  1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
    - STUPCNT = 3 in OTG_DOEPTSIZx
  2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
    - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
    - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the
receive data FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**
  
  1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
     - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
  
  2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
     - The first word contains control information used internally by the core
     - The second word contains the first 4 bytes of the SETUP command
     - The third word contains the last 4 bytes of the SETUP command

  3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.

  4. On the AHB side, SETUP packets are emptied by the application.

  5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.

  6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**
  
  1. Program the OTG_DOEPTSIZx register.
     - STUPCNT = 3
  
  2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.

  3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
     - On this interrupt, the application must read the OTG_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.
Handling more than three back-to-back SETUP packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_HS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

Setting the global OUT NAK

Internal data flow:
1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEF interrupt (OTG_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:
1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   – $SGONAK = 1$ in OTG_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set $SGONAK$ in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   – $GONAKEFFM = 0$ in the OTG_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the $SGONAK$ bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   – $CGONAK = 1$ in OTG_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   – $GONAKEFFM = 1$ in OTG_GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   – $SGONAK = 1$ in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   – $EPDIS = 1$ in OTG_DOEPCTLx
   – $SNAK = 1$ in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   – $EPDIS = 0$ in OTG_DOEPCTLx
   – $EPENA = 0$ in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   – $SGONAK = 0$ in OTG_DCTL

- **Transfer Stop Programming for OUT endpoints**

The application must use the following programing sequence to stop any transfers (because of an interrupt from the host, typically a reset).

Sequence of operations:
1. Enable all OUT endpoints by setting
   - EPENA = 1 in all OTG_DOEPCTLx registers.
2. Flush the RxFIFO as follows
   - Poll OTG_GRSTCTL_AHBIDL until it is 1. This indicates that AHB master is idle.
   - Perform read modify write operation on OTG_GRSTCTL_RXFFLUSH =1
   - Poll OTG_GRSTCTL_RXFFLUSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the RxFIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in “Setting the global OUT NAK on page 2908”. This ensures that data in the RxFIFO is sent to the application successfully. Set SGONAK = 1 in OTG_DCTL
4. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
   - EPDIS = 1 in registers OTG_DOEPCTLx
   - SNAK = 1 in registers OTG_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG_DOEPINTx indicates that the corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:
   - EPENA = 0 in registers OTG_DOEPCTLx
   - EPDIS = 0 in registers OTG_DOEPCTLx
   - SNAK = 0 in registers OTG_DOEPCTLx

**Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:
1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   - transfer size[EPNUM] = n \times (MPSIZ[EPNUM] + 4 – (MPSIZ[EPNUM] mod 4))
   - packet count[EPNUM] = n
   - n > 0
3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
   - Payload size in memory = application programmed initial transfer size – core updated final transfer size
   - Number of USB packets in which this payload was received = application programmed initial packet count – core updated final packet count
Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.

2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, resends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.

3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.

4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.

5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.

6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)

7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   – EPENA = 1 in OTG_DOEPCTLx
   – CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   – This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**
  This section describes a regular isochronous OUT data transfer.

**Application requirements:**
1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

**Internal data flow:**
1. The internal data flow for isochronous OUT endpoints is the same as that for non- isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
   – EOUNUM (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

**Application programming sequence:**
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.

2. Program the OTG_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
   - EPENA = 1
   - CNAK = 1
   - EONUM = (0: Even/1: Odd)

3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.

4. The assertion of the XFRC interrupt (in OTG_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.

5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG_GINTSTS.

6. Read the OTG_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
   - RXDPID = DATA0 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 1
   - RXDPID = DATA1 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 2
   - RXDPID = D2 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 3

   The number of USB packets in which this payload was received = Application programmed initial packet count – core updated final packet count

   The application can discard invalid data packets.

- **Incomplete isochronous OUT data transfers**

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application may fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:
   - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
   - When the isochronous OUT data packet is received with CRC errors
   - When the isochronous OUT token received by the core is corrupted
   - When the application is very slow in reading the data from the receive FIFO

2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At
this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the INCOMPSISOOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.

2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   − When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.

3. When it receives an INCOMPSISOOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   − EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   − EPENA = 1 (in OTG_DOEPCTLx)

4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.

5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.

6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   − Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

• **Stalling a non-isochronous OUT endpoint**

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode.

2. Disable the required endpoint
   − When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
     TheSTALL bit always takes precedence over the NAK bit.

3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG_DOEPCTLx) must be cleared.

4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

**Examples**

This section describes and depicts some fundamental transfer types and scenarios.

• **Bulk OUT transaction**
Figure 818 depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

Figure 818. Bulk OUT transaction

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting $\text{CNAK} = 1$ and $\text{EPENA} = 1$ (in OTG_DOEPCTLx), and setting a suitable $\text{XFRSIZ}$ and $\text{PKTCNT}$ in the OTG_DOEPTSIZx register.

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the $\text{PKTCNT}$ number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to $\text{XFRSIZ}$), the core generates an XFRC interrupt (in OTG_DOEPIINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPIINTx) to determine that the intended transfer is complete.

IN data transfers

- Packet write

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.
1. The application can either choose the polling or the interrupt mode.
   - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
   - To write zero length packet, the application must not look at the FIFO space.

2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

  Internal data flow:
  1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.
  2. Non-isochronous IN tokens receive a NAK handshake reply
     - Isochronous IN tokens receive a zero-data-length packet reply
  3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.
  4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

  Application programming sequence:
  1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
     - SNAK = 1 in OTG_DIEPCTLx
  2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
  3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
  4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
     - INEPNEM = 0 in OTG_DIEPMSK
  5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNE interrupt (in OTG_DIEPINTx).
6. If the application masked this interrupt earlier, it must be unmasked as follows:
   \[ \text{INEPNEM} = 1 \] in OTG_DIEPMSK

**IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:
1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   \[ \text{SNAK} = 1 \] in OTG_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG_DIEPINTx.
4. Set the following bits in the OTG_DIEPCTLx register for the endpoint that must be disabled.
   \[ \text{EPDIS} = 1 \] in OTG_DIEPCTLx
   \[ \text{SNAK} = 1 \] in OTG_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   \[ \text{EPENA} = 0 \] in OTG_DIEPCTLx
   \[ \text{EPDIS} = 0 \] in OTG_DIEPCTLx
6. The application must read the OTG_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG_GRSTCTL register:
   \[ \text{TXFNUM} \text{ (in OTG_GRSTCTL)} = \text{Endpoint transmit FIFO number} \]
   \[ \text{TXFFLSH} \text{ in (OTG_GRSTCTL)} = 1 \]

The application must poll the OTG_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

**Transfer Stop Programming for IN endpoints**

The application must use the following programing sequence to stop any transfers (because of an interrupt from the host, typically a reset).
**Sequence of operations:**

1. Disable the IN endpoint by setting:
   - EPDIS = 1 in all OTG_DIEPCTLx registers

2. Wait for the EPDIS interrupt in OTG_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
   - EPDIS = 0 in OTG_DIEPCTLx
   - EPENA = 0 in OTG_DIEPCTLx

3. Flush the TxFIFO by programming the following bits:
   - TXFFLSH = 1 in OTG_GRSTCTL
   - TXFNUM = “FIFO number specific to endpoint” in OTG_GRSTCTL

4. The application can start polling till TXFFLSH in OTG_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

- **Generic non-periodic IN data transfers**

**Application requirements:**

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.

2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     Transfer size[EPNUM] = x × MPSIZ[EPNUM] + sp
     If (sp > 0), then packet count[EPNUM] = x + 1.
     Otherwise, packet count[EPNUM] = x
   - To transmit a single zero-length data packet:
     Transfer size[EPNUM] = 0
     Packet count[EPNUM] = 1
   - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
     First transfer: transfer size[EPNUM] = x × MPSIZ[EPNUM]; packet count = n;
     Second transfer: transfer size[EPNUM] = 0; packet count = 1;

3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.

4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
   - Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) × MPSIZ[EPNUM]
   - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)
Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DIEPTSIZx register with the transfer size and corresponding packet count.
2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

• **Generic periodic IN data transfers**

This section describes a typical periodic IN data transfer.

Application requirements:
1. Application requirements 1, 2, 3, and 4 of **Generic non-periodic IN data transfers on page 2918** also apply to periodic IN data transfers, except for a slight modification of requirement 2.
   - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To
transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

\[
\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}
\]

(where \(x\) is an integer \(\geq 0\), and \(0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]\))

If \((\text{sp} > 0)\), \(\text{packet count}[\text{EPNUM}] = x + 1\)
Otherwise, \(\text{packet count}[\text{EPNUM}] = x;\)

\[\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\]

- The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:
  - \(\text{transfer size}[\text{EPNUM}] = 0\)
  - \(\text{packet count}[\text{EPNUM}] = 1\)
  - \(\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\)

2. The application can only schedule data transfers one frame at a time.
   - \((\text{MCNT} - 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}\)
   - \(\text{PKTCNT} = \text{MCNT} \) (in OTG_DIEPTSIZx)
   - If \(\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}\), the last data packet of the transfer is a short packet.
   - Note that: \(\text{MCNT} \) is in OTG_DIEPTSIZx, \(\text{MPSIZ} \) is in OTG_DIEPCTLx, \(\text{PKTCNT}\) is in OTG_DIEPTSIZx and \(\text{XFERSIZ} \) is in OTG_DIEPTSIZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
   - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
   - A NAK handshake would be transmitted on the USB for interrupt IN endpoints

Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO
mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
- A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:
   - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
   - For interrupt endpoints, when an ACK handshake is transmitted
   - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFIIVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:

1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- Incomplete isochronous IN data transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it
eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:
1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).
2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   - SNAK = 1 in OTG_DIEPCTLx
   - EPDIS = 1 in OTG_DIEPCTLx
6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.

2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   - STALL = 1 in OTG_DIEPCTLx
   - The STALL bit always takes precedence over the NAK bit

3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.

4. The application must flush the non-periodic or periodic transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints that do not need to be stalled, to transmit data.

5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG_DIEPCTLx.

6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt in OTG_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

60.15.7 Worst case response time

When the OTG_HS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token may come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

Choosing the value of TRDT in OTG_GUSBCFG

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

*Figure 819* has the following signals:
- tkn_rcvd: Token received information from MAC to PFC
- dynced_tkn_rcvd: Doubled sync tkn_rcvd, from PCLK to HCLK domain
- spr_read: Read to SPRAM
- spr_addr: Address to SPRAM
- spr_rdata: Read data from SPRAM
- srcbuf_push: Push to the source buffer
- srcbuf_rdata: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to *Table 540: TRDT values.*

*Figure 819. TRDT max timing case*
60.15.8 OTG programming model

The OTG_HS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG_HS controller turns off VBUS to conserve power. SRP is a method by which the B-device signals the A-device to turn on VBUS power. A device must perform both data-line pulsing and VBUS pulsing, but a host can detect either data-line pulsing or VBUS pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

A-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_HS controller to detect SRP as an A-device.

Figure 820. A-device SRP

1. DRV_VBUS = VBUS drive signal to the PHY
   VBUS_VALID = VBUS valid signal from PHY
   A_VALID = A-peripheral VBUS level signal to PHY
   D+ = Data plus line
   D- = Data minus line

The following points refer and describe the signal numeration shown in the Figure 820:

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when VBUS power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG_HS controller detects data-line pulsing.
5. The device drives VBUS above the A-device session valid (2.0 V minimum) for VBUS pulsing.
   The OTG_HS controller interrupts the application on detecting SRP. The session
request detected bit is set in Global interrupt status register (SRQINT set in OTG_GINTSTS).

6. The application must service the session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS_VALID signal.

7. When the USB is powered, the device connects, completing the SRP process.

**B-device session request protocol**

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_HS controller to initiate SRP as a B-device. SRP is a means by which the OTG_HS controller can request a new session from the host.

**Figure 821. B-device SRP**

1. To save power, the host suspends and turns off port power when the bus is idle. The OTG_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register.

2. The PHY indicates the session’s end to the device. This is the initial condition for SRP. The OTG_HS controller requires 2 ms of SE0 before initiating SRP. For a USB 1.1 full-speed serial transceiver, the application must wait until VBUS discharges to 0.2 V after BSVLD (in OTG_GOTGCTL) is deasserted. This discharge
time can be obtained from the transceiver vendor and varies from one transceiver to another.

3. The OTG_HS core informs the PHY to speed up $V_{BUS}$ discharge.

4. The application initiates SRP by writing the session request bit in the OTG control and status register. The OTG_HS controller perform data-line pulsing followed by $V_{BUS}$ pulsing.

5. The host detects SRP from either the data-line or $V_{BUS}$ pulsing, and turns on $V_{BUS}$. The PHY indicates $V_{BUS}$ power-on to the device.

6. The OTG_HS controller performs $V_{BUS}$ pulsing. The host starts a new session by turning on $V_{BUS}$, indicating SRP success. The OTG_HS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.

7. When the USB is powered, the OTG_HS controller connects, completing the SRP process.

**A-device host negotiation protocol**

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_HS controller to perform HNP as an A-device.

**Figure 822. A-device HNP**

1. $DPPULLDOWN = \text{signal from core to PHY to enable/disble the pull-down on the DP line inside the PHY.}$

2. $DMPULLDOWN = \text{signal from core to PHY to enable/disble the pull-down on the DM line inside the PHY.}$

The following points refer and describe the signal numeration shown in the *Figure 822*:

1. The OTG_HS controller sends the B-device a SetFeature $b_{hnp\_enable}$ descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP enable bit in the OTG control.
and status register to indicate to the OTG_HS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the port suspend bit in the host port control and status register.

3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG_HS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG_HS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG_HS controller for data traffic.

5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register.

6. In Negotiated mode, the OTG_HS controller detects the suspend, disconnects, and switches back to the host role. The OTG_HS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.

7. The OTG_HS controller sets the connector ID status change interrupt in the OTG interrupt status register. The application must read the connector ID status in the OTG control and status register to determine the OTG_HS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.

8. The B-device connects, completing the HNP process.

**B-device host negotiation protocol**

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_HS controller to perform HNP as a B-device.
The following points refer and describe the signal numeration shown in the Figure 823:

1. **DPPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.
   **DMPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The A-device sends the SetFeature b_hnp_enable descriptor to enable HNP support.
The OTG_HS controller’s ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG control and status register to indicate HNP support.
The application sets the HNP request bit in the OTG control and status register to indicate to the OTG_HS controller to initiate HNP.

2. When it has finished using the bus, the A-device suspends by writing the port suspend bit in the host port control and status register.
The OTG_HS controller sets the Early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register.
The OTG_HS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG_HS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.
The A-device responds by activating its OTG_DP pull-up resistor within 3 ms of detecting SE0. The OTG_HS controller detects this as a connect.
The OTG_HS controller sets the host negotiation success status change interrupt in the OTG interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG control and status register to determine...
host negotiation success. The application must read the current Mode bit in the core interrupt register (OTG_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG_HPRT) and the OTG_HS controller issues a USB reset and enumerates the A-device for data traffic.

4. The OTG_HS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the port suspend bit in the host port control and status register.

5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG_HS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.

6. The application must read the current mode bit in the core interrupt (OTG_GINTSTS) register to determine the host mode operation.

7. The OTG_HS controller connects, completing the HNP process.
61 Ethernet (ETH): media access control (MAC) with DMA controller

61.1 Ethernet introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

The Ethernet peripheral enables to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard.

The peripheral is configurable to meet the needs of a large variety of consumer and industrial applications.

61.2 Ethernet main features

The Ethernet peripheral embeds a dedicated DMA for direct memory interface, a media access controller (MAC) and a PHY interface block supporting several formats.

61.2.1 Standard compliance

The Ethernet peripheral is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC and media independent interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization (PTP)
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and AHB slave ports
- RMII specification version 1.2 from RMII consortium

61.2.2 MAC features

MAC Tx and Rx common features

- Separate transmission, reception, and control interfaces to the application
- 10, 100 Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD protocol support
  - Flow control using backpressure (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs
• 32-bit data transfer interface on the application side
• Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
• Network statistics with RMON or MIB counters (partial support of RFC2819/RFC2665)
• Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping are supported in Tx direction.
• Flexibility to control pulse-per-second (PPS) output signal (eth_ptp_pps_out and ETH_PPS_OUT)
• MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

MAC Tx features
• Preamble and start-of-frame data (SFD) insertion
• Separate 32-bit status for each packet transmitted from the application
• Automatic CRC and pad generation controllable on a per-frame basis
• Programmable packet length to support Standard or Jumbo Ethernet packets of up to 16 Kbytes
• Programmable Inter Packet Gap (40–96 bit times in steps of 8)
• IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in Full-duplex mode)
• Source address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
• Insertion, replacement, or deletion of up to two VLAN tags
• Option to transmit packets with reduced preamble size in Full-duplex mode
• Insert, replace, or delete queue/channel-based VLAN tags

MAC Rx features
• Automatic Pad and CRC stripping options
• Option to disable automatic CRC checking
• Preamble and SFD deletion
• Separate 112-bit or 128-bit status
• Programmable watchdog timeout limit
• Flexible address filtering modes:
  – Four 48-bit perfect (DA) address filters with masks for each byte
  – Four 48-bit SA address comparison check with masks for each byte
  – 64 bit Hash filter for multicast and unicast (DA) addresses
• Option to pass all multicast addressed packets
• Promiscuous mode to pass all packets without any filtering for network monitoring
• Pass all incoming packets (as per filter) with a status report
• Additional packet filtering:
  – VLAN tag-based: Perfect match and Hash-based filtering based either on the outer or inner VLAN tag
  – Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
• IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
• Detection of remote wake-up packets and AMD magic packets
• Optional forwarding of received Pause packets to the application (in Full-duplex mode)
• Layer 3/Layer 4 checksum offload for received packets
• Stripping of up to two VLAN tags and providing the tags in the status

61.2.3 Transaction layer (MTL) features

MTL Tx and Rx Common Features
• 32-bit Transaction Layer block (bridges the application and the MAC)
• Optimization for packet-oriented transfers with packets delimiters
• Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
• Programmable threshold capability for each queue (default of 64 bytes)

MTL Tx features
• 2048-byte Transmit FIFO with programmable threshold capability
• Store-and-forward mechanism or threshold mode (cut-through) for transmission to the MAC
• Automatic retransmission of collision packets in Half-duplex mode
• Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
• Module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum on frames transmitted in Store-and-forward mode
• Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
• Packet-level control for
  – VLAN tag insertion or replacement
  – Ethernet source address insertion
  – Layer 3/Layer 4 checksum insertion control
  – One-step timestamp
  – Timestamp control
  – CRC and pad control
MTL Rx features

- 2048-byte Receive FIFO with configurable threshold
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level

61.2.4 DMA block features

The DMA block exchanges data between the peripheral and the system memory. DMA transfers are driven by software descriptors structure. The application can use a set of registers (see Section 61.11.2: Ethernet DMA registers) to control the DMA operations. The DMA block supports the following features:

- 32-bit data transfers
- Separate DMA in Transmit path and receive paths
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture allowing large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 Kbytes of data)
- Comprehensive status reporting normal operation and transfer errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host control (AHB) access and host data interface
- Tx DMA channel with TCP segmentation offload (TSO) feature enabled
- Programmable control for Transmit Descriptor posted writes to improve the throughput

61.2.5 Bus interface features

AHB master interface

The AHB master interface features are the following:

- Interfaces with the application through AHB
- 32-bit data on the AHB master port
- Split, Retry, and Error AHB responses
- AHB 1-Kbyte boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)
The AHB master interface does not generate the following:
- Wrap burst
- Locked or protected transfers

**AHB slave interface**

The AHB slave interface supports the following features:
- Interfaces with the application through AHB
- AHB slave interface (32-bit) for CSR access
- All AHB burst types

The AHB slave interface does not generate the following responses:
- Split
- Retry
- Error

### 61.3 Ethernet pins and internal signals

*Table 543* lists the Ethernet inputs and output signals connected to package pins or balls. Active pins depend on the PHY type selected (MII or RMII) and on the device configuration. *Table 544* shows the internal Ethernet signals.

**Table 543. Ethernet peripheral pins**

### 61.4 Ethernet architecture

The Ethernet peripheral is composed of 4 main functional modules:

- **The control and status register module (CSR)** that controls the registers access through AHB 32-bit slave interface
- **The direct memory access interface (DMA)**
  This is the logical DMA module with one physical channel for reception and one for transmission. It controls the data transfers between MAC and system memory through the AMBA AHB 32-bit master interface.
- **The media access control module (MAC)** in charge of implementing the Ethernet protocol
- **The MAC transaction layer (MTL)** in charge of controlling the data flow between application and MAC.

A protocol adaption module is added to support the RMII PHY Media Independent Interfaces.

61.4.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines. The Tx engine transfers data from the system memory to the MAC Transaction Layer (MTL), whereas the Rx engine transfers data from the device port (PHY) to the system memory.

The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

DMA data structures

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx buffer in system memory and Tx data packets from the Tx buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The base address of each list is written to the respective Tx and Rx registers: Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR).
The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The number of descriptors in the list is programmed in the respective Tx/Rx, Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR).

Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List address register to create a descriptor ring. The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used and physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet, but cannot exceed a single packet. Buffers contain only data. The buffer status is saved in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

Descriptors are specified in Section 61.10: Descriptors.

DMA arbitration

The DMA module incorporates an arbiter that performs the arbitration between the Tx and Rx channels accesses from the AHB master interface. The following two types of arbitrations are supported and can be selected through DMA mode register (ETH_DMAMR):

- Round-robin arbitration: the arbiter allocates the data bus between Rx and Tx in ratio set by Bits [14:12] of ETH_DMAMR.
- Fixed-priority arbitration: by default Rx DMA always gets priority over Tx DMA for data access. Setting bit 11 of ETH_DMAMR register gives priority to the Tx DMA.
DMA transmission in default mode

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application shifts the Descriptor tail pointer offset value of the Transmit channel.
3. The DMA fetches the descriptor from the application memory.
4. If the DMA detects one of the following conditions, the transmission from that channel is suspended, bit 2 and 16 of the corresponding DMA channel Status register are set, and the Tx engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3[31] = 0).
   - The descriptor tail pointer is equal to the current descriptor pointer in Ring Descriptor list mode.
   - An error condition occurs.
5. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.
7. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end-of-Ethernet-packet data is transferred to the MTL.
8. When packet transmission is complete, if IEEE 1588 timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step. If the timestamp feature is disabled for this packet, the DMA does not alter TDES0 and TDES1 contents.
9. Bit 0 of Channel status register (ETH_DMACSR) is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.
10. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 0 of Transmit control register of corresponding DMA channel, the DMA enters the Stop state.
DMA transmission in OSP (Operate on Second Packet) mode

In Run state, if bit 4 is set in the Channel transmit control register (ETH_DMACTXCR), the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. While the Transmit process completes the first packet transfer, it immediately polls the Transmit descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.
In OSP mode, DMA transmission in the Run state operates as described in the following sequence:

1. The DMA executes steps 1 to 7 of the DMA transmission sequence in default mode (see Section: DMA transmission in default mode).
2. The DMA fetches the next descriptor without closing previous packet last descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and jumps to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor. If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA performs the following operations:
   a) The DMA writes the timestamp (if enabled for the current packet) to TDES2 and TDES3.
   a) The DMA writes the status to the corresponding TDES3.
   a) The DMA sets the relevant interrupts and returns to Suspend mode.
   If no status is pending and the application stopped the DMA by clearing bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (it goes either to step 1 or to step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

A description of the basic DMA transmission flow in OSP mode is given in Figure 827: Receive DMA flow.
Figure 826. DMA transmission flow (OSP mode)
DMA reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel.

The reception sequence for Rx DMA engine is as follows (see also Figure 827: Receive DMA flow):

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]). The application must set the correct value in the Receive descriptor tail pointer register of corresponding DMA channel.

2. When bit 0 of Channel receive control register (ETH_DMACRXCR) is set, the DMA enters the Run state. The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor tail pointer register values. If there are no free descriptors, the DMA channel enters the Suspend state and goes to step 11.

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.

4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).

5. The DMA processes the incoming packets and stores them in the data buffers of acquired descriptor.

6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.

7. The DMA retrieves the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last descriptor bit set.

8. The DMA writes the Frame Length to RDES3 and the VLAN tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.

9. The DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).

10. If more descriptors are available in the Rx DMA descriptor ring, go to step 3, otherwise go to the Suspend state (step 11).

11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application increments the channel Receive tail pointer register. The engine proceeds to step 2 and fetches again the next descriptor.

          - Yes: Stop Rx DMA
          - No: (Re)Fetch next descriptor
Priority scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channel 0 to access descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA mode register (ETH_DMAMR) specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a given channel.

If the Tx DMA and Rx DMA of a given channel are enabled, the DMA which gets the bus when the channel gets control of the bus must be specified. The priority between the corresponding Tx DMA and Rx DMA can be configured through the TXPR field of the DMA mode register (ETH_DMAMR). For round-robin arbitration, the weighted priority between the Tx DMA and Rx DMA is configured through the PR field of the DMA mode register (ETH_DMAMR). Table 545 provides information about the priority scheme between Tx DMA and Rx DMA.

</tbody>
</table>
61.4.2 MTL

The MAC Transaction Layer (MTL) provides the FIFO memory interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer features two 32-bit wide data paths: the Transmit path and the Receive Path.

