on the master start or timer A start), a pulse is sent on the HRTIM_SCOUT output when exiting the burst mode.

Note: TxBM bit must not be set when the balanced idle mode is active (DLYPRT[1:0] = 0x11).

Burst mode clock

The burst mode controller counter can be clocked by several sources, selected with BMCLK[3:0] bits in the HRTIM_BMCR register:

- BMCLK[3:0] = 0000 to 0101: Master timer and TIMA..E reset/roll-over events. This allows to have burst mode idle and run periods aligned with the timing unit counting period (both in free-running and counter reset mode).
- BMCLK[3:0] = 0110 to 1001: The clocking is provided by the general purpose timers, as in Table 341. In this case, the burst mode idle and run periods are not necessarily aligned with timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with modified duty cycle for instance.
- BMCLK[3:0] = 1010: The \( f_{HRTIM} \) clock prescaled by a factor defined with BMPRSC[3:0] bits in HRTIM_BMCR register. In this case, the burst mode idle and run periods are not necessarily aligned with the timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with a modified duty cycle, for instance.
The pulsewidth on TIMxx OC output must be at least $N \cdot f_{HRTIM}$ clock cycles long to be detected by the HRTIM burst mode controller.

**Burst mode triggers**

To trigger the burst operation, 32 sources are available and are selected using the HRTIM_BMTRGR register:

- Software trigger (set by software and reset by hardware)
- 6 Master timer events: repetition, reset/roll-over, Compare 1 to 4
- 5 x 4 events from timers A..E: repetition, reset/roll-over, Compare 1 and 2
- hrtim_evt7 (including TIMA event filtering) and hrtim_evt8 (including TIMD event filtering)
- Timer A period following hrtim_evt7 (including TIMA event filtering)
- Timer D period following hrtim_evt8 (including TIMD event filtering)
- On-chip events coming from other general purpose timer (hrtim_bm_trg output:TIM7_TRGO output)

These sources can be combined to have multiple concurrent triggers.

Burst mode is not re-triggerable. In continuous mode, new triggers are ignored until the burst mode is terminated, while in single-shot mode, the triggers are ignored until the current burst completion including run periods (HRTIM_BMPER+1 cycles). This is also valid for software trigger (the software bit is reset by hardware even if it is discarded).

*Figure 360* shows how the burst mode is started in response to an external event, either immediately or on the timer period following the event.

**Table 341. Burst mode clock sources from general purpose timer**

</tr>
</tbody>
</table>

*Figure 360. Burst mode trigger on external event*
For TAAEV7 and TDEEV8 combined triggers (trigger on a Timer period following an external event), the external event detection is always active, regardless of the burst mode programming and the on-going burst operation:

- When the burst mode is enabled (BME=1) or the trigger is enabled (TAAEV7 or TDEEV8 bit set in the BMTRG register) in between the external event and the timer period event, the burst is triggered.

- The single-shot burst mode is re-triggered even if the external event occurs before the burst end (as long as the corresponding period happens after the burst).

Note: TAAEV7 and TDEEV8 triggers are valid only after a period event. If the counter is reset before the period event, the pending hrtim_evt7/8 event is discarded.

Burst mode delayed entry

By default, the outputs are taking their idle level (as per IDLES1 and IDLES2 setting) immediately after the burst mode trigger.

It is also possible to delay the burst mode entry and force the output to an inactive state during a programmable period before the output takes its idle state. This is useful when driving two complementary outputs, one of them having an active idle state, to avoid a deadtime violation as shown on Figure 361. This prevents any risk of shoot through current in half-bridges, but causes a delayed response to the burst mode entry.
The delayed burst entry mode is enabled with DIDLx bit in the HRTIM_OUTxR register (one enable bit per output). It forces a deadtime insertion before the output takes its idle state. Each TIMx output has its own deadtime value:
- DTRx[8:0] on output 1 when DIDL1 = 1
- DTFx[8:0] on output 2 when DIDL2 = 1

DIDLx bits can be set only if one of the outputs has an active idle level during the burst mode (IDLES = 1) and only when positive deadtimes are used (SDTR/SDTF set to 0).

Note: The delayed burst entry mode uses deadtime generator resources. Consequently, when any of the 2 DIDLx bits is set and the corresponding timing unit uses the deadtime insertion (DTEN bit set in HRTIM_OUTxR), it is not possible to use the timerx output 2 as a filter for external events (Tx2 filtering signal is not available).

When durations defined by DTRx[8:0] and DTFx[8:0] are lower than 3 \( f_{\text{HRTIM}} \) clock cycle periods, the limitations related to the narrow pulse management listed in Section 39.3.6 must be applied.

When the burst mode entry arrives during the regular deadtime, it is aborted and a new deadtime is re-started corresponding to the inactive period, as on Figure 362.
Burst mode exit

The burst mode exit is either forced by software (in continuous mode) or once the idle period is elapsed (in single-shot mode). In both cases, the counter is re-started immediately (if it was hold in a reset state with MTBM or TxBM bit = 1), but the effective output state transition from the idle to active mode only happens after the programmed set/reset event.

A burst period interrupt is generated in single-shot and continuous modes when BMPERIE enable bit is set in the HRTIM_IER register. This interrupt can be used to synchronize the burst mode exit with a burst period in continuous burst mode.

*Figure 363* shows how a normal operation is resumed when the deadtime is enabled. Although the burst mode exit is immediate, this is only effective on the first set event on any of the complementary outputs.

Two different cases are presented:

1. The burst mode ends while the signal is inactive on the crossbar output waveform. The active state is resumed on Tx1 and Tx2 on the set event for the Tx1 output, and the Tx2 output does not take the complementary level on burst exit.

2. The burst mode ends while the crossbar output waveform is active: the activity is resumed on the set event of Tx2 output, and Tx1 does not take the active level immediately on burst exit.
The behavior described above is slightly different when the push-pull mode is enabled. The push-pull mode forces an output reset at the beginning of the period if the output is inactive, or symmetrically forces an active level if the output was high during the preceding period.

Consequently, an output with an active idle state can be reset at the time the burst mode is exited even if no transition is explicitly programmed. For symmetrical reasons, an output can be set at the time the burst mode is exited even if no transition is explicitly programmed, in case it was active when it entered in idle state.

**Burst mode registers preloading and update**

BMPREN bit (Burst mode Preload Enable) allows to have the burst mode compare and period registers preloaded (HRTIM_BMCMP and HRTIM_BMPER).

When BMPREN is set, the transfer from preload to active register happens:
- when the burst mode is enabled (BME = 1),
- at the end of the burst mode period.

A write into the HRTIM_BMPER period register disables the update temporarily, until the HRTIM_BMCMP compare register is written, to ensure the consistency of the two registers when they are modified.
If the compare register only needs to be changed, a single write is necessary. If the period only needs to be changed, it is also necessary to re-write the compare to have the new values taken into account.

When BMPREN bits is reset, the write access into BMCMPR and BMPER directly updates the active register. In this case, it is necessary to consider when the update is done during the overall burst period, for the 2 cases below:

a) Compare register update

If the new compare value is above the current burst mode counter value, the new compare is taken into account in the current period.

If the new compare value is below the current burst mode counter value, the new compare is taken into account in the next burst period in continuous mode, and ignored in single-shot mode (no compare match will occur and the idle state will last until the end of the idle period).

b) Period register update

If the new period value is above the current burst mode counter value, the change is taken into account in the current period.

Note: If the new period value is below the current burst mode counter value, the new period will not be taken into account, the burst mode counter will overflow (at 0xFFFF) and the change will be effective in the next period. In single-shot mode, the counter will roll over at 0xFFFF and the burst mode will re-start for another period up to the new programmed value.

Burst mode emulation using a compound register

The burst mode controller only controls one or a set of timers for a single converter. When the burst mode is necessary for multiple independent timers, it is possible to emulate a simple burst mode controller using the DMA and the HRTIM_CMP1CxR compound register, which holds aliases of both the repetition and the Compare 1 registers.

This is applicable to a converter which only requires a simple PWM (typically a buck converter), where the duty cycle only needs to be updated. In this case, the CMP1 register is used to reset the output (and define the duty cycle), while it is set on the period event.

In this case, a single 32-bit write access in CMP1CxR is sufficient to define the duty cycle (with the CMP1 value) and the number of periods during which this duty cycle is maintained (with the repetition value). To implement a burst mode, it is then only necessary to transfer by DMA (upon repetition event) two 32-bit data in continuous mode, organized as follows:

\[ \text{CMPC1xR} = \{\text{REP\_Run}; \text{CMP1} = \text{Duty\_Cycle}\}, \{\text{REP\_Idle}; \text{CMP1} = 0\} \]

For instance, the values:

\{0x0003 0000\}: CMP1 = 0 for 3 periods
\{0x0001 0800\}: CMP1 = 0x0800 for 1 period

will provide a burst mode with 2 periods active every 6 PWM periods, as shown on Figure 364.
### 39.3.14 Chopper

A high-frequency carrier can be added on top of the timing unit output signals to drive isolation transformers. This is done in the output stage before the polarity insertion, as shown on Figure 365, using CHP1 and CHP2 bits in the HRTIM_OUTxR register, to enable chopper on outputs 1 and 2, respectively.

### Figure 365. Carrier frequency signal insertion
The chopper parameters can be adjusted using the HRIM_CHPxR register, with the possibility to define a specific pulsewidth at the beginning of the pulse, to be followed by a carrier frequency with programmable frequency and duty cycle, as in Figure 366.

CARFRQ[3:0] bits define the frequency, ranging from 156 MHz to 25 MHz (for $f_{HRTIM} = 400$ MHz) following the formula $F_{CHPFRQ} = f_{HRTIM} / (16 \times (CARFRQ[3:0]+1))$.

The duty cycle can be adjusted by 1/8 step with CARDTY[2:0], from 0/8 up to 7/8 duty cycle. When CARDTY[2:0] = 000 (duty cycle = 0/8), the output waveform only contains the starting pulse following the rising edge of the reference waveform, without any added carrier.

The pulsewidth of the initial pulse is defined using the STRPW[3:0] bitfield as follows: $t_{1STPW} = (STRPW[3:0]+1) \times 16 \times t_{HRTIM}$ and ranges from 40 ns to 0.63 µs (for $f_{HRTIM}$=400 MHz).

The carrier frequency parameters are defined based on the $f_{HRTIM}$ frequency, and are not dependent from the CKPSC[2:0] setting.

In chopper mode, the carrier frequency and the initial pulsewidth are combined with the reference waveform using an AND function. A synchronization is performed at the end of the initial pulse to have a repetitive signal shape.

The chopping signal is stopped at the end of the output waveform active state, without waiting for the current carrier period to be completed. It can thus contain shorter pulses than programmed.

**Figure 366. HRTIM outputs with Chopper mode enabled**

Note: CHP1 and CHP2 bits must be set prior to the output enable done with TxyOEN bits in the HRTIM_OE NR register.

CARFRQ[2:0], CARDTY[2:0] and STRPW[3:0] bitfields cannot be modified while the chopper mode is active (at least one of the two CHPx bits is set).

### 39.3.15 Fault protection

The HRTIMER has a versatile fault protection circuitry to disable the outputs in case of an abnormal operation. Once a fault has been triggered, the outputs take a predefined safe state. This state is maintained until the output is re-enabled by software. In case of a permanent fault request, the output will remain in its fault state, even if the software attempts to re-enable them, until the fault source disappears.

The HRTIM has 5 FAULT input channels; all of them are available and can be combined for each of the 5 timing units, as shown on Figure 367.
Each fault channel is fully configurable using HRTIM_FLTINR1 and HRTIM_FLTINR2 registers before being routed to the timing units. FLTxSRC bit selects the source of the Fault signal, that can be either a digital input or an internal event (built-in comparator output).

*Table 342* summarizes the available sources for each of the 10 faults channels:

<table>
<thead>
<tr>
<th>Fault channel</th>
<th>External Input (FLTxSRC = 0)</th>
<th>On-chip source (FLTxSRC = 1)</th>
</tr>
</thead>

</tr>
</tbody>
</table>

The polarity of the signal can be selected to define the active level, using the FLTxP polarity bit in HRTIM_FLTINRx registers. If FLTxP = 0, the signal is active at low level; if FLTxP = 1, it is active when high.

The fault information can be filtered after the polarity setting. If FLTxF[3:0] bitfield is set to 0000, the signal is not filtered and will act asynchronously, independently from the f_{HRTIM} clock. For all other FLTxF[3:0] bitfield values, the signal is digitally filtered. The digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external
event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected). Figure 368 shows how a spurious fault signal is filtered.

**Figure 368. Fault signal filtering (FLTxF[3:0]= 0010: f\textsubscript{SAMPLING} = f\textsubscript{HRTIM}, N = 4)**

![Diagram showing fault signal filtering](image_url)

The filtering period ranges from 2 cycles of the f\textsubscript{HRTIM} clock up to 8 cycles of the f\textsubscript{FLTS} clock divided by 32. f\textsubscript{FLTS} is defined using FLTSD[1:0] bits in the HRTIM_FLTINR2 register. Table 343 summarizes the sampling rate and the filter length. A jitter of 1 sampling clock period must be subtracted from the filter length to take into account the uncertainty due to the sampling and have the effective filtering.

**Table 343. Sampling rate and filter length vs FLTFxF[3:0] and clock setting**

</tbody>
</table>
System fault input (hrtim_sys_flt)

This fault is provided by the MCU Class B circuitry (see the System configuration controller (SYSCFG) section for details) and corresponds to a system fault coming from:

- the Clock Security System
- the SRAM parity checker
- the Cortex®-M7-lockup signal
- the PVD detector

This input overrides the FAULT inputs and disables all outputs having FAULTy[1:0] = 01, 10, 11.

For each FAULT channel, a write-once FLTxLCK bit in the HRTIM_FLTxR register allows to lock FLTxE, FLTxP, FLTxSRC, FLTxF[3:0] bits (it renders them read-only), for functional safety purpose. If enabled, the fault conditioning set-up is frozen until the next HRTIM or system reset.

Once the fault signal is conditioned as explained above, it is routed to the timing units. For any of them, the 5 fault channels are enabled using bits FLT1EN to FLT5EN in the HRTIM_FLTxR register, and they can be selected simultaneously (the sysfault is automatically enabled as long as the output is protected by the fault mechanism). This allows to have, for instance:

- One fault channel simultaneously disabling several timing units
- Multiple fault channels being ORed to disable a single timing unit

A write-once FLTLCK bit in the HRTIM_FLTxR register allows to lock FLTxEN bits (it renders them read-only) until the next reset, for functional safety purpose. If enabled, the timing unit fault-related set-up is frozen until the next HRTIM or system reset.

For each of the timers, the output state during a fault is defined with FAULT1[1:0] and FAULT2[1:0] bits in the HRTIM_OUTxR register (see Section 39.3.12).

### 39.3.16 Auxiliary outputs

Timer A to E have auxiliary outputs in parallel with the regular outputs going to the output stage. They provide the following internal status, events and signals:

- SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset
- External event filters following a Tx2 output copy (see details in Section 39.3.8)

</tbody>
</table>
The auxiliary outputs are taken either before or after the burst mode controller, depending on the HRTIM operating mode. An overview is given on Figure 369.

By default, the auxiliary outputs are copies of outputs Tx1 and Tx2. The exceptions are:

- The delayed idle and the balanced idle protections, when the deadtime is disabled (DTEN = 0). When the protection is triggered, the auxiliary outputs are maintained and follow the signal coming out of the crossbar. On the contrary, if the deadtime is enabled (DTEN = 1), both main and auxiliary outputs are forced to an inactive level.
- The burst mode (TCEN=1, IDLEMx=1); there are 2 cases:
  a) If DTEN=0 or DIDLx=0, the auxiliary outputs are not affected by the burst mode entry and continue to follow the reference signal coming out of the crossbar (see Figure 370).
  b) If the deadtime is enabled (DTEN=1) together with the delayed burst mode entry (DIDLx=1), the auxiliary outputs have the same behavior as the main outputs. They are forced to the IDLES level after a deadtime duration, then they keep this level during all the burst period. When the burst mode is terminated, the IDLES level is maintained until a transition occurs to the opposite level, similarly to the main output.
The signal on the auxiliary output can be slightly distorted when exiting from the burst mode or when re-enabling the outputs after a delayed protection, if this happens during a deadtime. In this case, the deadtime applied to the auxiliary outputs is extended so that the deadtime on the main outputs is respected. Figure 371 gives some examples.
39.3.17 Synchronizing the HRTIM with other timers or HRTIM instances

The HRTIM provides options for synchronizing multiple HRTIM instances, as a master unit (generating a synchronization signal) or as a slave (waiting for a trigger to be synchronized). This feature can also be used to synchronize the HRTIM with other timers, either external or on-chip. The synchronization circuitry is controlled inside the master timer.

Synchronization output

This section explains how the HRTIM must be configured to synchronize external resources and act as a master unit.

Four events can be selected as the source to be sent to the synchronization output. This is done using SYNCSRC[1:0] bits in the HRTIM_MCR register, as follows:

- **00: Master timer Start**
  This event is generated when MCEN bit is set or when the timer is re-started after having reached the period value in single-shot mode. It is also generated on a reset which occurs during the counting (when CONT or RETRIG bits are set).

- **01: Master timer Compare 1 event**

- **10: Timer A start**
  This event is generated when TACEN bit is set or when the counter is reset and re-starts counting in response to this reset. The following counter reset events are not propagated to the synchronization output: counter roll-over in continuous mode, and discarded reset request in single-shot non-retriggerable mode. The reset is only taken into account when it occurs during the counting (CONT or RETRIG bits are set).

- **11: Timer A Compare 1 event**

SYNCSRC[1:0] bits in the HRTIM_MCR register specify how the synchronization event is generated.

The synchronization pulses are generated on the HRTIM_SCOUT output pin, with SYNCSRC[1:0] = 1x. SYNCSRC[0] bit specifies the polarity of the synchronization signal. If SYNCSRC[0] = 0, the HRTIM_SCOUT pin has a low idle level and issues a positive pulse of 16 \( f_{\text{HRTIM}} \) clock cycles length for the synchronization). If SYNCSRC[0] = 1, the idle level is high and a negative pulse is generated.

**Note:** The synchronization pulse is followed by an idle level of 16 \( f_{\text{HRTIM}} \) clock cycles during which any new synchronization request is discarded. Consequently, the maximum synchronization frequency is \( f_{\text{HRTIM}}/32 \).

The idle level on the HRTIM_SCOUT pin is applied as soon as the SYNCSRC[1:0] bits are enabled (i.e. the bitfield value is different from 00).

The synchronization output initialization procedure must be done prior to the configuration of the MCU outputs and counter enable, in the following order:

1. SYNCSRC[1:0] and SYNCSRC[1:0] bitfield configuration in HRTIM_MCR
2. HRTIM_SCOUT pin configuration (see the General-purpose I/Os section)
3. Master or Timer A counter enable (MCEN or TACEN bit set)

When the synchronization input mode is enabled and starts the counter (using SYNSTRTM/SYNCSSTRTx bits) simultaneously with the synchronization output mode (SYNCSRC[1:0] = 00 or 10), the output pulse is generated only when the counter is starting or is reset while running. Any reset request clearing the counter without causing it to start will not affect the synchronization output.
Synchronization input

The HRTIM can be synchronized by external sources, as per the programming of the SYNCIN[1:0] bits in the HRTIM_MCR register:

- 00: synchronization input is disabled
- 01: reserved configuration
- 10: the on-chip TIM1 general purpose timer (TIM1 TRGO output)
- 11: a positive pulse on the HRTIM_SCIN input pin

This bitfield cannot be changed once the destination timer (master timer or timing unit) is enabled (MCEN and/or TxCEN bit set).

The HRTIM_SCIN input is rising-edge sensitive. The timer behavior is defined with the following bits present in HRTIM_MCR and HRTIM_TIMxCR registers (see Table 344 for details):

- Synchronous start: the incoming signal starts the timer’s counter (SYNCSTRTM and/or SYNCSTRTx bits set). TxCEN (MCEN) bits must be set to have the timer enabled and the counter ready to start. In continuous mode, the counter will not start until the synchronization signal is received.
- Synchronous reset: the incoming signal resets the counter (SYNCRSTM and/or SYNCRSTx bits set). This event decrements the repetition counter as any other reset event.

The synchronization events are taken into account only once the related counters are enabled (MCEN or TxCEN bit set). A synchronization request triggers a SYNC interrupt.

Note: A synchronized start event resets the counter if the current counter value is above the active period value.

The effect of the synchronization event depends on the timer operating mode, as summarized in Table 344.

</tbody>
</table>
39.3.18 ADC triggers

The ADCs can be triggered by the master and the 5 timing units.

4 independent triggers are available to start both the regular and the injected sequencers of the 2 ADCs. Up to 32 events can be combined (ORed) for each trigger output, in registers HRTIM_ADC1R to HRTIM_ADC4R, as shown on Figure 373. Triggers 1/3 and 2/4 are using the same source set.