- Transmit path
  The application or internal DMA pushes the Ethernet packets read from the application or system memory into the Tx FIFO. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application or internal DMA. The Tx queue size is 2048 bytes.

- Receive path
  The MTL Rx module receives the packets from the MAC and pushes them into the Rx queue. The status (fill level) of the queue is indicated to the application or to DMA when it crosses the configured Receive threshold (RTC bits[1:0] defined in Rx queue operating mode register (ETH_MTLRXQOMR)), or when the complete packet was received. The MTL also indicates the queue fill level so that the DMA can initiate preconfigured burst transfers towards the master interface. The Rx queue size is 2048 bytes.

61.4.3 MAC

The MAC is responsible of the Ethernet protocol processing. In Transmission mode, it receives data from MTL before transferring it to the PHY interface. In Reception mode, the MAC receives data from the PHY interface before transferring them to the Rx FIFO of the MTL module.

This section briefly describes transmission and reception sequences.

MAC transmission

The transmission sequence is as follows:

1. Transmission is initiated when the MTL application pushes in data with the SOP (Start of packet) signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins the transmission to the MII.
3. When the EOP (End of packet) is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and provides the transmission status to the MTL.
   - If a normal collision (in Half-duplex mode) occurs during transmission, the MAC provides the Transmit status to the MTL, with the Retry bit set. The MAC provides the Retry request till one of the following is true: the packet was successfully transmitted; the maximum number of Retry requests expires. In this case, the MAC aborts the packet transmission with Excessive Collision Transmit status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP when a Retry request (in the Status) is observed from the MAC.
If any one of the following event happens, the MAC aborts the packet transmission:
- no carrier (Half-duplex mode)
- loss of carrier (Half-duplex mode)
- excessive deferral (Half-duplex mode)
- late collisions (Half-duplex mode)
- jabber

the MAC accepts and drops all further data until the next SOP is received.

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.

5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

*Figure 828: Overview of MAC transmission flow* illustrates the MAC transmission process flow.
Figure 828. Overview of MAC transmission flow

NO →

Drop all the data received from MTL and abort transmission

Normal transmission completed and Transmission status conveyed to MTL
MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

The reception sequence is as follows:

1. When the receive data valid signal (RxDV) of MII becomes active, the Receive State Machine (RSM) starts looking for the SFD field (0xD nibble).

   The state machine drops received packets until it detects SFD.

2. When SFD is detected, the state machine starts sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).

3. If IEEE 1588 timestamp feature is enabled, the MAC takes a snapshot of the system time at which SFD of any packet is detected on MII. If this packet is not dropped during MAC filtering, the timestamp is passed to the application. The MAC converts the received nibble data into bytes and forwards the valid packet data to the RFC module.

4. The Receive State Machine decodes the Length/Type field of the Ethernet packet being received.

   If the Length/Type field is less than 1,536 and if the MAC is programmed for the Auto CRC/Pad Stripping (bit 20 of the Operating mode configuration register (ETH_MACCR)), the state machine sends the packet data up to the count specified in the Length/Type field and starts dropping bytes (including the FCS field). The state machine decodes the Length/Type field and checks for the Length interpretation.

5. If the Length/Type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if you have not enabled the CRC stripping for Type packet in Bit 21 of the Operating mode configuration register (ETH_MACCR). However, if the CRC stripping has been enabled for Type packets and not enabled the Receive Checksum Offload Engine, the MAC strips and drops the last 4 bytes of all packets of ether type before forwarding the packets to the application.

6. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets above 2,048 (10,240 if Jumbo Packet is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, you can use a programmable watchdog timer (bit 16 of Watchdog timeout register (ETH_MACWTR)) to override the fixed timeout of 2,048 or 10,240 bytes. You can disable the watchdog timer by programming bit 19 of Operating mode configuration register (ETH_MACCR).

   However, even if the watchdog timer is disabled, a packet greater than 32 Kbytes is cut off and a watchdog timeout status is given.
Figure 829. MAC reception flow

Start

Wait for phy_rxdv_i from GMII/MII

Wait until SFD is detected

Start sending the received Ethernet packet to the application layer, starting from DA field

IEEE 1588 timestamp feature enabled?

NO

Length/Type field <1536 & Auto CRC/Pad stripping enabled?

NO

Send only the number of bytes (specified in the Length field) of the received Ethernet packet to RFC. Drop extra padding and FCS field

YES

Store the snapshot of the system time when SFD detected

Length/Type field ≥1536

CRC stripping for Type packets enabled?

NO

Send all received Ethernet packet data to RFC

YES

Receive checksum Offload engine enabled?

NO

Send the packet, timestamp and Status to the Application layer

CRC error? OR Packet to be filtered?

NO

Send all received Ethernet packet data to RFC

YES

Drop the last 4 bytes of all Ether type packets and send the remaining bytes to RFC

Drop the packet and send the Status to the Application layer
### 61.5 Ethernet functional description: MAC

#### 61.5.1 Double VLAN processing

The Ethernet peripheral supports the double VLAN (Virtual LAN) tagging feature in which the MAC can process up to two VLAN tags (inner and outer).

The MAC supports the following:
- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

**Transmit path**

*Table 546: Double VLAN processing features in Tx path* describes the features supported by the MAC on the Transmit side.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Support for C-VLAN and S-VLAN Tag types | The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of *VLAN inclusion register (ETH_MACVIR)* and *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. The Ethernet peripheral supports processing of any sequence of outer and inner VLAN tags. However, it does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following:
  - The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled.
  - The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled.
  - The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN.
  - The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN. |
| VLAN Tag deletion | VLAN tag deletion can be enabled for outer or inner tag through VLC field in the *VLAN inclusion register (ETH_MACVIR)* or *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag. |
| VLAN Tag Insertion or Replacement | VLAN tag insertion or replacement can be enabled for outer or inner tag through VLC field in the *VLAN inclusion register (ETH_MACVIR)* or *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. When VLAN tag insertion or replacement is enabled, the VLT1 bit in the previous register is used to determine whether the VLAN tag should be taken from the register or the control word. |
Receive path

*Table 547: Double VLAN processing in Rx path* describes the features supported by the MAC on the Receive side and the corresponding bits in the VLAN tag register (*ETH_MACVTR*).

### 61.5.2 Source address and VLAN insertion, replacement, or deletion

**Source address insertion or replacement**

The software can use the SA (source address) insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address registers in the SA field
- Replace the content of the SA field with the content of the MAC Address registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

SA insertion or replacement feature can be enabled for all Transmit packets or selective packets:

- **Enabling SA insertion or replacement for all packets**
  To enable this feature for all packets, program the SARC field of the *Operating mode configuration register (ETH_MACCR)*.

- **Enabling SA insertion or replacement for selective packets**
  To enable this feature for selective packets, use the following program the SA Insertion Control field (bits[25:23] of Transmit Descriptor Word 3/TDES3, refer to *Section 61.10.3: Transmit descriptor* in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or
replacement by MAC Address1 registers. When bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 registers are not enabled, the MAC Address0 registers are used for insertion or replacement whatever of the value of the most-significant bit of the SA Insertion Control field.

**VLAN insertion, replacement, or deletion**

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is performed based on the setting of VLTI bit in the VLAN inclusion register (ETH_MACVIR) as described in Table 548: VLAN insertion or replacement based on VLTI bit.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLTI bit is set</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of</td>
</tr>
<tr>
<td></td>
<td>VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with VT field of Transmit context descriptor of the packet</td>
</tr>
<tr>
<td>VLTI bit is reset</td>
<td>The MAC inserts or replaces the following:</td>
</tr>
<tr>
<td></td>
<td>VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of</td>
</tr>
<tr>
<td></td>
<td>VLAN inclusion register (ETH_MACVIR))</td>
</tr>
<tr>
<td></td>
<td>VLAN Tag field with the VLT field of VLAN inclusion register (ETH_MACVIR)</td>
</tr>
</tbody>
</table>

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88A8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- To enable this feature for all packets, program the VLC and VLP fields of VLAN inclusion register (ETH_MACVIR).
- To enable this feature for selective packets, program the VTIR field of TDES2 Normal Descriptor (see Table 581: TDES2 normal descriptor (read format)).

In addition, the VLP (VLAN Priority control) bit must be reset in VLAN inclusion register (ETH_MACVIR) (for outer VLAN) and Inner VLAN inclusion register (ETH_MACIVIR) (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.
61.5.3 Packet filtering

The MAC supports the following types of filtering for Rx packets:

- **MAC source or destination address filtering**: the Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet.
- **VLAN filtering**: the MAC supports the VLAN tag-based and VLAN Hash filtering.
- **Layer 3 and Layer 4 filtering**: Layer 3 filtering refers to IP source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering.

The three filter types can be cascaded. *Figure 830* shows the filtering sequence for Rx packets.

![Packet filtering sequence](image)

The sequence shown in *Figure 830* is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control.

For example, when RA bit of *Packet filtering control register (ETH_MACPFR)* is set to 1, all the discarded packets are forwarded to the host but with their packet status indicating the
specific filter failure. If RA bit is cleared to 0, VTFE and IPFE bits of Packet filtering control register (ETH_MACPFR) control if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

**MAC source or destination address filtering**

The MAC address filtering module checks the source address (SA) and destination address (DA) fields of each incoming packet.

**Unicast destination address filtering**

The MAC supports 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Packet filtering control register (ETH_MACPFR) is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr3 addresses are selected with an individual enable bit. You can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in MAC Address x high register (ETH_MACAxHR). This enables group address filtering for the DA.

In Hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For Hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

**Multicast destination address filtering**

To program the MAC to pass all multicast packets, set the PM bit in Packet filtering control register (ETH_MACPFR). If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of Packet filtering control register (ETH_MACPFR).

In Perfect filtering mode, the multicast address is compared with the programmed MAC destination address registers. Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register and a value of 11111 selects bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

**Hash or Perfect address filtering**

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in Packet filtering control register (ETH_MACPFR). This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

**Broadcast address filtering**

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in Packet filtering control register (ETH_MACPFR).

**Unicast source address filtering**
The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers to use SA instead of DA for comparison by setting bit 30 of MAC Address x high register (ETH_MACAxHR).

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in Packet filtering control register (ETH_MACPFR). Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see Table 550). When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

**Inverse filtering**

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of Packet filtering control register (ETH_MACPFR). The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 549 and Table 550 summarize the DA and SA filtering based on the type of packets received.

**Note:** When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx status.

</table>
VLAN filtering

The MAC supports Perfect and Hash VLAN filtering. Refer to Section 61.9.14: Programming guidelines to perform VLAN filtering on the receive for detailed programming steps.

VLAN tag Perfect filtering

In VLAN tag Perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag Perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of VLAN tag register (ETH_MACVTR). In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of VLAN tag register (ETH_MACVTR). The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

VLAN tag Hash filtering

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag. The VLAN tag Hash filtering feature can be enabled using the VTHM (VLAN tag Hash Table match enable) bit of the VLAN tag register (ETH_MACVTR). If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

</tr>
</tbody>
</table>
Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in ETH_MACVTR register.

When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of VLAN Hash table register (ETH_MACVHTR).

When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of VLAN tag register (ETH_MACVT).

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the Perfect or Hash filter, the packet should be dropped. If the VLAN perfect and VLAN Hash match are enabled, a packet is considered as matched if either the VLAN Hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and Hash filters indicate mismatch.

*Table 551* shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of Packet filtering control register (ETH_MACPFR) is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 normal descriptor (write-back format). When the RA bit is not set and the VTFE bit is set in Packet filtering control register (ETH_MACPFR), the packet is dropped if the final VLAN match status is Fail. In *Table 551*, value X means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of VLAN tag register (ETH_MACVT), all VLAN-tagged packets are considered as perfect matched but the status of the VLAN Hash match depends on the VTHM and VTIM bits in VLAN tag register (ETH_MACVT).

1. In this table, ‘X’ represents any value.
Layer 3 and Layer 4 filtering

The MAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the Operating mode configuration register (ETH_MACCR) to enable the Rx Checksum Offload engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- **Matched packets**
  - The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of Operating mode configuration register (ETH_MACCR) is set and one of the following conditions is true:
    - All enabled Layer 3 and Layer 4 fields match.
    - At least one of the enabled field matches and other fields are bypassed or disabled
  - When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.

  **Note:** The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- **Unmatched packets**
  - The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets are dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value. Such packet transfer to the application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.

- **Non-TCP or UDP IP Packets**
  - By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 filtering

The MAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.
For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

**Layer 4 filtering**

The MAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

**Layer 3 and Layer 4 filters register set**

The MAC implements two sets of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as `L3 and L4 control 0 register (ETH_MACL3L4C0R)`, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- `Layer4 Address filter 0 register (ETH_MACL4A0R)`
- `Layer3 Address 0 filter 0 register (ETH_MACL3A00R)`
- `Layer3 Address 1 filter 0 register (ETH_MACL3A10R)`
- `Layer3 Address 2 filter 0 register (ETH_MACL3A20R)`
- `Layer3 Address 3 filter 0 register (ETH_MACL3A30R)`

The second, and independent set of registers are: `L3 and L4 control 1 register (ETH_MACL3L4C1R)`, `Layer 4 address filter 1 register (ETH_MACL4A1R)`, `Layer3 address 0 filter 1 Register (ETH_MACL3A01R)`, `Layer3 address 1 filter 1 register (ETH_MACL3A11R)`, `Layer3 address 2 filter 1 Register (ETH_MACL3A21R)` and `Layer3 address 3 filter 1 register (ETH_MACL3A31R)`.

### 61.5.4 IEEE 1588 timestamp support

The IEEE 1588 standard defines a precision time protocol (PTP) which allows precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimal network and local clock computing resources.

This chapter contains the following sections:

- `IEEE 1588 timestamp support`
- `IEEE 1588 system time source`
- `IEEE 1588 auxiliary snapshots`
- `Flexible pulse-per-second output`
IEEE 1588 timestamp support

The Ethernet peripheral supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588 2008 supports PTP transported over Ethernet. The peripheral provides programmable support for both standards. It supports the following features:

- Support of both timestamp formats
- Optional snapshot of all packets or only PTP type packets
- Optional snapshot of only event messages
- Optional snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Optional selection of the node to act as master or slave for ordinary and boundary clock
- Identification of the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Optional measurement subsecond time in digital or binary format

Clock types

The MAC supports the following clock types defined in the IEEE 1588-2008 specifications:

- Ordinary clock
  
  The ordinary clock of a domain supports a single copy of the protocol. It has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

  The ordinary clock can be a grandmaster or a slave clock. It supports the following features:
  
  - Transmission and reception of PTP messages. The timestamp snapshot can be controlled as described in Timestamp control Register (ETH_MACTSCR).
  - Maintenance of the data sets such as timestamp values.

  The table below shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

<table>
<thead>
<tr>
<th>Master</th>
<th>Slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay_Req</td>
<td>SYNC</td>
</tr>
</tbody>
</table>

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in Timestamp control Register (ETH_MACTSCR).

- Boundary clock
The boundary clock typically has several physical ports which communicate with the network. The messages related to synchronization, master-slave hierarchy, and signaling end in the protocol engine of the boundary clock. Such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

### End-to-end transparent clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in Table 553. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the Timestamp control Register (ETH_MACTSCR).

<table>
<thead>
<tr>
<th>PTP messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNC</td>
</tr>
<tr>
<td>Delay_Req</td>
</tr>
</tbody>
</table>

### Peer-to-peer transparent clock

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdelay_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 561.
You can take the snapshot by setting the SNAPTYPESEL bit to 11 in Timestamp control Register (ETH_MACTSCR).

**Delay request-response mechanism**

The system or network is classified into the master and slave nodes for distributing the timing and clock information. **Figure 831** shows the process that PTP uses for synchronizing a slave node with a master node by exchanging PTP messages.

**Figure 831. Networked time synchronization**

As shown in **Figure 831**, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at \( t_1 \). This time must be captured for Ethernet ports at MII.
2. The slave receives the SYNC message and also captures the exact time, \( t_2 \), using its timing reference.
3. The master sends a Follow_up message to the slave, which contains \( t_1 \) information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, \( t_3 \), at which this packet leaves the MII interface.

<tr>
<td></td>
<td>t3m</td>
<td>t1, t2, t3, t4</td>
</tr>
<tr>
<td></td>
<td>t4</td>
<td></td>
</tr>
</tbody>
</table>
5. The master receives the message, capturing the exact time $t_4$, at which the message enters its system.
6. The master sends the $t_4$ information to the slave in the Delay Resp message.
7. The slave uses the four values of $t_1$, $t_2$, $t_3$, and $t_4$ to synchronize its local timing reference with the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

**Peer-to-peer PTP transparent clock (P2P TC) message support**

The IEEE 1588-2008 standard supports peer-to-peer PTP (Pdelay) message in addition to the Sync, Delay Request, Follow-up, and Delay Response messages. *Figure 832* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

*Figure 832. Propagation delay calculation in clocks supporting peer-to-peer path correction*

As shown in *Figure 832*, the propagation delay is calculated as follows:
1. Port 1 issues a Pdelay_Req message and generates a timestamp ($t_1$) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp ($t_2$) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t₃) for this message.
   To minimize errors caused by frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t₂ and t₃ in the Pdelay_Resp message
   - Difference between the timestamps t₂ and t₃ in the Pdelay_Resp_Follow_Up message
   - Timestamps t₂ and t₃ in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t₄) on receiving the Pdelay_Resp message.

5. Port 1 uses all four timestamps to compute the mean link delay.

**Timestamp correction**

According to the IEEE 1588 specifications, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network.

As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (MII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (clock domain crossing) circuits add an error the depends on the clock period of the MII and PTP clocks.

**Ingress correction**

In the Receive side, the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet SFD bit is received at the port boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the Timestamp Ingress correction nanosecond register (ETH_MACTSICNR).

The correction value consists of the following three components:

1. External latency in the PHY layer between boundary point and the input of the core
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from the PHY datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point
   The latency differs based on the active PHY interface (such as MII or RMII) and the operating speed, as shown in Table 555.

3. CDC synchronization
   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_ptp_ref_i).
The values determined from these three components should be added by the software and must be written into the TSIC field of the Timestamp Ingress correction nanosecond register (ETH_MACTSICNR).

**Note:** The value written to the register must be negative (two’s complement), because it has to be subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1 ns. So bit 31 of TSIC must be set to 1 (for negative value) and bits 30 to 0 must be programmed with "$10^{31} – \text{total ingress_correction_value}[\text{nanosecond part}]" represented in binary. For example, if the required correction value is −5 ns, then the value is 0xBB9A C9FB.

When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466 ns. Therefore, bits[30:0] must be written with "$2^{31} – \text{total ingress_correction_value}" represented in binary with bit[31] = 1.

### Egress correction

In the Transmit side, the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet SFD bit is output at the port boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the Timestamp Egress correction nanosecond register (ETH_MACTSECNR).

The correction value consists of the following three components:

1. **External latency in the PHY layer between the output of the core and the boundary of the port and the network**
   
   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has registers indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from the PHY datasheet or timing characteristics.

2. **Internal latency from the internal capture point and the output of the core**
   
   The latency differs based on the active PHY interface (RMII, MII, etc.) and the operating speed as shown in Table 555.

3. **CDC synchronization error**
   
   The timestamp correction because of synchronization is compensated by adding

   \[
   \text{EGRESS\_SYNC\_CORR} = (1 \times \text{PTP\_CLK\_PER} + 4 \times \text{TX\_CLK\_PER})
   \]

Table 555 lists the Egress and Ingress latency values for various PHY interfaces:

<table>
<thead>
<tr>
<th>PHY interface</th>
<th>Egress latency</th>
<th>Ingress latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGMII 1 Gbps</td>
<td>12</td>

<td>40</td>
<td>40</td>
</tr>
<tr>
<td>RGMII 10 Mbps</td>
<td>400</td>
<td>400</td>
</tr>
</tbody>
</table>
The timestamp information are transferred across asynchronous clock domains, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four clock cycles of MII and three clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

The PTP clock frequency limitations are the following:

- **Maximum PTP clock frequency**
  The maximum PTP clock frequency is limited by the maximum resolution of the reference time (10 ns at 100 MHz). In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

- **Minimum PTP clock frequency**
  The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time with the MII clock domain. This relationship is given by the following equation:
  \[ 3 \times \text{PTP clock period} + 4 \times \text{MII clock period} \leq \text{Minimum gap between two SFDs} \]
  The MII clock frequency is fixed by IEEE specifications. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in Table 556.

1. The controlField is used in version 1. In version 2, the messageType field is used for detecting different message types.

Some fields of the Ethernet payload can be used to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP packets over IPv4
- PTP frames over IPv6
- PTP packets over Ethernet

PTP packets over IPv4

Table 558 provides information about the fields that are matched to control the snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 557.

Transmit path functions

The MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. The packets, for which a timestamp has to be captured, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. The packets for which a timestamp has to be captured must be specified. The packets can be defined by using the control bits in the Transmit Descriptor (see Section 61.10.3: Transmit descriptor). The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus automatically connecting the timestamp to the specific PTP packet.

The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. The snapshot of the time to be sent to the application can be controlled by using the following options of the Timestamp control Register (ETH_MACTSCR):

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp

Table 560. Ethernet PTP packet fields required for control and status (continued)

The DMA returns the timestamp to the software application inside the corresponding
Receive descriptor. The extended status, containing the timestamp message status and the
IPC status, is written in the RDES1 normal descriptor and the snapshot of the timestamp is
written in RDES0 and RDES1 fields of the context descriptor. The RDES0 field holds the 32
least significant bits of the timestamp.

Programming guidelines for IEEE 1588 timestamping (system time correction)

See Section : System time correction in Section 61.9.9: Programming guidelines for IEEE
1588 timestamping on page 3036.

IEEE 1588 system time source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined
in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

Description of IEEE 1588 system time source

The peripheral uses the reference clock input and uses it to internally generate the
Reference time (also called the system time) and capture timestamps.

The timestamp has the following fields:
- UInteger48 seconds field
The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bit wide. For example, 2.000000001 seconds are represented as seconds Field = 0x0000 0000 0002.

- **UInteger32 nanosecondsField**
  
  The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000 0001.
  
  The nanoseconds field supports the following two modes:
  
  - **Digital rollover mode**: In this mode, the maximum value in the nanoseconds field is 0x3B9A C9FF, that is, (10e9-1) nanoseconds.
  - **Binary rollover mode**: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF FFFF. Accuracy is ~0.466 ns per bit.

  These modes can be set through TSCTRLSSR bit in **Timestamp control Register (ETH_MACTSCR)**.

**System time register module**

The 64-bit PTP time is updated using the PTP input reference clock, clk_ptp_ref_i. This PTP time is used as a source to take snapshots (timestamps) of the Ethernet frames being transmitted or received at the MII.

The system time counter can be initialized or corrected using either the coarse or the fine correction method.

In the coarse correction method, the initial value or the offset value is written to the timestamp update register. For initialization, the system time counter is programmed with the value in the timestamp update registers, whereas for system time correction the offset value (timestamp update register) is added to or subtracted from the system time.

In the fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588-2002 specifications) is corrected over a period of time, unlike in the coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register as shown in **Figure 833**. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This system time update algorithm is shown in **Figure 833**.
The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz/50 MHz = 1.32. Therefore, the default addend value to be set in the register is $2^{32} / 1.32$, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, that is 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC 4EC4.

If the clock drifts higher, for example to 67 MHz, the addend register must be set to 0xBF0B 7672. When there is not clock drift, the default addend value of 0xC1F0 7C1F ($2^{32} / 1.32$) must be programmed.

In Figure 833, the constant value used to accumulate the subsecond register is decimal 43, which achieves a system time accuracy of 20 ns (in other words, it is incremented in 20 ns steps).

The software must calculate the drift in frequency based on the SYNC messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue}_0 = 2^{32} / \text{FreqDivisionRatio}$$
If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-syncronize with the master using the new value.

The algorithm is as follows:

1. At time MasterSyncTime\(_n\) the master sends the slave clock a SYNC message. The slave receives this message when its local clock is SlaveClockTime\(_n\) and computes MasterClockTime\(_n\) as follows:
   \[
   \text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n
   \]

2. The master clock counts for current Sync cycle, MasterClockCount\(_n\) is
   \[
   \text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}
   \]
   (assuming that MasterToSlaveDelay is the same for Sync cycles \(n\) and \(n-1\))

3. The slave clock count for current Sync cycle, SlaveClockCount\(_n\) is
   \[
   \text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}
   \]

4. The difference between master and slave clock counts for current Sync cycle, ClockDiffCount\(_n\) is
   \[
   \text{ClockDiffCount}_n = \text{MasterClockTime}_n - \text{SlaveClockTime}_n
   \]

5. The frequency-scaling factor for slave clock, FreqScaleFactor\(_n\) is
   \[
   \text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n
   \]

6. The frequency compensation value for Addend register, FreqCompensationValue\(_n\) is
   \[
   \text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n \times \text{FreqCompensationValue}_{n-1}
   \]

In theory, this algorithm achieves the lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value by the master, the algorithm corrects it at the cost of additional Sync cycles.

Refer to Section 61.9.9: Programming guidelines for IEEE 1588 timestamping for detailed programming steps.

**IEEE 1588 auxiliary snapshots**

The auxiliary snapshot feature enables to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the eth_ptp_trgx (where \(x = 1\) to \(4\)) sideband signal.

Up to four auxiliary snapshot inputs can be configured and up to four snapshots can be stored. A FIFO is accessible through registers: Auxiliary timestamp seconds register (ETH_MACATSSR) and Auxiliary timestamp nanoseconds register (ETH_MACATSNR).

The snapshots taken for any input are stored in a common FIFO; only 64 bits are kept. The application can read the Timestamp status register (ETH_MACTSSR) to know the timestamp of which input is available for reading at the top of this FIFO.
When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the Timestamp status register (ETH_MACTSSR). This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in Auxiliary control register (ETH_MACACR). When multiple snapshots are present in the FIFO, the count is indicated in bits[27:25] of Timestamp status register (ETH_MACTSSR).

**Flexible pulse-per-second output**

The MAC supports either a fixed pulse-per-second output mode (also called fixed mode) or a flexible pulse-per-second output mode for the ETH_PPS_OUT and eth_ptp_pps_out outputs:

- **Fixed pulse-per-second output**
  
  In this mode, only the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).

- **Flexible pulse-per-second output**
  
  In this mode, the software has the flexibility to program the start or stop time, width, and interval of the pulse generated on the eth_ptp_pps_out output:
  
  The start and stop times are programmed through PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).
  
  The PPS width and interval are programmed in terms of granularity of system time (number of the units of subsecond increment value) through PPS width register (ETH_MACPSPSWR) and PPS interval register (ETH_MACPSSWR), respectively.

*Note:* By default, the peripheral is in Fixed mode and indicates one second interval. When Fixed mode is selected by clearing PPSEN0 to 0 in the PPS control register (ETH_MACPPSCR):

- the output on all PPS outputs is controlled by the value programmed in the PPSCTRL_PPSCMD field. Independent control of individual PPS output is not supported in Fixed mode.

- PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) are used only for generating target time reached interrupt; they are not used for PPS output generation.

- TRGTMODSEL0/1/2/3 must be programmed to 0.

- the frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register (ETH_MACPPSCR).
Description of flexible pulse-per-second (PPS) output

The peripheral supports the following features with the flexible PPS outputs:

- Programming the start or stop time in terms of system time.
- Programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Programming the stop time in advance, that is, the stop time can be programmed before the actual start time has elapsed.
- Programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of subsecond increment value programmed in the Subsecond increment register (ETH_MACSSIR). The pulse width can be programmed from 1 to 232–1 units of subsecond increment value.
- Programming the interval, between the rising edges of PPS signal, in terms of number of units of subsecond increment value. You can program the interval between pulses from 1 to 232–1 units of subsecond increment value.
- Option to cancel the programmed PPS start or stop request.
- Error if the start or stop time being programmed has already elapsed.

Note: The PTP reference clock mentioned in the following sections is the clock at which the system time is updated. When the TSCFUPDT bit of Timestamp control Register (ETH_MACTSCR) is set to 0, this clock is similar to the clk_ptp_ref_i clock. In Fine correction mode, this is the clock tick at which the system time is updated (using Subsecond increment register (ETH_MACSSIR) (as shown in Figure 833).

Refer to Section 61.9.12: Programming guidelines for flexible pulse-per-second (PPS) output for further details on how configuring flexible pulse output.

PPS start and stop times

The initial start time can be programmed in the Target Time registers.

If required, the start or stop time can be programmed again. However, this can be done only after the earlier programmed value is synchronized with the PTP clock domain. Bit 31 of PPS target time nanoseconds register (ETH_MACPPSTTNR) indicates that the synchronization is complete. This enables to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, it is recommended to program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS width and interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of subsecond increment value. For example, to obtain a PPS pulse width of 40 ns and an interval of 100 ns with a PTP reference clock of 50 MHz, program the width and interval to values 2 and 5, respectively. Smaller granularity can be achieved by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, program or update the interval and width of the PPS signal output.
PTP timestamp offload function

This feature enables the automatic generation of specific PTP packets to be performed, when the MAC operates as a specific node in the PTP network.

These packets can be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. It helps to offload certain PTP node functions with better accuracy and lower response latency.

The PTP offload feature is selected through **PTP Offload control register (ETH_MACPOCR)**. 80-bit PTP node identity is configured through the following three registers: **PTP Source Port Identity 0 Register (ETH_MACSPI0R)**, **PTP Source port identity 1 register (ETH_MACSPI1R)** and **PTP Source port identity 2 register (ETH_MACSPI2R)**.

Description of PTP offload function

Depending on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application, or based on reception of a particular PTP message. **Table 562** indicates the PTP message generation criteria.

</table>

All other programming combinations are invalid for PTP Offload feature.

Note: Clocks supporting peer delay mechanism must not generate delay request/delay response messages, according to IEEE 1588-2008 specifications. However, the peripheral controller supports this for flexibility, with a programmable control bit (DRRDIS) in the PTP Offload control register (ETH_MACPOCR).

The DRRDIS bit can be used to control the response generation for delay request/delay response message. For example, in transparent slave mode, delay request is generated in response to received SYNC only when the bit is reset.

When the MAC is set as an Ordinary or Boundary Slave clock in the PTP network, it can respond to the reception of SYNC messages with an automatic generation and transmission of the corresponding Delay_Req message. Similarly, various other modes of operation are explained in Table 562.

The MAC supports the multicast communication model for the generation of SYNC and Pdelay_Req PTP messages. For instance, the Destination Address field of the generated PTP over Ethernet packet is the defined special multicast addresses (0x011B 1900 0000 for all except peer delay mechanism messages and 0x0180 C200 000E for peer delay mechanism messages).

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with special multicast destination address, it also uses the corresponding special multicast address in the DA field of the automatically generated Delay_Req, Delay_Resp, and Pdelay_Resp PTP messages, respectively.

When the MAC responds to received SYNC, Delay_Req and Pdelay_Req PTP messages with unicast destination address, it takes the SA field of the received packets and makes
them as the DA field of the automatically generated Delay_REQ, Delay_RESP, and Pdelay_Resp PTP messages, respectively.

At the same time, all the received PTP messages are forwarded to the application along with Rx status, indicating whether the response was generated by the MAC, if it satisfies the packet filtering logic of the MAC receiver.

When the MAC automatically generates a PdelayReq or responds with a Delay_Req, the egress timestamp of these two PTP messages are provided in the Tx TS status (Tx Timestamp Status register and interrupt generated).

In addition to messageType and versionPTP fields match for basic PTP over Ethernet message detection, the following additional fields are matched to qualify the received PTP message type:

1. The domainNumber field is checked for a match against the value programmed in the CSR.
2. The twoStepFlag in flagField field is checked for one-step indication (0b0).
3. The transportSpecific field is checked for Default PTP over Ethernet (0b0000) or 802.1AS mode (0b1111) when enabled.

PTP packet generation

This section explains the format and content of the automatically generated PTP packets by the MAC when this mode is enabled. It provides the template of the common PTP message header, as well as the detailed description of the fields of the specific PTP packets generated.

PTP message header fields

- **messageType**
  The following encoded values are used for PTP message types:
  - SYNC: 0000
  - Delay_REQ: 0001
  - Pdelay_REQ: 0010
  - Pdelay_RESP: 0011
  - Delay_RESP: 1001

- **transportSpecific**
  The following transport protocol encoding is used:
  - Default PTP over Ethernet: 0000
  - 802.1AS mode: 0001

- **versionPTP**
  It is always set to 2 because PTP version 2 is supported.

- **domainNumber**
  This field contains the value from the PTP Offload control register (ETH_MACPOCR).

- **flagField**
  The following values are used:
  - alternateMasterFlag (Octet 0 bit 0): 0 for SYNC and Delay_RESP
  - twoStepFlag (Octet 0 bit 1): 0 for SYNC and Pdelay_RESP
  - unicastFlag (Octet 0 bit 2): 0 for Multicast Address, 1 for Unicast Address

- **correctionField**
  For more information, see Table 564.

- **sourcePortIdentity**
  This field takes the value programmed in the PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R).

- **sequenceId**
  Pdelay_RESP and Delay_RESP use the same sequenceId field from received Pdelay_REQ and Delay_REQ PTP messages. For SYNC/Delay_REQ, Pdelay_REQ, a separate sequenceId counter is maintained. These sequenceId counters get incremented by 1 every time the corresponding message is generated and transmitted.

- **controlField**
  The following encoded values are used for controlField:
  - SYNC: 0000 0000
  - Delay_REQ: 0000 0001
  - Pdelay_REQ: 0000 0010
  - Pdelay_RESP: 0000 0101
  - Delay_RESP: 0000 0111

- **logMessageInterval**
  - SYNC:
    This field contains logSyncInterval from the corresponding MAC_Log_Message_Interval register.
– **Delay Resp:**
  This field contains the sum of DRSYNCR and logSyncInterval value taken from the
  Log message interval register (ETH_MACLMIR) for a multicast PTP message
  and 0111 1111 for unicast PTP message.

– **Delay Req, Pdelay Req and Pdelay Resp:** 0111 1111
  where logSyncInterval = \log_2 (\text{Mean Value of Interval in seconds})

The MAC supports values of –15 to 15 for logSyncInterval fields, which translates to a range
from 32.768 micro second (2–15) to 215 second. For a given value of log sync interval (N),
the time interval between two SYNC packets is given by the following:
- \(2^{(30+N)}\) ns, when N is negative (–1 to –15)
- \(2^N\) seconds, when N is positive (0 to 15)

For example:
- When logSyncInterval is programmed to 1, the interval is \(2^1\); therefore, the SYNC
  message is sent once every 2 seconds.
- When logSyncInterval is programmed to -1, the interval is \(2^{-1} = 0.536\) seconds;
  therefore, the SYNC message is sent once every 536 milliseconds. The value is 0.536
  seconds, because \(2^{-30} = 1\) ns.
- When logSyncInterval is programmed to –5, the interval is \(2^{-5} = 33.55\) ms; therefore,
  the SYNC message is sent once every 33.55 ms.

*Note:* The MAC uses the PTP system time to generate the intervals for periodic packet
transmission. For negative values of log message interval programmed, the generated
period may deviate from the value given by the equation \(2^{(30+N)}\), because of the non-binary
nature of the nanoseconds field of the system time.

**PTP message-specific fields**
The message-specific fields are the following:

- **messageLength**
  There is no suffix supported, so this field contains the length of the PTP message that
  includes 34-byte PTP common header and the body specific to the message type.
  For SYNC and Delay Req packets, this field contains 44, whereas for Delay Resp,
  Pdelay Req and Pdelay Resp, it contains 54.

- **originTimestamp**
  This field is the captured egress timestamp for SYNC, Delay Req, and Pdelay Req
  PTP messages.

- **receiveTimestamp**
  For Delay Resp PTP message, this is the ingress timestamp of the corresponding
  received Delay Req PTP message.

- **requestingPortIdentity**
  For Delay Resp and Pdelay Resp PTP messages, this is the sourcePortIdentity field
  taken from the corresponding received Delay Req and Pdelay Req PTP messages.

- **requestReceiptTimestamp**
  For the Pdelay Resp PTP message, this field is set to 0.
**One-step timestamp**

The MAC supports the one-step timestamp feature that enables to identify the offset in the packet and inserts the timestamp received from the application at that offset.

**MAC Transmit PTP mode for one-step timestamp**

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

*Table 564* shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the *Timestamp control Register (ETH_MACTSCR)* and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

(1) For details of Per packet control, please refer to the specific section related to packet control in the document.
Note: Residence time/turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp. Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

Enabling one-step timestamp

The one-step timestamp feature can be enabled for a given packet by setting bit 20 (OSTC) in TDES3 context descriptor. To update the correction field in certain PTP packets, the ingress timestamp must be given in the TSSL and TSSH fields.

The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets.

61.5.5 Checksum offload engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, as well as error detection in the Receive path.

Transmit checksum offload engine

In the transmit path, the MAC calculates the checksum and inserts it in the Tx packet. This feature helps reducing the load on the software and can improve the overall system throughput.

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits[17:16]).
Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, the Tx FIFO automatically operates in the Store-and-forward mode even if the MAC is configured in Threshold (cut-through) mode.

Make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter, the reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid deadlock. In such a case, the COE fails as the start of the packet header is read out before the payload checksum can be calculated and inserted. Therefore, the checksum insertion must be enabled only in the packets that are less than the number of bytes, given by the following equation:

\[
\text{Packet size} < T_x\text{QSize} - (PBL + 7) \times 4
\]

where

- \(T_x\text{QSize}\) corresponds to the TQS bitfield of \(Tx\) queue operating mode Register \((ETH\_MTLTXQOMR)\)
- \(PBL\) corresponds to the TxPBL bitfield of Channel transmit control register \((ETH\_DMACTXCR)\)

Refer to IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

**IP header checksum engine**

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

Note: IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status in the Transmit status (bit 0 in Table 586: TDES3 normal descriptor (write-back format)).

This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as
indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86DD but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (bit 12 in Table 586: TDES3 normal descriptor (write-back format)). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 565 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: Do not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Section: Transmit checksum offload engine because it might result in incorrect checksum insertion or unexpected behavior.

Receive checksum offload engine

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

The Receive Checksum Offload Engine (Rx COE) can be enabled by setting the IPC bit of Operating mode configuration register (ETH_MACCR). When this bit is set, both IPv4 and IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the VLAN tag register (ETH_MACVTR) is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

Packets with TCP/IP errors (header or payload) are dropped in MTL when DIS_TCP_EF bit of the Rx queue operating mode register (ETH_MTLRXQOMR) is reset and FEP bit is set.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

*Table 566: Receive checksum offload engine functions for different packet types* describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

*Note:* The MAC does not append any payload checksum bytes to the received Ethernet packets.

61.5.6 TCP segmentation offload

The MAC supports the TCP segmentation offload (TSO) feature in which the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in Figure 834.

This feature is enabled by programming the TSE bit of corresponding ETH_DMACCR register (see Channel transmit control register (ETH_DMACTXCR)). It is only supported when the MAC operates in Full-duplex mode.

For detailed programming steps, refer to Section 61.9.13: Programming guidelines for TSO.

Figure 834. TCP segmentation offload overview
DMA operation with TSO feature

*Figure 835* shows the TSO flow.

**Figure 835. TCP segmentation offload flow**

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet packet data.
2. The application increases the offset value of the Descriptor tail pointer of the DMA Tx channel.
3. While in the Run state, the DMA fetches the next available descriptor and performs one of the following actions:
   - If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.

If the descriptor is a normal descriptor, the DMA checks the TSE bit. If the TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).

4. The DMA calculates the number of segments from the TCP payload length (TDES3[17:0]) and the MSS value.

5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.

6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size). If the current segmented packet is not the first segment, it fetches again the header buffer in system memory, as done for the first segment. In such cases, the DMA does not close the first descriptor containing the header buffer until the header for last segment is fetched.

7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL Tx queue.

8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory, and directly pushes it into the MTL Tx queue. If the buffer(s) in the descriptor do(es) not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.

9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the Tx queue.

10. The DMA closes the last descriptor and the first descriptor (containing the header buffer when it is not stored in TSO memory), and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no more descriptor are available, the DMA enters the suspend state.

Note: The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.

**TCP/IP header fields**

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 567* describes how the TCP and IP headers are updated.

<table>
<thead>
<tr>
<th>Packet sequence</th>
<th>TCP header</th>
<th>IP header</th>
</tr>
</thead>
</table>
| **First packet** | 1. The sequence number is not updated. The value provided in the header is used.  
2. If set, the FIN and PSH flags are cleared.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = MSS + TCP Header Length + IP Header Length  
– Identification field is not modified. It is sent as per the header provided by the software.  
– IPv4 Header Checksum is recalculated  
IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length |
| **Subsequent packets** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.  
2. If set, the FIN and PSH flags are cleared.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = MSS + TCP Header Length + IP Header Length  
– Identification Field = Previous Identification Field + 1  
– IPv4 Header Checksum is recalculated  
IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length |
| **Last packet** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment.  
2. If FIN and PSH flags were set in original header, these flags are set.  
3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = Remaining Payload + TCP Header Length + IP Header Length  
– Identification Field = Previous Identification Field + 1  
– IPv4 Header Checksum is recalculated  
IPv6 Header  
– Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length |
Header and payload fields of segmented packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in Table 567: TSO: TCP and IP header fields. Figure 836: Header and payload fields of segmented packets shows how same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Context descriptor sequence

The context descriptor can provide the maximum segment size (MSS) value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application needs to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset (refer to Section 61.10.3: Transmit descriptor).

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this value for all subsequent packets for which the TSO is enabled through the TSE bit of TDES3 normal descriptor.
If the application places a context descriptor in the middle of a packet (between the first and last descriptors of a packet), the DMA does the following:

1. The DMA ignores the context and closes the descriptor.
2. The DMA indicates the error in descriptor status.
3. The DMA generates an interrupt if the CDEE bit is set in the Interrupt enable register corresponding to a DMA channel (see Channel interrupt enable register (ETH_DMACIER)).

The application can read the interrupt status through CDE bit of Status register corresponding to a DMA channel (see Channel status register (ETH_DMACSR)).

Building the Descriptor and the packet for the TSO feature

To enable segmentation for a packet, the application must set the TSE bit of TDES3 of first normal descriptor (see Section 61.10.3: Transmit descriptor). If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 Kbytes.

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in ETH_DMACCIR (see Channel control register (ETH_DMACCIR)) or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)) should be lesser than the Tx queue size programmed in TQS field of ETH_MTLTXQOMR register (see Tx queue operating mode Register (ETH_MTLTXQOMR)). A MSS plus header equal to half the programmed Tx queue size is recommended.

The DMA also supports segmentation of VLAN-tagged TCP/IP frames. If the TCP packet has a VLAN tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits are used for all segments.
If the Double VLAN feature is selected, then the DMA passes both tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN tag Insert/Replace control bits for both tags is applicable to all segments. If the Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning this is an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 00 (MAC does CRC and padding) and checksum insertion control bits are forced to 11 (hardware does the checksum calculation for both header and payload).

61.5.7 IPv4 ARP offload

The MAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows to process the IPv4 ARP request packet in the receive path and to generate the corresponding ARP response packet in the transmit path.

The MAC generates the ARP reply packets for appropriate ARP request packets. ARP packets for IPv4 are L2 layer packets with Length/Type of 0x0806.

The ARP offloading sequence is as follows:
1. The MAC receiver gets an ARP request if the request Target Protocol Address matches the IPv4 address programmed in the MAC L3 register.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   – DA field of the Ethernet packet header
   – Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   – SA field of the Ethernet packet header
   – Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for the generated ARP reply packet.
9. The MAC transmitter sends the ARP reply

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to the application with ARP Reply Not Generated status bit set (bit 34). However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request. If the Disable CRC check (DCRCC) bit of the Extended operating mode configuration register (ETH_MACECR) is set, then the MAC does not check for valid CRC of a ARP
request packet. It can generate an ARP response packet if the other conditions are valid. The ARP request packet must always have a valid CRC.

Note: When the received ARP request is less than the 64-byte packet length, the MAC does not send an ARP response. It is treated as a normal packet and forwarded to the application based on the MAC filter settings.

61.5.8 Loopback

The MAC supports loopback of transmitted packets to its receiver.

Guidelines for using Loopback mode

Below some guidelines for using the Loopback mode:

- Enable loopback only with the Full-duplex mode. In Half-duplex mode, the carrier sense signal or collision signal inputs get sampled which may result into issues such as packet dropping.
- If the Loopback mode is enabled without connecting a PHY chip, externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets since they may get corrupted in the loopback FIFO.

The Transmit and Receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the transmitted data to the Receive path. The FIFO is free-running to write on the write clock (eth_mii_tx_clk) and read on every read clock (eth_mii_rx_clk). At the start of each packet read from the FIFO, the write and read pointers are reinitialized to have an offset of four (in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer, and ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between MII Transmit and Receive clock frequencies.

Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module. The MAC does not process ARP or PMT packets that are looped back.

Enabling Loopback mode

To enable this feature, program the LM bit of the Operating mode configuration register (ETH_MACCR). Loopback can be enabled for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII interface, irrespective of which PHY interface is selected.

The loopback data is also passed through the corresponding transmit PHY interface block, onto the Ethernet line.

Note: During loopback, the data/packet is reflected on mii_txd signal.
Preemption is not supported in Loopback mode.
Flow control

The transmit flow control involves transmitting Pause packets in Full-duplex mode and back-pressure in Half-duplex mode to control the flow of packets from the remote end. This section describes the flow control for transmit and receive paths.

Flow control in Full-duplex mode

In Full-duplex mode, the MAC uses IEEE 802.3x Pause packets for flow control. Table 568 describes the fields of a Pause packet.

Table 568. Pause packet fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA</td>
<td>Contains the special multicast address</td>
</tr>
<tr>
<td>SA</td>
<td>Contains the MAC address 0</td>
</tr>
<tr>
<td>Type</td>
<td>Contains 8808</td>
</tr>
<tr>
<td>MAC Control opcode</td>
<td>Contains 0001 for IEEE 802.3x Pause Control packets</td>
</tr>
<tr>
<td>PT</td>
<td>Contains Pause time specified in the PT field of the Tx Queue flow control register (ETH_MACQTXFCR)</td>
</tr>
</tbody>
</table>

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Flow control in Half-duplex mode

In Half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Table 569 describes the flow control in the Tx path based on the setting of the following bits:

- TFE bit of Tx Queue flow control register (ETH_MACQTXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

Flow control is similar for all queues.
Transmit flow control

The transmit flow control is enabled when TFE bit is set in Tx Queue flow control register (ETH_MACQTXFCR).

Flow control trigger

The application can request the MAC to send a Pause packet or initiate backpressure by setting the FCB bit in the corresponding Tx Queue flow control register (ETH_MACQTXFCR).

Receive flow control

In the Receive path, the flow control is functional only in Full-duplex mode. If any Pause packet is received in Half-duplex mode, the packet is considered as a normal control packet.

Description of receive flow control

Table 570 describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of Rx flow control register (ETH_MACRXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

Table 569. Tx MAC flow control

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.</td>
</tr>
</tbody>
</table>

The following sequence describes the Rx flow control:

1. The MAC checks the destination address (DA) of the received Pause packet for either of the following:
   - Multicast destination address: the DA matches the unique multicast address specified for the control packet (0x0180 C200 0001).
   - Unicast destination address: the DA matches the content of the MAC Address 0 registers (MAC Address 0 high register (ETH_MACA0HR) and MAC Address x
low register (ETH_MACAxLR)) and the UP bit of Rx flow control register (ETH_MACRXFCR) is set.

If the UP bit is set, the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.

2. The MAC decodes the following fields of the received packet:
   – Type field: this field is checked for 0x8808.
   – Opcode field: this field is checked for 0x0001 (Pause packet).
   – Pause time: the Pause time (for Pause packet) is captured to determine the time for which the transmitter needs to be blocked.

3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).

If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

**Enabling receive flow control**

Set the RFE bit in the Rx flow control register (ETH_MACRXFCR) to enable the Pause flow control.
61.5.10 MAC management counters

The peripheral supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC management counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the AHB slave interface in the same way the CSR registers are accessed. The organization of these registers is shown in Section 61.11.4: Ethernet MAC and MMC registers.

The MMC counters are free running. There is no separate enable for the counters to start. A particular MMC counter starts counting when corresponding packet is received or transmitted.

The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set bit 0 in the Packet filtering control register (ETH_MACPFR). The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

In addition to control registers, two sets of registers are implemented:

- Six registers used for collision, error, and good packet counters:
  - Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)
  - Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)
  - Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)
  - Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)
  - Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)
  - Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)

- Four registers to record LPI mode transition:
  - Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR)
  - Tx LPI transition counter register (ETH_TX_LPI_tran_CNTR)
  - Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)
  - Rx LPI transition counter register (ETH_RX_LPI_tran_CNTR)
Definitions

The following terminology is used in MMC register descriptions:

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber timeout
  - No carrier or loss of carrier
  - Late collision
  - Packet underflow
  - Excessive deferral
  - Excessive collision

- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of range (non-Type packet only, longer than 1518 bytes)

- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN frame maxsize = 1,522
  - Jumbo frame maxsize = 9,018
  - JumboVLAN frame maxsize = 9,022

- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the Table 571.

<table>

61.5.11 Interrupts generated by the MAC

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA on the eth_sbd_intr_it signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The interrupt status register (ETH_MACISR) describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the eth_sbd_intr_it signals by setting the corresponding mask bits in the interrupt enable register (ETH_MACIER).

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

61.5.12 MAC and MMC register descriptions

Refer to Section 61.11.4: Ethernet MAC and MMC registers.
61.6 Ethernet functional description: PHY interfaces

The Ethernet peripheral support several PHY interfaces. The root interface is the MII one. All other interfaces are derived from it as shown in Figure 837.

Figure 837. Supported PHY interfaces

This section describes the SMA module used for PHY control and different PHY interfaces. It contains the following sections:

- Station management agent (SMA)
- Media independent interface (MII)
- Reduced media independent interface (RMII)

61.6.1 Station management agent (SMA)

The application can access the PHY registers through the station management agent (SMA) module. The SMA includes a two-wire station management interface (MIM).