The external events can be used as a trigger. They are taken right after the conditioning defined in HRTIM_EECRx registers, and are not depending on EEFxR1 and EEFxR2 register settings.

Multiple triggering is possible within a single switching period by selecting several sources simultaneously. A typical use case is for a non-overlapping multiphase converter, where all phases can be sampled in a row using a single ADC trigger output.
HRTIM_ADC1R to HRTIM_ADC4R registers are preloaded and can be updated synchronously with the timer they are related to. The update source is defined with ADxUSRC[2:0] bits in the HRTIM_CR1 register.

For instance, if ADC trigger 1 outputs Timer A CMP2 events (HRTIM_ADC1R = 0x0000 0400), HRTIM_ADC1R will be typically updated simultaneously with Timer A (AD1USRC[2:0] = 001).

When the preload is disabled (PREEN bit reset) in the source timer, the HRTIM_ADCxR registers are not preloaded either: a write access will result in an immediate update of the trigger source.

### 39.3.19 DAC triggers

The HRTIMER allows to have the embedded DACs updated synchronously with the timer updates.

The update events from the master timer and the timer units can generate DAC update triggers on any of the 3 hrtim_dac_trgx outputs.

**Note:** Each timer has its own DAC-related control register.

DACSYNC[1:0] bits of the HRTIM_MCR and HRTIM_TIMxCR registers are programmed as follows:

- 00: No update generated
- 01: Update generated on hrtim_dac_trg1
- 10: Update generated on hrtim_dac_trg2
- 11: Update generated on hrtim_dac_trg3

An output pulse of 1 f_HRTIM clock periods is generated on the hrtim_dac_trgx output.
When DACSYNC[1:0] bits are enabled in multiple timers, the hrtim_dac_trgx output will consist of an OR of all timers’ update events. For instance, if DACSYNC = 1 in timer A and in timer B, the update event in timer A will be ORed with the update event in timer B to generate a DAC update trigger on the corresponding hrtim_dac_trgx output, as shown on Figure 374.

**Figure 374. Combining several updates on a single hrtim_dac_trgx output**

hrtim_dac_trgx pins are connected to the DACs as follows:

- **hrtim_dac_trg1**: DAC1_CH1 trigger input 9 (TSEL1[2:0] = 1001 in DAC_CR of DAC1 peripheral)
- **hrtim_dac_trg2**: DAC1_CH2 trigger input 10 (TSEL1[2:0] = 1010 in DAC_CR of DAC1 peripheral)
- **hrtim_dac_trg3**: not connected
39.3.20 HRTIM Interrupts

7 interrupts can be generated by the master timer:
- Master timer registers update
- Synchronization event received
- Master timer repetition event
- Master Compare 1 to 4 event

14 interrupts can be generated by each timing unit:
- Delayed protection triggered
- Counter reset or roll-over event
- Output 1 and output 2 reset (transition active to inactive)
- Output 1 and output 2 set (transition inactive to active)
- Capture 1 and 2 events
- Timing unit registers update
- Repetition event
- Compare 1 to 4 event

8 global interrupts are generated for the whole HRTIM:
- System fault and Fault 1 to 5 (regardless of the timing unit attribution)
- Burst mode period completed

The interrupt requests are grouped in 7 vectors as follows:
- hrtim_mst_it: Master timer interrupts (Master Update, Sync Input, Repetition, MCMP1..4) and global interrupt except faults (Burst mode period)
- hrtim_tima_it: TIMA interrupts
- hrtim_timb_it: TIMB interrupts
- hrtim_timc_it: TIMC interrupts
- hrtim_timd_it: TIMD interrupts
- hrtim_time_it: TIME interrupts
- hrtim_fault_it: Dedicated vector all fault interrupts to allow high-priority interrupt handling

*Table 345* is a summary of the interrupt requests, their mapping and associated control, and status bits.

39.3.21 DMA

Most of the events able to generate an interrupt can also generate a DMA request, even both simultaneously. Each timer (master, TIMA...E) has its own DMA enable register.

The individual DMA requests are ORed into 6 channels as follows:
- 1 channel for the master timer
- 1 channel per timing unit

**Note:** Before disabling a DMA channel (DMA enable bit reset in TIMxDIER), it is necessary to disable first the DMA controller.

*Table 346* is a summary of the events with their associated DMA enable bits.

**Table 346. HRTIM DMA request summary**

**Burst DMA transfers**

In addition to the standard DMA requests, the HRTIM features a DMA burst controller to have multiple registers updated with a single DMA request. This allows to:

- update multiple data registers with one DMA channel only,
- reprogram dynamically one or several timing units, for converters using multiple timer outputs.

The burst DMA feature is only available for one DMA channel, but any of the 6 channels can be selected for burst DMA transfers.

The principle is to program which registers are to be written by DMA. The master timer and TIMA.E have the burst DMA update register, where most of their control and data registers are associated with a selection bit: HRTIM_BDMUPR, HRTIM_BDTAUPR to HRTIM_BDTEUPR (this is applicable only for registers with write accesses). A redirection mechanism allows to forward the DMA write accesses to the HRTIM registers automatically, as shown on Figure 375.

**Figure 375. DMA burst overview**

When the DMA trigger occurs, the HRTIM generates multiple 32-bit DMA requests and parses the update register. If the control bit is set, the write access is redirected to the associated register. If the bit is reset, the register update is skipped and the register parsing is resumed until a new bit set is detected, to trigger a new request. Once the 6 update registers (HRTIM_BDMUPR, 5x HRTIM_BDTxUPR) are parsed, the burst is completed and the system is ready for another DMA trigger (see the flowchart on Figure 376).

*Note:* Any trigger occurring while the burst is on-going is discarded, except if it occurs during the very last data transfer.

The burst DMA mode is permanently enabled (there is no enable bit). A burst DMA operation is started by the first write access into the HRTIM_BDMADR register.
It is only necessary to have the DMA controller pointing to the HRTIM_BDMADR register as the destination, in the memory, to the peripheral configuration with the peripheral increment mode disabled (the HRTIM handles internally the data re-routing to the final destination register).

To re-initialize the burst DMA mode if it was interrupted during a transaction, it is necessary to write at least to one of the 6 update registers.

**Figure 376. Burst DMA operation flowchart**

Several options are available once the DMA burst is completed, depending on the register update strategy.

If the PREEN bit is reset (preload disabled), the value written by the DMA is immediately transferred into the active register and the registers are updated sequentially, following the DMA transaction pace.

When the preload is enabled (PREEN bit set), there are 3 use cases:

1. The update is done independently from DMA burst transfers (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 00 in HRTIM_MCR). In this case, and if it is necessary to have all transferred data taken into account simultaneously, the user must check that the DMA burst is completed before the update event takes place. On the contrary, if the update event happens while the DMA transfer is on-going, only part of the registers will be loaded and the complete register update will require 2 consecutive update events.

2. The update is done when the DMA burst transfer is completed (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 01 in HRTIM_MCR). This mode guarantees that all new register values are transferred simultaneously. This is done independently
from the counter value and can be combined with regular update events, if necessary (for instance, an update on a counter reset when TxRSTU is set).

3. The update is done on the update event following the DMA burst transfer completion (UPDGAT[3:0] = 0010 in HRTIM_TIMxCR and BRSTDMA[1:0] = 10 in HRTIM_MCR). This mode guarantees both a coherent update of all transferred data and the synchronization with regular update events, with the timer counter. In this case, if a regular update request occurs while the transfer is on-going, it will be discarded and the effective update will happen on the next coming update request.

The chronogram on Figure 377 presents the active register content for 3 cases: PREEN=0, UPDGAT[3:0] = 0001 and UPDGAT[3:0] = 0001 (when PREEN = 1).

**Figure 377. Registers update following DMA burst transfer**

---

### 39.3.22 HRTIM initialization

This section describes the recommended HRTIM initialization procedure, including other related MCU peripherals.

The HRTIM clock source must be enabled in the Reset and Clock control unit (RCC).

The HRTIM control registers can be initialized as per the power converter topology and the timing units use case. All inputs have to be configured (source, polarity, edge-sensitivity).
The HRTIM outputs must be set up eventually, with the following sequence:

- the polarity must be defined using POLx bits in HRTIM_OUTxR
- the FAULT and IDLE states must be configured using FAULTx[1:0] and IDLESx bits in HRTIM_OUTxR

The HRTIM outputs are ready to be connected to the MCU I/Os. In the GPIO controller, the selected HRTIM I/Os have to be configured as per the alternate function mapping table in the product datasheet.

From this point on, the HRTIM controls the outputs, which are in the IDLE state.

The outputs are configured in RUN mode by setting TxyOEN bits in the HRTIM_OENR register. The 2 outputs are in the inactive state until the first valid set/reset event in RUN mode. Any output set/reset event (except software requests using SST, SRT) are ignored as long as TxCEN bit is reset, as well as burst mode requests (IDLEM bit value is ignored). Similarly, any counter reset request coming from the burst mode controller is ignored (if TxBM bit is set).

**Note:** When the deadtime insertion is enabled (DTEN bit set), it is necessary to force the output state by software, using SST and RST bits, to have the outputs in a complementary state as soon as the RUN mode is entered.

The HRTIM operation can eventually be started by setting TxCEN or MCEN bits in HRTIM_MCR.

If the HRTIM peripheral is reset with the Reset and Clock Controller, the HRTIM outputs are put in IDLE mode with a low level. It is recommended to first disconnect the HRTIMER from the outputs (using the GPIO controller) before performing a peripheral reset.

### 39.3.23 Debug

When a microcontroller enters the debug mode (Cortex®-M7 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_HRTIM_STOP configuration bit in DBG module:

- DBG_HRTIM_STOP = 0: no behavior change, the HRTIM continues to operate.
- DBG_HRTIM_STOP = 1: all HRTIM timers, including the master, are stopped. The outputs in RUN mode enter the FAULT state if FAULTx[1:0] = 01, 10, 11, or keep their current state if FAULTx[1:0] = 00. The outputs in idle state are maintained in this state. This is permanently maintained even if the MCU exits the halt mode. This allows to maintain a safe state during the execution stepping. The outputs can be enabled again by settings TxyOEN bit (requires the use of the debugger).

**Timer behavior during MCU halt when DBG_HRTIM_STOP = 1**

The set/reset crossbar, the dead-time and push-pull unit, the idle/balanced fault detection and all the logic driving the normal output in RUN mode are not affected by debug. The output will keep on toggling internally, so as to retrieve regular signals of the outputs when TxyOEN will be set again (during or after the MCU halt). Associated triggers and filters are also following internal waveforms when the outputs are disabled.

FAULT inputs and events (any source) are enabled during the MCU halt.

Fault status bits can be set and TxyOEN bits reset during the MCU halt if a fault occurs at that time (TxyOEN and TxyODS are not affected by DBG_HRTIM_STOP bit state).
Synchronization, counter reset, start and reset-start events are discarded in debug mode, as well as capture events. This is to keep all related registers stable as long as the MCU is halted.

The counter stops counting when a breakpoint is reached. However, the counter enable signal is not reset; consequently no start event will be emitted when exiting from debug. All counter reset and capture triggers are disabled, as well as external events (ignored as long as the MCU is halted). The outputs SET and RST flags are frozen, except in case of forced software set/reset. A level-sensitive event is masked during the debug but will be active again as soon as the debug will be exited. For edge-sensitive events, if the signal is maintained active during the MCU halt, a new edge is not generated when exiting from debug.

The update events are discarded. This prevents any update trigger on hrtim_upd_en[3:1] inputs. DMA triggers are disabled. The burst mode circuit is frozen: the triggers are ignored and the burst mode counter stopped.

### 39.4 Application use cases

#### 39.4.1 Buck converter

Buck converters are of common use as step-down converters. The HRTIM can control up to 10 buck converters with 6 independent switching frequencies.

The converter usually operates at a fixed frequency and the Vin/Vout ratio depends on the duty cycle D applied to the power switch:

\[ V_{out} = D \times V_{in} \]

The topology is given on Figure 378 with the connection to the ADC for voltage reading.

![Figure 378. Buck converter topology](MS32343V3)

*Figure 379 presents the management of two converters with identical frequency PWM signals. The outputs are defined as follows:*

- HRTIM_ChA1 set on period, reset on CMP1
- HRTIM_ChA2 set on CMP3, reset on PER

The ADC is triggered twice per period, precisely in the middle of the ON time, using CMP2 and CMP4 events.*
Timers A..E provide either 10 buck converters coupled by pairs (both with identical switching frequencies) or 6 completely independent converters (each of them having a different switching frequency), using the master timer as the 6th time base.

### 39.4.2 Buck converter with synchronous rectification

Synchronous rectification allows to minimize losses in buck converters, by means of a FET replacing the freewheeling diode. Synchronous rectification can be turned on or off on the fly depending on the output current level, as shown on Figure 380.

![Figure 380. Synchronous rectification depending on output current](MS32345V3)

The main difference vs. a single-switch buck converter is the addition of a deadtime for an almost complementary waveform generation on HRTIM_CHA2, based on the reference waveform on HRTIM_CHA1 (see Figure 381).
39.4.3 Multiphase converters

Multiphase techniques can be applied to multiple power conversion topologies (buck, flyback). Their main benefits are:

- Reduction of the current ripple on the input and output capacitors
- Reduced EMI
- Higher efficiency at light load by dynamically changing the number of phases (phase shedding)

The HRTIM is able to manage multiple converters. The number of converters that can be controlled depends on the topologies and resources used (including the ADC triggers):

- 5 buck converters with synchronous rectification (SR), using the master timer and the 5 timers
- 4 buck converters (without SR), using the master timer and 2 timers
- ...

Figure 383 presents the topology of a 3-phase interleaved buck converter.
The master timer is responsible for the phase management: it defines the phase relationship between the converters by resetting the timers periodically. The phase-shift is 360° divided by the number of phases, 120° in the given example.

The duty cycle is then programmed into each of the timers. The outputs are defined as follows:

- HRTIM_CHA1 set on master timer period, reset on TACMP1
- HRTIM_CHB1 set on master timer MCMP1, reset on TBCMP1
- HRTIM_CHC1 set on master timer MCMP2, reset on TCCMP1

The ADC trigger can be generated on TxCMP2 compare event. Since all ADC trigger sources are phase-shifted because of the converter topology, it is possible to have all of them combined into a single ADC trigger to save ADC resources (for instance 1 ADC regular channel for the full multi-phase converter).
39.4.4 Transition mode Power Factor Correction

The basic operating principle is to build up current into an inductor during a fixed Ton time. This current will then decay during the Toff time, and the period will be re-started when it becomes null. This is detected using a Zero Crossing Detection circuitry (ZCD), as shown on Figure 384. With a constant Ton time, the peak current value in the inductor is proportional to the rectified AC input voltage, which provides the power factor correction.
This converter is operating with a constant Ton time and a variable frequency due the Toff time variation (depending on the input voltage). It must also include some features to operate when no zero-crossing is detected, or to limit the Ton time in case of over-current (OC). The OC feedback is usually conditioned with the built-in comparator and routed onto an external event input.

*Figure 385* presents the waveform during the various operating modes, with the following parameters defined:

- **Ton Min**: masks spurious overcurrent (freewheeling diode recovery current), represented as OC blanking.
- **Ton Max**: practically, the converter set-point. It is defined by CMP1.
- **Toff Min**: limits the frequency when the current limit is close to zero (demagnetization is very fast). It is defined with CMP2.
- **Toff Max**: prevents the system to be stuck if no ZCD occurs. It is defined with CMP4 in auto-delayed mode.

Both Toff values are auto-delayed since the value must be relative to the output falling edge.

---

Bits 31:30  **BRSTDMA[1:0]:** Burst DMA Update

These bits define how the update occurs relatively to a burst DMA transaction.
- 00: Update done independently from the DMA burst transfer completion
- 01: Update done when the DMA burst transfer is completed
- 10: Update done on master timer roll-over following a DMA burst transfer completion. This mode only works in continuous mode.
- 11: reserved

Bit 29  **MREPU:** Master Timer Repetition update

This bit defines whether an update occurs when the master timer repetition period is completed (either due to roll-over or reset events). MREPU can be set only if BRSTDMA[1:0] = 00 or 01.
- 0: Update on repetition disabled
- 1: Update on repetition enabled

Bit 28  Reserved, must be kept at reset value.

Bit 27  **PREEN:** Preload enable

This bit enables the registers preload mechanism and defines whether the write accesses to the memory mapped registers are done into HRTIM active or preload registers.
- 0: Preload disabled: the write access is directly done into the active register
- 1: Preload enabled: the write access is done into the preload register

Bits 26:25  **DACSYNC[1:0]:** DAC Synchronization

A DAC synchronization event can be enabled and generated when the master timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to Section 39.3.19: DAC triggers for connections details).
- 00: No DAC trigger generated
- 01: Trigger generated on hrtim_dac_trg1
- 10: Trigger generated on hrtim_dac_trg2
- 11: Trigger generated on hrtim_dac_trg3

Bits 24:22  Reserved, must be kept at reset value.

Bit 21  **TECEN:** Timer E counter enable

This bit starts the Timer E counter.
- 0: Timer E counter disabled
- 1: Timer E counter enabled

Note: This bit must not be changed within a minimum of 8 cycles of f_HRTIM clock.
Bit 20 **TDCEN**: Timer D counter enable  
This bit starts the Timer D counter.  
0: Timer D counter disabled  
1: Timer D counter enabled  
*Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.*

Bit 19 **TCCEN**: Timer C counter enable  
This bit starts the Timer C counter.  
0: Timer C counter disabled  
1: Timer C counter enabled  
*Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.*

Bit 18 **TBCEN**: Timer B counter enable  
This bit starts the Timer B counter.  
0: Timer B counter disabled  
1: Timer B counter enabled  
*Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.*

Bit 17 **TACEN**: Timer A counter enable  
This bit starts the Timer A counter.  
0: Timer A counter disabled  
1: Timer A counter enabled  
*Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.*

Bit 16 **MCEN**: Master timer counter enable  
This bit starts the Master timer counter.  
0: Master counter disabled  
1: Master counter enabled  
*Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.*

Bits 15:14 **SYNCSRC[1:0]**: Synchronization source  
These bits define the source and event to be sent on the synchronization outputs SYNCOUT[2:1]  
00: Master timer Start  
01: Master timer Compare 1 event  
10: Timer A start/reset  
11: Timer A Compare 1 event

Bits 13:12 **SYNCOUT[1:0]**: Synchronization output  
These bits define the routing and conditioning of the synchronization output event.  
00: disabled  
01: Reserved.  
10: Positive pulse on HRTIM_SCOUT output (16x f_{HRTIM} clock cycles)  
11: Negative pulse on HRTIM_SCOUT output (16x f_{HRTIM} clock cycles)  
*Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set)*

Bit 11 **SYNCCSTRTM**: Synchronization Starts Master  
This bit enables the Master timer start when receiving a synchronization input event:  
0: No effect on the Master timer  
1: A synchronization input event starts the Master timer

Bit 10 **SYNCCRSTM**: Synchronization Resets Master  
This bit enables the Master timer reset when receiving a synchronization input event:  
0: No effect on the Master timer  
1: A synchronization input event resets the Master timer
Bits 9:8  **SYNCIN[1:0]  Synchronization input**

These bits are defining the synchronization input source.
00: disabled. HRTIM is not synchronized and runs in standalone mode.
01: Reserved.
10: Internal event: the HRTIM is synchronized with the on-chip timer (see Synchronization input).
11: External event (input pin). A positive pulse on HRTIM_SCIN input triggers the HRTIM.

*Note: This parameter cannot be changed once the impacted timers are enabled.*

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **HALF: Half mode**

This bit enables the half duty-cycle mode: the HRTIM_MCMP1xR active register is automatically updated with HRTIM_MPER/2 value when HRTIM_MPER register is written.
0: Half mode disabled
1: Half mode enabled

Bit 4  **RETRIG: Re-triggerable mode**

This bit defines the behavior of the master timer counter in single-shot mode.
0: The timer is not re-triggerable: a counter reset can be done only if the counter is stopped (period elapsed)
1: The timer is re-triggerable: a counter reset is done whatever the counter state (running or stopped)

Bit 3  **CONT: Continuous mode**

0: The timer operates in single-shot mode and stops when it reaches the MPER value
1: The timer operates in continuous (free-running) mode and rolls over to zero when it reaches the MPER value

Bits 2:0  **CKPSC[2:0]: Clock prescaler**

These bits define the master timer clock prescaler ratio.
The counter clock equivalent frequency \( f_{\text{COUNTER}} \) is equal to \( f_{\text{HRCK}} / 2^{(\text{CKPSC}[2:0]-5)} \).
The prescaling ratio cannot be modified once the timer is enabled.
000: Reserved
001: Reserved
010: Reserved
011: Reserved
100: Reserved
101: \( f_{\text{COUNTER}} = f_{\text{HRTIM}} \)
110: \( f_{\text{COUNTER}} = f_{\text{HRTIM}} / 2 \)
111: \( f_{\text{COUNTER}} = f_{\text{HRTIM}} / 4 \)

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **MUPDDE**: Master Update DMA request Enable
This bit is set and cleared by software to enable/disable the Master update DMA requests.
0: Master update DMA request disabled
1: Master update DMA request enabled

Bit 21 **SYNCDE**: Sync Input DMA request Enable
This bit is set and cleared by software to enable/disable the Sync input DMA requests.
0: Sync input DMA request disabled
1: Sync input DMA request enabled

Bit 20 **MREPDE**: Master Repetition DMA request Enable
This bit is set and cleared by software to enable/disable the Master timer repetition DMA requests.
0: Repetition DMA request disabled
1: Repetition DMA request enabled

Bit 19 **MCMP4DE**: Master Compare 4 DMA request Enable
Refer to MCMP1DE description

Bit 18 **MCMP3DE**: Master Compare 3 DMA request Enable
Refer to MCMP1DE description

Bit 17 **MCMP2DE**: Master Compare 2 DMA request Enable
Refer to MCMP1DE description

Bit 16 **MCMP1DE**: Master Compare 1 DMA request Enable
This bit is set and cleared by software to enable/disable the Master timer Compare 1 DMA requests.
0: Compare 1 DMA request disabled
1: Compare 1 DMA request enabled

Bits 15:6 Reserved, must be kept at reset value.