The SMA module supports accessing up to 32 PHYs. The application can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in Figure 838.

Figure 838. SMA Interface block
SMA functional overview

The MAC initiates the management write or read operation with respect to the MDC clock. The MDC clock is derived from the CSR clock (eth_hclk). The maximum operating frequency of the ETH_MDC pin is 2.5 MHz, as specified in IEEE 802.3 specifications. However, a different divider can be selected if the system supports higher clock frequencies. The division factor depends on the clock range setting through CR[3:0] in the MDIO address register (ETH_MACMDIOAR) register. The MDC clock is selected as follows:

<table>
<thead>
<tr>
<th>Selection</th>
<th>MDC clock</th>

</tbody>
</table>

The data exchange between the MAC and the PHY is performed through a three-state buffer and brought out as ETH_MDIO line connected to the PHY.

*Figure 839* shows the structure of a Clause 45 MDIO packet, while *Table 573* provides a detailed description of the packet fields.

</tbody>
</table>

The frame structure for Clause 22 frames is also supported. The C45E bit in MDIO address register (ETH_MACMDIOAR) can be programmed to enable Clause 22 or Clause 45 mode of operation. Figure 840 shows the structure of a Clause 22 MDIO packet, while Table 574 provides a detailed description of the packet fields.

Figure 840. MDIO packet structure (Clause 22)
In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

**MII management write operations**

After the station management agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

*Figure 841* illustrates the flow for a write operation from the SMA module to the PHY registers.

<table>

| TA | Turnaround  
– 0bZ0: Read and post-read increment address  
– 0b10: Write and address MDIO accesses  
where Z is the tri-state level |
| DATA | Any 16-bit value. In a Write operation, the MAC drives ETH_MDIO. In a Read operation, the PHY drives it. |
When bits[3:2] are set to 01 and bit 0 to 1 in the **MDIO address register (ETH_MACMDIOAR)**, the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (**MDIO data register (ETH_MACMDIODR)**) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII management Interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the **MDIO address register (ETH_MACMDIOAR)** or the **MDIO data register**.
(ETH_MACMDIODR) during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit. The packet format for the Write operation is as follows:

**Figure 842. Write data packet**

<table>

</tbody>
</table>

MII management read operation

When bits[3:2] are set to 11 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MDIO address register (ETH_MACMDIOAR) or MDIO data register (ETH_MACMDIODR) during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface. When the Read operation is complete, the SMA indicates this to the CSR. The CSR resets the Busy bit and updates the MDIO data register (ETH_MACMDIODR) with the data read from the PHY. The MAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

**Figure 843. Read data packet**

</table>
Preamble suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The peripheral provides controls to support preamble suppression. It transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting the PSE bit in MDIO address register (ETH_MACMDIOAR).

Trailing clocks and back-to-back transactions

The peripheral drives the ETH_MDC clock for the duration of the MDIO frame. There is no clock driven during the idle period. The trailing clock feature can be used if the PHY needs the ETH_MDC clock to be active for some cycles after the MDIO frame. The NTC[2:0] bitfield in MDIO address register (ETH_MACMDIOAR) allows the programming of trailing clocks from 0 to 7.

The peripheral supports back-to-back transactions which allow starting the next MDIO frame even before the trailing clocks are complete for previous MDIO frame. This feature can be enabled by setting BTB bit in MDIO address register (ETH_MACMDIOAR) when the trailing clock feature is also enabled. When back-to-back transactions are enabled, the GMII busy bit (GB) is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by the peripheral while trailing clocks are still on for the previous MDIO frame. When (GB) transactions are not enabled, the GMII busy bit is cleared after the trailing clocks are complete for the MDIO frame.

Interrupt for MDIO transaction completion

The peripheral can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII busy bit of the MDIO address register (ETH_MACMDIOAR) to know the completion of MDIO commands.
61.6.2 Media independent interface (MII)

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

MII signals are given in Figure 844: Media independent interface (MII) signals.

Figure 844. Media independent interface (MII) signals

- TX_CLK: continuous clock that provides the timing reference for Tx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s and 25 MHz at 100 Mbit/s.
- TXD[3:0]: transmit data. TXD is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the TX_EN signal. TXD[0] is the least significant bit, TXD[3] is the most significant bit. While TX_EN is deasserted, the transmit data must have no effect upon the PHY.
- TX_EN: transmission enable signal indicating that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (TX_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- TX_ER (optional): required only for Energy Efficient Ethernet (EEE). The transmit error is indicated by inverting the CRC. The remote station can detect the Transmit error through incorrect CRC.
- RX_CLK: continuous clock that provides the timing reference for Rx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s, 25 MHz at 100 Mbit/s.
- RXD[3:0]: receive data. RXD is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the RX_DV signal. RXD[0] is the least significant bit, RXD[3] is...
the most significant bit. While RX_EN is deasserted and RX_ER is asserted, a specific RXD[3:0] value is used to transfer specific information from the PHY.

- RX_DV: receive data valid
  This signal indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (RX_CLK) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the RX_DV signal must encompass the frame, starting no later than the SFD field.

- RX_ER: receive error
  This signal must be asserted for one or more clock periods (RX_CLK) to indicate to the MAC sublayer that an error was detected somewhere in the frame. This error condition must be qualified by RX_DV assertion.

- CRS: carrier sense.
  This signal is asserted by the PHY when either the transmit or receive medium is non idle. It is deasserted by the PHY when both transmit and receive media are idle. The PHY must ensure that the CS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode the state of this signal is don’t care for the MAC sublayer.

- COL: collision detection signal
  This signal must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode, the state of this signal is don’t care for the MAC sublayer.

61.6.3 Reduced media independent interface (RMII)

The reduced media independent interface (RMII) specification reduces the pin count between Ethernet PHYs and STM32 MCU. According to the IEEE 802.3u, an MII contains 16 pins for data and control. RMII specification reduces the pin count to 7.

Part of the Ethernet peripheral, the RMII module is instantiated at the MAC output. This helps in translating the MII of the MAC into the RMII. The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock references externally.
RMII block diagram

Figure 845: RMII block diagram shows the position of the RMII block relative to the MAC and RMII PHY. The RMII block is placed in front of the MAC to translate the MII signals to RMII signals.

Figure 845. RMII block diagram

- RMII_REF_CLK: continuous 50 MHz reference clock input
- TXD[1:0]: transmit data
- TX_EN: transmit data enable. When high, this bit indicates that valid data are being transmitted on TXD[1:0].
- RXD[1:0]: receive data
- CRS_DV: carrier Sense (CRS) and RX_Data Valid (RX_DV) multiplexed on alternate clock cycles. In 10 Mbit/s mode, it alternates every 10 clock cycles.
Transmit bit order

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in Figure 846: Transmission bit order. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

Figure 846. Transmission bit order
Receive bit order

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in Figure 847: Receive bit order. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 847. Receive bit order
61.7 Ethernet low-power modes

61.7.1 Low-power management

The Ethernet peripheral supports the following techniques to save power:

- Magic packet
- Remote wakeup

The magic packet and remove wakeup techniques are used to save power in the host system when it is in low-power mode, and has to be woken up only at the reception of specific packets from the Ethernet network. In low-power mode, the clocks on most of the host logic, along with the majority of the peripherals (except the MAC receiver logic), can be disabled. On receiving the specific packets from the network, the MAC generates the trigger to wake up the host system and come back to normal state. Refer to the power control (PWR) section of the reference manual for the list of the system operating modes that support Ethernet low-power modes.

The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit in the near future and puts the transmitter port (MAC controller, PCS and PHY layers) in low-power mode. Similarly, the receiver port can also be put in low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the peripheral.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported.

Description of magic packet mode

This section describes how to save power through magic packet detection.

Note: The magic packet feature is based on the magic packet technology white paper from Advanced Micro Device (AMD).

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the magic-packet-based power saving mode, the reception of a valid magic packet by the MAC receiver triggers an exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the magic-packet-based power saving mode is enabled by setting the MGKPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
• The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
• The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

Magic packet data format
The content of the unique pattern in magic packets is described as follows:
• Six bytes of all-ones (0xFF FF FF FF FF FF) called synchronization stream. There can be more than six bytes of 0xFF, but only the last six are considered.
• The synchronization stream is immediately followed by 16 repetitions of the Destination address field of the packet (MAC Address 0 high register (ETH_MACA0HR) and the MAC Address 0 low register (ETH_MACA0LR)) or multicast/broadcast address.
• No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions.

If the MAC address of a node is 0x00 11 22 33 44 55, the MAC scans for the following data sequence:
   Destination Address Source Address Length/Type..................... FF FF FF FF FF FF
   00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
   00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
   00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
   …CRC

Description of remote wakeup packet mode
This section describes the power saving mode based on remote wakeup packet.

Note: The remote wakeup packet feature implementation is based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the remote-wakeup-magic-packet-based power saving mode, the reception of expected remote wakeup packet by the MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit in PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the remote-wakeup-magic-packet-based power saving mode is enabled by programming RWPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The MAC implements a filter lookup table (programmed through Remote wakeup packet filter register (ETH_MACRWKPFR)) in which CRC, offset, and byte mask of the pattern embedded in remote wakeup packet and the filter operation commands are programmed.

The pattern embedded in the remote wakeup packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wakeup packet:
• The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
- The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
- The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

When a valid remote wakeup packet is received, the MAC receiver sets the RWKPRCVD bit in PMT control status register (ETH_MACPCSR) and triggers the interrupt on pmt_intr_o output port. The PMTIS bit in Interrupt status register (ETH_MACISR) is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application on the sbd_intr_o output port when interrupt is enabled (PMTIE bit in Interrupt enable register (ETH_MACIER) is set) and CSR clock is not gated off in low-power mode.

Remote wakeup packet filters

When the remote-wakeup-based power saving mode is enabled, four remote wakeup filters can be selected. The structure of the remote wakeup filters is shown in Table 575: Remote wakeup packet filter register.

**Table 575. Remote wakeup packet filter register**

### Table 576. Description of the remote wakeup filter fields

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
</table>
| Filter i Byte mask | The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 or 3) to determine whether or not a packet is a wakeup packet.  
  – The MSB (31st bit) must be zero.  
  – Bit [30:0] is the byte mask.  
  – If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored. |
| Filter i Command | The 4-bit filter i command controls the filter i operation.  
  – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.  
  – Bit 2 (Inverse mode), when set, reverses the logic of the CRC16 Hash function signal, to reject a packet with matching CRC_16 value.  
  – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.  
  – Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled. |
| Filter i Offset | This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.  
  – This 8-bit pattern-offset is the offset for the filter i first byte to be examined.  
  – The minimum allowed offset is 12, which refers to the 13th byte of the packet.  
  – The offset value 0 refers to the first byte of the packet. |
| Filter i CRC-16 | This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wakeup filter register block.  
  – The 16-bit CRC calculation uses the following polynomial:  
  \[ G(x) = x^{16} + x^{15} + x^{2} + 1 \]  
  Each mask, used in the Hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:  
  – 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.  
  – 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations. |

---

1. The And_Previous bit setting is applicable within a set of four filters. Setting And_Previous bit of a filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of four filters has no effect. For example, setting And_Previous bit of Filter 0 has no effect. If And_Previous bit is set for a given filter to form an AND chained filter, the AND chain breaks when it finds a disabled filter. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting Filter 2 And_Previous bit has no effect, only Filter 1 result ORed with Filter 3 result is considered.  
If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, then a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address types.
The remote wakeup filter registers are implemented as eight indirect access registers (wkuppktfilter_reg#i) for four remote wakeup filters, and accessed by the application through Remote wakeup packet filter register (ETH_MACRWKPFR). The entire set of wkuppktfilter_reg registers must be written to program the remote wakeup filters. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in Remote wakeup packet filter register (ETH_MACRWKPFR) for wkuppktfilter_reg0 to wkuppktfilter_reg3, respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of PMT control status register (ETH_MACPCSR).

Note: If the Remote wakeup packet filter register (ETH_MACRWKPFR) is accessed in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when the CPU accesses Lane 3.

When Remote wakeup packet filter register (ETH_MACRWKPFR) is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation. There should not be any further write to the Remote wakeup packet filter register (ETH_MACRWKPFR) until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two write operations to the Remote wakeup packet filter register (ETH_MACRWKPFR) should be at least 4 cycles of the PHY receive clock.

PMT interrupt

The PMT interrupt signal is asserted when a valid remote wakeup packet is received. Table 577 lists the remote wakeup scenarios in which PMT interrupt is generated.

1. In all other combinations, the Remote Wakeup packet is not detected and PMT interrupt is not generated.

In addition to sbd_intr_o signal, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the power-down mode. It is ORed with lpi_intr_o signal (see Section : LPI interrupt) and tied to the EXTI peripheral (line 96).

As the pmt_intr_o signal is generated in the PHY Rx clock domain, it is not cleared immediately when the PMT control status register (ETH_MACPCSR) is read. This is
because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear
the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant
when the peripheral is operating in the 10 Mbps mode. When the application clears the
PWRDWN bit in Remote wakeup packet filter register (ETH_MACRWKPFR), the MAC
comes out of the power-down mode, but this event does not generate the PMT interrupt.

Power-down sequence
The software must perform the following tasks to initiate the power-down sequence:

- Disable the Transmit DMA (if applicable) by clearing the ST bit of the Channel transmit
  control register (ETH_DMACTXCR).
- Wait for any previous frame transmissions to complete. You can check this by reading
  TFCSTS[1:0] and TPESTS bits in Debug register (ETH_MACDR) and TXQSTS bit in
  Tx queue debug register (ETH_MTLTXQDR) of all MTL Tx Queues.
- Disable the MAC transmitter and MAC receiver by clearing TE and RE bits in Operating
  mode configuration register (ETH_MACCR).
- Wait till the Receive DMA empties all frames from the Rx FIFO. You can check this by
  reading PRXQ[13:0] in Rx queue debug register (ETH_MTLRXQDR) of all Rx Queues.
  If these bits are zero, it indicates that the Rx FIFO is empty.
- Configure the magic packet (MGKPKTEN) and/or remote wake-up (RWKPKTEN)
  detection in the PMT control status register (ETH_MACPCSR).
- Set bit 31 (ARPEN) in the Operating mode configuration register (ETH_MACCR).
- Enable the MAC Receiver by setting RE bit and then set PWRDWN bit in the PMT
  control status register (ETH_MACPCSR) to initiate the power-down sequence in MAC.

Note: If the feature is enabled and the MAC Transmitter is in the LPI mode when it is put into the
power-down mode, then the MII interface gets clamped to assert the LPI pattern. If the MAC
Transmitter is not in the LPI mode when it is put into the power-down mode, the GMII or MII
interface gets clamped to all zero.

Power-up sequence
The MAC wakes up on receiving the magic packet or remote wake-up frame. The power-up
sequence is as follows:

- The MAC asserts pmt_intr_o. When only clock-gating is employed in low-power mode,
  the pmt_intr_o signal can be used to start the clocks that were gated-off after entering
  low-power mode.
- The software performs the following tasks:
  - De-assert the pmt_intr_o by reading the PMT control status register
    (ETH_MACPCSR).
  - Perform a write operation (with reset values) to the PMT control status register
    (ETH_MACPCSR) and the Remote wakeup packet filter register
    (ETH_MACRWKPFR) so that the corresponding values in the always-on block
    gets synchronized. Otherwise, the values of these registers are different.
  - Perform write operations to the Operating mode configuration register
    (ETH_MACCR), MAC Address 0 high register (ETH_MACA0HR) and MAC
    Address 0 low register (ETH_MACA0LR) to synchronize the values in the CSR
    module and the respective bits in the always-on block. Otherwise, the MAC
    receiver is on even though the Receive Enable bit is set to 0.
After completing these steps, the software must initialize all registers, enable the transmitter, and program the DMA (in DMA configurations) to resume the normal operation.

61.7.2 Energy Efficient Ethernet (EEE)

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The peripheral supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows saving power by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Transmit path functions

The transmit path functions include tasks that the MAC must perform to make the PHY enter the LPI state.

In the transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER LST[9:0] bitfield of LPI timers control register (ETH_MACLTCR). The PHY Link Status PLS bit of the LPI control and status register (ETH_MACLCSR) indicates the link status of the PHY.

Note: The EEE feature is not supported when the MAC is configured to use the RMII.

According to the standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
To bring the PHY out of the LPI state, that is when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER:
   The MAC cannot start the transmission until the wakeup time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the LPI timers control register (ETH_MACLTCR).
3. Updates the LPI exit status (TLPIEX bit of the LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

*Figure 848* shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

**Note:** The MAC does not stop the TX_CLK clock. The application can stop this clock (as shown in *Figure 848*) if the PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after nine Tx Clock Cycles, one Pulse Synchronizer delay, and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal depends on the LPITCSE bit of the LPI control and status register (ETH_MACLCSR) and can be done automatically as shown on *Figure 849*.

If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern and so the Tx Clock cannot be gated.

If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

*Figure 848. LPI transitions (Transmit, 100 Mbds)*
Automated entry/exit from LPI mode in transmit path

The MAC transmitter can be programmed to enter and exit LPI Idle mode automatically based on whether it is Idle for a specific period of time or has a packet to transfer. These modes are enabled and controlled by the LPI control and status register (ETH_MACLCSR).

When LPITXA and LPIEN of LPI control and status register (ETH_MACLCSR) are set, the MAC transmitter enters LPI Idle state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI Idle state and clears the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when LPITE is also set, the MAC transmitter enters LPI Idle state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in LPI entry timer register (ETH_MACLETR). In this mode also, the MAC transmitter exits the LPI Idle state as soon as any of the functions becomes non-idle. However, the LPIEN bit is not cleared but remains active so that reentry to LPI Idle state is possible without any software intervention when the MAC becomes idle again.

When both LPITE and LPITXA bits are cleared, the application can directly control the entry and exit of LPI Idle state by programming the LPIEN bit.

Receive path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[3:0] to 0x1 (for 100 Mbps).
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the LPI control and status register (ETH_MACLCSR) and immediately generates an interrupt.
Note: The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.

If the duration between the end of the current Rx LPI pattern and the start of the next Rx LPI pattern is very short (that is, less than two Rx clock cycles), then the MAC exits and enters again the Rx LPI mode. The MAC does not trigger the Rx LPI Exit and Entry interrupts.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the LPI control and status register (ETH_MACLCSR) and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 850 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 850. LPI transitions (receive, 100 Mbps)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in Figure 850.

If the MAC is in LPI mode and the application issues a soft reset or hard reset, the MAC receiver exits from LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver enters again the LPI state.

If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.

When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.
LPI timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

The following LPI timers are loaded with the respective values from the LPI timers control register (ETH_MACLTCR) and LPI entry timer register (ETH_MACLETR):

- **LPI LS TIMER**
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the LST[9:0] bitfield in the LPI timers control register (ETH_MACLTCR). The LPI LS TIMER is 10-bit wide. The software can program up to 1023 milliseconds.

- **LPI TW TIMER**
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[15:0] of LPI timers control register (ETH_MACLTCR). The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.

  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 micro seconds.

- **LPI AUTO ENTRY TIMER**
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in LPI control and status register (ETH_MACLCSR) is set.

LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt sbd_intr_o is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the LPI control and status register (ETH_MACLCSR).

When the MAC exits the Rx LPI state, then in addition to the sbd_intr_o, the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. The lpi_intr_o signal can be used to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the LPI state. It is ORed with pmt_intr_o signal (see Section : PMT interrupt) and tied to the EXTI peripheral (line 86).

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the LPI control and status register (ETH_MACLCSR) is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode.

Programming guidelines for Energy Efficient Ethernet

For detailed guidelines on the programming guidelines, see Section 61.9.11: Programming guidelines for Energy Efficient Ethernet (EEE) on page 3041.
# 61.8 Ethernet Interrupts

The Ethernet peripheral generates a single interrupt signal (eth_sbd_intr_it). This signal can be raised as a result of various events. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the Interrupt status register (ETH_DMAISR) register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- ETH_DMACSR: Channel Status (see Channel status register (ETH_DMACSR))
- ETH_MTLISR: Interrupt Status (see Interrupt status Register (ETH_MTLISR))
- ETH_MACISR: Interrupt Status (see Interrupt status register (ETH_MACISR))

## 61.8.1 DMA Interrupts

### Interrupt registers description

The ETH_DMACSR: Channel Status register (see Channel status register (ETH_DMACSR)) captures all the interrupt events of that TxDMA and RxDMA channel. The ETH_DMACIER: Channel Interrupt Enable register (see Channel interrupt enable register (ETH_DMACIER)) contains the corresponding enable bits for each of the interrupt event.

There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of ETH_DMACSR register respectively. The normal group is for events that happen during the normal transfer of packets (TI: transmit interrupt, RI: receive interrupt, TBU: Transmit buffer unavailable) while the abnormal interrupt events are for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. An interrupt is generated only once for multiple events. The driver must scan the Interrupt status register (ETH_DMAISR) for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of Interrupt status register (ETH_DMAISR) are cleared.

### Periodic scheduling of Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet peripheral gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31] in Table 581: TDES2 normal descriptor (read format)) once for every “required” number of packets to be transmitted.

2. Similarly, set the IOC (RDES3[30] in Table 594: RDES3 normal descriptor (read format)) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.
In addition to above, an interrupt timer (ETH_DMACRXIWTR: Channel Rx Interrupt Watchdog Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30] in Table 594: RDES3 normal descriptor (read format)) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

**Channel transfer complete interrupt**

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in the Channel Status register (Channel status register (ETH_DMACSR)). The TI bit is set whenever the Tx DMA channel closes the descriptor in which the IOC bit is set (Interrupt On Completion - TDES2[31]). Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with the LD bit set and, in any of the descriptors used for transferring that packet, IOC bit is set (Interrupt Enable on completion - RDES3[30]).

The interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in the channel interrupt enable register (Channel interrupt enable register (ETH_DMACIER)).

The behavior of the RI/TI interrupts changes depending on the settings of INTM field (bits[17:16]) in the ETH_DMAMR register (DMA mode register (ETH_DMAMR)). Table 578 explains the behavior of the Transfer Complete interrupt.

<table>
<thead>
<tr>
<th>Interrupt Mode</th>
<th>Behavior of TI/RI and interrupt signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTM=0</td>
<td>The TI/RI status signals are set whenever the Transfer complete event is detected. These bits are cleared whenever the software driver writes 1 to these bits. The interrupt signal is asserted whenever the corresponding interrupts are also enabled in ETH_DMACIER register.</td>
</tr>
<tr>
<td>INTM=1</td>
<td>The TI/RI is set as explained above. However, the interrupt is not asserted for any RI/TI event.</td>
</tr>
<tr>
<td>INTM=2</td>
<td>The RI/TI status bits are set whenever the Transfer Complete event is detected and are reset whenever software driver clears them by writing 1. However, if another Transfer complete event is detected before it is cleared (serviced) by the software, then these status bits are automatically set again. However, the interrupt is not generated based on TI/RI.</td>
</tr>
</tbody>
</table>
61.8.2 MTL interrupts

MTL interrupt events are combined with the events in the DMA to generate the interrupt signal.

The register Interrupt status Register (ETH_MTLISR) report the queue number responsible for the event. ETH_MTLQICSR: Queue Interrupt Control Status shall be read for event description.

The MTL interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt status Register (ETH_MTLISR) register.

MTL interrupt signal is driven by one of these events:
- Receive Queue Overflow Interrupt
- Transmit Queue Underflow

61.8.3 MAC Interrupts

MAC interrupt events are combined with the events in the DMA to generate the interrupt signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The Interrupt status register (ETH_MACISR) describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt status register (ETH_MACISR).

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

MAC interrupt signal is driven by one of these events:
- Receive Status Interrupt
- Transmit Status Interrupt
- Timestamp Interrupt Status
- MMC Interrupt Status
  - MMC Receive Checksum Offload Interrupt Status
  - MMC Transmit Interrupt Status
  - MMC Receive Interrupt Status
- LPI Interrupt Status
- PMT Interrupt Status
- PHY Interrupt

Note: Two sidebands signals are generated together with LPI and PMT interrupts: lpi_intr_o and pmt_intr_o. They are used for wakeup event detection at EXTI level.
61.9 Ethernet programming model

This chapter provides the instructions for initializing the DMA or MAC registers in the proper sequence. It contains the following sections:

- DMA initialization (see Section 61.9.1)
- MTL initialization (see Section 61.9.2)
- MAC initialization (see Section 61.9.3)
- Performing Normal Receive and Transmit Operation (see Section 61.9.4)
- Stopping and Starting Transmission (see Section 61.9.5)
- Programming Guidelines for MII Link State Transitions (see Section 61.9.8)
- Programming Guidelines for IEEE 1588 Timestamping (see Section 61.9.9)
- Programming Guidelines for Energy Efficient Ethernet (see Section 61.9.11)
- Programming Guidelines for flexible pulse-per-second (PPS) output (see Section 61.9.12)
- Programming Guidelines for VLAN filtering on Receive (see Section 61.9.14)

61.9.1 DMA initialization

Complete the following steps to initialize the DMA:

1. Provide a software reset to reset all MAC internal registers and logic (bit 0 of DMA mode register (ETH_DMAMR)).
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register (ETH_DMAMR), which is cleared when the reset operation is completed).
3. Program the following fields to initialize the System bus mode register (ETH_DMASBMR):
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface.
4. Create a transmit and a receive descriptor list. In addition, ensure that the receive descriptors are owned by the DMA (set bit 31 of TDES3/RDES3 descriptor). For more information on descriptors, refer to Section 61.10: Descriptors.

**Note:** Descriptor address from start to end of the ring should not cross the 4GB boundary.

5. Program ETH_DMACTXRLR and ETH_DMACRXRLR registers (see Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR)). The programmed ring length must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor (Channel Tx descriptor list address register (ETH_DMACTXDLAR), Channel Rx descriptor list address register (ETH_DMACRXDLAR)). In addition, program the transmit and receive tail pointer registers that inform the DMA about the available descriptors (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) and Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).
7. Program ETH_DMACCR, ETH_DMACTXCR and ETH_DMACRXCR registers (see Channel control register (ETH_DMACCR), Channel transmit control register (ETH_DMACTXCR) and Channel receive control register (ETH_DMACRXCR)) to...
configure the parameters such as the maximum burst-length (PBL) initiated by the DMA, descriptor skip lengths, OSP for TxDMA, RBSZ[13:0] for RxDMA, and so on.

8. Enable the interrupts by programming the ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)).

9. Start the Receive and Transmit DMAs by setting SR (bit 0) of Channel receive control register (ETH_DMACRXCR) and ST (bit 0) of the ETH_DMACTXCR (see Channel transmit control register (ETH_DMACTXCR)).

61.9.2 MTL initialization

Complete the following steps to initialize the MTL registers:

1. Program the following fields to initialize the operating mode in Tx queue operating mode Register (ETH_MTLTXQOMR):
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) if the Threshold mode is used.
   b) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue 0.
   c) Transmit Queue Size (TQS).

2. Program the following fields to initialize the operating mode in the ETH_MTLRXQOMR register (see Rx queue operating mode register (ETH_MTLRXQOMR)):
   a) Receive Store and Forward (RSF) or RTC if Threshold mode is used.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP).
   d) Receive Queue Size (RQS).

61.9.3 MAC initialization

The MAC configuration registers establish the operating mode of the MAC. If possible, these registers must be initialized before initializing the DMA. The following MAC Initialization operations can also be performed after DMA initialization. If the MAC initialization is complete before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC Address x low register (ETH_MACAxLR), MAC Address 0 high register (ETH_MACA0HR) and MAC Address x high register (ETH_MACAxHR).

2. Program the following fields to set the appropriate filters for the incoming frames in the Packet filtering control register (ETH_MACPFR):
   a) Receive All.
   b) Promiscuous mode.
   c) Hash or Perfect Filter.
   d) Unicast, multicast, broadcast, and control frames filter settings.

3. Program the following fields for proper flow control in the Tx Queue flow control register (ETH_MACQTXFCR):
   a) Pause time and other Pause frame control bits.
   b) Transmit Flow control bits.
   c) Flow Control Busy.
4. Program the **Interrupt enable register (ETH_MACIER)** as required, if it is applicable for your configuration.

5. Program the appropriate fields in the **Operating mode configuration register (ETH_MACCR)** register. For example, Inter-packet gap while transmission and jabber disable.

6. Set bit 0 and 1 in **Operating mode configuration register (ETH_MACCR)** register to start the MAC transmitter and receiver.

To support Jumbo Transmit/Receive packets, follow these steps:

- In the **Operating mode configuration register (ETH_MACCR)**
  a) Set JE bit to 1.
  b) Set JD and WD bits to 0 to avoid giant packet error reporting.
  c) Set GPSLCE bit to 1
  d) Set GPSL bitfield of the **Extended operating mode configuration register (ETH_MACECR)** to a value > 9026

To support Transmit/Receive packets, up to 16K, follow these steps:

- In the **Operating mode configuration register (ETH_MACCR)**
  a) Set JD and WD bits to 1 to avoid giant packet error reporting.
  b) Set GPSLCE bit to 1.
  c) Set GPSL bitfield of the **Extended operating mode configuration register (ETH_MACECR)** to 16383.

### 61.9.4 Performing normal receive and transmit operation

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptor by reading the status of the descriptor owned by the Host (either transmit or receive).

2. Set the descriptors to appropriate values. Make sure that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.

3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into Suspend state. The transmission or reception can be resumed by freeing the descriptors and writing the ETH_DMACCTXDTPR (see **Channel Tx descriptor tail pointer register (ETH_DMACCTXDTPR)**) and ETH_DMACRXDTPR (see **Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)**).

4. In debug mode, the values of the current host transmitter or receiver descriptor address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see **Channel current application transmit descriptor register (ETH_DMACCATXDR)** and **Channel current application receive descriptor register (ETH_DMACCARXDR)**).

5. In debug mode, the values of the current host transmit buffer address pointer and receive buffer address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see **Channel current application transmit descriptor register (ETH_DMACCATXDR)** and **Channel current application receive descriptor register (ETH_DMACCARXDR)**).
61.9.5 Stopping and starting transmission

Complete the following steps to pause the transmission for some time:

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)).

2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01 and TXQSTS = 0).

3. Disable the MAC transmitter and MAC receiver by clearing RE and TE bits of the Operating mode configuration register (ETH_MACCR) Register.

4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR), PRXQ=0 and RXQSTS[1:0] = 0).

5. Make sure that both Tx queue and Rx queue are empty (TXQSTS is 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] is set to 00).

6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.

Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

61.9.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in Suspend state, as explained below:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to Suspend state due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of an RxFIFO overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into Stop state.

61.9.7 Programming guidelines for switching the AHB clock frequency

To dynamically change the AHB clock frequency (without applying soft reset or hard reset), follow these steps:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. When the frame transmissions is complete, the Tx FIFO becomes empty and the Tx DMA enters Stop state. The Tx FIFO status is given in the Tx queue debug
register (ETH_MTLTXQDR) and the status of DMA is given in Debug status register (ETH_DMADSR).

2. Disable the MAC transmitter and the MAC receiver by clearing the appropriate bits in Operating mode configuration register (ETH_MACCR).

3. Disable the Receive DMA (if applicable) after making sure that the data in the Rx FIFO is transferred to the system memory. The Rx FIFO empty status is given in Rx queue debug register (ETH_MTLRXQDR).

4. Ensure that the application does not perform any register read or write operation.

5. Change the frequency of the AHB clock.

6. Enable the MAC Transmitter or the MAC Receiver and the Transmit or Receive DMA. These steps ensure that no valid data is present in the Tx FIFO or Rx FIFO at the time of clock frequency switching and prevent any data corruption.

### 61.9.8 Programming guidelines for MII link state transitions

**Transmit and Receive clocks are running when the link is down**

Complete the following steps when the link is down while the Transmit and Receive clocks are running:

1. Disable the Transmit DMA (if applicable) by clearing bit 0 (ST) of Channel control register (ETH_DMACCR).

2. Disable the MAC receiver by clearing RE bit of Operating mode configuration register (ETH_MACCR).

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01).

   or

   Flush the Tx FIFO for faster empty operation.

4. Disable the MAC transmitter by clearing TE bit of the Operating mode configuration register (ETH_MACCR) Register.

5. Make sure that both Tx and Rx queues are empty (TXQSTS is set to 0 in Tx queue debug register (ETH_MTLTXQDR) and RXQSTS[1:0] to 00 in Rx queue debug register (ETH_MTLRXQDR)).

6. After the link is up, read the PHY registers to identify the latest configuration and program the MAC registers accordingly.

7. Restart the operation by starting the Tx DMA. Then enable the MAC Transmitter and Receiver.

   The Rx DMA does not need to be enabled: since the Receiver is disabled, there are no data in the Rx FIFO.
Transmit and Receive clocks are stopped when the link is down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing RE and TE bits in the **Operating mode configuration register (ETH_MACCR)**. This will not take immediate effect as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait until the transfer of any partial frame is complete if any was ongoing when the Transmit/Receive clock is stopped. This can be checked by reading the **Debug register (ETH_MACDR)** (all bits should be set to 0). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to identify the latest operating mode and program the MAC registers accordingly.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

### 61.9.9 Programming guidelines for IEEE 1588 timestamping

#### Initializing the System time generation

The timestamp feature can be enabled by setting bit 0 of the **Timestamp control Register (ETH_MACTSCR)**. However, it is essential that the timestamp counter is initialized after this bit is set. Complete the following steps to perform the peripheral initialization:

1. Mask the Timestamp Trigger interrupt by clearing bit 12 of **Interrupt enable register (ETH_MACIER)**.
2. Set bit 0 of **Timestamp control Register (ETH_MACTSCR)** to enable timestamping.
3. Program **Subsecond increment register (ETH_MACSSIR)** based on the PTP clock frequency.
4. If you use the Fine Correction method, program **Timestamp addend register (ETH_MACTSAR)** and set bit 5 of **Timestamp control Register (ETH_MACTSCR)**.
5. Poll the **Timestamp control Register (ETH_MACTSCR)** until bit 5 is cleared.
6. Program bit 1 of **Timestamp control Register (ETH_MACTSCR)** to select the Fine Update method (if required).
7. Program **System time seconds update register (ETH_MACSTSUR)** and **System time nanoseconds update register (ETH_MACSTNUR)** with the appropriate time value.
8. Set bit 2 in **Timestamp control Register (ETH_MACTSCR)**.
   The timestamp counter starts as soon as it is initialized with the value written in the timestamp update registers. If one-step timestamping is required:
   a) Enable one-step timestamping by programming bit 27 of the TDES3 Context Descriptor.
   b) Program **Timestamp Ingress asymmetric correction register (ETH_MACTSIACR)** to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

**Note:** If timestamp operation is disabled by clearing bit 0 of **Timestamp control Register (ETH_MACTSCR)**, repeat all these steps to restart the timestamp operation.
System time correction

To synchronize or update the system time in one shot (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR)).
2. Set bit 3 (TSUPDT) of the Timestamp control Register (ETH_MACTSCR).
   The value in the timestamp update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm described in Section : System time register module, calculate at which rate you intend to increment or decrement the system time.
2. Update the Timestamp addend register (ETH_MACTSAR) with the new value and set bit 5 of the Timestamp control Register (ETH_MACTSCR) Register.
3. Wait for the time during which you want the new value of the Addend register to be active. This can be done by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).
5. Enable the Timestamp interrupt in bit 12 of Interrupt enable register (ETH_MACIER).
6. Set bit 4 in Register Timestamp control Register (ETH_MACTSCR).
7. When this trigger generates an interrupt, read Interrupt status register (ETH_MACISR).
8. Reprogram Timestamp addend register (ETH_MACTSAR) with the old value and set bit 5 again.

61.9.10 Programming guidelines for PTP offload feature

Programming guidelines to enable automatic periodic generation of PTP sync messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program SNAPTYPSEL, TSMSTRENA, and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively, to configure the node as Ordinary or Boundary Master (1, 1, and 1 for Transparent Master).
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Sync message.
3. Program the ASYNCEN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Sync messages.
4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP
Source port identity 2 register (ETH_MACSPI2R) to send in egress PTP Sync message.

5. Program the LSI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Sync messages.

For example, a value of 1 corresponds to $2^1$ which translates to PTP Sync message every 2 seconds, and a value of 0xFF (two's complement of -1) corresponds to $2^{-1}$ which translates to PTP Sync message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable periodic generation of PTP Pdelay_Req messages

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively to configure the node as Transparent Slave (1, 1, and 1 for Transparent Master OR 3, X, and X for Peer-to-Peer Transparent).

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Pdelay_Req message.

3. Program the APDREQEN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Pdelay_Req messages.

4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to send in egress PTP Pdelay_Req message.

5. Program the LMPDRI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Pdelay_Req messages.

For example, a value of 1 corresponds to $2^1$ which translates to PTP Pdelay_Req message every 2 seconds, and a value of 0xFF (two's complement of -1) corresponds to $2^{-1}$ which translates to PTP Pdelay_Req message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Master mode

Follow these steps to enable the generation of PTP response messages for Ordinary or Boundary Master mode (Periodic PTP Sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message):
1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.

4. Program the DRSYNCR and LSI fields in Log message interval register (ETH_MACLimir). The sum of both fields is updated in logMinDelayReqInterval field of PTP Delay_Resp message.

**Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Slave mode**

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Slave mode (PTP Delay_Req message generated in response to PTP Sync message):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 0, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync message and send in egress PTP Delay_Req message.

4. Program the DRSYNCR field in Log message interval register (ETH_MACLimir) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

**Programming guidelines to enable the generation of PTP response messages for Transparent Slave mode**

Follow these steps to enable generation of PTP response messages for Transparent Slave mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated)

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync or
Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Respon Pdelay_Req message.

4. Program the DRSYNCR and LMPDRI fields in Log message interval register (ETH_MACLMIR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Master mode

Follow these steps to enable generation of PTP response messages for Transparent Master mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

4. Program the DRSYNCR, LSI and LMPDRI fields in Log message interval register (ETH_MACLMIR), the sum of DRSYNCR and LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Peer-to-Peer Transparent mode

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):
1. Program the SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of *Timestamp control Register (ETH_MACTSCR)* to 3, X, and X respectively.

2. Program the PTOEN bit and DN field of *PTP Offload control register (ETH_MACPOCR)* to enable PTP Offload feature and domain Number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

3. Program the 80-bit Source Port Identity in *PTP Source Port Identity 0 Register (ETH_MACSPI0R)*, *PTP Source port identity 1 register (ETH_MACSPI1R)* and *PTP Source port identity 2 register (ETH_MACSPI2R)* to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

4. Program the LMPDRI field in *Log message interval register (ETH_MACLMIR)* to indicate periodicity of the PTP Pdelay_Req messages

5. Program the TSIE bit of *Interrupt enable register (ETH_MACIER)* to enable generation of Timestamp interrupt

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in *Timestamp status register (ETH_MACTSSSR)*. It indicates that the timestamp for PTP Sync message is captured in *Tx timestamp status seconds register (ETH_MACTXTSSSR)* and *Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)* for egress PTP Pdelay_Req and Pdelay_Resp messages.

### 61.9.11 Programming guidelines for Energy Efficient Ethernet (EEE)

**Entering and exiting Tx LPI mode**

EEE enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-power idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the *LPI control and status register (ETH_MACLCSR)* to indicate to the MAC to stop transmission and initiate the LPI protocol.

Complete the following steps during MAC initialization:

1. Read the PHY register through the MDIO interface and check if the remote end has the EEE capability. Then negotiate the timer values.

2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode or not).

3. Program bits 25 to 16 and bits 15 to 0 in *LPI timers control register (ETH_MACLTCR)*.

4. Read the PHY link status by using the MDIO interface and update bit 17 of *LPI control and status register (ETH_MACLCSR)*.

   Update *LPI control and status register (ETH_MACLCSR)* accordingly. This update should be done whenever the link status in the PHY chip changes.

5. Program *One-microsecond-tick counter register (ETH_MAC1USTCR)* as per the frequency of the clock used for accessing the CSR slave port.

6. Program the LPIET bit in the *LPI entry timer register (ETH_MACLETR)* with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bits 20 to 19) of **LPI control and status register (ETH_MACLCSR)** to enable LPI auto-entry and MAC auto-exit from LPI state.

8. Set bit 16 of **LPI control and status register (ETH_MACLCSR)** to put the MAC transmitter in LPI state.

   The MAC enters the LPI state when all scheduled packets are completed. It remains IDLE for the time indicated by LPIET bits. It sets the TLPIEN (bit 0) after entering LPI state.

9. When a packet transmission is scheduled (when the TxDMA exits IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter automatically exits LPI state. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. The MAC Transmitter enters again LPI state if it remains IDLE for LPIET time. It then sets the TLPIEN bit and the entry-exit cycle continues.

11. Reset LPIEN bit if the application needs to override the auto-entry/exit modes and directly exit the MAC Transmitter from LPI state.

**Note:** To make sure the MAC enters the LPI state only after the transmission of all the queued frames in the Tx FIFO is complete, set LPITXA bit in **LPI control and status register (ETH_MACLCSR)**.

To switch off the CSR clock or power to the rest of the system during the LPI state, wait for the TLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)** to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

### Gating Off the CSR Clock in the LPI mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

### Gating off the CSR clock in the Rx LPI mode

The following operations are performed when the MAC receives the LPI pattern from the PHY:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status (RLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.

After the sbd_intr_o interrupt is asserted and the MAC Tx is also in the LPI mode, the CSR clock can be gated off. If the MAC TX is not in LPI mode when the CSR clock is gated off, the events on the MAC transmitter do not get reported or updated in the CSR. To restore the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when **LPI control and status register (ETH_MACLCSR)** is read.

### Gating off the CSR clock in the Tx LPI mode

The following operations are performed when bit 16 (LPIEN) of **LPI control and status register (ETH_MACLCSR)** is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.
After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, the CSR clock can be gated off. If the MAC RX is not in LPI mode when the CSR clock is gated off, the events on the MAC receiver do not get reported or updated in the CSR. To restore the CSR clock, switch on the CSR clock when the MAC has exited TX LPI mode. After the CSR clock is resumed, reset bit 16 (LPIEN) of LPI control and status register (ETH_MACLCSR) to exit the MAC from LPI mode.

### 61.9.12 Programming guidelines for flexible pulse-per-second (PPS) output

#### Generating a single pulse on PPS

To generate a single pulse on PPS:

1. Program TRGTMODSEL[1:0] bit to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) as start time of PPS signal output.

2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR) Register.

4. Program PPSCMD[3:0] of PPS control register (ETH_MACPPSCR) to 0001. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers.

#### Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time has elapsed. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be higher than the time at which the falling edge occurs for the previous pulse.

2. Program the width of the next PPS signal output in PPS width register (ETH_MACPPSWR).

3. Program PPSCMD[3:0] bits of PPS control register (ETH_MACPPSCR) to generate a single pulse after the previous pulse is deasserted. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in Target Time registers.

   If this command is given before the previous pulse becomes low, then the new command overwrites the previous command and the peripheral may generate only 1 extended pulse.

#### Generating a pulse train on PPS

To generate a pulse train on PPS:

1. Program TRGTMODSEL[1:0] bits to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS
target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) for start time of the PPS signal output.

2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the interval value between the train of pulses on the PPS signal output in PPS interval register (ETH_MACPPISR).

4. Program the width of the PPS signal output in PPS width register (ETH_MACPPPSWR).

5. Program PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0010. This instructs the MAC to generate a train of pulses on the PPS signal output at the start time programmed in Target Time registers.

    By default, the PPS pulse train is free-running unless it is stopped by issuing a ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in PPS target time nanoseconds register (ETH_MACPPSTTNR) is reset before programming the Target Time registers again.

7. Program the PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0100 to stop the train of pulses on PPS signal output after the programmed stop time specified at step 6 has elapsed.

The pulse train can be stopped at any time by programming 0101 in the PPSCMD[3:0] field.

Similarly, the Stop Pulse train command (given in Step 7) can be canceled by programming PPSCMD[3:0] bits to 0110 before the time (programmed at step 6) has elapsed.

The pulse train generation can be stopped by programming PPSCMD[3:0] to 0011 before the start time programmed at step 2) has elapsed.

**Generating an interrupt without affecting the PPS**

TRGTMODSEL[1:0] bits in PPS control register (ETH_MACPPSCR) enable you to program the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt event:

1. Program TRGTMODSEL[1:0] bits of PPS control register (ETH_MACPPSCR) to 00 (for interrupt). This instructs the MAC to use the Target Time registers for target time interrupt.

2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

    If TRGTMODSEL[1:0] bits are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

**Note:** The TSTRGTEERR0 bit in Timestamp status register (ETH_MACTSSR) is set when the programmed target time is smaller (that is corresponds to a time in the past) compared to
the system time in the System time seconds register (ETH_MACSTSR) and System time
nanoseconds register (ETH_MACSTNR).

An interrupt is generated (sbd_intr_o) if the TSIE bit in the Interrupt enable register
(ETH_MACIER) is set.

Therefore, to avoid unwanted interrupt, the correct writing order is as follow:
1. PPS target time nanoseconds register (ETH_MACPPSTTNR).
2. PPS target time seconds register (ETH_MACPPSTTSR).
3. PPS interval register (ETH_MACPPIR).
4. PPS width register (ETH_MACPPSWR).
5. PPSCTRL[3:0] and PPSCTRL[3:0] and PPSEN0 bitfields of PPS control register
(ETH_MACPPSCR).

61.9.13 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation
functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet
segmentation, and program descriptor fields to enable TSO for the current packet.

Follow the steps below to program TSO:
1. Program TSE bit of the corresponding Channel transmit control register
(ETH_DMACTXCR) to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must
be programmed to enable TSO for the current packet:
   a) Enable TSE of TDES3 (bit 18).
   b) Program the length of the unsegmented TCP/IP packet payload in bits 17 to 0 of
      TDES3, and the TCP header in bits 22 to 19 of TDES3.
   c) Program the maximum size of the segment in:
      – MSS[13:0] of Channel control register (ETH_DMACCR)
      – or MSS in the context descriptor
         If MSS[13:0] field is programmed in both Channel control register
         (ETH_DMACCR) and in the context descriptor, the latest software programmed
         sequence is considered.
3. The unsegmented TCP/IP packet header should be stored in Buffer 1 of the first
descriptor. This buffer must not hold any payload bytes. The payload is allocated to
Buffer 2 and the buffers of the subsequent descriptors.

Caution: If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.
61.9.14 Programming guidelines to perform VLAN filtering on the receive

Follow the sequence below to perform VLAN filtering on the receiver:

1. Program **VLAN tag register (ETH_MACVTR)** for the following bit to select the filtering method:
   - ETV: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   - VTHM: VLAN Tag Hash Table Match Enable.
   - ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   - ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   - DOVLTC: Ignores VLAN Type for Tag Match
   - VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL bit in **VLAN tag register (ETH_MACVTR)** for the 12-bit or 16-bit VLAN tag.

3. If VLAN tag Hash filtering is enabled, program **VLAN Hash table register (ETH_MACVHTR)**:
   - When the ETV bit is reset, the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and used to index the content of the **VLAN Hash table register (ETH_MACVHTR)**.
   - When ETV bit is set, the upper 4 bits of the calculated CRC-32 of VLAN tag are used to index the content of **VLAN Hash table register (ETH_MACVHTR)**.

For example, when ETV bit is set, a hash value of 0b1000 selects bit 8 of the VLAN Hash table. When ETV bit is reset, a hash value of 0b1000 selects bit 7 of the VLAN Hash table.

61.10 Descriptors

61.10.1 Descriptor overview

In the Ethernet peripheral, the DMA transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory (SRAM). The following two types of descriptors are supported:

- **Normal descriptors**
  The normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.

- **Context descriptors**
  The context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

There is no limit to the number of descriptors that can be used for a single packet.
61.10.2 Descriptor structure

The Ethernet peripheral supports the ring structure for DMA descriptors.

In a ring structure, descriptors are separated by the 32-bit word number programmed in the DSL field of the Channel control register (ETH_DMACCR). The application needs to program the total ring length, that is the total number of descriptors in ring span, in the following registers of a DMA channel:

- Channel Tx descriptor ring length register (ETH_DMACTXRLR)
- Channel Rx descriptor ring length register (ETH_DMACRXRLR)

The Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) or Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR) contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA enters the Suspend state when this condition occurs. The application must perform a write operation to the Descriptor tail pointer register and update the tail pointer so that the following condition is met:

Current Descriptor Pointer < Descriptor Tail Pointer;
The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 852: DMA descriptor ring.

Figure 852. DMA descriptor ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0.

For descriptors owned by the DMA, the OWN bit is set to 1.