Bit 6 **MUPDIE**: Master Update Interrupt Enable
This bit is set and cleared by software to enable/disable the Master timer registers update interrupts
0: Master update interrupts disabled
1: Master update interrupts enabled
Bit 5  **SYNCIE**: Sync Input Interrupt Enable
This bit is set and cleared by software to enable/disable the Sync input interrupts
0: Sync input interrupts disabled
1: Sync input interrupts enabled

Bit 4  **MREPIE**: Master Repetition Interrupt Enable
This bit is set and cleared by software to enable/disable the Master timer repetition interrupts
0: Master repetition interrupt disabled
1: Master repetition interrupt enabled

Bit 3  **MCMP4IE**: Master Compare 4 Interrupt Enable
Refer to MCMP1IE description

Bit 2  **MCMP3IE**: Master Compare 3 Interrupt Enable

MCNT[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 MCNT[15:0]: Counter value

Holds the master timer counter value. This register can only be written when the master timer is stopped (MCEN = 0 in HRTIM_MCR).

Note: The timer behavior is not guaranteed if the counter value is set above the HRTIM_MPER register value.

39.5.6 HRTIM Master Timer Period Register (HRTIM_MPER)

MPER[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 MPER[15:0]: Master Timer Period value

This register defines the counter overflow value.
The period value must be above or equal to 3 periods of the f_HRTIM clock.
The maximum value is 0x0000 FFDF.
39.5.7 **HRTIM Master Timer Repetition Register (HRTIM_MREP)**

Address offset: 0x0018h  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:8</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bits 7:0 | **MREP[7:0]: Master Timer Repetition period value**  
This register holds the repetition period value for the master counter. It is either the preload register or the active register if preload is disabled. |

39.5.8 **HRTIM Master Timer Compare 1 Register (HRTIM_MCMP1R)**

Address offset: 0x001Ch  
Reset value: 0x0000 0000

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | **MCMP1[15:0]: Master Timer Compare 1 value**  
This register holds the master timer Compare 1 value. It is either the preload register or the active register if preload is disabled.  
The compare value must be above or equal to 3 periods of the \( f_{\text{HRTIM}} \) clock. |
39.5.9 HRTIM Master Timer Compare 2 Register (HRTIM_MCMP2R)

Address offset: 0x0024h
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP2[15:0]: Master Timer Compare 2 value**
This register holds the master timer Compare 2 value. It is either the preload register or the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the fHRTIM clock.

39.5.10 HRTIM Master Timer Compare 3 Register (HRTIM_MCMP3R)

Address offset: 0x0028h
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP3[15:0]: Master Timer Compare 3 value**
This register holds the master timer Compare 3 value. It is either the preload register or the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the fHRTIM clock.
### 39.5.11 HRTIM Master Timer Compare 4 Register (HRTIM_MCMP4R)

#### Bits 31:28 UPDGAT[3:0]: Update Gating

These bits define how the update occurs relatively to the burst DMA transaction and the external update request on update enable inputs 1 to 3 (see Table 334: Update enable inputs and sources)

- The update events, as mentioned below, can be: MSTU, TEU, TDU, TCU, TBU, TAU, TxRSTU, TxREP.

- 0000: the update occurs independently from the DMA burst transfer
- 0001: the update occurs when the DMA burst transfer is completed
- 0010: the update occurs on the update event following the DMA burst transfer completion
- 0011: the update occurs on a rising edge of HRTIM update enable input 1 (hrtim_upd_en1)
- 0100: the update occurs on a rising edge of HRTIM update enable input 2 (hrtim_upd_en2)
- 0101: the update occurs on a rising edge of HRTIM update enable input 3 (hrtim_upd_en3)
- 0110: the update occurs on the update event following a rising edge of HRTIM update enable input 1 (hrtim_upd_en1)
- 0111: the update occurs on the update event following a rising edge of HRTIM update enable input 2 (hrtim_upd_en2)
- 1000: the update occurs on the update event following a rising edge of HRTIM update enable input 3 (hrtim_upd_en3)

Other codes: reserved

**Note:** This bitfield must be reset before programming a new value.

For UPDGAT[3:0] values equal to 0001, 0011, 0100, 0101, it is possible to have multiple concurrent update source (for instance RSTU and DMA burst).

#### Bit 27 PREEN: Preload enable

This bit enables the registers preload mechanism and defines whether a write access into a preloadable register is done into the active or the preload register.

- 0: Preload disabled: the write access is directly done into the active register
- 1: Preload enabled: the write access is done into the preload register

#### Bits 26:25 DACSYNC[1:0] DAC Synchronization

A DAC synchronization event is generated when the timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to Section 39.3.19: DAC triggers for connections details).

- 00: No DAC trigger generated
- 01: Trigger generated on hrtim_dac_trg1
- 10: Trigger generated on hrtim_dac_trg2
- 11: Trigger generated on hrtim_dac_trg3
Bit 24 **MSTU: Master Timer update**
Register update is triggered by the master timer update.
- 0: Update by master timer disabled
- 1: Update by master timer enabled

Bit 23 **In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR:**

**TEU: Timer E update**
Register update is triggered by the timer E update
- 0: Update by timer E disabled
- 1: Update by timer E enabled

**In HRTIM_TIMECR:**
Reserved, must be kept at reset value

Bit 22 **In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR:**

**TDU: Timer D update**
Register update is triggered by the timer D update
- 0: Update by timer D disabled
- 1: Update by timer D enabled

**In HRTIM_TIMDCR:**
Reserved, must be kept at reset value

Bit 21 **In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMECR:**

**TCU: Timer C update**
Register update is triggered by the timer C update
- 0: Update by timer C disabled
- 1: Update by timer C enabled

**In HRTIM_TIMCCR:**
Reserved, must be kept at reset value

Bit 20 **In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMECR:**

**TBU: Timer B update**
Register update is triggered by the timer B update
- 0: Update by timer B disabled
- 1: Update by timer B enabled

**In HRTIM_TIMBCR:**
Reserved, must be kept at reset value

Bit 19 **In HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR:**

**TAU: Timer A update**
Register update is triggered by the timer A update
- 0: Update by timer A disabled
- 1: Update by timer A enabled

**In HRTIM_TIMACR:**
Reserved, must be kept at reset value
Bit 18 **TxRSTU**: Timer x reset update
Register update is triggered by Timer x counter reset or roll-over to 0 after reaching the period value in continuous mode.
0: Update by timer x reset / roll-over disabled
1: Update by timer x reset / roll-over enabled

Bit 17 **TxREPU**: Timer x Repetition update
Register update is triggered when the counter rolls over and HRTIM_REPx = 0
0: Update on repetition disabled
1: Update on repetition enabled

Bit 16 Reserved, must be kept at reset value.

Bits 15:14 **DELCMP4[1:0]**: CMP4 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see Auto-delayed mode).
00: CMP4 register is always active (standard compare mode)
01: CMP4 value is recomputed and is active following a capture 2 event
10: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 1 match (timeout function if capture 2 event is missing)
11: CMP4 value is recomputed and is active following a capture event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bits 13:12 **DELCMP2[1:0]**: CMP2 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see Auto-delayed mode).
00: CMP2 register is always active (standard compare mode)
01: CMP2 value is recomputed and is active following a capture 1 event
10: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after Compare 1 match (timeout function if capture event is missing)
11: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 11 **SYNCSTRTx**: Synchronization Starts Timer x
This bit defines the Timer x behavior following the synchronization event:
0: No effect on Timer x
1: A synchronization input event starts the Timer x

Bit 10 **SYNCRSTx**: Synchronization Resets Timer x
This bit defines the Timer x behavior following the synchronization event:
0: No effect on Timer x
1: A synchronization input event resets the Timer x

Bits 9:7 Reserved, must be kept at reset value.

Bit 6 **PSHPLL**: Push-Pull mode enable
This bit enables the push-pull mode.
0: Push-Pull mode disabled
1: Push-Pull mode enabled

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set)
Bit 5 **HALF: Half mode enable**
This bit enables the half duty-cycle mode: the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/2 value when HRTIM_PERxR register is written.
0: Half mode disabled
1: Half mode enabled

Bit 4 **RETRIG: Re-triggerable mode**
This bit defines the counter behavior in single shot mode.
0: The timer is not re-triggerable: a counter reset is done if the counter is stopped (period elapsed in single-shot mode or counter stopped in continuous mode)
1: The timer is re-triggerable: a counter reset is done whatever the counter state.

Bit 3 **CONT: Continuous mode**
This bit defines the timer operating mode.
0: The timer operates in single-shot mode and stops when it reaches TIMxPER value
1: The timer operates in continuous mode and rolls over to zero when it reaches TIMxPER value

Bits 2:0 **CKPSCx[2:0]: HRTIM Timer x Clock prescaler**
These bits define the master timer clock prescaler ratio.
The counter clock equivalent frequency ($f_{COUNTER}$) is equal to $f_{HRCK} / 2^{\text{CKPSCx[2:0]-5}}$.
The prescaling ratio cannot be modified once the timer is enabled.
000: Reserved
001: Reserved
010: Reserved
011: Reserved
100: Reserved
101: $f_{COUNTER} = f_{HRTIM}$
110: $f_{COUNTER} = f_{HRTIM} / 2$
111: $f_{COUNTER} = f_{HRTIM} / 4$
### 39.5.13 HRTIM Timerx Interrupt Status Register (HRTIM_TIMxISR)

</tbody>
</table>

**Bits 31:22** Reserved, must be kept at reset value.

**Bit 21** O2CPY: Output 2 Copy
- This status bit is a raw copy of the output 2 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.
  - 0: Output 2 is inactive
  - 1: Output 2 is active

**Bit 20** O1CPY: Output 1 Copy
- This status bit is a raw copy of the output 1 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.
  - 0: Output 1 is inactive
  - 1: Output 1 is active

**Bit 19** O2STAT: Output 2 Status
- This status bit indicates the output 2 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.
  - 0: Output 2 was inactive
  - 1: Output 2 was active

**Bit 18** O1STAT: Output 1 Status
- This status bit indicates the output 1 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.
  - 0: Output 1 was inactive
  - 1: Output 1 was active

**Bit 17** IPPSTAT: Idle Push Pull Status
- This status bit indicates on which output the signal was applied, in push-pull mode balanced fault mode or delayed idle mode, when the protection was triggered (whatever the output state, active or inactive).
  - 0: Protection occurred when the output 1 was active and output 2 forced inactive
  - 1: Protection occurred when the output 2 was active and output 1 forced inactive

**Bit 16** CPPSTAT: Current Push Pull Status
- This status bit indicates on which output the signal is currently applied, in push-pull mode. It is only significant in this configuration.
  - 0: Signal applied on output 1 and output 2 forced inactive
  - 1: Signal applied on output 2 and output 1 forced inactive

**Bit 15** Reserved

**Bit 14** DLYPRT: Delayed Protection Flag
- This bit indicates delayed idle or the balanced idle mode entry.
Bit 13 **RST**: Reset and/or roll-over Interrupt Flag
This bit is set by hardware when the timer x counter is reset or rolls over in continuous mode.
0: No TIMx counter reset/roll-over interrupt occurred
1: TIMx counter reset/roll-over interrupt occurred

Bit 12 **RSTx2**: Output 2 Reset Interrupt Flag
Refer to RSTx1 description

Bit 11 **SETx2**: Output 2 Set Interrupt Flag
Refer to SETx1 description

Bit 10 **RSTx1**: Output 1 Reset Interrupt Flag
This bit is set by hardware when the Tx1 output is reset (goes from active to inactive mode).
0: No Tx1 output reset interrupt occurred
1: Tx1 output reset interrupt occurred

Bit 9 **SETx1**: Output 1 Set Interrupt Flag
This bit is set by hardware when the Tx1 output is set (goes from inactive to active mode).
0: No Tx1 output set interrupt occurred
1: Tx1 output set interrupt occurred

Bit 8 **CPT2**: Capture2 Interrupt Flag
Refer to CPT1 description

Bit 7 **CPT1**: Capture1 Interrupt Flag
This bit is set by hardware when the timer x capture 1 event occurs.
0: No timer x Capture 1 reset interrupt occurred
1: Timer x output 1 reset interrupt occurred

Bit 6 **UPD**: Update Interrupt Flag
This bit is set by hardware when the timer x update event occurs.
0: No timer x update interrupt occurred
1: Timer x update interrupt occurred

Bit 5 Reserved, must be kept at reset value.

Bit 4 **REP**: Repetition Interrupt Flag
This bit is set by hardware when the timer x repetition period has elapsed.
0: No timer x repetition interrupt occurred
1: Timer x repetition interrupt occurred

Bit 3 **CMP4**: Compare 4 Interrupt Flag
Refer to CMP1 description

Bit 2 **CMP3**: Compare 3 Interrupt Flag
Refer to CMP1 description

Bit 1 **CMP2**: Compare 2 Interrupt Flag
Refer to CMP1 description

Bit 0 **CMP1**: Compare 1 Interrupt Flag
This bit is set by hardware when the timer x counter matches the value programmed in the Compare 1 register.
0: No Compare 1 interrupt occurred
1: Compare 1 interrupt occurred
### 39.5.14  HRTIM Timerx Interrupt Clear Register (HRTIM_TIMxICR)

Address offset: 0x0008h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

Bit 31  Reserved

Bit 30  DLYPR: Delayed Protection DMA request Enable
This bit is set and cleared by software to enable/disable DMA requests on delayed protection.
0: Delayed protection DMA request disabled
1: Delayed protection DMA request enabled

Bit 29  RSTDE: Reset/roll-over DMA request Enable
This bit is set and cleared by software to enable/disable DMA requests on timer x counter reset or roll-over in continuous mode.
0: Timer x counter reset/roll-over DMA request disabled
1: Timer x counter reset/roll-over DMA request enabled

Bit 28  RSTx2DE: Output 2 Reset DMA request Enable
Refer to RSTx1DE description

Bit 27  SETx2DE: Output 2 Set DMA request Enable
Refer to SETx1DE description

Bit 26  RSTx1DE: Output 1 Reset DMA request Enable
This bit is set and cleared by software to enable/disable Tx1 output reset DMA requests.
0: Tx1 output reset DMA request disabled
1: Tx1 output reset DMA request enabled

Bit 25  SETx1DE: Output 1 Set DMA request Enable
This bit is set and cleared by software to enable/disable Tx1 output set DMA requests.
0: Tx1 output set DMA request disabled
1: Tx1 output set DMA request enabled

Bit 24  CPT2DE: Capture 2 DMA request Enable
Refer to CPT1DE description

Bit 23  CPT1DE: Capture 1 DMA request Enable
This bit is set and cleared by software to enable/disable Capture 1 DMA requests.
0: Capture 1 DMA request disabled
1: Capture 1 DMA request enabled

Bit 22  UPDDE: Update DMA request Enable
This bit is set and cleared by software to enable/disable DMA requests on update event.
0: Update DMA request disabled
1: Update DMA request enabled
Bit 21 Reserved, must be kept at reset value.

Bit 20 REPDE: Repetition DMA request Enable
This bit is set and cleared by software to enable/disable DMA requests on repetition event.
0: Repetition DMA request disabled
1: Repetition DMA request enabled

Bit 19 CMP4DE: Compare 4 DMA request Enable
Refer to CMP1DE description

Bit 18 CMP3DE: Compare 3 DMA request Enable
Refer to CMP1DE description

Bit 17 CMP2DE: Compare 2 DMA request Enable
Refer to CMP1DE description

Bit 16 CMP1DE: Compare 1 DMA request Enable
This bit is set and cleared by software to enable/disable the Compare 1 DMA requests.
0: Compare 1 DMA request disabled
1: Compare 1 DMA request enabled

Bit 15 Reserved

Bit 14 DLPRTIE: Delayed Protection Interrupt Enable
This bit is set and cleared by software to enable/disable interrupts on delayed protection.
0: Delayed protection interrupts disabled
1: Delayed protection interrupts enabled

Bit 13 RSTIE: Reset/roll-over Interrupt Enable
This bit is set and cleared by software to enable/disable interrupts on timer x counter reset or roll-over in continuous mode.
0: Timer x counter reset/roll-over interrupt disabled
1: Timer x counter reset/roll-over interrupt enabled

Bit 12 RSTx2IE: Output 2 Reset Interrupt Enable
Refer to RSTx1IE description

Bit 11 SETx2IE: Output 2 Set Interrupt Enable
Refer to SETx1IE description

Bit 10 RSTx1IE: Output 1 Reset Interrupt Enable
This bit is set and cleared by software to enable/disable Tx1 output reset interrupts.
0: Tx1 output reset interrupts disabled
1: Tx1 output reset interrupts enabled

Bit 9 SETx1IE: Output 1 Set Interrupt Enable
This bit is set and cleared by software to enable/disable Tx1 output set interrupts.
0: Tx1 output set interrupts disabled
1: Tx1 output set interrupts enabled

Bit 8 CPT2IE: Capture Interrupt Enable
Refer to CPT1IE description

Bit 7 CPT1IE: Capture Interrupt Enable
This bit is set and cleared by software to enable/disable Capture 1 interrupts.
0: Capture 1 interrupts disabled
1: Capture 1 interrupts enabled
Bit 6 **UPDIE**: Update Interrupt Enable
   This bit is set and cleared by software to enable/disable update event interrupts.
   0: Update interrupts disabled
   1: Update interrupts enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4 **REPIE**: Repetition Interrupt Enable
   This bit is set and cleared by software to enable/disable repetition event interrupts.
   0: Repetition interrupts disabled
   1: Repetition interrupts enabled

Bit 3 **CMP4IE**: Compare 4 Interrupt Enable
   Refer to CMP1IE description

Bit 2 **CMP3IE**: Compare 3 Interrupt Enable
   Refer to CMP1IE description

Bit 1 **CMP2IE**: Compare 2 Interrupt Enable
   Refer to CMP1IE description

Bit 0 **CMP1IE**: Compare 1 Interrupt Enable
   This bit is set and cleared by software to enable/disable the Compare 1 interrupts.
   0: Compare 1 interrupt disabled
   1: Compare 1 interrupt enabled
39.5.16  HRTIM Timerx Counter Register (HRTIM_CNTxR)

Address offset: 0x0010h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  PERx[15:0]: Timerx Period value

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The period value must be above or equal to 3 periods of the fHRTIM clock.

The maximum value is 0x0000 FFDF.
39.5.18 HRTIM Timerx Repetition Register (HRTIM_REPxR)

Address offset: 0x18h (this offset address is relative to timer x base address)
Reset value: 0x0000 0000

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 CMP1x[15:0]: Timerx Compare 1 value
This register holds the compare 1 value.
This register holds either the content of the preload register or the content of the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the \( f_{HRTIM} \) clock.
### 39.5.20 HRTIM Timerx Compare 1 Compound Register (HRTIM_CMP1CxR)

</tbody>
</table>

**Bits 31:16** Reserved, must be kept at reset value.

**Bits 15:0** **CMP2x[15:0]: Timerx Compare 2 value**

This register holds the Compare 2 value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The compare value must be above or equal to 3 periods of the \( f_{HRTIM} \) clock.

This register can behave as an auto-delayed compare register, if enabled with DELCMP2[1:0] bits in HRTIM_TIMxCR.
39.5.22 HRTIM Timerx Compare 3 Register (HRTIM_CMP3xR)

Address offset: 0x28h (this offset address is relative to timer x base address)
Reset value: 0x0000 0000

Bit 16 **TIMEVNT5:** *Timer Event 5*
   Refer to TIMEVNT1 description

Bit 15 **TIMEVNT4:** *Timer Event 4*
   Refer to TIMEVNT1 description

Bit 14 **TIMEVNT3:** *Timer Event 3*
   Refer to TIMEVNT1 description

Bit 13 **TIMEVNT2:** *Timer Event 2*
   Refer to TIMEVNT1 description

Bit 12 **TIMEVNT1:** *Timer Event 1*
   Timers event 1 forces the output to its active state (refer to Table 327 for Timer Events assignments)

Bit 11 **MSTCMP4:** *Master Compare 4*
   Master Timer Compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3:** *Master Compare 3*
   Master Timer Compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2:** *Master Compare 2*
   Master Timer Compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1:** *Master Compare 1*
   Master Timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER:** *Master Period*
   The master timer counter roll-over in continuous mode, or to the master timer reset in single-shot mode forces the output to its active state.