At the beginning, if the application has only one descriptor, it sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA then processes the first descriptor and waits for the application to increment the tail pointer.
61.10.3 Transmit descriptor

The Ethernet peripheral DMA requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor features control fields which can be used to manage the MAC operation on per-transmit packet basis. The Transmit normal descriptor has the following two formats: Read format and Write-back format

Transmit normal descriptor (read format)

*Figure 853* shows the Read format for Transmit normal descriptor. *Table 579* to *Table 582* provide a detailed description of all Transmit normal descriptors (read format).

| 13:0 | HL or B1L| Header length or buffer 1 length  
For Header length, only bits [9:0] are taken into account. Bits 13 to 0 are applicable only to buffer 1 length.  
If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length (expressed in bytes) from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length. |

| 31   | OWN   | Own bit  
1: the DMA owns the descriptor.  
0: the application owns the descriptor.  
The DMA clears this bit after it completes the transfer of data given in the associated buffer(s). |
| 30   | CTXT  | Context Type  
This bit should be set to 0 for normal descriptor. |
| 29   | FD    | First Descriptor  
When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28   | LD    | Last Descriptor  
When this bit is set, it indicates that the buffer contains the last segment of the packet. B1L or B2L field should have a non-zero value. |
### Table 582. TDES3 normal descriptor (read format) (continued)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 27:26| CPC      | **CRC Pad Control**  
This field controls the CRC and Pad Insertion for Tx packet. It is valid only when the first descriptor bit (TDES3[29]) is set. The values of bits[27:26] are the following:  
00: CRC and Pad Insertion  
The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packets whose length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes.  
01: CRC Insertion (Disable Pad Insertion)  
The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes.  
10: Disable CRC Insertion  
The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.  
11: CRC Replacement  
The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.  
When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation. |
| 25:23| SAIC     | **SA Insertion Control**  
These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must appropriately set the CRC Pad Control bits when SA Insertion Control is enabled for the packet.  
Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.  
The following list describes the values of Bits[24:23]:  
00: Do not include the source address  
01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.  
10: Replace the source address. For reliable transmission, the application must provide frames with source addresses.  
11: Reserved  
These bits are valid when the First Segment control bit (TDES3 [29]) is set. |
| 22:19| THL      | **THL: TCP Header Length**  
If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. THL value must be equal to 2 for UDP header. This field is valid only for the first descriptor. |
| 18   | TSE      | **TCP Segmentation Enable**  
When this bit is set, the DMA performs the TCP/UDP segmentation for a packet. This bit is valid only if the FD bit is set. |
Table 582. TDES3 normal descriptor (read format) (continued)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 17:16 | CIC/TPL | Checksum Insertion Control or TCP Payload Length  
These bits control the checksum calculation and insertion. They can take the following values:  
00: Checksum insertion disabled.  
01: Only IP header checksum calculation and insertion are enabled.  
10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware.  
11: IP header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.  
This field is valid when the TSE bit is reset. When the TSE bit is set, it contains the upper bits [17:16] of the TCP Payload length. This allows the TCP packet length field to be spanned across TDES3[17:0] to provide 256 Kbyte packet length support. |
| 15    | TPL     | Reserved or TCP Payload Length  
When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is bit 15 of the TCP payload length [17:0]. |
| 14:0  | FL/TPL  | Reserved or TCP Payload Length  
When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length. This length does not include Ethernet header or TCP/UDP/IP header length.  
When the TSE bit is reset, this bit is reserved. |

Transmit normal descriptor (write-back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

*Figure 854* shows the write-back format for Transmit normal descriptors. *Table 583 to Table 586* provide a detailed description of all Transmit Normal descriptors (Write-Back Format).
Figure 854. Transmit descriptor write-back format

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>

</tr>
</tbody>
</table>
Transmit context descriptor

The Transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, and VLAN Tag ID for VLAN insertion feature. Write-back is only done on a context descriptor to reset the OWN bit.

Note: The VLAN tag IDs and MSS values, which are provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.

When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag.
stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 855 shows the format for Transmit context descriptors. Table 587 to Table 590 provide a detailed description of all Transmit context descriptors.

### Table 590. TDES3 context descriptor (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 26  | TCMSSV | One-Step Timestamp Correction Input or MSS Valid  
When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.  
When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid. |
| 25:24 | Reserved | |
| 23  | CDE | Context Descriptor Error  
When this bit is set, it indicates that the context descriptor is incorrect. The DMA sets this bit during write-back while closing the context descriptor.  
The Context Descriptor errors can be:  
– Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet.  
– All 1s.  
– CD, LD, and FD bits set to 1.  
Note: When a Context Descriptor error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the Channel status register (ETH_DMACSR).  
Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.  
This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported) |
| 22:20 | Reserved | |
| 19:18 | IVTIR | Inner VLAN Tag Insert or Replace  
When these bits are set, they request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.  
This bitfield has the following values:  
00: Do not add the inner VLAN tag.  
01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames.  
10: Insert an inner VLAN tag with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor.  
11: Replace the inner VLAN tag in packets with the tag value programmed in the Inner VLAN inclusion register (ETH_MACIVIR) or context descriptor. This option should be used only with the VLAN frames. |
| 17  | IVLTV | Inner VLAN Tag Valid  
When this bit is set, it indicates that the IVT field of TDES2 is valid. |

<th>Description</th>
</tr>
</thead>
</table>
| 16  | VLTV | VLAN Tag Valid  
When this bit is set, it indicates that the VT field of TDES3 is valid. |
| 15:0 | VT | VLAN Tag  
This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the VLAN inclusion register (ETH_MACVIR) is reset. |
61.10.4 Receive descriptor

The DMA in the Ethernet peripheral attempts to read a descriptor only if the Tail pointer is different from the Base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC; otherwise, the performance of the DMA is greatly impacted because of the unavailability of the descriptors. In such a situation, the MTL RxFIFO becomes full and starts dropping packets.

The following Receive descriptors are present:

- Normal descriptors with read and write-back formats
- Context descriptors

All received descriptors are prepared by the software and given to the DMA as “normal” descriptors (see Figure 856: Receive normal descriptor (read format) for a description of their content). The DMA reads this descriptor and, after transferring a received packet (or part of it) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The status format is given in Figure 857: Receive normal descriptor (write-back format).

For some packets, the normal descriptor bits are not sufficient to write the complete status. For such packets, the Rx DMA will write the extended status to the next descriptor (without processing or using the Buffers pointers embedded in that descriptor). The format and content of this write-back descriptor is described in Figure 858: Receive context descriptor.

Receive normal descriptor (read format)

Figure 856 shows the read format for Receive normal descriptors. Table 591 to Table 594 provide a detailed description of all Receive normal descriptors (read format).

![Figure 856. Receive normal descriptor (read format)](image)

Note: In the Receive descriptor (read format), if the Buffer Address field contains only 0s, the MAC does not transfer data to this buffer and skips to the next buffer or next descriptor.
- RDES0 normal descriptor (read format)

<td>Buffer 1 Address Pointer</td>
</tr>
<tr>
<td></td>
<td></td>
<td>These bits indicate the physical address of Buffer 1. The application can program a byte-aligned address for this buffer, which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a write operation with RDES2[1:0]=0 in case of 64-/128-bit configuration) as zero. However, the packet data is shifted by the actual offset as given in the buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.</td>

| 3   | IPHE | IP Header Error  
– When this bit is set, it indicates either of the following:  
– The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes.  
– The IP datagram version is not consistent with the Ethernet Type value.  
– Ethernet packet does not have the expected number of IP header bytes.  
This bit is valid when either bit 5 or bit 4 is set. |
| 2:0 | PT   | Payload Type  
These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE):  
000: Unknown type or IP/AV payload not processed  
001: UDP  
010: TCP  
011: ICMP  
100: IGMP if IPv4 Header Present bit is set  
Others: reserved.  
If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000. |

1. The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

</table>
Table 597. RDES2 normal descriptor (write-back format) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 15  | VF   | VLAN Filter Status  
When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter. |
| 14:11 | Reserved | |
| 10  | ARPNR | ARP Reply Not Generated  
When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). |
| 9:0 | Reserved | |

• RDES3 normal descriptor (write-back format)

Table 598. RDES3 normal descriptor (write-back format)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31  | OWN  | Own bit  
1: The DMA owns the descriptor.  
0: The application owns the descriptor.  
The DMA clears this bit when either of the following conditions is true:  
The DMA completes the packet reception  
The buffers associated with the descriptor are full |
| 30  | CTXT | Receive Context Descriptor  
When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0 to this bit for normal receive descriptor.  
When CTXT and FD bits are used together, {CTXT, FD} possible values are:  
00: Intermediate Descriptor  
01: First Descriptor  
10: Reserved  
11: Descriptor error (due to all 1s)  
Note: When a Descriptor error occurs, the Receive DMA closes the receive descriptor indicating a Descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. The receive DMA sets the CDE field of the Channel status register (ETH_DMACSR) but does not set the RI field, even when IOC field is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data. |

</tbody>
</table>
Table 598. RDES3 normal descriptor (write-back format) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 19  | DE   | Dribble Bit Error  
|     |      | When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. |
| 18:16 | LT   | Length/Type Field  
|      |      | This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows:  
|      |      | 000: The packet is a length packet  
|      |      | 001: The packet is a type packet.  
|      |      | 011: The packet is a ARP Request packet type  
|      |      | 100: The packet is a type packet with VLAN Tag  
|      |      | 101: The packet is a type packet with Double VLAN tag  
|      |      | 110: The packet is a MAC Control packet type  
|      |      | 111: The packet is a OAM packet type  
|      |      | 010: Reserved |
| 15  | ES   | Error Summary  
|     |      | When this bit is set, it indicates the logical OR of the following bits:  
|     |      | RDES3[19]: Dribble Error  
|     |      | RDES3[20]: Receive Error  
|     |      | RDES3[21]: Overflow Error  
|     |      | RDES3[22]: Watchdog Timeout  
|     |      | RDES3[23]: Giant Packet  
|     |      | RDES3[24]: CRC Error  
|     |      | This field is valid only when the LD bit of RDES3 is set. |
| 14:0 | PL   | Packet Length  
|      |      | These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).  
|      |      | This field is valid when both the LD bit of RDES3 is set and the Overflow Error bit is reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.  
|      |      | When LD bit of RDES3 is reset, this field contains the accumulated number of bytes (partial) that have been transferred for the current packet. |
Receive context descriptor

This descriptor is read-only for the application. This descriptor can be written only by the DMA.

The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor. 

Figure 858 shows the format for Receive context descriptors. Table 599 to Table 602 provide a detailed description of all Receive context descriptors.

61.11 Ethernet registers

61.11.1 Ethernet register maps

This section provides the following register maps:

- DMA registers (see Section 61.11.2: Ethernet DMA registers)
- MTL registers (see Section 61.11.3: Ethernet MTL registers)
- MAC registers including MMC register (see Section 61.11.4: Ethernet MAC and MMC registers)

61.11.2 Ethernet DMA registers

DMA mode register (ETH_DMAMR)

Address offset: 0x1000
Reset value: 0x0000 0000

The DMA mode register establishes the bus operating modes for the DMA.

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 INTM[1:0]: Interrupt Mode

This field defines the interrupt mode of the Ethernet peripheral.

The behavior of the interrupt signal and of the RI/TI bits in the ETH_DMACSR register changes depending on the INTM value (refer to Table 578: Transfer complete interrupt behavior).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 PR[2:0]: Priority ratio

These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set.

000: The priority ratio is 1:1
001: The priority ratio is 2:1
010: The priority ratio is 3:1
011: The priority ratio is 4:1
100: The priority ratio is 5:1
101: The priority ratio is 6:1
110: The priority ratio is 7:1
111: The priority ratio is 8:1

Bit 11 TXPR: Transmit priority

When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.
Bits 10:2  Reserved, must be kept at reset value.

Bit 1  **DA**: DMA Tx or Rx Arbitration Scheme

This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels:

0: Weighted Round-Robin with Rx:Tx or Tx:Rx

The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit.

1: Fixed priority

The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.

Bit 0  **SWR**: Software Reset

When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all clock domains. Before reprogramming any register, a value of zero should be read in this bit.

**Note:** *The reset operation is complete only when all resets in all active clock domains are deasserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock.*
System bus mode register (ETH_DMABSR)

Address offset: 0x1004

Reset value: 0x0000 0000

The System bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **RB**: Rebuild INCRx Burst

When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.

Bit 14 **MB**: Mixed Burst

When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).

Bit 13 Reserved, must be kept at reset value.

Bit 12 **AAL**: Address-Aligned Beats

When this bit is set to 1, the master performs address-aligned burst transfers on Read and Write channels.

Bits 11:1 Reserved, must be kept at reset value.

Bit 0 **FB**: Fixed Burst Length

When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE).

When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.
Interrupt status register (ETH_DMAISR)

Address offset: 0x1008
Reset value: 0x0000 0000

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **MACIS**: MAC Interrupt Status
This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.

Bit 16  **MTLIS**: MTL Interrupt Status
This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.

Bits 15:1  Reserved, must be kept at reset value.

Bit 0  **DC0IS**: DMA Channel Interrupt Status
This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source.

Debug status register (ETH_DMADSR)

Address offset: 0x100C
Reset value: 0x0000 0000

The Debug status register gives the Receive and Transmit process status for DMA Channel for debugging purpose.

**STS**
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **TPS0[3:0]:** DMA Channel Transmit Process State
This field indicates the Tx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Transmit Command issued)
- 001: Running (Fetching Tx Transfer Descriptor)
- 010: Running (Waiting for status)
- 011: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO))
- 100: Timestamp write state
- 101: Reserved for future use
- 110: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
- 111: Running (Closing Tx Descriptor)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 11:8  **RPS0[3:0]:** DMA Channel Receive Process State
This field indicates the Rx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Receive Command issued)
- 001: Running (Fetching Rx Transfer Descriptor)
- 010: Reserved for future use
- 011: Running (Waiting for Rx packet)
- 100: Suspended (Rx Descriptor Unavailable)
- 101: Running (Closing the Rx Descriptor)
- 110: Timestamp write state
- 111: Running (Transferring the received packet data from the Rx buffer to the system memory)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 7:1  Reserved, must be kept at reset value.

**Bit 0 AXWHSTS:** AHB Master Write Channel
When high, this bit indicates that the write channel of the AHB master FMSs are in non-idle state.

### Channel control register (ETH_DMACCR)

**Address offset:** 0x1100

**Reset value:** 0x0000 0000

The DMA Channel control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

</table>
Bits 31:21 Reserved, must be kept at reset value.

Bits 20:18 DSL[2:0]: Descriptor Skip Length
This bit specifies the 32-bit word number to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor.
When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.

Bit 17 Reserved, must be kept at reset value.

Bit 16 PBLX8: 8xPBL mode
When this bit is set, the PBL value programmed in Bits[21:16] in Channel transmit control register (ETH_DMACTXCR) and in Bits[21:16] in Channel receive control register (ETH_DMACRXC) is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 MSS[13:0]: Maximum Segment Size
This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of Channel transmit control register (ETH_DMACTXCR) is set.
The value programmed in this field must be more than the configured Data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

Channel transmit control register (ETH_DMACTXCR)
Address offset: 0x1104
Reset value: 0x0000 0000
The DMA Channel Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:16  **TXPBL[5:0]:** Transmit Programmable Burst Length

These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a) Set the PBLx8 mode in ETH_DMACCR.

b) Set the TXPBL[5:0].

Note: The maximum value of TXPBL must be less than or equal to half the Tx Queue size (TQS field of Tx queue operating mode Register (ETH_MTLTXQOMR)) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. The total locations in Tx Queue of size 2048 bytes is 512, TXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **TSE:** TCP Segmentation Enabled

When this bit is set, the DMA performs the TCP segmentation for packets in Channel x. The TCP segmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than or equal to 4.

Bits 11:5  Reserved, must be kept at reset value.

Bit 4  **OSF:** Operate on Second Packet

When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **ST:** Start or Stop Transmission Command

When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the base address of the Transmit list set by the ETH_DMACTXDLAR register.
- The position at which the transmission was previously stopped

If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the ETH_DMACSR is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the ETH_DMACTXDLAR register, the DMA behavior is unpredictable.

When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted.

To change the list address, you need to program ETH_DMACTXDLAR register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.
Channel receive control register (ETH_DMACRXCR)

Address offset: 0x1108
Reset value: 0x0000 0000

The DMA Channel Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

<table>
<thead>
<tr>
<th>Bit 31 RPF</th>
<th>DMA Rx Channel Packet Flush</th>
</tr>
</thead>
<tbody>
<tr>
<td>When this bit is set to 1, the Ethernet peripheral will automatically flush the packet from the Rx queues destined to DMA Rx Channel when the DMA Rx Channel is stopped after a system bus error has occurred. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx queue. When this bit is set to 0 the Ethernet peripheral does not flush the packet in the Rx queue destined to DMA Rx Channel after the DMA is stopped due to a system bus error. This might cause head-of-line blocking in the corresponding RxQueue.</td>
<td></td>
</tr>
</tbody>
</table>

Note: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in ETH_DMACRXCR register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel.

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:16 **RXPBL[5:0]**: Receive Programmable Burst Length

These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a) Set the PBLx8 mode in the ETH_DMACCR.

b) Set the RXPBL[5:0].

Note: The maximum value of RXPBL must be less than or equal to half the Rx Queue size (RQS field of Rx queue operating mode register (ETH_MTLRXQOMR)) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the MTL Rx Queue Controller is transferring data to MAC. The total locations in Rx Queue of size 2048 bytes is 512, RXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.
Bit 15  Reserved, must be kept at reset value.

Bits 14:1  **RBSZ[13:0]:** Receive Buffer size

This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes.

**Note:** The buffer size must be a multiple of 4. This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, it may result into an undefined behavior.

The LSB bits (1:0) are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).

Bit 0  **SR:** Start or Stop Receive

When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets.

The DMA tries to acquire descriptor from either of the following positions:
- The current position in the list: this is the address set by the Channel Rx descriptor list address register (ETH_DMACRXDLAR).
- The position at which the Rx process was previously stopped

If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the ETH_DMACSR is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the Channel Rx descriptor list address register (ETH_DMACRXDLAR), the DMA behavior is unpredictable.

When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.
Channel Tx descriptor list address register (ETH_DMACTXDLAR)

Address offset: 0x1114
Reset value: 0x0000 0000

Channel Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in ETH_DMACTXCR register. When stopped, this register can be written with a new descriptor list address. When you set ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

| TDESLA[31:16]   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
|------------------|------------------|
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
| TDESLA[15:0]     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

Bits 31:0 TDESLA[31:0]: Start of Transmit List

This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).
Channel Rx descriptor list address register (ETH_DMACRXDLAR)

Address offset: 0x111C
Reset value: 0x0000 0000

The Channel Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in ETH_DMACRXCR register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Bits 31:0 **TDT[31:0]**: Transmit Descriptor Tail Pointer
This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.
Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)
Address offset: 0x1128
Reset value: 0x0000 0000
The Channel Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 TDRL[9:0]: Transmit Descriptor Ring Length
This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. It is recommended to put a minimum ring descriptor length of 4.
For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.
Channel Rx descriptor ring length register (ETH_DMACRXRLR)

Address offset: 0x1130
Reset value: 0x0000 0000

The Channel Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **NIE**: Normal Interrupt Summary Enable
When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
When this bit is reset, the normal interrupt summary is disabled.

Bit 14  **AIE**: Abnormal Interrupt Summary Enable
When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 1: Transmit Process Stopped
- Bit 7: Rx Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 9: Receive Watchdog Timeout
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
When this bit is reset, the abnormal interrupt summary is disabled.

Bit 13  **CDEE**: Context Descriptor Error Enable
When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.

Bit 12  **FBEE**: Fatal Bus Error Enable
When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Bit 11  **ERIE**: Early Receive Interrupt Enable
When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Bit 10  **ETIE**: Early Transmit Interrupt Enable
When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.

Bit 9  **RWTE**: Receive Watchdog Timeout Enable
When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.

Bit 8  **RSE**: Receive Stopped Enable
When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.

Bit 7  **RBU**: Receive Buffer Unavailable Enable
When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.

Bit 6  **RIE**: Receive Interrupt Enable
When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Bits 5:3  Reserved, must be kept at reset value.
Bit 2 **TBUE**: Transmit Buffer Unavailable Enable
When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.

Bit 1 **TXSE**: Transmit Stopped Enable
When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.

Bit 0 **TIE**: Transmit Interrupt Enable
When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.
Figure 859. Generation of ETH_DMAISR flags

![Diagram showing the generation of ETH_DMAISR flags](image-url)
Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR)

Address offset: 0x1138
Reset value: 0x0000 0000

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the Channel status register (ETH_DMACSR).

</table>

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 RWTU[1:0]: Receive Interrupt Watchdog Timer Count Units

This field indicates the number of system clock cycles corresponding to one unit in RWT[7:0] field.
00: 256
01: 512
10: 1024
11: 2048

For example, when RWT[7:0] = 2 and RWTU[1:0] = 1, the watchdog timer is set for 2 * 512 = 1024 system clock cycles.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 RWT[7:0]: Receive Interrupt Watchdog Timer Count

This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set.

The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the ETH_DMACSR, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30].

When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.
Channel current application transmit descriptor register  
(ETH_DMACCATXDR)
Address offset: 0x1144
Reset value: 0x0000 0000
The Channel Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Bits 31:0  CURTDESAPTR[31:0]: Application Transmit Descriptor Address Pointer
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

Channel current application receive descriptor register  
(ETH_DMACCARXDR)
Address offset: 0x114C
Reset value: 0x0000 0000
The Channel Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Bits 31:0  CURRDESAPTR[31:0]: Application Receive Descriptor Address Pointer
The DMA updates this pointer during Rx operation. This pointer is cleared on reset.
**Channel current application transmit buffer register (ETH_DMACCATXBR)**

Address offset: 0x1154
Reset value: 0x0000 0000

The Channel Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

```
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|CURTBUFAPTR[15:0]| r | r | r | r | r | r | r | r | r | r | r | r | r | r | r |
```

Bits 31:0 **CURTBUFAPTR[31:0]**: Application Transmit Buffer Address Pointer
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

**Channel current application receive buffer register (ETH_DMACCARXBR)**

Address offset: 0x115C
Reset value: 0x0000 0000

The Channel Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

```
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|CURRBBUFAPTR[15:0]| r | r | r | r | r | r | r | r | r | r | r | r | r | r | r |
```

Bits 31:0 **CURRBBUFAPTR[31:0]**: Application Receive Buffer Address Pointer
The DMA updates this pointer during Rx operation. This pointer is cleared on reset.

**Channel status register (ETH_DMACSR)**

Address offset: 0x1160
Reset value: 0x0000 0000

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

```
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+

```

**STMicroelectronics**

RM0399 Rev 4 3093/3556
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:19  **REB[2:0]**: Rx DMA Error Bits

This field indicates the type of error that caused a Bus Error. For example, error response on
the AHB interface.

Bit [2]: Error during data transfer by Rx DMA when 1, no Error during data transfer by Rx
DMA when 0.

Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0

Bit[0]: Error during read transfer when 1, Error during write transfer when 0

This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bits 18:16  **TEB[2:0]**: Tx DMA Error Bits

This field indicates the type of error that caused a Bus Error. For example, error response on
the AHB interface.

Bit[2]: Error during data transfer by Tx DMA when 1, no Error during data transfer by Tx DMA
when 0

Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0

Bit[0]: Error during read transfer when 1, Error during write transfer when 0

This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bit 15  **NIS**: Normal Interrupt Summary

Normal Interrupt Summary bit value is the logical OR of the following bits when the
 corresponds interrupt bits are enabled in the ETH_DMACIER register:

Bit 0: Transmit Interrupt
Bit 2: Transmit Buffer Unavailable
Bit 6: Receive Interrupt
Bit 11: Early Receive Interrupt

Only unmasked bits (interrupts for which interrupt enable is set in ETH_DMACIER register)
affect the Normal Interrupt Summary bit.

This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding
bit which causes NIS to be set is cleared.

Bit 14  **AIS**: Abnormal Interrupt Summary

Abnormal Interrupt Summary bit value is the logical OR of the following when the
 correspond interrupt bits are enabled in the ETH_DMACIER register:

Bit 1: Transmit Process Stopped
Bit 7: Receive Buffer Unavailable
Bit 8: Receive Process Stopped
Bit 10: Early Transmit Interrupt
Bit 12: Fatal Bus Error
Bit 13: Context Descriptor Error

Only unmasked bits affect the Abnormal Interrupt Summary bit.

This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding
bit, which causes AIS to be set, is cleared.

Bit 13  **CDE**: Context Descriptor Error

This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates
 invalid context in the middle of packet flow (intermediate descriptor) or all one’s descriptor in
Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer
address as ones which is considered to be invalid.

Bit 12  **FBE**: Fatal Bus Error

This bit indicates that a bus error occurred (as described in the EB field). When this bit is set,
the corresponding DMA channel engine disables all bus accesses.
Bit 11 **ERI**: Early Receive Interrupt
This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit.

Bit 10 **ETI**: Early Transmit Interrupt
This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO.

Bit 9 **RWT**: Receive Watchdog Timeout
This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.

Bit 8 **RPS**: Receive Process Stopped
This bit is asserted when the Rx process enters the Stopped state.

Bit 7 **RBU**: Receive Buffer Unavailable
This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor.

Bit 6 **RI**: Receive Interrupt
This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.

The reception remains in the Running state.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **TBU**: Transmit Buffer Unavailable
This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPSi field of the **Debug status register (ETH_DMADSR)** register explains the Transmit Process state transitions.
To resume processing the Transmit descriptors, the application should do the following:
1. Change the ownership of the descriptor by setting Bit 31 of TDES3.
2. Issue a Transmit Poll Demand command.
For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel.

Bit 1 **TPS**: Transmit Process Stopped
This bit is set when the transmission is stopped.

Bit 0 **TI**: Transmit Interrupt
This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.
Channel missed frame count register (ETH_DMACMFCR)

Address offset: 0x116C
Reset value: 0x0000 0000

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in Channel receive control register (ETH_DMACRXCR) register.

<table>

</tr>
</thead>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **MFCO**: Overflow status of the MFC Counter
When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MFC[10:0]**: Dropped Packet Counters
This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in Channel receive control register (ETH_DMACRXCR). The counter gets cleared when this register is read.

### 61.11.3 Ethernet MTL registers

**Operating mode Register (ETH_MTLOMR)**

Address offset: 0x0C00  
Reset value: 0x0000 0000  
The Operating Mode register establishes the Transmit and Receive operating modes and commands.

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:10  Reserved, must be kept at reset value.

**Bit 9 CNTCLR: Counters Reset**  
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.  
If this bit is set along with CNTPRST bit, CNTPRST has precedence.

**Bit 8 CNTPRST: Counters Preset**  
When this bit is set:  
- Tx queue underflow register (ETH_MTLTXQUR) is initialized/preset to 0x7F0.  
- Missed Packet and Overflow Packet counters in Rx queue missed packet and overflow counter register (ETH_MTLRXQMPOCR) is initialized/preset to 0x7F0  
This bit is cleared automatically.

**Bit 7 Reserved, must be kept at reset value.**

**Bits 6:2  Reserved, must be kept at reset value.**

**Bit 1 DTXSTS: Drop Transmit Status**  
When this bit is set, the Tx packet status received from the MAC is dropped in the MTL.  
When this bit is reset, the Tx packet status received from the MAC is forwarded to the application.

**Bit 0 Reserved, must be kept at reset value.**
Interrupt status Register (ETH_MTLISR)

Address offset: 0x0C20
Reset value: 0x0000 0000

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

<table>
<thead>
<tr>

</tr>
<tr>
<td>15-7</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
</tbody>
</table>
Bits 6:4 TTC[2:0]: Transmit Threshold Control
These bits control the threshold level of the MTL Tx queue. The transmission starts when
the packet size within the MTL Tx queue is larger than the threshold. In addition, full
packets with length less than the threshold are also transmitted. These bits are used only
when the TSF bit is reset.
000: 32
001: 64
010: 96
011: 128
100: 192
101: 256
110: 384
111: 512

Bits 3:2 TXQEN[1:0]: Transmit Queue Enable
This field is used to enable/disable the transmit queue.
00: Not enabled
10: Enabled
Others: Reserved, must not be used.
Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the
Tx queue by programming this field.

Bit 1 TSF: Transmit Store and Forward
When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue.
When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This
bit should be changed only when the transmission is stopped.

Bit 0 FTQ: Flush Transmit Queue
When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all
the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing
operation is complete. Until this bit is reset, you should not write to the ETH_MTLTXQOMR
register. The data which is already accepted by the MAC transmitter is not flushed. It is
scheduled for transmission and results in underflow and runt packet transmission.
Note: The flush operation is complete only when the Tx queue is empty and the application
has accepted the pending Tx Status of all transmitted packets. To complete this flush
operation, the PHY Tx clock (eth_mii_tx_clk) should be active.

Tx queue underflow register (ETH_MTLTXQUR)
Address offset: 0x0D04
Reset value: 0x0000 0000
The Queue Underflow Counter register contains the counter for packets aborted because of
Transmit queue underflow and packets missed because of Receive queue packet flush
The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

### Bits 31:12 Reserved, must be kept at reset value.

### Bit 11 **UFCNTOVF**: Overflow Bit for Underflow Packet Counter

This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.

### Bits 10:0 **UFFRMCNT[10:0]**: Underflow Packet Counter

This field indicates the number of packets aborted by the controller because of Tx queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read.

### Tx queue debug register (ETH_MTLTXQDR)

**Address offset**: 0x0D08

**Reset value**: 0x0000 0000

The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

### Bits 31:23 Reserved, must be kept at reset value.

### Bits 22:20 **STXSTSF[2:0]**: Number of Status Words in Tx Status FIFO of Queue

This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.

### Bit 19 Reserved, must be kept at reset value.

### Bits 18:16 **PTXQ[2:0]**: Number of Packets in the Transmit Queue

This field indicates the current number of packets in the Tx queue. When the DTXSTS bit of Operating mode Register (ETH_MTLOMR) register is set to 1, this field does not reflect the number of packets in the Transmit queue.

### Bits 15:6 Reserved, must be kept at reset value.

### Bit 5 **TXSTSFSTS**: MTL Tx Status FIFO Full Status

When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.

### Bit 4 **TXQSTS**: MTL Tx Queue Not Empty Status

When this bit is high, it indicates that the MTL Tx queue is not empty and some data is left for transmission.
Bit 3 **TWCSTS**: MTL Tx Queue Write Controller Status
When high, this bit indicates that the MTL Tx queue Write Controller is active, and it is
transferring the data to the Tx queue.

Bits 2:1 **TRCSTS[1:0]**: MTL Tx Queue Read Controller Status
This field indicates the state of the Tx Queue Read Controller:
00: Idle state
01: Read state (transferring data to the MAC transmitter)
10: Waiting for pending Tx Status from the MAC transmitter
11: Flushing the Tx queue because of the Packet Abort request from the MAC

Bit 0 **TXQPAUSED**: Transmit Queue in Pause
When this bit is high and the Rx flow control is enabled, it indicates that the Tx queue is in the
Pause condition (in the Full-duplex only mode) because of the following:
– Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled
– Reception of 802.3x Pause packet when PFC is disabled

Queue interrupt control status Register (ETH_MTLQICSR)
Address offset: 0x0D2C
Reset value: 0x0000 0000
This register contains the interrupt enable and status bits for the queue interrupts.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RXOIE**: Receive Queue Overflow Interrupt Enable
When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset,
the Receive Queue Overflow interrupt is disabled.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **RXOVFIS**: Receive Queue Overflow Interrupt Status
This bit indicates that the Receive Queue had an overflow while receiving the packet. If a
partial packet is transferred to the application, the overflow status is set in RDES3[21]. This
bit is cleared when the application writes 1 to this bit.

Bits 15:9 Reserved, must be kept at reset value.
Bit 8 **TXUIE**: Transmit Queue Underflow Interrupt Enable
   When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **TXUNFIS**: Transmit Queue Underflow Interrupt Status
   This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit.
Rx queue operating mode register (ETH_MTLRXQOMR)

Address offset: 0x0D30
Reset value: 0x0070 0000

The Queue Receive operating Mode register establishes the Receive queue operating modes and command.

</tbody>
</table>

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:20  **RQS[2:0]:** Receive Queue Size

This field is read-only and the configured Rx FIFO size in blocks of 256 bytes is reflected in the reset value. The size of the Queue is (RQS + 1) * 256 bytes.

Bits 19:7  Reserved, must be kept at reset value.

Bit 6  **DIS_TCP_EF:** Disable Dropping of TCP/IP Checksum Error Packets

When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

When this bit is reset, all error packets are dropped if the FEP bit is reset.

Bit 5  **RSF:** Receive Queue Store and Forward

When this bit is set, the Ethernet peripheral reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Bit 4  **FEP:** Forward Error Packets

When this bit is set, the Rx queue drops packets with error status (CRC error, receive error, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped.

When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
Bit 3 **FUP**: Forward Undersized Good Packets
   When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **RTC[1:0]**: Receive Queue Threshold Control
   These bits control the threshold level of the MTL Rx queue (in bytes):
   - 00: 64
   - 01: 32
   - 10: 96
   - 11: 128
   The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred.
   This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
Rx queue missed packet and overflow counter register
(ETH_MTLRXQMPOCR)

Address offset: 0x0D34
Reset value: 0x0000 0000

The Queue missed packet and overflow counter registers contain the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

| Bits 31:28 | Reserved, must be kept at reset value.
| Bit 27 | **MISCNTOVF**: Missed Packet Counter Overflow Bit
  - When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit.
| Bits 26:16 | **MISPKTCNT[10:0]**: Missed Packet Counter
  - This field indicates the number of packets missed by the Ethernet peripheral because the application requested to flush the packets for this queue. This counter is reset when this register is read.
  - This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.
| Bits 15:12 | Reserved, must be kept at reset value.
| Bit 11 | **OVFCNTO VF**: Overflow Counter Overflow Bit
  - When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit.
| Bits 10:0 | **OVFPKTCNT[10:0]**: Overflow Packet Counter
  - This field indicates the number of packets discarded by the Ethernet peripheral because of Receive queue overflow. This counter is incremented each time the Ethernet peripheral discards an incoming packet because of overflow. This counter is reset when this register is read.
Rx queue debug register (ETH_MTLRXQDR)

Address offset: 0x0D38
Reset value: 0x0000 0000

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 PRXQ[13:0]: Number of Packets in Receive Queue
This field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256Kbyte/16bytes = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:4 RXQSTS[1:0]: MTL Rx Queue Fill-Level Status
This field gives the status of the fill-level of the Rx queue:
00: Rx queue empty
01: Rx queue fill-level below flow-control deactivate threshold
10: Rx queue fill-level above flow-control activate threshold
11: Rx queue full

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 RRCSTS[1:0]: MTL Rx Queue Read Controller State
This field gives the state of the Rx queue Read controller:
00: Idle state
01: Reading packet data
10: Reading packet status (or timestamp)
11: Flushing the packet data and status

Bit 0 RWCSTS: MTL Rx Queue Write Controller Active Status
When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue.
## Ethernet MTL register map and reset values

### Table 605. ETH_MTL register map and reset values

**Notes:**
- The table shows the reset values for various registers in the Ethernet MTL module.
- Each register is identified by its offset and register name.
- The reset values are listed in hexadecimal format, with 0x prefix.

Refer to *Section 2.3 on page 134* for the register boundary addresses.
61.11.4 Ethernet MAC and MMC registers

Operating mode configuration register (ETH_MACCR)

Address offset: 0x0000
Reset value: 0x0000 0000

The MAC Configuration Register establishes the operating mode of the MAC.

Bit 31 **ARPEN**: ARP Offload Enable
When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus.
When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.

Bits 30:28 **SARC[2:0]**: Source Address Insertion or Replacement Control
This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]:
010: the MAC inserts the content of the MAC Address 0 registers (**MAC Address 0 high register (ETH_MACA0HR)** and **MAC Address x low register (ETH_MACAxLR)**) in the SA field of all transmitted packets.
011: the MAC replaces the content of the MAC Address 0 registers (**MAC Address 0 high register (ETH_MACA0HR)** and **MAC Address x low register (ETH_MACAxLR)**) in the SA field of all transmitted packets.
110: the MAC inserts the content of the MAC Address 1 registers (**MAC Address x high register (ETH_MACAxHR)** and **MAC Address x low register (ETH_MACAxLR)**) in the SA field of all transmitted packets.
111: the MAC replaces the content of the MAC Address 1 registers (**MAC Address x high register (ETH_MACAxHR)** and **MAC Address x low register (ETH_MACAxLR)**) in the SA field of all transmitted packets.
Others: Reserved, must not be used.

**Note**: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bit 27 **IPC**: Checksum Offload
When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.
The Layer 3 and Layer 4 Packet Filter feature automatically selects the IPC Full Checksum Offload Engine on the Receive side. When this feature is enabled, you must set the IPC bit.

Bits 26:24 **IPG[2:0]**: Inter-Packet Gap
These bits control the minimum IPG between packets during transmission.
000: 96 bit times
001: 88 bit times
010: 80 bit times
...
111: 40 bit times
This range of minimum IPG is valid in Full-duplex mode.
In the Half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.
When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.
The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in ETH_MACECR register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in ETH_MACECR register.

Bit 23 **GPSLCE**: Giant Packet Size Limit Control Enable
When this bit is set, the MAC considers the value in GPSL field in ETH_MACECR register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit.
When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).
The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.

Bit 22 **S2KP**: IEEE 802.3as Support for 2K Packets
When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets.
When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the giant packet status, see Table 606: Giant Packet Status based on S2KP and JE Bits.
Note: When the JE bit is set, setting this bit has no effect on the giant packet status.

Bit 21 **CST**: CRC stripping for Type packets
When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.
This function is valid when Type 2 Checksum Offload Engine is enabled.
Note: For information about how the settings of the ACS bit and this bit impact the packet length, see Table 607: Packet Length based on the CST and ACS bits.
Bit 20  **ACS**: Automatic Pad or CRC Stripping
   When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.
   When this bit is reset, the MAC passes all incoming packets to the application, without any modification.
   **Note**: For information about how the settings of CST bit and this bit impact the packet length, see Table 607: Packet Length based on the CST and ACS bits.

Bit 19  **WD**: Watchdog Disable
   When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes.
   When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **JD**: Jabber Disable
   When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes.
   When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.

Bit 16  **JE**: Jumbo Packet Enable
   When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
   For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 606: Giant Packet Status based on S2KP and JE Bits.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **FES**: MAC Speed
   This bit selects the speed in the 10/100 Mbps mode:
   0: 10 Mbps
   1: 100 Mbps

Bit 13  **DM**: Duplex Mode
   When this bit is set, the MAC operates in the Full-duplex mode in which it can transmit and receive simultaneously.

Bit 12  **LM**: Loopback Mode
   When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (eth_mii_rx_clk) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Bit 11  **ECRSFD**: Enable Carrier Sense Before Transmission in Full-duplex mode
   When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the Full-duplex mode. The MAC starts the transmission only when the CRS signal is low.
   When this bit is reset, the MAC transmitter ignores the status of the CRS signal.

Bit 10  **DO**: Disable Receive Own
   When this bit is set, the MAC disables the reception of packets when the ETH_TX_EN is asserted in the Half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY.
   This bit is not applicable in the Full-duplex mode. This bit is reserved and read-only (RO) with default value in the Full-duplex-only configurations.
Bit 9 **DCRS**: Disable Carrier Sense During Transmission

When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the Half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission.

When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.

Bit 8 **DR**: Disable Retry

When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status.

When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the Half-duplex mode.

Bit 7 **Reserved, must be kept at reset value.**

Bits 6:5 **BL[1:0]**: Back-Off Limit

The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision:

- 00: k = min (n, 10)
- 01: k = min (n, 8)
- 10: k = min (n, 4)
- 11: k = min (n, 1)

where n = retransmission attempt

The random integer r takes the value in the range 0 <= r < 2^k.

This bit is applicable only in the Half-duplex mode.

Bit 4 **DC**: Deferral Check

When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode.

Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted.

When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive.

This bit is applicable only in the Half-duplex mode.

Bits 3:2 **PRELEN[1:0]**: Preamble Length for Transmit packets

These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the Full-duplex mode.

- 00: 7 bytes of preamble
- 01: 5 bytes of preamble
- 10: 3 bytes of preamble
- 11: Reserved, must not be used
Bit 1 TE: Transmitter Enable
When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Bit 0 RE: Receiver Enable
When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

Table 606 shows how the settings of S2KP and JE bits of the ETH_MACCR register impact the giant packet status.

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **EIPG[4:0]: Extended Inter-Packet Gap**

The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits) along with IPG field in Operating mode configuration register (ETH_MACCR), gives the minimum IPG greater than 96 bit times in steps of 8 bit times. For example:

- EIPG = 0 and IPG = 0 give 104 bit times
- EIPG = 0 and IPG = 1 give 112 bit times
- EIPG = 0 and IPG = 2 give 120 bit times
- ...  
- EIPG = 7 and IPG = 31 give 2144 bit times

Bit 24  **EIPGEN: Extended Inter-Packet Gap Enable**

When this bit is set, the MAC interprets EIPG field and IPG field in Operating mode configuration register (ETH_MACCR) together as minimum IPG greater than 96 bit times in steps of 8 bit times.

When this bit is reset, the MAC ignores EIPG field and interprets IPG field in Operating mode configuration register (ETH_MACCR) as minimum IPG less than or equal to 96 bit times in steps of 8 bit times.

**Note:** The extended Inter-Packet Gap feature must be enabled when operating in Full-duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-duplex mode.

Bits 23:19  Reserved, must be kept at reset value.

Bit 18  **USP: Unicast Slow Protocol Packet Detect**

When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR). The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02).

When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
Bit 17 **SPEN**: Slow Protocol Detection Enable
When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid subtypes. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.

Bit 16 **DCRCC**: Disable CRC Checking for Received Packets
When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **GPSL[13:0]**: Giant Packet Size Limit
If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes.
For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. For double VLAN tagged packets, the MAC adds 8 bytes to the programmed value. The value in this field is applicable when the GPSLCE bit is set in ETH_MACCR register.

**Packet filtering control register (ETH_MACPFR)**
Address offset: 0x0008
Reset value: 0x0000 0000

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

</table>

Bit 31 **RA**: Receive All
When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.

Bits 30:22 Reserved, must be kept at reset value.

Bit 21 **DNTU**: Drop Non-TCP/UDP over IP Packets
When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forwards only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
Bit 20  **IPFE**: Layer 3 and Layer 4 Filter Enable
When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.
When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.

Bits 19:17  Reserved, must be kept at reset value.

Bit 16  **VTFE**: VLAN Tag Filter Enable
When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **HPF**: Hash or Perfect Filter
When this bit is set, the address filter passes a packet if it matches either the perfect filtering or Hash filtering as set by the HMC or HUC bit.
When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Bit 9  **SAF**: Source Address Filter Enable
When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet.
When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison.

**Note:** According to the IEEE specification, Bit 47 of the SA is reserved. However, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.

Bit 8  **SAIF**: SA Inverse Filtering
When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter.
When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.

Bits 7:6  **PCF[1:0]**: Pass Control Packets
These bits control the forwarding of all control packets (including unicast and multicast Pause packets).
00: The MAC filters all control packets from reaching the application.
01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter.
10: The MAC forwards all control packets to the application even if they fail the Address filter.
11: The MAC forwards the control packets that pass the Address filter.

Bit 5  **DBF**: Disable Broadcast Packets
When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings.
When this bit is reset, the AFM module passes all received broadcast packets.

Bit 4  **PM**: Pass All Multicast
When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is ‘1’) are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
Bit 3 **DAIF**: DA Inverse Filtering
When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.

Bit 2 **HMC**: Hash Multicast
When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the Hash table.
When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 1 **HUC**: Hash Unicast
When this bit is set, the MAC performs the destination address filtering of unicast packets according to the Hash table.
When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 0 **PR**: Promiscuous Mode
When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

**Watchdog timeout register (ETH_MACWTR)**
Address offset: 0x000C
Reset value: 0x0000 0000
The Watchdog Timeout register controls the watchdog timeout for received packets.
Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PWE**: Programmable Watchdog Enable
When this bit is set and the WD bit of the *Operating mode configuration register (ETH_MACCR)* register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in *Operating mode configuration register (ETH_MACCR)* register.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **WTO[3:0]**: Watchdog Timeout
When the PWE bit is set and the WD bit of the *Operating mode configuration register (ETH_MACCR)* register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.

Encoding is as follows:
- 0x0: 2 Kbytes
- 0x1: 3 Kbytes
- 0x2: 4 Kbytes
- 0x3: 5 Kbytes
- ..
- 0xC: 14 Kbytes
- 0xD: 15 Kbytes
- 0xE: 16383 Bytes
- 0xF: Reserved, must not be used

*Note*: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

**Hash Table 0 register (ETH_MACHT0R)**
Address offset: 0x0010
Reset value: 0x0000 0000

The Hash Table Register 0 contains the first lower 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 0b10000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.
Hash Table 1 register (ETH_MACHT1R)

Address offset: 0x0014
Reset value: 0x0000 0000

The Hash Table 1 register contains the upper 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determine the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

Bits 31:0 HT31T0[31:0]: MAC Hash Table First 32 Bits
This field contains the first 32 Bits [31:0] of the Hash table.

</tr>
</tbody>
</table>

| Bit 23  | Reserved, must be kept at reset value. |
Bits 22:21 **EVLS[1:0]:** Enable VLAN Tag Stripping on Receive
   This field indicates the stripping operation on the outer VLAN Tag in received packet:
   00: Do not strip
   01: Strip if VLAN filter passes
   10: Strip if VLAN filter fails
   11: Always strip

Bit 20 **DOVLTc:** Disable VLAN Type Check
   When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.
   When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Bit 19 **ERSVLM:** Enable Receive S-VLAN Match
   When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
   The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

Bit 18 **ESVL:** Enable S-VLAN
   When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.

Bit 17 **VTIM:** VLAN Tag Inverse Match Enable
   When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Bit 16 **ETV:** Enable 12-Bit VLAN Tag Comparison
   When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for Hash-based VLAN filtering.
   When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN Hash filtering.

Bits 15:0 **VL[15:0]:** VLAN Tag Identifier for Receive Packets
   This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:
   Bits[15:13]: User Priority
   Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
   Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
   When the ETV bit is set, only the VID is used for comparison.
   If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.
VLAN Hash table register (ETH_MACVHTR)

Address offset: 0x0058
Reset value: 0x0000 0000

When the VTHM bit of VLAN tag register (ETH_MACVTR) register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For Hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of VLAN tag register (ETH_MACVTR) register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a Hash value of 1000 selects Bit 8 of the VLAN Hash table.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
2. Perform bitwise reversal for the value obtained in step 1.
3. Take the upper four bits from the value obtained in step 2.

</tbody>
</table>

Bits 31:21: Reserved, must be kept at reset value.

Bit 20: **VLTI**: VLAN Tag Input
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.

Bit 19: **CSVL**: C-VLAN or S-VLAN
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

0: C-LAN
1: S-LAN

Bit 18: **VLP**: VLAN Priority Control
When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.

Bits 17:16: **VLC[1:0]**: VLAN Tag Control in Transmit Packets
00: No VLAN tag deletion, insertion, or replacement
01: VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags.
10: VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88A8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.
11: VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88A8).

*Note:* Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

Bits 15:0: **VLT[15:0]**: VLAN Tag for Transmit Packets
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.

The following list describes the bits of this field:

Bits[15:13]: User Priority
Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
Inner VLAN inclusion register (ETH_MACIVIR)

Address offset: 0x0064
Reset value: 0x0000 0000

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

</tbody>
</table>

Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bits 15:0 **VLT[15:0]**: VLAN Tag for Transmit Packets

This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.

The following list describes the bits of this field:
- Bits[15:13]: User Priority
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

**Tx Queue flow control register (ETH_MACQTXFCR)**

Address offset: 0x0070

Reset value: 0x0000 0000

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

**DZPQ**: Disable Zero-Quanta Pause

When this bit is set, it disables the automatic generation of the zero-quanta Pause packets. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
Bits 6:4  **PLT[2:0]: Pause Low Threshold**

This field configures the threshold of the Pause timer at which the input flow is checked for automatic retransmission of the Pause packet.

The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted at 228 (256-28) slot times after the first Pause packet is transmitted.

The following list provides the threshold values for different values:

- 000: Pause Time minus 4 Slot Times (PT -4 slot times)
- 001: Pause Time minus 28 Slot Times (PT -28 slot times)
- 010: Pause Time minus 36 Slot Times (PT -36 slot times)
- 011: Pause Time minus 144 Slot Times (PT -144 slot times)
- 100: Pause Time minus 256 Slot Times (PT -256 slot times)
- 101: Pause Time minus 512 Slot Times (PT -512 slot times)
- 110 to 111: Reserved, must not be used

The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **TFE: Transmit Flow Control Enable**

**Full-duplex mode:** when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.

**Half-duplex mode:** when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.

Bit 0  **FCB_BPA: Flow Control Busy or Backpressure Activate**

This bit initiates a Pause packet in the Full-duplex mode and activates the backpressure function in the Half-duplex mode if the TFE bit is set.

**Full-Duplex mode:** this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared.

**Half-duplex mode:** When this bit is set (and TFE bit is set) in the Half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the Full-duplex mode, the BPA is automatically disabled.
Rx flow control register (ETH_MACRXFCR)

Address offset: 0x0090

Reset value: 0x0000 0000

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Bits 31:2  Reserved, must be kept at reset value.

Bit 1 UP: Unicast Pause Packet Detect
A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC Address 0 high register (ETH_MAC0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR).

When this bit is reset, the MAC only detects Pause packets with unique multicast address.

Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_00_01) is as specified in IEEE 802.1 Qbb-2011.

Bit 0 RFE: Receive Flow Control Enable
When this bit is set and the MAC is operating in Full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in Half-duplex mode, the decode function of the Pause packet is disabled.

When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.
Interrupt status register (ETH_MACISR)

Address offset: 0x00B0
Reset value: 0x0000 0000

The Interrupt Status register contains the status of interrupts.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 RXSTSIS: Receive Status Interrupt
This bit indicates the status of received packets. This bit is set when the RWT bit is set in the Rx Tx status register (ETH_MACRXTXSR). This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.

Bit 13 TXSTSIS: Transmit Status Interrupt
This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the Rx Tx status register (ETH_MACRXTXSR):
- Excessive Collision (EXCOL)
- Late Collision (LCOL)
- Excessive Deferral (EXDEF)
- Loss of Carrier (LCARR)
- No Carrier (NCARR)
- Jabber Timeout (TJT)
This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.
Bit 12  **TSIS**: Timestamp Interrupt Status
If the Timestamp feature is enabled, this bit is set when any of the following conditions is true:
- The system time value is equal to or exceeds the value specified in the Target Time High and Low registers.
- There is an overflow in the Seconds register.
- The Target Time Error occurred, that is, programmed target time already elapsed.
If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted.
When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register** (ETH_MACTXTSSNR) and **Tx timestamp status seconds register** (ETH_MACTXTSSSR) registers.
When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register** (ETH_MACTXTSSNR) and **Tx timestamp status seconds register** (ETH_MACTXTSSSR) registers, for PTO generated Delay Request and Pdelay request packets.
This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of **CSR software control register** (ETH_MACCSRSWCR) is set) in the **Timestamp status register** (ETH_MACTSSR).

Bit 11  Reserved, must be kept at reset value.

Bit 10  **MMCTXIS**: MMC Transmit Interrupt Status
This bit is set high when an interrupt is generated in the **MMC Tx interrupt register** (ETH_MMC_TX_INTERRUPT). This bit is cleared when all bits in this interrupt register are cleared.