Bit 6 **CMP4:** *Timer x Compare 4*
   Timer A compare 4 event forces the output to its active state.

Bit 5 **CMP3:** *Timer x Compare 3*
   Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2:** *Timer x Compare 2*
   Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1:** *Timer x Compare 1*
   Timer A compare 1 event forces the output to its active state.

Bit 2 **PER:** *Timer x Period*
   Timer A Period event forces the output to its active state.

Bit 1 **RESYNC:** *Timer A resynchronization*
   Timer A reset event coming solely from software or SYNC input forces the output to its active state.
   
   *Note: Other timer reset are not affecting the output when RESYNC=1*

Bit 0 **SST:** *Software Set trigger*
   This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
   
   *Note: This bit is not preloaded*

- 1100: Blanking from another timing unit: TIMFLTR8 source (see Table 331 for details)
- 1101: Windowing from counter reset/roll-over to Compare 2
- 1110: Windowing from counter reset/roll-over to Compare 3
- 1111: Windowing from another timing unit: TIMWIN source (see Table 332 for details)

*Note:* Whenever a compare register is used for filtering, the value must be strictly above 0.

This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 0  **EE1LTCH: External Event 1 latch**

- 0: Event 1 is ignored if it happens during a blank, or passed through during a window.
- 1: Event 1 is latched and delayed till the end of the blanking or windowing period.

*Note:* A timeout event is generated in window mode (EE1FLTR[3:0]=1101, 1110, 1111) if \( EE1LTCH = 0 \), except if the External event is programmed in fast mode (EExFAST = 1).

This bitfield must not be modified once the counter is enabled (TxCEN bit set)

The timer A counter is reset upon timer C Compare 1 event.

Bit 21 **TBCMP4**: Timer B Compare 4
The timer A counter is reset upon timer B Compare 4 event.

Bit 20 **TBCMP2**: Timer B Compare 2
The timer A counter is reset upon timer B Compare 2 event.

Bit 19 **TBCMP1**: Timer B Compare 1
The timer A counter is reset upon timer B Compare 1 event.

Bit 18 **EXTEVNT10**: External Event
The timer A counter is reset upon external event 10.

Bit 17 **EXTEVNT9**: External Event 9
The timer A counter is reset upon external event 9.
Bit 16 **EXTEVNT8**: *External Event 8*
The timer A counter is reset upon external event 8.

Bit 15 **EXTEVNT7**: *External Event 7*
The timer A counter is reset upon external event 7.

Bit 14 **EXTEVNT6**: *External Event 6*
The timer A counter is reset upon external event 6.

Bit 13 **EXTEVNT5**: *External Event 5*
The timer A counter is reset upon external event 5.

Bit 12 **EXTEVNT4**: *External Event 4*
The timer A counter is reset upon external event 4.

Bit 11 **EXTEVNT3**: *External Event 3*
The timer A counter is reset upon external event 3.

Bit 10 **EXTEVNT2**: *External Event 2*
The timer A counter is reset upon external event 2.

Bit 9 **EXTEVNT1**: *External Event 1*
The timer A counter is reset upon external event 1.

Bit 8 **MSTCMP4**: *Master compare 4*
The timer A counter is reset upon master timer Compare 4 event.

Bit 7 **MSTCMP3**: *Master compare 3*
The timer A counter is reset upon master timer Compare 3 event.

Bit 6 **MSTCMP2**: *Master compare 2*
The timer A counter is reset upon master timer Compare 2 event.

Bit 5 **MSTCMP1**: *Master compare 1*
The timer A counter is reset upon master timer Compare 1 event.

Bit 4 **MSTPER**: *Master timer Period*
The timer A counter is reset upon master timer period event.

Bit 3 **CMP4**: *Timer A compare 4 reset*
The timer A counter is reset upon Timer A Compare 4 event.

Bit 2 **CMP2**: *Timer A compare 2 reset*
The timer A counter is reset upon Timer A Compare 2 event.

Bit 1 **UPDT**: *Timer A Update reset*
The timer A counter is reset upon update event.

Bit 0 Reserved, must be kept at reset value.

Bits 31:11 Reserved, must be kept at reset value.
Bits 10:7 **STRPW[3:0]: Timerx start pulsewidth**  
This register defines the initial pulsewidth following a rising edge on output signal.  
This bitfield cannot be modified when one of the CHPx bits is set.  
\[ t_{1STPW} = (STRPW[3:0]+1) \times 16 \times t_{HRTIM} \]  
0000: 40 ns (1/25 MHz)  
...  
1111: 640 ns (16/25 MHz)  

Bits 6:4 **CARDTY[2:0]: Timerx chopper duty cycle value**  
This register defines the duty cycle of the carrier signal. This bitfield cannot be modified when one of the CHPx bits is set.  
000: 0/8 (i.e. only 1st pulse is present)  
...  
111: 7/8  

Bits 3:0 **CARFRQ[3:0]: Timerx carrier frequency value**  
This register defines the carrier frequency \( F_{CHPFRQ} = \frac{f_{HRTIM}}{16 \times (CARFRQ[3:0]+1)} \).  
This bitfield cannot be modified when one of the CHPx bits is set.  
0000: 25 MHz \( (f_{HRTIM} / 16) \)  
...  
1111: 1.56 MHz \( (f_{HRTIM} / 256) \)

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **DIDL2**: Output 2 Deadtime upon burst mode Idle entry

This bit can delay the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering in idle state during a burst mode operation.

0: The programmed Idle state is applied immediately to the Output 2
1: Deadtime (inactive level) is inserted on output 2 before entering the idle mode. The deadtime value is set by DTFx[8:0].

*Note: This parameter cannot be changed once the timer x is enabled.*

**DIDL=1 can be set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).**

Bit 22  **CHP2**: Output 2 Chopper enable

This bit enables the chopper on output 2
0: Output signal is not altered
1: Output signal is chopped by a carrier signal

*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 21:20  **FAULT2[1:0]**: Output 2 Fault state

These bits select the output 2 state after a fault event
00: No action: the output is not affected by the fault input and stays in run mode.
01: Active
10: Inactive
11: High-Z

*Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.*

Bit 19  **IDLES2**: Output 2 Idle State

This bit selects the output 2 idle state
0: Inactive
1: Active

*Note: This parameter must be set prior to have the HRTIM controlling the outputs.*

Bit 18  **IDLEM2**: Output 2 Idle mode

This bit selects the output 2 idle mode
0: No action: the output is not affected by the burst mode operation
1: The output is in idle state when requested by the burst mode controller.

*Note: This bit is preloaded and can be changed during run-time, but must not be changed while the burst mode is active.*
Bit 17 **POL2**: Output 2 polarity
- This bit selects the output 2 polarity
  - 0: positive polarity (output active high)
  - 1: negative polarity (output active low)

Note: This parameter cannot be changed once the timer x is enabled.

Bits 16:12 Reserved, must be kept at reset value.

Bits 12:10 **DLYPRT[2:0]**: Delayed Protection
- These bits define the source and outputs on which the delayed protection schemes are applied.
  - In HRTIM_OUTAR, HRTIM_OUTBR, HRTIM_OUTCR:
    - 000: Output 1 delayed Idle on external Event 6
    - 001: Output 2 delayed Idle on external Event 6
    - 010: Output 1 and output 2 delayed Idle on external Event 6
    - 011: Balanced Idle on external Event 6
    - 100: Output 1 delayed Idle on external Event 7
    - 101: Output 2 delayed Idle on external Event 7
    - 110: Output 1 and output 2 delayed Idle on external Event 7
    - 111: Balanced Idle on external Event 7
  - In HRTIM_OUTDR, HRTIM_OUTER:
    - 000: Output 1 delayed Idle on external Event 8
    - 001: Output 2 delayed Idle on external Event 8
    - 010: Output 1 and output 2 delayed Idle on external Event 8
    - 011: Balanced Idle on external Event 8
    - 100: Output 1 delayed Idle on external Event 9
    - 101: Output 2 delayed Idle on external Event 9
    - 110: Output 1 and output 2 delayed Idle on external Event 9
    - 111: Balanced Idle on external Event 9

Note: This bitfield must not be modified once the delayed protection is enabled (DLYPRTEN bit set)

Bit 9 **DLYPRTEN**: Delayed Protection Enable
- This bit enables the delayed protection scheme
  - 0: No action
  - 1: Delayed protection is enabled, as per DLYPRT[2:0] bits

Note: This parameter cannot be changed once the timer x is enabled (TxEN bit set).

Bit 8 **DTEN**: Deadtime enable
- This bit enables the deadtime insertion on output 1 and output 2
  - 0: Output 1 and output 2 signals are independent.
  - 1: Deadtime is inserted between output 1 and output 2 (reference signal is output 1 signal generator)

Note: This parameter cannot be changed once the timer is operating (TxEN bit set) or if its outputs are enabled and set/reset by another timer.

Bit 7 **DIDL1**: Output 1 Deadtime upon burst mode Idle entry
- This bit can delay the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering the idle state during a burst mode operation.
  - 0: The programmed Idle state is applied immediately to the Output 1
  - 1: Deadtime (inactive level) is inserted on output 1 before entering the idle mode. The deadtime value is set by DTRx[8:0].

Note: This parameter cannot be changed once the timer x is enabled.

DIDL=1 can be set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).
Bit 6  **CHP1**: Output 1 Chopper enable  
This bit enables the chopper on output 1  
0: Output signal is not altered  
1: Output signal is chopped by a carrier signal  
*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 5:4  **FAULT1[1:0]**: Output 1 Fault state  
These bits select the output 1 state after a fault event  
00: No action: the output is not affected by the fault input and stays in run mode.  
01: Active  
10: Inactive  
11: High-Z  
*Note: This parameter cannot be changed once the timer x is enabled (TxEN bit set), if FLTENx bit is set or if the output is in FAULT state.*

Bit 3  **IDLES1**: Output 1 Idle State  
This bit selects the output 1 idle state  
0: Inactive  
1: Active  
*Note: This parameter must be set prior to HRTIM controlling the outputs.*

Bit 2  **IDLEM1**: Output 1 Idle mode  
This bit selects the output 1 idle mode  
0: No action: the output is not affected by the burst mode operation  
1: The output is in idle state when requested by the burst mode controller.  
*Note: This bit is preloaded and can be changed during runtime, but must not be changed while burst mode is active.*

Bit 1  **POL1**: Output 1 polarity  
This bit selects the output 1 polarity  
0: positive polarity (output active high)  
1: negative polarity (output active low)  
*Note: This parameter cannot be changed once the timer x is enabled.*

Bit 0  Reserved
### 39.5.38 HRTIM Timerx Fault Register (HRTIM_FLTxR)

  Refer to TA1ODS description

- **Bit 0** TA1ODS: Timer A Output 1 disable status  
  Reading the bit returns the output disable status. It is not significant when the output is active (Tx1OEN or Tx2OEN = 1).
  0: output HRTIM_CHA1 disabled, in Idle state.
  1: output HRTIM_CHA1 disabled, in Fault state.
### 39.5.47 HRTIM Burst Mode Control Register (HRTIM_BMCR)

Address offset: 0x3A0h  
Reset value: 0x0000 0000

| Bit 31 | BMSTAT: Burst Mode Status  
This bit gives the current operating state.  
0: Normal operation  
1: Burst operation on-going. Writing this bit to 0 causes a burst mode early termination.  

Bits 30:22 Reserved, must be kept at reset value.  

Bit 21 TEBM: Timer E Burst Mode  
Refer to TABM description  

Bit 20 TDBM: Timer D Burst Mode  
Refer to TABM description  

Bit 19 TCBM: Timer C Burst Mode  
Refer to TABM description  

Bit 18 TBBM: Timer B Burst Mode  
Refer to TABM description  

Bit 17 TABM: Timer A Burst Mode  
This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.  
0: Timer A counter clock is maintained and the timer operates normally  
1: Timer A counter clock is stopped and the counter is reset  

*Note:* This bit must not be set when the balanced idle mode is active (DLYPRT[2:0] = 0x11)  

Bit 16 MTBM: Master Timer Burst Mode  
This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.  
0: Master Timer counter clock is maintained and the timer operates normally  
1: Master Timer counter clock is stopped and the counter is reset  

Bits 15:11 Reserved, must be kept at reset value.  

Bit 10 BMPREN: Burst Mode Preload Enable  
This bit enables the registers preload mechanism and defines whether a write access into a preloadable register (HRTIM_BMCMPR, HRTIM_BMPER) is done into the active or the preload register.  
0: Preload disabled: the write access is directly done into active registers  
1: Preload enabled: the write access is done into preload registers

Bits 9:6 **BMPRSC[3:0]: Burst Mode Prescaler**
Defines the prescaling ratio of the \( f_{\text{HRTIM}} \) clock for the burst mode controller. This bitfield cannot be changed while the burst mode is enabled.
0000: Clock not divided
0001: Division by 2
0010: Division by 4
0011: Division by 8
0100: Division by 16
0101: Division by 32
0110: Division by 64
0111: Division by 128
1000: Division by 256
1001: Division by 512
1010: Division by 1024
1011: Division by 2048
1100: Division by 4096
1101: Division by 8192
1110: Division by 16384
1111: Division by 32768

Bits 5:2 **BMCLK[3:0]: Burst Mode Clock source**
This bitfield defines the clock source for the burst mode counter. It cannot be changed while the burst mode is enabled (refer to Table 341 for on-chip events 1..4 connections details).
0000: Master timer counter reset/roll-over
0001: Timer A counter reset/roll-over
0010: Timer B counter reset/roll-over
0011: Timer C counter reset/roll-over
0100: Timer D counter reset/roll-over
0101: Timer E counter reset/roll-over
0110: On-chip Event 1 (hrtim_bm_ck1), acting as a burst mode counter clock
0111: On-chip Event 2 (hrtim_bm_ck2) acting as a burst mode counter clock
1000: On-chip Event 3 (hrtim_bm_ck3) acting as a burst mode counter clock
1001: On-chip Event 4 (hrtim_bm_ck4) acting as a burst mode counter clock
1010: Prescaled \( f_{\text{HRTIM}} \) clock (as per BMPRSC[3:0] setting)
Other codes reserved

Bit 1 **BMOM: Burst Mode operating mode**
This bit defines if the burst mode is entered once or if it is continuously operating.
0: Single-shot mode
1: Continuous operation

Bit 0 **BME: Burst Mode enable**
This bit starts the burst mode controller which becomes ready to receive the start trigger.
Writing this bit to 0 causes a burst mode early termination.
0: Burst mode disabled
1: Burst mode enabled

#### Bit 31 OCHPEV: On-chip Event
A rising edge on an on-chip Event (see Section: Burst mode triggers) triggers a burst mode entry.

#### Bit 30 EEV8: External Event 8 (TIMD filters applied)
The external event 8 conditioned by TIMD filters is starting the burst mode operation.

#### Bit 29 EEV7: External Event 7 (TIMA filters applied)
The external event 7 conditioned by TIMA filters is starting the burst mode operation.

#### Bit 28 TDEEV8: Timer D period following External Event 8
The timer D period following an external event 8 (conditioned by TIMD filters) is starting the burst mode operation.

#### Bit 27 TAEV7: Timer A period following External Event 7
The timer A period following an external event 7 (conditioned by TIMA filters) is starting the burst mode operation.

#### Bit 26 TECMP2: Timer E Compare 2 event
Refer to TACMP1 description

#### Bit 25 TECMP1: Timer E Compare 1 event
Refer to TACMP1 description

#### Bit 24 TEREPT: Timer E repetition
Refer to TAREP description

#### Bit 23 TERST: Timer E counter reset or roll-over
Refer to TARST description

#### Bit 22 TDCMP2: Timer D Compare 2 event
Refer to TACMP1 description

#### Bit 21 TDCMP1: Timer D Compare 1 event
Refer to TACMP1 description

#### Bit 20 TDREP: Timer D repetition
Refer to TAREP description

#### Bit 19 TDRST: Timer D reset or roll-over
Refer to TARST description

#### Bit 18 TCCMP2: Timer C Compare 2 event
Refer to TACMP1 description
Bit 17 **TCCMP1**: Timer C Compare 1 event  
Refer to TACMP1 description

Bit 16 **TCREP**: Timer C repetition  
Refer to TAREP description

Bit 15 **TCRST**: Timer C reset or roll-over  
Refer to TARST description

Bit 14 **TBCMP2**: Timer B Compare 2 event  
Refer to TACMP1 description

Bit 13 **TBCMP1**: Timer B Compare 1 event  
Refer to TACMP1 description

Bit 12 **TBREP**: Timer B repetition  
Refer to TAREP description

Bit 11 **TBRST**: Timer B reset or roll-over  
Refer to TARST description

Bit 10 **TACMP2**: Timer A Compare 2 event  
Refer to TACMP1 description

Bit 9 **TACMP1**: Timer A Compare 1 event  
The timer A compare 1 event is starting the burst mode operation.

Bit 8 **TAREP**: Timer A repetition  
The Timer A repetition event is starting the burst mode operation.

Bit 7 **TARST**: Timer A reset or roll-over  
The Timer A reset or roll-over event is starting the burst mode operation.

Bit 6 **MSTCMP4**: Master Compare 4  
Refer to MSTCMP1 description

Bit 5 **MSTCMP3**: Master Compare 3  
Refer to MSTCMP1 description

Bit 4 **MSTCMP2**: Master Compare 2  
Refer to MSTCMP1 description

Bit 3 **MSTCMP1**: Master Compare 1  
The master timer Compare 1 event is starting the burst mode operation.

Bit 2 **MSTREP**: Master repetition  
The master timer repetition event is starting the burst mode operation.

Bit 1 **MSTRST**: Master reset or roll-over  
The master timer reset and roll-over event is starting the burst mode operation.

Bit 0 **SW**: Software start  
This bit is set by software and automatically reset by hardware.  
When set, It starts the burst mode operation immediately.  
This bit is not active if the burst mode is not enabled (BME bit is reset).
39.5.49  HRTIM Burst Mode Compare Register (HRTIM_BMCMPR)

Address offset: 0x3A8h
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMCMP[15:0]:** Burst mode compare value
- Defines the number of periods during which the selected timers are in idle state.
- This register holds either the content of the preload register or the content of the active register if the preload is disabled.

*Note: BMCMP[15:0] cannot be set to 0x0000 when using the \( f_{\text{HRTIM}} \) clock without a prescaler as the burst mode clock source (BMCLK[3:0] = 1010 and BMPRESC[3:0] = 0000).*

39.5.50  HRTIM Burst Mode Period Register (HRTIM_BMPER)

Address offset: 0x3AC
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMPER[15:0]:** Burst mode Period
- Defines the burst mode repetition period.
- This register holds either the content of the preload register or the content of the active register if preload is disabled.

*Note: The BMPER[15:0] must not be null when the burst mode is enabled.*

  Refer to EE1SRC[1:0] description
- **Bit 11**: **EE2FAST**: *External Event 2 Fast mode*  
  Refer to EE1FAST description
- **Bits 10:9**: **EE2SNS[1:0]**: *External Event 2 Sensitivity*  
  Refer to EE1SNS[1:0] description
- **Bit 8**: **EE2POL**: *External Event 2 Polarity*  
  Refer to EE1POL description
Bits 7:6 **EE2SRC[1:0]: External Event 2 Source**  
Refer to EE1SRC[1:0] description

Bit 5 **EE1FAST**: *External Event 1 Fast mode*  
0: External Event 1 is re-synchronized by the HRTIM logic before acting on outputs, which adds a $f_{HRTIM}$ clock-related latency  
1: External Event 1 is acting asynchronously on outputs (low latency mode)  
*Note: This bit must not be modified once the counter in which the event is used is enabled (TxCEN bit set)*

Bits 4:3 **EE1SNS[1:0]: External Event 1 Sensitivity**  
00: On active level defined by EE1POL bit  
01: Rising edge, whatever EE1POL bit value  
10: Falling edge, whatever EE1POL bit value  
11: Both edges, whatever EE1POL bit value

Bit 2 **EE1POL**: *External Event 1 Polarity*  
This bit is only significant if EE1SNS[1:0] = 00.  
0: External event is active high  
1: External event is active low  
*Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.*

Bits 1:0 **EE1SRC[1:0]: External Event 1 Source**  
00: hrtim_evt11  
01: hrtim_evt12  
10: hrtim_evt13  
11: hrtim_evt14  
*Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.*

**Bit 31** ADC3TEPER: ADC trigger 3 on Timer E Period  
Refer to ADC3TAPER description

**Bit 30** ADC3TEC4: ADC trigger 3 on Timer E Compare 4  
Refer to ADC3TAC2 description

**Bit 29** ADC3TEC3: ADC trigger 3 on Timer E Compare 3  
Refer to ADC3TAC2 description

**Bit 28** ADC3TEC2: ADC trigger 3 on Timer E Compare 2  
Refer to ADC3TAC2 description

**Bit 27** ADC3TDPER: ADC trigger 3 on Timer D Period  
Refer to ADC3TAPER description

**Bit 26** ADC3TDC4: ADC trigger 3 on Timer D Compare 4  
Refer to ADC3TAC2 description

**Bit 25** ADC3TDC3: ADC trigger 3 on Timer D Compare 3  
Refer to ADC3TAC2 description

**Bit 24** ADC3TDC2: ADC trigger 3 on Timer D Compare 2  
Refer to ADC3TAC2 description

**Bit 23** ADC3TCPER: ADC trigger 3 on Timer C Period  
Refer to ADC3TAPER description

**Bit 22** ADC3TCC4: ADC trigger 3 on Timer C Compare 4  
Refer to ADC3TAC2 description

**Bit 21** ADC3TCC3: ADC trigger 3 on Timer C Compare 3  
Refer to ADC3TAC2 description

**Bit 20** ADC3TCC2: ADC trigger 3 on Timer C Compare 2  
Refer to ADC3TAC2 description

**Bit 19** ADC3TBRST: ADC trigger 3 on Timer B Reset and counter roll-over  
Refer to ADC3TBRST description

**Bit 18** ADC3TBPER: ADC trigger 3 on Timer B Period  
Refer to ADC3TAPER description

**Bit 17** ADC3TBC4: ADC trigger 3 on Timer B Compare 4  
Refer to ADC3TAC2 description
Bit 16 **ADC3TBC3**: *ADC trigger 3 on Timer B Compare 3*
Refer to ADC3TAC2 description

Bit 15 **ADC3TBC2**: *ADC trigger 3 on Timer B Compare 2*
Refer to ADC3TAC2 description

Bit 14 **ADC3TARST**: *ADC trigger 3 on Timer A Reset and counter roll-over*
This bit enables the generation of an ADC Trigger upon Timer A reset and roll-over event, on ADC Trigger 1 output.

Bit 13 **ADC3TAPER**: *ADC trigger 3 on Timer A Period*
This bit enables the generation of an ADC Trigger upon Timer A period event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 12 **ADC3TAC4**: *ADC trigger 3 on Timer A Compare 4*
Refer to ADC3TAC2 description

Bit 11 **ADC3TAC3**: *ADC trigger 3 on Timer A Compare 3*
Refer to ADC3TAC2 description

Bit 10 **ADC3TAC2**: *ADC trigger 3 on Timer A Compare 2*
This bit enables the generation of an ADC Trigger upon Timer A Compare 2 event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 9 **ADC3EEV5**: *ADC trigger 3 on External Event 5*
Refer to ADC3EEV1 description

Bit 8 **ADC3EEV4**: *ADC trigger 3 on External Event 4*
Refer to ADC3EEV1 description

Bit 7 **ADC3EEV3**: *ADC trigger 3 on External Event 3*
Refer to ADC3EEV1 description

Bit 6 **ADC3EEV2**: *ADC trigger 3 on External Event 2*
Refer to ADC3EEV1 description

Bit 5 **ADC3EEV1**: *ADC trigger 3 on External Event 1*
This bit enables the generation of an ADC Trigger upon External event 1, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 4 **ADC3MPER**: *ADC trigger 3 on Master Period*
This bit enables the generation of an ADC Trigger upon Master timer period event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 3 **ADC3MC4**: *ADC trigger 3 on Master Compare 4*
Refer to ADC3MC1 description

Bit 2 **ADC3MC3**: *ADC trigger 3 on Master Compare 3*
Refer to ADC3MC1 description

Bit 1 **ADC3MC2**: *ADC trigger 3 on Master Compare 2*
Refer to ADC3MC1 description

Bit 0 **ADC3MC1**: *ADC trigger 3 on Master Compare 1*
This bit enables the generation of an ADC Trigger upon Master Compare 1 event, on ADC Trigger 3 output (hrtim_adc_trg3).

---

**Address offset:** 0x3C8h  
**Reset value:** 0x0000 0000
Bit 17 **ADC4TBPER**: ADC trigger 4 on Timer B Period
Refer to ADC4TAPER description

Bit 16 **ADC4TBC4**: ADC trigger 4 on Timer B Compare 4
Refer to ADC4TAC2 description

Bit 15 **ADC4TBC3**: ADC trigger 4 on Timer B Compare 3
Refer to ADC4TAC2 description

Bit 14 **ADC4TBC2**: ADC trigger 4 on Timer B Compare 2
Refer to ADC4TAC2 description

Bit 13 **ADC4TAPER**: ADC trigger 4 on Timer A Period
This bit enables the generation of an ADC Trigger upon Timer A event, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 12 **ADC4TAC4**: ADC trigger 4 on Timer A Compare 4
Refer to ADC4TAC2 description

Bit 11 **ADC4TAC3**: ADC trigger 4 on Timer A Compare 3
Refer to ADC4TAC2 description

Bit 10 **ADC4TAC2**: ADC trigger 4 on Timer A Compare 2
This bit enables the generation of an ADC Trigger upon Timer A Compare 2, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 9 **ADC4EEV10**: ADC trigger 4 on External Event 10 (1)
Refer to ADC4EEV6 description

Bit 8 **ADC4EEV9**: ADC trigger 4 on External Event 9 (1)
Refer to ADC4EEV6 description

Bit 7 **ADC4EEV8**: ADC trigger 4 on External Event 8 (1)
Refer to ADC4EEV6 description

Bit 6 **ADC4EEV7**: ADC trigger 4 on External Event 7 (1)
Refer to ADC4EEV6 description

Bit 5 **ADC4EEV6**: ADC trigger 4 on External Event 6 (1)
This bit enables the generation of an ADC Trigger upon external event 6, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 4 **ADC4MPER**: ADC trigger 4 on Master Period
This bit enables the generation of an ADC Trigger upon Master period event, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 3 **ADC4MC4**: ADC trigger 4 on Master Compare 4
Refer to ADC4MC1 description

Bit 2 **ADC4MC3**: ADC trigger 4 on Master Compare 3
Refer to ADC4MC1 description

Bit 1 **ADC4MC2**: ADC trigger 4 on Master Compare 2
Refer to ADC4MC1 description

Bit 0 **ADC4MC1**: ADC trigger 4 on Master Compare 1
This bit enables the generation of an ADC Trigger upon Master Compare 1 event, on ADC Trigger 4 output (hrtim_adc_trg4).

1. These triggers are differing from HRTIM_ADC1R/HRTIM_ADC3R to HRTIM_ADC2R/HRTIM_ADC4R.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FLTSD[1:0]**: Fault Sampling clock division  
This bitfield indicates the division ratio between the timer clock frequency (f\(_{HRTIM}\)) and the fault signal sampling clock (f\(_{FLTS}\)) used by the digital filters.  
00: \(f_{FLTS} = f_{HRTIM}\)  
01: \(f_{FLTS} = f_{HRTIM} / 2\)  
10: \(f_{FLTS} = f_{HRTIM} / 4\)  
11: \(f_{FLTS} = f_{HRTIM} / 8\)

Note: This bitfield must be written prior to any of the FLTxE enable bits.

Bits 23:8 Reserved, must be kept at reset value.

Bit 7 **FLT5LCK**: Fault 5 Lock  
The FLT5LCK bit modifies the write attributes of the fault programming bit, so that they can be protected against spurious write accesses.  
This bit is write-once. Once it has been set, it cannot be modified till the next system reset.  
0: FLT5E, FLT5P, FLT5SRC, FLT5F[3:0] bits are read/write.  
1: FLT5E, FLT5P, FLT5SRC, FLT5F[3:0] bits can no longer be written (read-only mode)
Bits 6:3 **FLT5[3:0]**: Fault 5 filter

This bitfield defines the frequency used to sample FLT5 input and the length of the digital filter applied to FLT5. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- **0000**: No filter, FLT5 acts asynchronously
- **0001**: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}} \), \( N = 2 \)
- **0010**: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}} \), \( N = 4 \)
- **0011**: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}} \), \( N = 8 \)
- **0100**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/2} \), \( N = 6 \)
- **0101**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/2} \), \( N = 8 \)
- **0110**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/4} \), \( N = 6 \)
- **0111**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/4} \), \( N = 8 \)
- **1000**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/8} \), \( N = 6 \)
- **1001**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/8} \), \( N = 8 \)
- **1010**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/16} \), \( N = 5 \)
- **1011**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/16} \), \( N = 6 \)
- **1100**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/32} \), \( N = 5 \)
- **1101**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/32} \), \( N = 6 \)
- **1110**: \( f_{\text{SAMPLING}} = f_{\text{FLTS}/32} \), \( N = 8 \)

**Note:** This bitfield can be written only when FLT5E enable bit is reset.

This bitfield cannot be modified when FLT5LOCK has been programmed.

Bit 2 **FLT5SRC**: Fault 5 source

This bit selects the FAULT5 input source (refer to Table 342 for connection details).

- **0**: Fault 1 input is HRTIM_FLT5 input pin
- **1**: Fault 1 input is hrtim_in_flt5 signal

**Note:** This bitfield can be written only when FLT5E enable bit is reset

Bit 1 **FLT5P**: Fault 5 polarity

This bit selects the FAULT5 input polarity.

- **0**: Fault 5 input is active low
- **1**: Fault 5 input is active high

**Note:** This bitfield can be written only when FLT5E enable bit is reset

Bit 0 **FLT5E**: Fault 5 enable

This bit enables the global FAULT5 input circuitry.

- **0**: Fault 5 input disabled
- **1**: Fault 5 input enabled

|       | This bit defines if the master timer MCR register is part of the list of registers to be updated by the Burst DMA.  
|       | 0: HRTIM_TIMxCR register is not updated by Burst DMA accesses
|       | 1: HRTIM_TIMxCR register is updated by Burst DMA accesses

Bits 31:0  BDMADR[31:0]: Burst DMA Data register
Write accesses to this register triggers:
- the copy of the data value into the registers enabled in BDTxUPR and BDMUPR register bits
- the increment of the register pointer to the next location to be filled
# 39.5.63 HRTIM register map

The tables below summarize the HRTIM registers mapping. The address offsets in Table 348 and Table 349 are referred to in the base address offsets given in Table 347.

**Table 347. RTIM global register map**

<table>
<thead>
<tr>
<th>Base address offset</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000 - 0x07F</td>
<td>Master timer</td>
</tr>
<tr>
<td>0x080 - 0x0FF</td>
<td>Timer A</td>
</tr>
<tr>
<td>0x100 - 0x17F</td>

**Table 350. HRTIM Register map and reset values: Common functions**

- **Offset:** Address range for each register.
- **Register name:** Name of the register.
- **Reset value:** The reset value for the register.

The table provides a detailed view of the registers associated with the high-resolution timer (HRTIM) and their reset values.
Table 350. HRTIM Register map and reset values: Common functions (continued)

1. This register can be preloaded (see Table 333 on page 1546).

Refer to Section 2.3 on page 134 for the register boundary addresses.
40 Advanced-control timers (TIM1/TIM8)

40.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 40.3.26: Timer synchronization.

40.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input Capture (but channels 5 and 6)
  - Output Compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

1. See Figure 429: Break and Break2 circuitry overview for details.
40.3 TIM1/TIM8 functional description

40.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 387 and Figure 388 give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 387. Counter timing diagram with prescaler division change from 1 to 2

Figure 388. Counter timing diagram with prescaler division change from 1 to 4
40.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 394. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = “01”), the counter counts up (Center aligned mode 2, CMS = “10”) the counter counts up and down (Center aligned mode 3, CMS = “11”).

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or
DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 400. Counter timing diagram, internal clock divided by 1, TIMx.ARR = 0x6**

1. Here, center-aligned mode 1 is used (for more details refer to *Section 40.4: TIM1/TIM8 registers*).
Figures 401 and 402 illustrate counter timing diagrams for internal clocks divided by 2 and 4, respectively. The diagrams show the CK_PSC, CNT_EN, Timer clock = CK_CNT, Counter register, Counter underflow, Update event (UEV), and Update interrupt flag (UIF) signals.

Figure 404. Counter timing diagram, update event with ARPE=1 (counter underflow)
40.3.3 Repetition counter

Section 40.3.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 406). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**Update Event**: If the repetition counter underflow occurs when the counter is equal to the auto-reload value.
40.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:

- external clock (external clock mode 2, see Section 40.3.5)
- trigger for the slave mode (see Section 40.3.26)
- PWM reset input for cycle-by-cycle current regulation (see Section 40.3.7)

Figure 407 below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield.

The ETR input comes from multiple sources: input pins (default configuration), comparator outputs and analog watchdogs. The selection is done with the ETRSEL[3:0] bitfield.

**Figure 407. External trigger input block**

**Figure 408. TIM1/TIM8 ETR input circuitry**
40.3.5 Clock selection

The counter clock can be provided by the following clock sources:
- Internal clock (CK_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Encoder mode

**Internal clock source (CK_INT)**

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 409* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

</table>

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.
1. Codes ranging from 01000 to 11111 are reserved

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The Figure 412 gives an overview of the external trigger input block.

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. Refer to Figure 408: TIM1/TIM8 ETR input circuitry.

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:
1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by proper ETPS prescaler setting.

**Figure 413. Control circuit in external clock mode 2**

![Control Circuit Diagram](image-url)
40.3.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 414 to Figure 417* give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPX) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

*Figure 414. Capture/compare channel (example: channel 1 input stage)*

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

*Figure 415. Capture/compare channel 1 main circuit*
Figure 416. Output stage of capture/compare channel (channel 1, idem ch. 2 and 3)

Figure 417. Output stage of capture/compare channel (channel 4)

1. OCxREF, where x is the rank of the complementary channel
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 40.3.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written with ‘0’.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been
detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

40.3.8 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):
1. Select the proper T11x source (internal or external) with the T11SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (T11 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (T11 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 419. PWM input mode timing

40.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.
40.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while Channel 5 and 6 are only available inside the device (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 420.
40.3.11 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
**PWM edge-aligned mode**

- **Upcounting configuration**
  
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the [Upcounting mode on page 1681](#).

  In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’.

  *Figure 421* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

  ![Figure 421. Edge-aligned PWM waveforms (ARR=8)](image)

- **Downcounting configuration**

  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the [Downcounting mode on page 1685](#).

  In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the
TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 1688.

*Figure 422* shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

**Figure 422. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

### 40.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

*Figure 423* represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
40.3.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 424 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
40.3.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 354: Output control bits for complementary OCx and OCxN channels with break feature on page 1756 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 426. Complementary output with dead-time insertion**

**Figure 427. Dead-time waveforms with delay greater than the negative pulse**
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 40.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.

**Re-directing OCxREF to OCx or OCxN**

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

**40.3.16 Using the break function**

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 and TIM8 timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, parity error,....) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.
The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows the outputs to be enabled/disabled by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 354: Output control bits for complementary OCx and OCxN channels with break feature on page 1756 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKE/BK2E and BKP/BK2P can be modified at the same time. When the BKE/BK2E and BKP/BK2P bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (BRK) channel are:
- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source:
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral
- A system break:
  - the Cortex®-M7 LOCKUP output
  - the PVD output
  - all SRAM and TCM ECC dual error detections (AXI-SRAM, ITCM, DTCM, SRAM1, SRAM2, SRAM3, SRAM4, BKRAM, refer to SYSCFG_CFGR register for details)
  - a flash memory ECC dual error detection
  - a clock failure event generated by the CSS detector

The sources for break2 (BRK2) are:
- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source coming from a comparator output.
- The analog watchdog output of the DFSDM1 peripheral
Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register. The software break generation using BG and B2G is active whatever the BKE and BK2E enable bits values.

All sources are ORed before entering the timer BRK or BRK2 inputs, as per Figure 429 below.

**Figure 429. Break and Break2 circuitry overview**
Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 \( \text{ck\_tim} \) clock cycles).
  - If OSSI=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value.

If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows the configuration of several parameters to be frozen (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 40.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8). The LOCK bits can be written only once after an MCU reset.

Figure 430 shows an example of behavior of the outputs in response to a break.
Figure 430. Various output behavior in response to a break event on BRK (OSSI = 1)
The two break inputs have different behaviors on timer outputs:

- The BRK input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- BRK2 can only disable (inactive state) the PWM outputs.

The BRK has a higher priority than BRK2 input, as described in Table 351.

Note: BRK2 must only be used with OSSR = OSSI = 1.

<table>

Figure 431 gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

Figure 431. PWM output state following BRK and BRK2 pins assertion (OSSI=1)
40.3.17 Bidirectional break inputs

Beside regular digital break inputs and internal break events coming from the comparators, the timer 1 and 8 are featuring bidirectional break inputs/outputs combining the two sources, as represented on Figure 433.

The TIMx_BKINy_COMPz pins are combining the COMPz output (to be configured in open drain) and the timer’s TIMx_BKINy input. They allow to have:

- A global break information available for external MCUs or gate drivers shut down inputs, with a single-pin.
- An internal comparator and multiple external open drain comparators outputs ORed together and triggering a break event, when the multiple internal and external break inputs must be merged.

40.3.18 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next transition to the active state, on the following PWM
cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode. The ocref_clr_int is connected to the ETRF signal (ETR after filtering).

When ETRF is chosen, ETR must be configured as follows:
1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

Figure 434 shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 434. Clearing TIMx OCxREF

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then OCxREF is enabled again at the next counter overflow.
40.3.19 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 435 describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 435. 6-step generation, COM example (OSSR=1)
40.3.20 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

For example one may want to generate a positive pulse on OC1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}} \text{ min}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 40.3.21 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 40.3.20:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones. This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
40.3.22 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to a quadrature encoder. Refer to Table 352. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=T11 if not filtered and not inverted, TI2FP2=T12 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

Note: The prescaler must be set to zero when encoder mode is enabled

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The Figure 438 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx_CCMR1 register, TI2FP2 mapped on TI2)
- CC1P='0' and CC1NP='0' (TIMx_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, TI1FP2 non-inverted, TI1FP2= TI2).
- SMS='011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

### Figure 438. Example of counter operation in encoder interface mode.
Figure 439 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

Figure 439. Example of encoder interface mode with TI1FP1 polarity inverted.

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

40.3.23 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.
40.3.24 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 440 below.

Figure 440. Measuring time interval between edges on 3 signals

40.3.25 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4) referred to as “interfacing timer” in Figure 441. The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See Figure 414: Capture/compare channel (example: channel 1 input stage) on page 1699). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.
Example: one wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx_CR2 register to ‘101’.

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The Figure 441 describes this example.
Figure 441. Example of Hall sensor interface
40.3.26 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 41.3.19: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on Ti1 input:

- Configure the channel 1 to detect rising edges on Ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCRER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select Ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until Ti1 rising edge. When Ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on Ti1 and the actual reset of the counter is due to the resynchronization circuit on Ti1 input.

Figure 442. Control circuit in reset mode
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=’0’ in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 443. Control circuit in Gated mode

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1
Advanced-control timers (TIM1/TIM8) RM0399

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 444. Control circuit in trigger mode**

**Slave mode: Combined reset + trigger mode**

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

**Slave mode: external clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.
In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

   A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

   The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 445. Control circuit in external clock mode 2 + trigger mode**

---

**Note:** The clock of the slave peripherals (timer, ADC, …) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
40.3.27 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the TRGO2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 425 on page 1711.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

40.3.28 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.
This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register to be updated once. If every CCRx
register is to be updated twice for example, the number of data to transfer should be 6. Let's
take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and
data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

40.3.29 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx
counter either continues to work normally or stops, depending on DBG_TIMx_STOP
configuration bit in DBG module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE
bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have
their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).
40.4 **TIM1/TIM8 registers**

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

40.4.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)

Address offset: 0x04

Reset value: 0x0000 0000

Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter

*Note*: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit
is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note*: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]:** Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (TRGO2) to be selected. The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on TRGO2 is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - the update event is selected as trigger output (TRGO2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (TRGO2).

0100: **Compare** - OC1REFC signal is used as trigger output (TRGO2)

0101: **Compare** - OC2REFC signal is used as trigger output (TRGO2)

0110: **Compare** - OC3REFC signal is used as trigger output (TRGO2)

0111: **Compare** - OC4REFC signal is used as trigger output (TRGO2)

1000: **Compare** - OC5REFC signal is used as trigger output (TRGO2)

1001: **Compare** - OC6REFC signal is used as trigger output (TRGO2)

1010: **Compare Pulse** - OC4REFC rising or falling edges generate pulses on TRGO2

1011: **Compare Pulse** - OC6REFC rising or falling edges generate pulses on TRGO2

1100: **Compare Pulse** - OC4REFC or OC6REFC rising edges generate pulses on TRGO2

1101: **Compare Pulse** - OC4REFC rising or OC6REFC falling edges generate pulses on TRGO2

1110: **Compare Pulse** - OC5REFC or OC6REFC rising edges generate pulses on TRGO2

1111: **Compare Pulse** - OC5REFC rising or OC6REFC falling edges generate pulses on TRGO2

**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19  Reserved, must be kept at reset value.

Bit 18  **OIS6:** Output Idle state 6 (OC6 output)

Refer to OIS1 bit

Bit 17  Reserved, must be kept at reset value.

Bit 16  **OIS5:** Output Idle state 5 (OC5 output)

Refer to OIS1 bit

Bit 15  Reserved, must be kept at reset value.

Bit 14  **OIS4:** Output Idle state 4 (OC4 output)

Refer to OIS1 bit

Bit 13  **OIS3N:** Output Idle state 3 (OC3N output)

Refer to OIS1N bit
Bit 12 **OIS3**: Output Idle state 3 (OC3 output)
   Refer to OIS1 bit

Bit 11 **OIS2**: Output Idle state 2 (OC2N output)
   Refer to OIS1N bit

Bit 10 **OIS2**: Output Idle state 2 (OC2 output)
   Refer to OIS1 bit

Bit 9 **OIS1**: Output Idle state 1 (OC1N output)
   0: OC1N=0 after a dead-time when MOE=0
   1: OC1N=1 after a dead-time when MOE=0
   
   Note: **This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed**
   (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
   0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
   1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0
   
   Note: **This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed**
   (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: TI1 selection
   0: The TIMx_CH1 pin is connected to TI1 input
   1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection
   These bits allow selected information to be sent in master mode to slave timers for
   synchronization (TRGO). The combination is as follows:

   000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the
   reset is generated by the trigger input (slave mode controller configured in reset mode)
   then the signal on TRGO is delayed compared to the actual reset.

   001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is
   useful to start several timers at the same time or to control a window in which a slave
   timer is enable. The Counter Enable signal is generated by a logic AND between CEN
   control bit and the trigger input when configured in gated mode. When the Counter
   Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the
   master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

   010: **Update** - The update event is selected as trigger output (TRGO). For instance a master
   timer can then be used as a prescaler for a slave timer.

   011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be
   set (even if it was already high), as soon as a capture or a compare match occurred.
   (TRGO).

   100: **Compare** - OC1REFC signal is used as trigger output (TRGO)
   101: **Compare** - OC2REFC signal is used as trigger output (TRGO)
   110: **Compare** - OC3REFC signal is used as trigger output (TRGO)
   111: **Compare** - OC4REFC signal is used as trigger output (TRGO)

   Note: **The clock of the slave timer or ADC must be enabled prior to receive events from the
   master timer, and must not be changed on-the-fly while triggers are received from the
   master timer.**

Bit 3 **CCDS**: Capture/compare DMA selection
   0: CCx DMA request sent when CCx event occurs
   1: CCx DMA requests sent when update event occurs
Bit 2  **CCUS:** Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note:* This bit acts only on channels that have a complementary output.

Bit 0  **CCPC:** Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note:* This bit acts only on channels that have a complementary output.

</tbody>
</table>

**ETP:**
This bit selects whether ETR or ETR is used for trigger operations
0: ETR is non-inverted, active at high level or rising edge.
1: ETR is inverted, active at low level or falling edge.

**ECE:**
This bit enables External clock mode 2.
0: External clock mode 2 disabled
1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note:* Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111).
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111).
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of $f_{CK\_INT}$ frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

- 00: Prescaler OFF
- 01: ETRP frequency divided by 2
- 10: ETRP frequency divided by 4
- 11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which $N$ consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at $f_{DTS}$
- 0001: $f_{SAMP\_IN}=f_{CK\_INT}$, $N=2$
- 0010: $f_{SAMP\_IN}=f_{CK\_INT}$, $N=4$
- 0011: $f_{SAMP\_IN}=f_{CK\_INT}$, $N=8$
- 0100: $f_{SAMP\_IN}=f_{DTS}/2$, $N=6$
- 0101: $f_{SAMP\_IN}=f_{DTS}/2$, $N=8$
- 0110: $f_{SAMP\_IN}=f_{DTS}/4$, $N=6$
- 0111: $f_{SAMP\_IN}=f_{DTS}/4$, $N=8$
- 1000: $f_{SAMP\_IN}=f_{DTS}/8$, $N=6$
- 1001: $f_{SAMP\_IN}=f_{DTS}/8$, $N=8$
- 1010: $f_{SAMP\_IN}=f_{DTS}/16$, $N=5$
- 1011: $f_{SAMP\_IN}=f_{DTS}/16$, $N=6$
- 1100: $f_{SAMP\_IN}=f_{DTS}/16$, $N=8$
- 1101: $f_{SAMP\_IN}=f_{DTS}/32$, $N=5$
- 1110: $f_{SAMP\_IN}=f_{DTS}/32$, $N=6$
- 1111: $f_{SAMP\_IN}=f_{DTS}/32$, $N=8$

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- 00111: External Trigger input (ETRF)

Others: Reserved

See Table 353: TIMx internal trigger connection on page 1742 for more details on ITRRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 **Reserved**, must be kept at reset value.
Bits 16, 2, 1, 0 SMS[3:0]: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

Codes above 1000: Reserved.

Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

</tbody>
</table>
Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.
1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

Refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).

0: No compare match / No input capture occurred
1: A compare match or an input capture occurred.

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
40.4.6 TIMx event generation register (TIMx_EGR)(x = 1, 8)

Address offset: 0x14

<table>
<thead>
<tr>
<th>Bit 15:9 Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

- **Bit 8 B2G**: Break 2 generation
  - This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

- **Bit 7 BG**: Break generation
  - This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

- **Bit 6 TG**: Trigger generation
  - This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

- **Bit 5 COMG**: Capture/Compare control update generation
  - This bit is set by software, it is automatically cleared by hardware
  - 0: No action
  - 1: When CCPC bit is set, it allows CCxE, CCxNE and OCxM bits to be updated.
  
  *Note: This bit acts only on channels having a complementary output.*

- **Bit 4 CC4G**: Capture/Compare 4 generation
  - Refer to CC1G description

- **Bit 3 CC3G**: Capture/Compare 3 generation
  - Refer to CC1G description
40.4.7 TIMx capture/compare mode register 1(TIMx_CCMR1)(x = 1, 8)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode:**

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output Compare 2 clear enable
Refer to OC1CE description.

Bits 24, 14:12 **OC2M[3:0]**: Output Compare 2 mode
Refer to OC1M[3:0] description.

Bit 11 **OC2PE**: Output Compare 2 preload enable
Refer to OC1PE description.

Bit 10 **OC2FE**: Output Compare 2 fast enable
Refer to OC1FE description.

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).*

Bit 7 **OC1CE**: Output Compare 1 clear enable
0: OC1Ref is not affected by the ETRF input
1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=’0’) as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=’1’).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1011: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1100: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1101: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.

Note: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

Note: The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event.

**Note:** These bits cannot be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

### 40.4.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 1, 8)

<table>
<thead>
<tr>

40.4.10  TIMx capture/compare mode register 2 [alternate]  
(TIMx_CCMR2)(x = 1, 8)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

<tr>
<td></td>
<td>Refer to CC1NE description</td>
</tr>
</tbody>
</table>
Bit 5  **CC2P**: Capture/Compare 2 output polarity
Refer to CC1P description

Bit 4  **CC2E**: Capture/Compare 2 output enable
Refer to CC1E description

Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity

**CC1 channel configured as output:**

- 0: OC1N active high.
- 1: OC1N active low.

**CC1 channel configured as input:**
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).*

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2  **CC1NE**: Capture/Compare 1 complementary output enable

- 0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
- 1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 1  **CC1P**: Capture/Compare 1 output polarity

- 0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
- 1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

**CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

**CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

**CC1NP=1, CC1P=1**: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

**CC1NP=1, CC1P=0**: The configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 0  CC1E: Capture/Compare 1 output enable
  0: Capture mode disabled / OC1 is not active (see below)
  1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 354 for details.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

</tr>
</tbody>
</table>

Note: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and the GPIO registers.

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

**Bit 31** **UIFCPY**: UIF copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

40.4.13 TIMx prescaler (TIMx_PSC)(x = 1, 8)
Address offset: 0x28
Reset value: 0x0000

| Bit 15 |    | Bit 14 |    | Bit 13 |    | Bit 12 |    | Bit 11 |    | Bit 10 |    | Bit 9  |    | Bit 8  |    | Bit 7  |    | Bit 6  |    | Bit 5  |    | Bit 4  |    | Bit 3  |    | Bit 2  |    | Bit 1  |    | Bit 0  |    |

**Bits 15:0** **PSC[15:0]**: Prescaler value
The counter clock frequency (CK_CNT) is equal to f_{CK_PSC} / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

40.4.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8)
Address offset: 0x2C
Reset value: 0xFFFF

</tbody>
</table>

Bits 15:0 **REP[15:0]:** Repetition counter value  
These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enabled, as well as the update interrupt generation rate, if this interrupt is enabled.  
Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken into account until the next repetition update event.  
It means in PWM mode (REP+1) corresponds to:  
the number of PWM periods in edge-aligned mode  
the number of half PWM period in center-aligned mode.

**40.4.16 TIMx capture/compare register 1  
(TIMx_CCR1)(x = 1, 8)**

</table>

Bits 15:0 **CCR1[15:0]:** Capture/Compare 1 value  
**If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).  
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.  
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx_CCR1 register is read-only and cannot be programmed.
40.4.17 TIMx capture/compare register 2
(TIMx_CCR2)(x = 1, 8)

Address offset: 0x38
Reset value: 0x0000

Bits 15:0 **CCR2[15:0]: Capture/Compare 2 value**

*If channel CC2 is configured as output:* CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC2 output.

*If channel CC2 is configured as input:* CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx_CCR2 register is read-only and cannot be programmed.

40.4.18 TIMx capture/compare register 3

Bits 15:0 **CCR3[15:0]: Capture/Compare value**

*If channel CC3 is configured as output:* CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC3 output.

*If channel CC3 is configured as input:* CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx_CCR3 register is read-only and cannot be programmed.
40.4.19  TIMx capture/compare register 4

</table>

**Note**: As the bits BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSR, OSSI, LOCK[1:0] and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

- Bits 31:26  Reserved, must be kept at reset value.

- **Bit 25  BK2P**: Break 2 polarity
  - 0: Break input BRK2 is active low
  - 1: Break input BRK2 is active high

  **Note**:  This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  **Note**:  Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 24  **BK2E**: Break 2 enable

This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 429: Break and Break2 circuitry overview).

0: Break2 function disabled
1: Break2 function enabled

**Note:** The BKIN2 must only be used with OSSR = OSSI = 1.

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 23:20  **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK2 acts asynchronously
0001: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 2 \)
0010: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 4 \)
0011: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 8 \)
0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
1100: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 19:16  **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, BRK acts asynchronously
0001: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 2 \)
0010: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 4 \)
0011: \( f_{SAMPLING} = f_{CK_INT} \), \( N = 8 \)
0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
1100: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 15 **MOE**: Main output enable
This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: In response to a break 2 event. OC and OCN outputs are disabled
1: In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
0: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details (Section 40.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

Bit 14 **AOE**: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 is active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity
0: Break input BRK is active low
1: Break input BRK is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable
This bit enables the complete break protection (including all sources connected to bk_acth and BRK sources, as per Figure 429: Break and Break2 circuitry overview).
0: Break function disabled
1: Break function enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode
This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.
See OC/OCN enable description for more details (Section 40.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).
0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 40.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

- 0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).
- 1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

- 00: LOCK OFF - No bit is write protected.
- 01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxn bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
- 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
- 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

- DTG[7:5] = 0xx => DT = DTG[7:0] x tDTG with tDTG = tDTS.
- DTG[7:5] = 10x => DT = (64 + DTG[5:0]) x tDTG with tDTG = 2 x tDTS.
- DTG[7:5] = 110 => DT = (32 + DTG[4:0]) x tDTG with tDTG = 8 x tDTS.
- DTG[7:5] = 111 => DT = (32 + DTG[4:0]) x tDTG with tDTG = 16 x tDTS.

Example if tDTS = 125 ns (8 MHz), dead-time possible values are:

- 0 to 15875 ns by 125 ns steps,
- 16 μs to 31750 ns by 250 ns steps,
- 32 μs to 63 μs by 1 μs steps,
- 64 μs to 126 μs by 2 μs steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

### 40.4.21 TIMx DMA control register

(TIMx_DCR)(x = 1, 8)

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 ETRSEL[3:0]: ETR source selection
These bits select the ETR input source.
0000: ETR input is connected to I/O
0001: COMP1 output
0010: COMP2 output
0011: ADC1 AWD1
0100: ADC1 AWD2
0101: ADC1 AWD3
0110: ADC3 AWD1
0111: ADC3 AWD2
1000: ADC3 AWD3
Others: Reserved
Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 13:12 Reserved, must be kept at reset value.
Bit 11 **BKCMP2P**: BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: COMP2 input polarity is not inverted (active low if BKP=0, active high if BKP=1)
- 1: COMP2 input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMP1P**: BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: COMP1 input polarity is not inverted (active low if BKP=0, active high if BKP=1)
- 1: COMP1 input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: BKIN input polarity is not inverted (active low if BKP=0, active high if BKP=1)
- 1: BKIN input polarity is inverted (active high if BKP=0, active low if BKP=1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKDF1BK0E**: BRK dfsdm1_break[0] enable

This bit enables the dfsdm1_break[0] for the timer's BRK input. dfsdm1_break[0] output is ‘ORed’ with the other BRK sources.

- 0: dfsdm1_break[0] input disabled
- 1: dfsdm1_break[0] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BKCMP2E**: BRK COMP2 enable

This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.

- 0: COMP2 input disabled
- 1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.

- 0: COMP1 input disabled
- 1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer’s BRK input. BKIN input is ‘ORed’ with the other BRK sources.

0: BKIN input disabled
1: BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Refer to Figure 408: TIM1/TIM8 ETR input circuitry and to Figure 429: Break and Break2 circuitry overview.

Bits 31:18 Reserved, must be kept at reset value.
Bits 17:14  **ETRSEL[3:0]:** ETR source selection  
These bits select the ETR input source.  
0000: ETR input is connected to I/O  
0001: COMP1 output  
0010: COMP2 output  
0011: ADC2 AWD1  
0100: ADC2 AWD2  
0101: ADC2 AWD3  
0110: ADC3 AWD1  
0111: ADC3 AWD2  
1000: ADC3 AWD3  
Others: Reserved  
Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 13:12 Reserved, must be kept at reset value.

Bit 11  **BKCMP2P:** BRK COMP2 input polarity  
This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.  
0: COMP2 input polarity is not inverted (active low if BKP=0, active high if BKP=1)  
1: COMP2 input polarity is inverted (active high if BKP=0, active low if BKP=1)  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10  **BKCMP1P:** BRK COMP1 input polarity  
This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.  
0: COMP1 input polarity is not inverted (active low if BKP=0, active high if BKP=1)  
1: COMP1 input polarity is inverted (active high if BKP=0, active low if BKP=1)  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9  **BKINP:** BRK BKIN input polarity  
This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.  
0: BKIN input polarity is not inverted (active low if BKP=0, active high if BKP=1)  
1: BKIN input polarity is inverted (active high if BKP=0, active low if BKP=1)  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8  **BKDF1BK2E:** BRK dfsdm1_break[2] enable  
This bit enables the dfsdm1_break[2] for the timer’s BRK input. dfsdm1_break[2] output is 'OREd' with the other BRK sources.  
0: dfsdm1_break[2] input disabled  
1: dfsdm1_break[2] input enabled  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 7:3 Reserved, must be kept at reset value.
Bit 2 **BKCMP2E**: BRK COMP2 enable
This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.
0: COMP2 input disabled
1: COMP2 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: BRK COMP1 enable
This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.
0: COMP1 input disabled
1: COMP1 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **BKINE**: BRK BKIN input enable
This bit enables the BKIN alternate function input for the timer’s BRK input. BKIN input is ‘ORed’ with the other BRK sources.
0: BKIN input disabled
1: BKIN input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BK2CMP2P**: BRK2 COMP2 input polarity
This bit selects the COMP2 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: COMP2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)
1: COMP2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 10 **BK2CMP1P**: BRK2 COMP1 input polarity
This bit selects the COMP1 input sensitivity. It must be programmed together with the BK2P polarity bit.
- 0: COMP1 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)
- 1: COMP1 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

Bit 9 **BK2INP**: BRK2 BKIN2 input polarity
This bit selects the BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.
- 0: BKIN2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1)
- 1: BKIN2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1)
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

Bit 8 **BK2DF1BK3E**: BRK2 dfsdm1_break[3] enable
This bit enables the dfsdm1_break[3] for the timer’s BRK2 input. dfsdm1_break[3] output is ‘ORed’ with the other BRK2 sources.
- 0: dfsdm1_break[3] input disabled
- 1: dfsdm1_break[3] input enabled
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BK2CMP2E**: BRK2 COMP2 enable
This bit enables the COMP2 for the timer’s BRK2 input. COMP2 output is ‘ORed’ with the other BRK2 sources.
- 0: COMP2 input disabled
- 1: COMP2 input enabled
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

Bit 1 **BK2CMP1E**: BRK2 COMP1 enable
This bit enables the COMP1 for the timer’s BRK2 input. COMP1 output is ‘ORed’ with the other BRK2 sources.
- 0: COMP1 input disabled
- 1: COMP1 input enabled
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

Bit 0 **BK2INE**: BRK2 BKIN input enable
This bit enables the BKIN2 alternate function input for the timer’s BRK2 input. BKIN2 input is ‘ORed’ with the other BRK2 sources.
- 0: BKIN2 input disabled
- 1: BKIN2 input enabled
\[\text{Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).}\]

\[\text{Note: Refer to Figure 429: Break and Break2 circuitry overview.}\]
40.4.30  TIM1 timer input selection register (TIM1_TISEL)

Address offset: 0x68
Reset value: 0x0000 0000

Bits 31:28  Reserved, must be kept at reset value.
Bits 27:24  **TI4SEL[3:0]**: selects TI4[0] to TI4[15] input
           0000: TIM1_CH4 input
           Others: Reserved
Bits 23:20  Reserved, must be kept at reset value.
Bits 19:16  **TI3SEL[3:0]**: selects TI3[0] to TI3[15] input
           0000: TIM1_CH3 input
           Others: Reserved
Bits 15:12  Reserved, must be kept at reset value.
Bits 11:8   **TI2SEL[3:0]**: selects TI2[0] to TI2[15] input
           0000: TIM1_CH2 input
           Others: Reserved
Bits 7:4    Reserved, must be kept at reset value.
Bits 3:0    **TI1SEL[3:0]**: selects TI1[0] to TI1[15] input
           0000: TIM1_CH1 input
           0001: COMP1 output
           Others: Reserved

40.4.31  TIM8 timer input selection register (TIM8_TISEL)

Address offset: 0x68
Reset value: 0x0000 0000

Bits 31:28  Reserved, must be kept at reset value.
Bits 27:24  **TI4SEL[3:0]**: selects TI4[0] to TI4[15] input
           0000: TIM8_CH4 input
           Others: Reserved
Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **TI3SEL[3:0]**: selects TI3[0] to TI3[15] input
  0000: TIM8_CH3 input
  Others: Reserved

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **TI2SEL[3:0]**: selects TI2[0] to TI2[15] input
  0000: TIM8_CH2 input
  Others: Reserved

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **TI1SEL[3:0]**: selects TI1[0] to TI1[15] input
  0000: TIM8_CH1 input
  0001: COMP2 output
  Others: Reserved
## TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

40.4.33 TIM8 register map

TIM8 registers are mapped as 16-bit addressable registers as described in the table below:

### Table 356. TIM8 register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | TIM8_CR1      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | TIM8_CR2      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x08   | TIM8_SMCR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x10   | TIM8_DIER     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | TIM8_SR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

### Table 355. TIM1 register map and reset values (continued)

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

41 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

41.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit/32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 41.3.19: Timer synchronization.

41.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3, TIM4) or 32-bit (TIM2 and TIM5) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

Reg

Preload registers transferred to active registers on U event according to control bit
41.3 TIM2/TIM3/TIM4/TIM5 functional description

41.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down but also down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 447* and *Figure 448* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 447. Counter timing diagram with prescaler division change from 1 to 2

Figure 448. Counter timing diagram with prescaler division change from 1 to 4
41.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 453. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)
Figure 454. Counter timing diagram, Update event when ARPE=1 (TIMx_ARR preloaded)

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.
The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

- Update interrupt flag (UIF)
Figure 457. Counter timing diagram, internal clock divided by 4

Figure 458. Counter timing diagram, internal clock divided by N
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or
DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 460. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6**

1. Here, center-aligned mode 1 is used (for more details refer to Section 41.4.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1826).

1. Center-aligned mode 2 or 3 is used with an UIF on overflow.
Figure 463. Counter timing diagram, internal clock divided by N

Figure 464. Counter timing diagram, Update event with ARPE=1 (counter underflow)
41.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer X can be configured to act as a prescaler for Timer Y. Refer to : Using one timer as prescaler for another timer on page 1820 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 466* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 01000 to 11111: ITRy.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= '01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 and CC2NP=0 in the TIMx_CCER register.

5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

6. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.

7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 468. Control circuit in external clock mode 1**

<table>
<thead>
<tr>
<th>TI2</th>
<th>CNT_EN</th>
<th>Counter clock = CK_CNT = CK_PSC</th>
<th>Counter register</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>34, 35, 36</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Write TIF=0</td>
</tr>
</tbody>
</table>

**External clock source mode 2**

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

*Figure 469* gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. Select the proper ETR source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most \( \frac{1}{4} \) of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.
41.3.4 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 41.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or
a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 41.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

**Figure 474. PWM input mode timing**

41.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

E.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

Ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

41.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, one must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 475.
41.3.9 **PWM mode**

Pulse width modulation mode permits to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx or TIMx_CNT ≥ TIMx_CCRx (depending on the direction of the counter). However, to comply with the OCREFCLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison or
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=‘110 or ‘111).

This forces the PWM by software while the timer is running.
The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

**PWM edge-aligned mode**

**Upcounting configuration**

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to *Upcounting mode on page 1785*.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxREF is held at '0'. *Figure 476* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

**Figure 476. Edge-aligned PWM waveforms (ARR=8)**

![Edge-aligned PWM waveforms](image)

**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 1788*.

In PWM mode 1, the reference signal ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then ocxref is held at 100%. PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from '00 (all the remaining configurations having the same effect on the ocxref/OCx signals). The
compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting) on page 1791.

Figure 477 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Figure 477. Center-aligned PWM waveforms (ARR=8)

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

41.3.10 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 2.

*Figure 478* shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1).
41.3.11 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

– OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
– OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 479 shows an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
41.3.12 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The ocref_clr_int is connected to the ETRF signal (ETR after filtering).

The OCxREF signal for a given channel can be reset by applying a high level on the ETRF input (OCxCE enable bit set to 1 in the corresponding TIMx_CCMRx register). OCxREF remains low until the next transition to the active state, on the following PWM cycle.

This function can be used only in the output compare and PWM modes. It does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application’s needs.
Figure 480 shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

**Figure 480. Clearing TIMx OCxREF**

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), OCxREF is enabled again at the next counter overflow.
One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- \( \text{CNT}<\text{CCR}x \leq \text{ARR} \) (in particular, \( 0<\text{CCR}x \)),

For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP=’0’ in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one wants to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

**Particular case: OCx fast enable:**

In One-pulse mode, the edge detection on T1x input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 41.3.14 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 41.3.13:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

**Note:** In retriggerable one pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
41.3.15 Encoder interface mode

To select Encoder Interface mode write SMS='001 in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to Table 357. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.
An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

Figure 483 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = '0' (TIMx_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = '0' (TIMx_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)</th>
<th>TI1FP1 signal</th>
<th>TI2FP2 signal</th>

</tr>
<tr>
<td>Counting on TI1 and TI2</td>
<td>High</td>
<td>Down</td>
<td>Up</td>
</tr>
</tbody>
</table>

Figure 484 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P=1).
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

41.3.16 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMx_CNT[31]). This permits to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

41.3.17 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1 to TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 40.3.25: Interfacing with Hall sensors on page 1727.
41.3.18 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

![Figure 485. Control circuit in reset mode](image_url)

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:
1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCMR1 register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 486. Control circuit in gated mode**

1. The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Note:** The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write
CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 487. Control circuit in trigger mode**

---

**Slave mode: External Clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 488. Control circuit in external clock mode 2 + trigger mode**

41.3.19 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 489: Master/Slave timer example* and *Figure 490: Master/slave connection example with 1 channel only timers* present an overview of the trigger selection and the master mode selection blocks.

**Figure 489. Master/Slave timer example**
The timers with one channel only (see Figure 490) do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the "TIMx internal trigger connection" table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave. The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

Using one timer as prescaler for another timer

For example, TIM3 can be configured to act as a prescaler for TIM2. Refer to Figure 489. To do this:

1. Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM3_CR2 register, a rising edge is output on TRGO each time an update event is generated.

2. To connect the TRGO output of TIM3 to TIM2, TIM2 must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM2_SMCR register (writing TS=00010).

3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes TIM2 to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).

4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

Using one timer to enable another timer

In this example, we control the enable of TIM2 with the output compare 1 of Timer 3. Refer to Figure 489 for connections. TIM2 counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT \( (f_{CK\_CNT} = f_{CK\_INT}/3) \).
1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).

2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).

3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).

4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).

5. Enable TIM2 by writing ‘1’ in the CEN bit (TIM2_CR1 register).

6. Start TIM3 by writing ‘1’ in the CEN bit (TIM3_CR1 register).

Note: The counter 2 clock is not synchronized with counter 1, this mode only affects the TIM2 counter enable signal.

In the example in Figure 491, the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM3. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to Figure 492), we synchronize TIM3 and TIM2. TIM3 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM3 is disabled by writing ‘0’ to the CEN bit in the TIM3_CR1 register:

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).

2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).

3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).

4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).

5. Reset TIM3 by writing ‘1’ in UG bit (TIM3_EGR register).

6. Reset TIM2 by writing ‘1’ in UG bit (TIM2_EGR register).

7. Initialize TIM2 to 0xE7 by writing ‘0xE7’ in the TIM2 counter (TIM2_CNTL).

8. Enable TIM2 by writing ‘1’ in the CEN bit (TIM2_CR1 register).

9. Start TIM3 by writing ‘1’ in the CEN bit (TIM3_CR1 register).

10. Stop TIM3 by writing ‘0’ in the CEN bit (TIM3_CR1 register).
Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 3. Refer to Figure 489 for connections. Timer 2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0 to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT (f_{CK_CNT} = f_{CK_INT}/3).

1. Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3_CR2 register).
2. Configure the TIM3 period (TIM3_ARR registers).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in trigger mode (SMS=110 in TIM2_SMCR register).
5. Start TIM3 by writing ‘1 in the CEN bit (TIM3_CR1 register).

Figure 493. Triggering TIM2 with update of TIM3

Write TIF = 0

MS33121V1
As in the previous example, both counters can be initialized before starting counting. Figure 494 shows the behavior with the same configuration as in Figure 493 but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).

**Figure 494. Triggering TIM2 with Enable of TIM3**

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to Figure 489 for connections. To ensure the counters are aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

1. Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the TIM3_CR2 register).
2. Configure TIM3 slave mode to get the input trigger from TI1 (TS=00100 in the TIM3_SMCR register).
3. Configure TIM3 in trigger mode (SMS=110 in the TIM3_SMCR register).
4. Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3_SMCR register).
5. Configure TIM2 to get the input trigger from TIM3 (TS=00000 in the TIM2_SMCR register).
6. Configure TIM2 in trigger mode (SMS=110 in the TIM2_SMCR register).

When a rising edge occurs on TI1 (TIM3), both counters starts counting synchronously on the internal clock and both TIF flags are set.

**Note:** In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM3.
Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

41.3.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

---

Figure 495. Triggering TIM3 and TIM2 with TIM3 TI1 input
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every
CCRx register is to be updated twice for example, the number of data to transfer should be
6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5
and data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

41.3.21 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx
counter either continues to work normally or stops, depending on TIMx configuration bit in
DBGMCU module. For more details, refer to Section 63.5.8: Microcontroller debug unit
(DBGMCU).

For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB1FZ2), the
outputs are disabled.
41.4 **TIM2/TIM3/TIM4/TIM5 registers**

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

41.4.1 **TIMx control register 1 (TIMx_CR1)(x = 2 to 5)**

<tbody>
<tr>
<td>0</td>
<td>Counter disabled</td>
</tr>
<tr>
<td>1</td>
<td>Counter enabled</td>
</tr>
</tbody>
</table>

**Note**: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

CEN is cleared automatically in one-pulse mode, when an update event occurs.
Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: TI1 selection
   0: The TIMx_CH1 pin is connected to TI1 input
   1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
   See also Section 40.3.25: Interfacing with Hall sensors on page 1727

Bits 6:4  **MMS[2:0]**: Master mode selection
   These bits permit to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:
   000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
   001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.
   When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
   010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
   011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
   (TRGO)
   100: **Compare** - OC1REFC signal is used as trigger output (TRGO)
   101: **Compare** - OC2REFC signal is used as trigger output (TRGO)
   110: **Compare** - OC3REFC signal is used as trigger output (TRGO)
   111: **Compare** - OC4REFC signal is used as trigger output (TRGO)

   **Note**: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3  **CCDS**: Capture/compare DMA selection
   0: CCx DMA request sent when CCx event occurs
   1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.

Bits 31:22 Reserved, must be kept at reset value.  
Bits 19:17 Reserved, must be kept at reset value.  

**Bit 15 ETP:** External trigger polarity  
This bit selects whether ETR or ETR is used for trigger operations  
0: ETR is non-inverted, active at high level or rising edge  
1: ETR is inverted, active at low level or falling edge

**Bit 14 ECE:** External clock enable  
This bit enables External clock mode 2.  
0: External clock mode 2 disabled  
1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.  

**Note:** Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111).  
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111).  
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

**Bits 13:12 ETPS[1:0]: External trigger prescaler**  
External trigger signal ETRP frequency must be at most 1/4 of CK_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.  
00: Prescaler OFF  
01: ETRP frequency divided by 2  
10: ETRP frequency divided by 4  
11: ETRP frequency divided by 8
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at \(f_{DTS}\)
- **0001**: \(f_{SAMPLING}=f_{CK\_INT}\), \(N=2\)
- **0010**: \(f_{SAMPLING}=f_{CK\_INT}\), \(N=4\)
- **0011**: \(f_{SAMPLING}=f_{CK\_INT}\), \(N=8\)
- **0100**: \(f_{SAMPLING}=f_{DTS}/2\), \(N=6\)
- **0101**: \(f_{SAMPLING}=f_{DTS}/2\), \(N=8\)
- **0110**: \(f_{SAMPLING}=f_{DTS}/4\), \(N=6\)
- **0111**: \(f_{SAMPLING}=f_{DTS}/4\), \(N=8\)
- **1000**: \(f_{SAMPLING}=f_{DTS}/8\), \(N=6\)
- **1001**: \(f_{SAMPLING}=f_{DTS}/8\), \(N=8\)
- **1010**: \(f_{SAMPLING}=f_{DTS}/16\), \(N=5\)
- **1011**: \(f_{SAMPLING}=f_{DTS}/16\), \(N=6\)
- **1100**: \(f_{SAMPLING}=f_{DTS}/16\), \(N=8\)
- **1101**: \(f_{SAMPLING}=f_{DTS}/32\), \(N=5\)
- **1110**: \(f_{SAMPLING}=f_{DTS}/32\), \(N=6\)
- **1111**: \(f_{SAMPLING}=f_{DTS}/32\), \(N=8\)

**Bit 7** **MSM**: Master/Slave mode

- **0**: No action
- **1**: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]:** Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- 00111: External Trigger input (ETRF)
- 01000: Internal Trigger 4 (ITR4)
- 01001: Internal Trigger 5 (ITR5)
- 01010: Internal Trigger 6 (ITR6)
- 01011: Internal Trigger 7 (ITR7)
- 01100: Internal Trigger 8 (ITR8)
- Others: Reserved

See Table 358: TIMx internal trigger connection on page 1832 for more details on ITRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.

Bits 16, 2, 1, 0  **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

- 0000: Slave mode disabled - if CEN = ‘1 then the prescaler is clocked directly by the internal clock.
- 0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
- 0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
- 0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
- 0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

**Note:** The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12  **CC4OF**: Capture/Compare 4 overcapture flag
refer to CC1OF description

Bit 11  **CC3OF**: Capture/Compare 3 overcapture flag
refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
refer to CC1OF description

Bit 9   **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.
Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
At overflow or underflow (for TIM2 to TIM4) and if UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

### 41.4.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5)

Address offset: 0x14
Reset value: 0x0000

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
- 0: No action
- 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
- 0: No action
- 1: A capture/compare event is generated on channel 1:
  - **If channel CC1 is configured as output**: CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
  - **If channel CC1 is configured as input**: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
- This bit can be set by software, it is automatically cleared by hardware.
- 0: No action
- 1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).
41.4.7  TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

- **IC2F[3:0]**: Input capture 2 filter
- **IC2PSC[1:0]**: Input capture 2 prescaler
- **CC2S[1:0]**: Capture/compare 2 selection
  - 00: CC2 channel is configured as output.
  - 01: CC2 channel is configured as input, IC2 is mapped on TI2.
  - 10: CC2 channel is configured as input, IC2 is mapped on TI1.
  - 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).
**Bits 7:4 IC1F[3:0]: Input capture 1 filter**

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fCK_INT, N=2
- 0010: fSAMPLING=fCK_INT, N=4
- 0011: fSAMPLING=fCK_INT, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

**Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler**

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

**Bits 1:0 CC1S[1:0]: Capture/Compare 1 selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*
41.4.8  TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) 
(x = 2 to 5)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture 
mode (previous section). The direction of a channel is defined by configuring the 
corresponding CCxS bits. All the other bits of this register have a different function in input 
and in output mode.

**Output compare mode:**

Bits 31:25  Reserved, must be kept at reset value.
Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12  **OC2M[3:0]**: Output compare 2 mode
refer to OC1M description on bits 6:4

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if 
an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCRER).*

Bit 7  **OC1CE**: Output compare 1 clear enable
0: OC1Ref is not affected by the ETRF input
1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 16, 6:4 \textbf{OC1M[3:0]}: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT<TIMx_CCR1 else active (OC1REF=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

\textbf{Note}: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

\textbf{Note}: The OC1M[3] bit is not contiguous, located in bit 16.
41.4.9 TIMx capture/register 2 (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

Bit 15  **CC4NP**: Capture/Compare 4 output Polarity.

Refer to CC1NP description

Bit 14  Reserved, must be kept at reset value.

Bit 13  **CC4P**: Capture/Compare 4 output Polarity.

Refer to CC1P description

Bit 12  **CC4E**: Capture/Compare 4 output enable.

Refer to CC1E description

Bit 11  **CC3NP**: Capture/Compare 3 output Polarity.

Refer to CC1NP description

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CC3P**: Capture/Compare 3 output Polarity.

Refer to CC1P description

Bit 8  **CC3E**: Capture/Compare 3 output enable.

Refer to CC1E description
Bit 7 **CC2NP**: Capture/Compare 2 output Polarity.
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity.
refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable.
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

**When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**Table 359. Output control bit for standard OCx channels**

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Output disabled (not driven by the timer: Hi-Z)</td>
</tr>
<tr>
<td>1</td>
<td>Output enabled (tim_ocx = tim_ocxref + Polarity)</td>
</tr>
</tbody>
</table>

**Note**: The state of the external IO pins connected to the standard OCx channels depends on the OCx channel state and the GPIO control and alternate function registers.

### 41.4.12 TIMx counter (TIMx_CNT)(x = 2 to 5)

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in TIMx_CR1 register:
- This section is for UIFREMAP = 0
- Next section is for UIFREMAP = 1
41.4.13 TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5)

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in TIMx_CR1 register:

- Previous section is for UIFREMAP = 0
- This section is for UIFREMAP = 1

Address offset: 0x24
Reset value: 0x0000 0000

41.4.14 TIMx prescaler (TIMx_PSC)(x = 2 to 5)

Address offset: 0x28
Reset value: 0x0000
Bits 15:0 **PSC[15:0]:** Prescaler value

The counter clock frequency CK_CNT is equal to \( f_{CK_PSC} / (PSC[15:0] + 1) \).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

### 41.4.15 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5)

Address offset: 0x2C

Reset value: 0xFFFF FFFF

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:16 **ARR[31:16]:** High auto-reload value (TIM2 and TIM5)

Bits 15:0 **ARR[15:0]:** Low Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the Section 41.3.1: Time-base unit on page 1783 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 41.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5)

Address offset: 0x34

Reset value: 0x0000 0000

</tbody>
</table>

**Bits 31:16 CCR4[31:16]:** High Capture/Compare 4 value (TIM2 and TIM5)  
**Bits 15:0 CCR4[15:0]:** Low Capture/Compare value

1. **If channel CC4 is configured as output:**  
   - CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).  
   - It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.  
   - The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC4 output.  

2. **If channel CC4 is configured as input:**  
   - CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx_CCR4 register is read-only and cannot be programmed.

### Notes:
41.4.20  TIMx DMA control register (TIMx_DCR)(x = 2 to 5)

Address offset: 0x48
Reset value: 0x0000

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th>DBL[4:0]</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>

<td>15</td>
<td>14</td>
<td>13</td>
<td>rw</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**
This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
00000: 1 transfer,
00001: 2 transfers,
00010: 3 transfers,
... 10001: 18 transfers.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**
This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR
...  Example: Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

41.4.21  TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x4C
Reset value: 0x0000

<table>
<thead>

<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
</tr>
</tbody>
</table>

Bits 15:0  **DMAB[15:0]: DMA register for burst accesses**
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 41.4.22 TIM2 alternate function option register 1 (TIM2_AF1)

Refer to Section 2.3 on page 134 for the register boundary addresses.
42 General-purpose timers (TIM12/TIM13/TIM14)

42.1 TIM12/TIM13/TIM14 introduction

The TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 42.3.17: Timer synchronization (TIM12).

42.2 TIM12/TIM13/TIM14 main features

42.2.1 TIM12 main features

The features of the TIM12 general-purpose timer include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare
42.2.2 TIM13/TIM14 main features

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed "on the fly")
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare
This signal can be used as trigger for some slave timers, see Section 42.3.18: Using timer output as trigger for other timers (TIM13/TIM14).
42.3 TIM12/TIM13/TIM14 functional description

42.3.1 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 498 and Figure 499* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 498. Counter timing diagram with prescaler division change from 1 to 2

- Prescaler counter: 0 0 1 2 3 0 1 2 3
42.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 500. Counter timing diagram, internal clock divided by 1
Figure 501. Counter timing diagram, internal clock divided by 2

Figure 502. Counter timing diagram, internal clock divided by 4
Figure 503. Counter timing diagram, internal clock divided by N

Figure 504. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)
42.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1 (for TIM12): external input pin (TIx)
- Internal trigger inputs (ITRx) (for TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to Section : Using one timer as prescaler for another timer for more details.

Internal clock source (CK_INT)

The internal clock source is the default clock source for TIM13/TIM14.

For TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS='000'). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 506* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1 (TIM12)

This mode is selected when SMS='111' in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F='0000').
4. Select the rising edge polarity by writing CC2P='0' and CC2NP='0' in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS='111' in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS='110' in the TIMx_SMCR register.
7. Enable the counter by writing CEN='1' in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.
The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

42.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

Figure 509 to Figure 511 give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 509. Capture/compare channel (example: channel 1 input stage)**

**Figure 510. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 42.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SSR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SSR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to '01' in the TIMx_CCMR1 register. As soon as CC1S becomes different from '00', the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICxF bits in the TIMx_CCMRx register if the input is one of the TIx inputs). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI11 when 8 consecutive samples with the
new level have been detected (sampled at $f_{DTS}$ frequency). Then write IC1F bits to ‘0011’ in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

42.3.6 PWM input mode (only for TIM12)

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):
1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to ‘01’ in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): program the CC1P and CC1NP bits to ‘00’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to ‘10’ in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): program the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to ‘00101’ in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to ‘100’ in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

**Figure 512. PWM input mode timing**

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 42.3.7 Forced output mode

In output mode (CCxS bits = ‘00’ in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write ‘0101’ in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=’0’ (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to ‘0100’ in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

42.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM='0000'), be set active (OCxM='0001'), be set inactive (OCxM='0010') or can toggle (OCxM='0011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = ‘0011’ to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = ‘0’ to disable preload register
   - Write CCxP = ‘0’ to select active high polarity
   - Write CCxE = ‘1’ to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 513.
42.3.9 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx.ARR register and a duty cycle determined by the value of the TIMx.CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx.CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx.CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx.CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx.EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx.CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx.CCER register. Refer to the TIMx.CCERx register description for more details.

In PWM mode (1 or 2), TIMx.CNT and TIMx.CCRx are always compared to determine whether TIMx.CNT ≤ TIMx.CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx.CNT < TIMx.CCRx else it becomes low. If the compare value in TIMx.CCRx is greater than the auto-reload value (in TIMx.ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 514 shows some edge-aligned PWM waveforms in an example where TIMx.ARR=8.
42.3.10 Combined PWM mode (TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

*Figure 515* represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
42.3.11 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

\[ CNT < CCRx \leq ARR \] (in particular, \( 0 < CCRx \))
For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Use TI2FP2 as trigger 1:
1. Select the proper TI2[\( x \)] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M='0111' in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.
Particular case: OCx fast enable

In One-pulse mode, the edge detection on TiX input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

42.3.12 Retriggerable one pulse mode (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in Section 42.3.11: One-pulse mode:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retrigerrable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 517. Retriggerable one pulse mode

42.3.13 UIF bit remapping

The UIFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the
UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

### 42.3.14 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 518.

![Figure 518. Measuring time interval between edges on 2 signals](image)

### 42.3.15 TIM12 external trigger synchronization

The TIM12 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = ‘01’ in the TIMx_CCMR1 register.
   Program CC1P and CC1NP to ‘00’ in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS='100' in TIMx_SMCR register. Select TI1 as the input source by writing TS='00101' in TIMx_SMCR register.
3. Start the counter by writing CEN='1' in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S='01' in TIMx_CCMR1 register. Program CC1P='1' and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS='101' in TIMx_SMCR register. Select TI1 as the input source by writing TS='00101' in TIMx_SMCR register.

3. Enable the counter by writing CEN='1' in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN='0', whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS='110' in TIMx_SMCR register. Select TI2 as the input source by writing TS='00110' in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.
42.3.16 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.
**42.3.17 Timer synchronization (TIM12)**

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 41.3.19: Timer synchronization for details.

*Note:* The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

**42.3.18 Using timer output as trigger for other timers (TIM13/TIM14)**

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer will detect the trigger.

For instance, if the destination’s timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

**42.3.19 Debug mode**

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBGMCU module. For more details, refer to Section 63.5.8: Microcontroller debug unit (DBGMCU).

**42.4 TIM12 registers**

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

**TIM12 control register 2 (TIM12_CR2)**

**Address offset:** 0x04

**Reset value:** 0x0000

**Bits 9:8** **CKD[1:0]: Clock division**
- This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (TIx).
  - 00: \( t_{DTS} = t_{CK\_INT} \)
  - 01: \( t_{DTS} = 2 \times t_{CK\_INT} \)
  - 10: \( t_{DTS} = 4 \times t_{CK\_INT} \)
  - 11: Reserved

**Bit 7** **ARPE: Auto-reload preload enable**
- 0: TIMx.ARR register is not buffered.
- 1: TIMx.ARR register is buffered.

**Bits 6:4** Reserved, must be kept at reset value.

**Bit 3** **OPM: One-pulse mode**
- 0: Counter is not stopped on the update event
- 1: Counter stops counting on the next update event (clearing the CEN bit).

**Bit 2** **URS: Update request source**
- This bit is set and cleared by software to select the UEV event sources.
  - 0: Any of the following events generates an update interrupt if enabled. These events can be:
    - Counter overflow
    - Setting the UG bit
    - Update generation through the slave mode controller
  - 1: Only counter overflow generates an update interrupt if enabled.

**Bit 1** **UDIS: Update disable**
- This bit is set and cleared by software to enable/disable update event (UEV) generation.
  - 0: UEV enabled. An UEV is generated by one of the following events:
    - Counter overflow
    - Setting the UG bit
    - Buffered registers are then loaded with their preload values.
  - 1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

**Bit 0** **CEN: Counter enable**
- 0: Counter disabled
- 1: Counter enabled
- CEN is cleared automatically in one-pulse mode, when an update event occurs.

*Note:* *External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*
Bits 15:8 Reserved, must be kept at reset value.

Bit 7 *T11S*: TI1 selection

0: The TIM12_CH1 pin is connected to TI1 input
1: The TIM12_CH1, CH2 pins are connected to the TI1 input (XOR combination)

Bits 6:4 *MMS*[2:0]: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:
000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
010: Update - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
100: Compare - OC1REFC signal is used as trigger output (TRGO).
101: Compare - OC2REFC signal is used as trigger output (TRGO).

Bits 3:0 Reserved, must be kept at reset value.

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 *MSM*: Master/Slave mode

0: No action
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]**: Trigger selection

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- Others: Reserved

See Table 361: TIMx internal trigger connection on page 1886 for more details on the meaning of ITRx for each timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS='000') to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

- 0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
- 0001: Reserved
- 0010: Reserved
- 0011: Reserved
- 0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
- Other codes: reserved.

**Note:** The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='00100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 TG: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in the TIMx_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.
Bit 2 **CC2G**: Capture/compare 2 generation
refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
   - **If channel CC1 is configured as output**: the CC1IF flag is set, the corresponding interrupt is sent if enabled.
   - **If channel CC1 is configured as input**: The current counter value is captured in the TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initializes the counter and generates an update of the registers. The prescaler counter is also cleared and the prescaler ratio is not affected. The counter is cleared.

### 42.4.7 TIM12 capture/compare mode register 1 (TIM12_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Input capture mode:**

<table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
42.4.8 TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the
corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Output compare mode:**

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15     Reserved, must be kept at reset value.

Bits 24, 14:12 **OC2M[3:0]:** Output compare 2 mode
Refer to OC1M[3:0] for bit description.

Bit 11     **OC2PE:** Output compare 2 preload enable

Bit 10     **OC2FE:** Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]:** Capture/Compare 2 selection
This bitsfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note:* The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7     Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas the active level of OC1 depends on the CC1P.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.
- **0001**: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1
- **0100**: Force inactive level - OC1REF is forced low
- **0101**: Force active level - OC1REF is forced high
- **0110**: PWM mode 1 - channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else it is inactive
- **0111**: PWM mode 2 - channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else it is active
- **1000**: Retrigerrable OPM mode 1 - The channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1001**: Retrigerrable OPM mode 2 - The channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.
- **1010**: Reserved,
- **1011**: Reserved,
- **1100**: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.
- **1101**: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.
- **1110**: Reserved,
- **1111**: Reserved

**Note:** In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Note:** The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles

1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 42.4.9 TIM12 capture/compare enable register (TIM12_CCER)

Address offset: 0x20

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity

Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity

Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable

Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity

CC1 channel configured as output: CC1NP must be kept cleared
CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity (refer to CC1P description).
Note: The states of the external I/O pins connected to the standard OCx channels depend on the state of the OCx channel and on the GPIO registers.

### 42.4.10 TIM12 counter (TIM12_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>UIFCPY: UIF Copy</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Table 362. Output control bit for standard OCx channels
42.4.11 TIM12 prescaler (TIM12_PSC)

Address offset: 0x28
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bits 15:0</th>
<th>PSC[15:0]</th>
<th>Prescaler value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PSC[15:0]</td>
<td>The counter clock frequency CK_CNT is equal to ( f_{CK_PSC} / (PSC[15:0] + 1) ).</td>
</tr>
</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value

The counter clock frequency \( f_{CK_PSC} \) is equal to \( f_{CK_PSC} / (PSC[15:0] + 1) \).

PSC contains the value to be loaded into the active prescaler register at each update event.

Including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

42.4.12 TIM12 auto-reload register (TIM12_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>Bits 15:0</th>
<th>ARR[15:0]</th>
<th>Auto-reload value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ARR[15:0]</td>
<td>ARR is the value to be loaded into the actual auto-reload register.</td>
</tr>
</tbody>
</table>

Bits 15:0 ARR[15:0]: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to the Section 42.3.1: Time-base unit on page 1861 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

42.4.13 TIM12 capture/compare register 1 (TIM12_CCR1)

Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bits 15:0</th>
<th>CCR1[15:0]</th>
<th>Capture/Compare 1 value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CCR1[15:0]</td>
<td>If channel CC1 is configured as output:</td>
</tr>
</tbody>
</table>

Bits 15:0 CCR1[15:0]: Capture/Compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded into the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (OC1PE bit). Else the preload value is copied into the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx_CNT counter and signaled on the OC1 output.

If channel CC1 is configured as input:

CCR1 is the counter value transferred by the last input capture 1 event (IC1).
42.4.14 TIM12 capture/compare register 2 (TIM12_CCR2)

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

*If channel CC2 is configured as output:*

CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register
(OC2PE bit). Else the preload value is copied into the active capture/compare 2 register
when an update event occurs.
The active capture/compare register contains the value to be compared to the TIMx_CNT
counter and signalled on the OC2 output.

*If channel CC2 is configured as input:*
CCR2 is the counter value transferred by the last input capture 2 event (IC2).

| 0x28   | TIMx_PSC      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | PSC[15:0]    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
Refer to Section 2.3 on page 134 for the register boundary addresses.
42.5 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

42.5.1 TIMx control register 1 (TIMx_CR1)(x = 13 to 14)

Address offset: 0x00
Reset value: 0x0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 ** CKD [1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (TIx),

00: \( t_{DTS} = t_{CK\_INT} \)
01: \( t_{DTS} = 2 \times t_{CK\_INT} \)
10: \( t_{DTS} = 4 \times t_{CK\_INT} \)
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the update interrupt (UEV) sources.
0: Any of the following events generate an UEV if enabled:
   – Counter overflow
   – Setting the UG bit
1: Only counter overflow generates an UEV if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.
0: UEV enabled. An UEV is generated by one of the following events:
   – Counter overflow
   – Setting the UG bit.
   Buffered registers are then loaded with their preload values.
1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 42.5.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13 to 14)

**Address offset:** 0x0C

**Reset value:** 0x0000

</tbody>
</table>
Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
- This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
- 0: No overcapture has been detected.
- 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bits 8:2  Reserved, must be kept at reset value.

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag
- This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
- 0: No compare match / No input capture occurred.
- 1: A compare match or an input capture occurred.

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag
- This bit is set by hardware on an update event. It is cleared by software.
- 0: No update occurred.
- 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - At overflow and if UDIS='0' in the TIMx_CR1 register.
  - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS='0' and UDIS='0' in the TIMx_CR1 register.

42.5.4  **TIMx event generation register (TIMx_EGR)(x = 13 to 14)**

Address offset: 0x14
Reset value: 0x0000

</tr>
</tbody>
</table>
Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/compare 1 generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
- 0: No action
- 1: A capture/compare event is generated on channel 1:
  - **If channel CC1 is configured as output**: CC1IF flag is set, corresponding interrupt or is sent if enabled.
  - **If channel CC1 is configured as input**: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
- This bit can be set by software, it is automatically cleared by hardware.
- 0: No action
- 1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 42.5.5 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13 to 14)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode**:

|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-------|----------|----------|
|     |     |     |     |     |     |     |     |     |     |     |     | rw     | rw       | rw       |

Bits 31:8 Reserved, must be kept at reset value.
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample Ti1 input and the length of the digital filter applied to Ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: $f_{SAMPLING} = f_{CK\_INT}$, $N=2$
0010: $f_{SAMPLING} = f_{CK\_INT}$, $N=4$
0011: $f_{SAMPLING} = f_{CK\_INT}$, $N=8$
0100: $f_{SAMPLING} = f_{DTS}/2$, $N=6$
0101: $f_{SAMPLING} = f_{DTS}/2$, $N=8$
0110: $f_{SAMPLING} = f_{DTS}/4$, $N=6$
0111: $f_{SAMPLING} = f_{DTS}/4$, $N=8$
1000: $f_{SAMPLING} = f_{DTS}/8$, $N=6$
1001: $f_{SAMPLING} = f_{DTS}/8$, $N=8$
1010: $f_{SAMPLING} = f_{DTS}/16$, $N=5$
1011: $f_{SAMPLING} = f_{DTS}/16$, $N=6$
1100: $f_{SAMPLING} = f_{DTS}/16$, $N=8$
1101: $f_{SAMPLING} = f_{DTS}/32$, $N=5$
1110: $f_{SAMPLING} = f_{DTS}/32$, $N=6$
1111: $f_{SAMPLING} = f_{DTS}/32$, $N=8$

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, IC1 is mapped on Ti1
10: Reserved
11: Reserved

Note: **CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER)**.

### 42.5.6  **TIMx capture/compare mode register 1 [alternate]**

(TIMx_CCMR1)(x = 13 to 14)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the
corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

Bits 31:17  Reserved, must be kept at reset value.

Bits 15:7  Reserved, must be kept at reset value.

**Bits 16, 6:4** **OC1M[3:0]:** Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.

- **0000:** Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

- **0001:** Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0010:** Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0011:** Toggle - OC1REF toggles when TIMx_CNT = TIMx_CCR1.

- **0100:** Force inactive level - OC1REF is forced low.

- **0101:** Force active level - OC1REF is forced high.

- **0110:** PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.

- **0111:** PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active

Others: Reserved

**Note:** In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.

**Note:** The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output compare 1 preload enable  
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.  
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable  
This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.  
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.  
1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC1 channel is configured as output.  
01: CC1 channel is configured as input, IC1 is mapped on TI1.  
10: Reserved.  
11: Reserved.  

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

</table>

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.  
CC1 channel configured as output: CC1NP must be kept cleared.  
CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define TI1FP1 polarity (refer to CC1P description).
Note: The state of the external I/O pins connected to the standard OCx channels depends on the OCx channel state and the GPIO registers.

42.5.8 TIMx counter (TIMx_CNT)(x = 13 to 14)

Address offset: 0x24
Reset value: 0x0000 0000

Bit 31 UIFCPY: UIF Copy
This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 CNT[15:0]: Counter value
42.5.9 TIMx prescaler (TIMx_PSC)(x = 13 to 14)

Address offset: 0x28
Reset value: 0x0000

<table>

<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value
- The counter clock frequency CK_CNT is equal to fCK_PSC / (PSC[15:0] + 1).
- PSC contains the value to be loaded in the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

42.5.10 TIMx auto-reload register (TIMx_ARR)(x = 13 to 14)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 ARR[15:0]: Auto-reload value
- ARR is the value to be loaded in the actual auto-reload register.
- Refer to Section 42.3.1: Time-base unit on page 1861 for more details about ARR update and behavior.
- The counter is blocked while the auto-reload value is null.

42.5.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13 to 14)

Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register
(bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signaled on OC1 output.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 42.5.12 TIM13 timer input selection register (TIM13_TISEL)

Address offset: 0x68
Reset value: 0x0000

43 General-purpose timers (TIM15/TIM16/TIM17)

43.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 43.4.22: Timer synchronization (TIM15).

43.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
43.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
**Figure 522. TIM15 block diagram**

- The internal break event source can be:
  - A clock failure event generated by CSS. For further information on the CSS, refer to Section 9.5.3: Clock Security System (CSS)
  - A PVD output
  - All SRAM and TCM double ECC errors
  - Flash double ECC error
  - Cortex®-M7 with FPU LOCKUP (Hardfault) output
  - COMP output

Notes:
- Reg Preload registers transferred to active registers on U event according to control bit

43.4 TIM15/TIM16/TIM17 functional description

43.4.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 524* and *Figure 525* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

43.4.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 526. Counter timing diagram, internal clock divided by 1

Figure 527. Counter timing diagram, internal clock divided by 2
Figure 528. Counter timing diagram, internal clock divided by 4

Figure 529. Counter timing diagram, internal clock divided by N
Figure 530. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

Figure 531. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)
43.4.3 Repetition counter

Section 43.4.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 532). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
43.4.4 Clock selection

The counter clock can be provided by the following clock sources:
- Internal clock (CK_INT)
- External clock mode 1: external input pin
- Internal trigger inputs (ITRx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15.
  Refer to Using one timer as prescaler for another timer on page 1820 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 533 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper Tlx source (internal or external) with the TlxSEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the Tlx input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCR1 register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select Tlx as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on Tlx, the counter counts once and the TIF flag is set. The delay between the rising edge on Tlx and the actual clock of the counter is due to the resynchronization circuit on Tlx input.

**Figure 535. Control circuit in external clock mode 1**

---

### 43.4.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 536 to Figure 539* give an overview of one Capture/Compare channel.

The input stage samples the corresponding Tlx input to generate a filtered signal TlxF. Then, an edge detector with polarity selection generates a signal (TlxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 537. Capture/compare channel 1 main circuit

![Capture/compare channel 1 main circuit diagram]
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 43.4.6 Input capture mode

In Input capture mode, the Capture/Compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at f_DTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

43.4.7 PWM input mode (only for TIM15)

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 540. PWM input mode timing

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

43.4.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

43.4.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 541.
43.4.10 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx \( \leq \) TIMx_CNT or TIMx_CNT \( \leq \) TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1917.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at...
‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 542 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 542. Edge-aligned PWM waveforms (ARR=8)

43.4.11 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 543 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
43.4.12 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 369: Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17) on page 1984 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 544. Complementary output with dead-time insertion.**

**Figure 545. Dead-time waveforms with delay greater than the negative pulse.**
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 43.6.14: TIMx break and dead-time register (TIMx_BDTR) (x = 16 to 17) on page 1987 for delay calculation.

**Re-directing OCxREF to OCx or OCxN**

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

**43.4.13 Using the break function**

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM15/TIM16/TIM17 timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.
The output enable signal and output levels during break are depending on several control bits:

- The MOE bit in TIMx_BDTR register allows to enable /disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode).
- The OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 367: Output control bits for complementary OCx and OCxN channels with break feature (TIM15) on page 1963 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

A programmable filter (BKF[3:0] bits in the TIMx_BDTR register allows to filter out spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_OR2 register.

The sources for break (BRK) channel are:

- An external source connected to one of the BKin pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering.
- An internal source:
  - The output from a comparator, with polarity selection and optional digital filtering.
  - The analog watchdog output of the DFSDM1 peripheral.
  - A system break:
    - The Cortex®-M7 with FPU LOCKUP output.
    - The PVD output.
    - All SRAM and TCM double ECC errors (AXI-SRAM, ITCM, DTCM, SRAM1, SRAM2, SRAM3, SRAM4, BKRAM, refer to SYSCFG_CFR register for details).
    - A Flash double ECC error.
    - A clock failure event generated by the CSS detector.
Figure 547. Break circuitry overview

Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their
active level together. Note that because of the resynchronization on MOE, the
dead-time duration is a bit longer than usual (around 2 \( \text{ck}_\text{tim} \) clock cycles).

- If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO
  which forces a Hi-Z state) else the enable outputs remain or become high as soon
  as one of the \( \text{CC}_x\text{E} \) or \( \text{CC}_x\text{NE} \) bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be
  generated if the BIE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again
  at the next update event UEV. This can be used to perform a regulation, for instance.
  Else, MOE remains low until it is written with 1 again. In this case, it can be used for
  security and the break input can be connected to an alarm from power drivers, thermal
  sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and
forced to inactive level or Hi-Z depending on OSSI value.
If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and
driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is
active (neither automatically nor by software). In the meantime, the status flag BIF cannot
be cleared.

The break can be generated by the BRK input which has a programmable polarity and an
enable bit BKE in the TIMx_BDTR register.

In addition to the break input and the output management, a write protection has been
implemented inside the break circuit to safeguard the application. It allows the configuration
of several parameters to be freezered (dead-time duration, OCx/OCxN polarities and state
when disabled, OCxM configurations, break enable and polarity). The protection can be
selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to
Section 43.6.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on
page 1987. The LOCK bits can be written only once after an MCU reset.

The Figure 548 shows an example of behavior of the outputs in response to a break.

### 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The *Figure 549* describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.
43.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT < CCRx ≤ ARR (in particular, 0 < CCRx)

Figure 550. Example of one pulse mode

For example one may want to generate a positive pulse on OC1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC 2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: OCx fast enable

In One-pulse mode, the edge detection on TiX input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 43.4.16 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 43.4.15:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
43.4.17 **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag, to be atomically read. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.
43.4.18 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 552.

Figure 552. Measuring time interval between edges on 2 signals
43.4.19 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

*Figure 553. Control circuit in reset mode*
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 554. Control circuit in gated mode

![Control circuit in gated mode diagram](image-url)
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:
1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P='1' and CC2NP='0' in the TIMx_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

43.4.20 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

43.4.21 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.
The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,

For example, the timer DMA burst feature could be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.
43.4.22 Timer synchronization (TIM15)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 41.3.19: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

43.4.23 Using timer output as trigger for other timers (TIM16/TIM17)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination’s timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

43.4.24 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on TIMx bit in DBGMCU module. For more details, refer to Section 63.5.8: Microcontroller debug unit (DBGMCU).

For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB2FZ1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.
43.5 TIM15 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

43.5.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x000

Reset value: 0x0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (TIx)
00: tDTS = tCK_INT
01: tDTS = 2 * tCK_INT
10: tDTS = 4 * tCK_INT
11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt if enabled. These events can be:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 43.5.2 TIM15 control register 2 (TIM15.CR2)

Address offset: 0x04
Reset value: 0x0000

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (OC2 output)
0: OC2=0 when MOE=0
1: OC2=1 when MOE=0

*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15.BDTR register).*

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15.BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15.BDTR register).*
Bit 7 **TI1S**: TI1 selection

0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000**: *Reset* - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- **001**: *Enable* - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **010**: *Update* - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
- **011**: *Compare Pulse* - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
- **100**: *Compare* - OC1REFC signal is used as trigger output (TRGO).
- **101**: *Compare* - OC2REFC signal is used as trigger output (TRGO).

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note:* This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note:* This bit acts only on channels that have a complementary output.
43.5.3 TIM15 slave mode control register (TIM15_SMCR)

Address offset: 0x08
Reset value: 0x0000 0000