Bit 9  **MMCRXIS**: MMC Receive Interrupt Status
This bit is set high when an interrupt is generated in the **MMC Rx interrupt register** (ETH_MMC_RX_INTERRUPT). This bit is cleared when all bits in this interrupt register are cleared.

Bit 8  **MMCIS**: MMC Interrupt Status
This bit is set high when MMCTXIS or MMCRXIS is set high. This bit is cleared only when all these bits are low.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **LPIS**: LPI Interrupt Status
This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of **LPI control and status register** (ETH_MACLCSR) is read.

Bit 4  **PMTIS**: PMT Interrupt Status
This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in ETH_MACPCSR register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the **PMT control status register** (ETH_MACPCSR).

Bit 3  **PHYIS**: PHY Interrupt
This bit is set when rising edge is detected on the ETH_PHY_INTN input. This bit is cleared when this register is read.

Bits 2:0  Reserved, must be kept at reset value.
Interrupt enable register (ETH_MACIER)

Address offset: 0x00B4
Reset value: 0x0000 0000

The Interrupt Enable register contains the masks for generating the interrupts.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14  RXSTSIE: Receive Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the Interrupt status register (ETH_MACISR).

Bit 13  TXSTSIE: Transmit Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the Interrupt status register (ETH_MACISR).

Bit 12  TSIE: Timestamp Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in Interrupt status register (ETH_MACISR).

Bits 11:6 Reserved, must be kept at reset value.

Bit 5   LPIIE: LPI Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in Interrupt status register (ETH_MACISR).

Bit 4   PMTIE: PMT Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in Interrupt status register (ETH_MACISR).

Bit 3   PHYIE: PHY Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in Interrupt status register (ETH_MACISR).

Bits 2:0 Reserved, must be kept at reset value.
Rx Tx status register (ETH_MACRXTXSR)

Address offset: 0x00B8
Reset value: 0x0000 0000

The Receive Transmit Status register contains the Receive and Transmit Error status.

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **RWT**: Receive Watchdog Timeout
This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the **Operating mode configuration register (ETH_MACCR)**. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the **Operating mode configuration register (ETH_MACCR)**.
Cleared on read (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **EXCOL**: Excessive Collisions
When the DTXSTS bit is set in the **Operating mode Register (ETH_MTLOMR)**, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the **Operating mode configuration register (ETH_MACCR)**, this bit is set after the first collision and the packet transmission is aborted.
Cleared on read (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 4 **LCOL**: Late Collision
When the DTXSTS bit is set in the **Operating mode Register (ETH_MTLOMR)**, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode. This bit is not valid if the Underflow error occurs.
Cleared on read (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 3 **EXDEF**: Excessive Deferral
When the DTXSTS bit is set in the **Operating mode Register (ETH_MTLOMR)** and the DC bit is set in the **Operating mode configuration register (ETH_MACCR)**, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled).
Cleared on read (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).
Bit 2  **LCARR**: Loss of Carrier
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the loss of carrier occurred during packet transmission, that is, the ETH_CRS signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSR_SWR) is set).

Bit 1  **NCARR**: No Carrier
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSR_SWR) is set).

Bit 0  **TJT**: Transmit Jabber Timeout
This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the Operating mode configuration register (ETH_MACCR).
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSR_SWR) is set).

**PMT control status register (ETH_MACCSR)**

</tbody>
</table>
Bit 10  **RWKPFE**: Remote wakeup Packet Forwarding Enable

When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected wakeup frame. All frames after that event including the received wakeup frame are forwarded to application. This bit is then self-cleared on receiving the wakeup packet.

The application can also clear this bit before the expected wakeup frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high.

*Note:* If Magic Packet Enable and wakeup Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wakeup frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.

Bit 9  **GLBLUCAST**: Global Unicast

When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wakeup packet.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6  **RWKPRCVD**: Remote wakeup Packet Received

When this bit is set, it indicates that the power management event is generated because of the reception of a remote wakeup packet. This bit is cleared when this register is read.

Bit 5  **MGKPRCVD**: Magic Packet Received

When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read (or written to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 4:3 Reserved, must be kept at reset value.

Bit 2  **RWKPKTEN**: Remote wakeup Packet Enable

When this bit is set, a power management event is generated when the MAC receives a remote wakeup packet.

Bit 1  **MGKPKTEN**: Magic Packet Enable

When this bit is set, a power management event is generated when the MAC receives a magic packet.

Bit 0  **PWRDWN**: Power Down

When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wakeup packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wakeup packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote wakeup Packet Enable bit is set high.

*Note:* You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
Remote wakeup packet filter register (ETH_MACRWKPFR)

Address offset: 0x00C4
Reset value: 0x0000 0000

Bits 31:0 MACRWKPFR[31:0]: Remote wakeup packet filter
Refer to Table 575, Table 576 and Table 577 for details on register content and programming sequence.

The ETH_MACRWKPFR register at address 0x00C4 loads the wakeup Packet Filter register.

To load values in a wakeup Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.

LPI control and status register (ETH_MACLCSR)

Address offset: 0x00D0
Reset value: 0x0000 0000

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **LPITCSE**: LPI Tx Clock Stop Enable
When this bit is set, the MAC asserts `sbd_tx_clk_gating_ctrl_o` signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert `sbd_tx_clk_gating_ctrl_o` signal high after it enters Tx LPI mode.
If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed.

Bit 20  **LPITE**: LPI Timer Enable
This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the ETH_MACLETR register.
After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again.
When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.

Bit 19  **LPITXA**: LPI Tx Automate
This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side.
If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of ETH_MTLTxQOMR, when the MAC is in the LPI mode, it exits the LPI mode.
When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **PLS**: PHY Link Status
This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER.
When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

Bit 16  **LPIEN**: LPI Enable
When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission.
This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **RLPIST**: Receive LPI State
When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.

Bit 8  **TLPIST**: Transmit LPI State
When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Bits 7:4  Reserved, must be kept at reset value.
LPI timers control register (ETH_MACLTCR)

Address offset: 0x00D4

Reset value: 0x03E8 0000

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.
Ethernet (ETH): media access control (MAC) with DMA controller

LPI entry timer register (ETH_MACLETR)
Address offset: 0x00D8
Reset value: 0x0000 0000

This register controls the Tx LPI entry timer. This counter is enabled only when LPITE bit of LPI control and status register (ETH_MACLCSR) register is set to 1.

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 LPIET[19:0]: LPI Entry Timer
This field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1.
Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

One-microsecond-tick counter register (ETH_MAC1USTCR)
Address offset: 0x00DC
Reset value: 0x0000 0000

This register controls the generation of the Reference time (one-microsecond tick) for all the LPI timers. This timer has to be programmed by the software initially.
Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  TIC_1US_CNTR[11:0]: 1 µs tick Counter
The application must program this counter so that the number of clock cycles of CSR clock is 1 µs (subtract 1 from the value before programming).
For example if the CSR clock is 100 MHz then this field needs to be programmed to 100 - 1 = 99 (which is 0x63).
This is required to generate the 1 µs events that are used to update some of the EEE related counters.

**Version register (ETH_MACVR)**

Address offset: 0x0110
Reset value: 0x0000 3142

The version register identifies the version of the Ethernet peripheral.

**Debug register (ETH_MACDR)**

Address offset: 0x0114
Reset value: 0x0000 0000

The Debug register provides the debug status of various MAC blocks.

ST

RM0399 Rev 4  3141/3556
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **TFCSTS[1:0]:** MAC Transmit Packet Controller Status
This field indicates the state of the MAC Transmit Packet Controller module:
00: Idle state
01: Waiting for one of the following:
   – Status of the previous packet
   – IPG or backoff period to be over
10: Generating and transmitting a Pause control packet (in Full-duplex mode)
11: Transferring input packet for transmission

Bit 16  **TPESTS:** MAC MII Transmit Protocol Engine Status
When this bit is set, it indicates that the MAC MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.

Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **RFCFCSTS[1:0]:** MAC Receive Packet Controller FIFO Status
When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.

Bit 0  **RPESTS:** MAC MII Receive Protocol Engine Status
When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving data, and it is not in the Idle state.

**HW feature 0 register (ETH_MACHWF0R)**

Address offset: 0x011C
Reset value: 0x0A0D 73F5

This register indicates the presence of first set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **ACTPHYSEL[2:0]:** Active PHY Selected
   When you have multiple PHY interfaces in your configuration, this field indicates the sampled
   value of phy_intf_sel_i during reset de-assertion:
   000: GMII or MII
   001: RGMII
   010: SGMII
   011: TBI
   100: RMII
   101: RTBI
   110: SMII
   Others: Reserved, must not be used

Bit 27  **SAVLAININS:** Source Address or VLAN Insertion Enable
   This bit is set to 1 when the Enable SA and VLAN Insertion on Tx option is selected

Bits 26:25  **TSSTSSEL[1:0]:** Timestamp System Time Source
   This bit indicates the source of the Timestamp system time:
   01: Internal
   10: External
   11: Both
   00: Reserved, must not be used
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bit 24  **MACADR64SEL:** MAC Addresses 64-127 Selected
   This bit is set to 1 when the Enable Additional 64 MAC Address Registers (64-127) option is
   selected

Bit 23  **MACADR32SEL:** MAC Addresses 32-63 Selected
   This bit is set to 1 when the Enable Additional 32 MAC Address Registers (32-63) option is
   selected

Bits 22:18  **ADDMACADRSEL[4:0]:** MAC Addresses 1-31 Selected
   This bit is set to 1 when the Enable Additional 1-31 MAC Address Registers option is
   selected

Bit 17  Reserved, must be kept at reset value.

Bit 16  **RXCOESEL:** Receive Checksum Offload Enabled
   This bit is set to 1 when the Enable Receive TCP/IP Checksum Check option is selected

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TXCOESEL:** Transmit Checksum Offload Enabled
   This bit is set to 1 when the Enable Transmit TCP/IP Checksum Insertion option is selected

Bit 13  **EEESEL:** Energy Efficient Ethernet Enabled
   This bit is set to 1 when the Enable Energy Efficient Ethernet (EEE) option is selected

Bit 12  **TSSEL:** IEEE 1588-2008 Timestamp Enabled
   This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **ARPOFFSEL:** ARP Offload Enabled
   This bit is set to 1 when the Enable IPv4 ARP Offload option is selected

Bit 8  **MMCSEL:** RMON Module Enable
   This bit is set to 1 when the Enable MAC management counters (MMC) option is selected
Bit 7 **MGKSEL**: PMT Magic Packet Enable
   This bit is set to 1 when the Enable Magic Packet Detection option is selected

Bit 6 **RWKSEL**: PMT Remote Wakeup Packet Enable
   This bit is set to 1 when the Enable Remote wakeup Packet Detection option is selected

Bit 5 **SMASEL**: SMA (MDIO) Interface
   This bit is set to 1 when the Enable Station Management (MDIO Interface) option is selected

Bit 4 **VLHASH**: VLAN Hash Filter Selected
   This bit is set to 1 when the Enable VLAN Hash Table Based Filtering option is selected

Bit 3 **PCSSEL**: PCS Registers (TBI, SGMII, or RTBI PHY interface)
   This bit is set to 1 when the TBI, SGMII, or RTBI PHY interface option is selected

Bit 2 **HDSEL**: Half-duplex Support
   This bit is set to 1 when the Half-duplex mode is selected

Bit 1 **GMIISEL**: 1000 Mbps Support
   This bit is set to 1 when 1000 Mbps is selected as operating mode.

Bit 0 **MISEL**: 10 or 100 Mbps Support
   This bit is set to 1 when 10/100 Mbps is selected as operating mode.

**HW feature 1 register (ETH_MACHWF1R)**

Address offset: 0x0120

Reset value: 0x1104 1904

This register indicates the presence of second set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:27  \textbf{L3L4NUM}[3:0]: Total number of L3 or L4 Filters
This field indicates the total number of L3 or L4 filters:
- 0000: No L3 or L4 Filter
- 0001: 1 L3 or L4 Filter
- 0010: 2 L3 or L4 Filters
- ...
- 1000: 8 L3 or L4

Bit 26  Reserved, must be kept at reset value.

Bits 25:24  \textbf{HASHTBLSZ}[1:0]: Hash Table Size
This field indicates the size of the Hash table:
- 00: No Hash table
- 01: 64
- 10: 128
- 11: 256

Bit 23  \textbf{POUOST}: One Step for PTP over UDP/IP Feature Enable
This bit is set to 1 when the Enable one step timestamp for PTP over UDP/IP feature is selected.

Bit 22  Reserved, must be kept at reset value.

Bit 21  \textbf{RAVSEL}: Rx Side Only AV Feature Enable
This bit is set to 1 when the Enable Audio video bridging option on Rx Side Only is selected.

Bit 20  \textbf{AVSEL}: AV Feature Enable
This bit is set to 1 when the Enable Audio video bridging option is selected.

Bit 19  \textbf{DBGMEMA}: DMA Debug Registers Enable
This bit is set to 1 when the Debug Mode Enable option is selected.

Bit 18  \textbf{TSOEN}: TCP Segmentation Offload Enable
This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected.

Bit 17  \textbf{SPHEN}: Split Header Feature Enable
This bit is set to 1 when the Enable Split Header Structure option is selected.

Bit 16  \textbf{DCBEN}: DCB Feature Enable
This bit is set to 1 when the Enable Data Center Bridging option is selected.

Bits 15:14  \textbf{ADDR64}[1:0]: Address width
This field indicates the configured address width.
- 00: 32 bits
- Others: Reserved, must not be used

Bit 13  \textbf{ADVTHWORD}: IEEE 1588 High Word Register Enable
This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected.

Bit 12  \textbf{PTOEN}: PTP Offload Enable
This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected.

Bit 11  \textbf{OSTEN}: One-Step Timestamping Enable
This bit is set to 1 when the Enable One-Step Timestamp Feature is selected.
Bits 10:6 \textbf{TXFIFOSIZE}[4:0]: MTL Transmit FIFO Size

This field contains the configured value of MTL Tx FIFO in bytes expressed as \( \log_2 \) to base 2 minus 7, that is, \( \log_2(\text{TXFIFO\_SIZE}) - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011 to 11111: Reserved, must not be used

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 \textbf{RXFIFOSIZE}[4:0]: MTL Receive FIFO Size

This field contains the configured value of MTL Rx FIFO in bytes expressed as \( \log_2 \) to base 2 minus 7, that is, \( \log_2(\text{RXFIFO\_SIZE}) - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011: 256 Kbytes
- 01100 to 11111: Reserved, must not be used
HW feature 2 register (ETH_MACHWF2R)

Address offset: 0x0124

Reset value: 0x4100 0000

This register indicates the presence of third set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **AUXSNAPNUM[2:0]:** Number of Auxiliary Snapshot Inputs

This field indicates the number of auxiliary snapshot inputs:

- 000: No auxiliary input
- 001: 1 auxiliary input
- 010: 2 auxiliary inputs
- 011: 3 auxiliary inputs
- 100: 4 auxiliary inputs
- 101 to 111: Reserved, must not be used

Bit 27  Reserved, must be kept at reset value.

Bits 26:24  **PPSOUTNUM[2:0]:** Number of PPS Outputs

This field indicates the number of PPS outputs:

- 000: No PPS output
- 001: 1 PPS output
- 010: 2 PPS outputs
- 011: 3 PPS outputs
- 100: 4 PPS outputs
- 101 to 111: Reserved, must not be used

Bits 23:22  **TDCSZ[1:0]:** Tx DMA Descriptor Cache Size in terms of 16-byte descriptors

- 00: Cache not configured
- 01: Four 16-byte descriptors
- 10: Eight 16-byte descriptors
- 11: Sixteen 16-byte descriptors

Bits 21:18  **TXCHCNT[3:0]:** Number of DMA Transmit Channels

This field indicates the number of DMA Transmit channels:

- 0000: 1 DMA Tx Channel
- 0001: 2 DMA Tx Channels
- ..
- 0111: 8 DMA Tx
Bits 17:16  **RDCSZ[1:0]**: Rx DMA Descriptor Cache Size in terms of 16-byte descriptors
- 00: Cache not configured
- 01: Four 16-byte descriptors
- 10: Eight 16-byte descriptors
- 11: Sixteen 16-byte descriptors

Bits 15:12  **RXCHCNT[3:0]**: Number of DMA Receive Channels
This field indicates the number of DMA Receive channels:
- 0000: 1 DMA Rx Channel
- 0001: 2 DMA Rx Channels
- ...
- 0111: 8 DMA Rx

Bits 11:10  Reserved, must be kept at reset value.

This field indicates the number of MTL Transmit queues:
- 0000: 1 MTL Tx queue
- 0001: 2 MTL Tx queues
- ...
- 0111: 8 MTL Tx

Bits 5:4   Reserved, must be kept at reset value.

Bits 3:0   **RXQNT[3:0]**: Number of MTL Receive Queues
This field indicates the number of MTL Receive queues:
- 0000: 1 MTL Rx queue
- 0001: 2 MTL Rx queues
- ...
- 0111: 8 MTL Rx
HW feature 3 register (ETH_MACHWF3R)

Address offset: 0x0128

Reset value: 0x0000 0020

This register indicates the presence of fourth set the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  **DVLAN**: Double VLAN processing enable
This bit is set to 1 when Double VLAN processing is enabled.

Bit 4  **CBTISEL**: Queue/Channel based VLAN tag insertion on Tx enable
This bit is set to 1 when the Enable Queue/Channel based VLAN tag insertion on Tx feature is selected.

Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **NRFV[2:0]**: Number of Extended VLAN Tag Filters Enabled
This field indicates the Number of Extended VLAN Tag Filters selected:

- 000: No Extended Rx VLAN Filters
- 001: 4 Extended Rx VLAN Filters
- 010: 8 Extended Rx VLAN Filters
- 011: 16 Extended Rx VLAN Filters
- 100: 24 Extended Rx VLAN Filters
- 101: 32 Extended Rx VLAN Filters
- 110 to 111: Reserved, must not be used
MDIO address register (ETH_MACMDIOAR)

Address offset: 0x0200
Reset value: 0x0000 0000

The MDIO Address register controls the management cycles to external PHY through a management interface.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PSE**: Preamble Suppression Enable

When this bit is set, the SMA suppresses the 32-bit preamble and transmit MDIO frames with only 1 preamble bit.
When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.

Bit 26 **BTB**: Back to Back transactions

When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame.
When this bit is reset, then the read/write command completion (MII busy is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame.
This bit must not be set when NTC=0.

Bits 25:21 **PA[4:0]**: Physical Layer Address

This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

Bits 20:16 **RDA[4:0]**: Register/Device Address

These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **NTC[2:0]**: Number of Training Clocks

This field controls the number of trailing clock cycles generated on ETH_MDC after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 011 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
Bits 11:8 **CR[3:0]: CSR Clock Range**

The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency (eth_hclk):

- 0000: MDC clock = eth_hclk / 42
- 0001: MDC clock = eth_hclk / 62
- 0010: MDC clock = eth_hclk / 16
- 0011: MDC clock = eth_hclk / 26
- 0100: MDC clock = eth_hclk / 102
- 0101: MDC clock = eth_hclk / 124
- 0110 to 0111: Reserved, must not be used

The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits to 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks:

- 1000: eth_hclk / 4
- 1001: eth_hclk / 6
- 1010: eth_hclk / 8
- 1011: eth_hclk / 10
- 1100: eth_hclk / 12
- 1101: eth_hclk / 14
- 1110: eth_hclk / 16
- 1111: eth_hclk / 18

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SKAP: Skip Address Packet**

When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.

Bits 3:2 **GOC[1:0]: MII Operation Command**

This bit indicates the operation command to the PHY.

- 00: Reserved, must not be used
- 01: Write
- 10: Post Read Increment Address for Clause 45 PHY
- 11: Read

When Clause 22 PHY is enabled, only Write and Read commands are valid.

Bit 1 **C45E: Clause 45 PHY Enable**

When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
Bit 0  **MB**: MII Busy

The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIOS. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in **MDIO address register (ETH_MACMDIOAR)** and **MDIO data register (ETH_MACMDIODR)** as long as this bit is set.

For write transfers, the application must first write 16-bit data in the MD field (and also RA field when C45E is set) in **MDIO data register (ETH_MACMDIODR)** register before setting this bit. When C45E is set, it should also write into the RA field of **MDIO data register (ETH_MACMDIODR)** before initiating a read transfer. When a read transfer is completed (MII busy=0), the data read from the PHY register is valid in the MD field of the **MDIO data register (ETH_MACMDIODR)**.

**Note**: Even if the addressed PHY is not present, there is no change in the functionality of this bit.

### MDIO data register (ETH_MACMDIODR)

**Address offset**: 0x0204

**Reset value**: 0x0000 0000

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in **MDIO address register (ETH_MACMDIOAR)**. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

### Bits 31:16  **RA[15:0]**: Register Address

This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.

### Bits 15:0  **MD[15:0]**: MII Data

This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.

### ARP address register (ETH_MACARPAR)

**Address offset**: 0x0210

**Reset value**: 0x0000 0000

The ARP Address register contains the IPv4 Destination Address of the MAC.
RM0399  Ethernet (ETH): media access control (MAC) with DMA controller

RM0399 Rev 4 3153/3556

**RM0399 Ethernet (ETH): media access control (MAC) with DMA controller**

**CSR software control register (ETH_MACCSRSWCR)**
Address offset: 0x0230
Reset value: 0x0000 0000
This register contains software-programmable controls for changing the CSR access response and status bits clearing.

Bits 31:0  **ARPPA[31:0]: ARP Protocol Address**
This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

**MAC Address 0 high register (ETH_MACA0HR)**
Address offset: 0x0300
Reset value: 0x8000 FFFF
The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.
If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

### MAC Address x low register (ETH_MACAxLR)
Address offset: 0x0304 + 0x8 * x, (x = 0 to 3)
Reset value: 0xFFFF FFFF

Bit 31  **AE**: Address Enable
When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

Bit 30  **SA**: Source Address
When this bit is set, the MAC Address x[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address x[47:0] is used to compare with the DA fields of the received packet.

0: DA
1: SA

Bits 29:24  **MBC[5:0]**: Mask Byte Control
These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH_MACAxHR[15:8]
- Bit 28: ETH_MACAxHR[7:0]
- Bit 27: ETH_MACAxLR[31:24]
- Bit 26: ETH_MACAxLR[23:16]
- Bit 25: ETH_MACAxLR[15:8]
- Bit 24: ETH_MACAxLR[7:0]

You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.

Bits 23:16  Reserved, must be kept at reset value.

Bits 15:0  **ADDRHI[15:0]**: MAC Address1 [47:32]
This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.
MMC control register (ETH_MMC_CONTROL)

Address offset: 0x0700
Reset value: 0x0000 0000

This register configures the MMC operating mode.

Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **UCDBC**: Update MMC Counters for Dropped Broadcast Packets

The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of **Packet filtering control register (ETH_MACPFR)**.

When reset, the MMC Counters are not updated for dropped Broadcast packets.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **CNTPRSTLVL**: Full-Half Preset

When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2Kbytes) and all packet-counters get preset to 0x7FFF_F800 (Half 2Kbytes). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2Kbytes) and all packet-counters get preset to 0xFFFF_F800 (Full 2Kbytes). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.

Bit 4  **CNTPRST**: Counters Preset

When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle.

This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.

Bit 3  **CNTFREEZ**: MMC Counter Freeze

When this bit is set, it freezes all MMC counters to their current value.

Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
Bit 2 **RSTOND**: Reset on Read
   When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset).
   The counters are cleared when the least significant byte lane (Bits[7:0]) is read.

Bit 1 **CNTSTOPR**: Counter Stop Rollover
   When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Bit 0 **CNTRST**: Counters Reset
   When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

**MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**

Address offset: 0x0704
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:
- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the CNTSTOPR is set in **MMC control register (ETH_MMC_CONTROL)**, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Bits 25:18 Reserved, must be kept at reset value.

- Bit 27 **RXLPIRTCIS**: MMC Receive LPI transition counter interrupt status
  This bit is set when the **Rx LPI transition counter register (ETH_RX_LPI_TRANS_CNTR)**
  counter reaches half of the maximum value or the maximum value.

- Bit 26 **RXLPIUSCIS**: MMC Receive LPI microsecond counter interrupt status
  This bit is set when the **Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR)**
  counter reaches half of the maximum value or the maximum value.

Bits 17:0 Reserved, must be kept at reset value.
Bit 17 **RXUCGPIIS**: MMC Receive Unicast Good Packet Counter Interrupt Status

This bit is set when the *Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RXALGNERPIS**: MMC Receive Alignment Error Packet Counter Interrupt Status

This bit is set when the *Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 5 **RXCRCERPIS**: MMC Receive CRC Error Packet Counter Interrupt Status

This bit is set when the *Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

**MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**

Address offset: 0x0708

Reset value: 0x0000 0000

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When CNTSTOPRO is set in **MMC control register (ETH_MMC_CONTROL)**, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXLPITRCIS**: MMC Transmit LPI transition counter interrupt status

This bit is set when the *Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR)* counter reaches half of the maximum value or the maximum value.

Bit 26  **TXLPITSCIS**: MMC Transmit LPI microsecond counter interrupt status

This bit is set when the *Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR)* counter reaches half of the maximum value or the maximum value.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  **TXGPKTIS**: MMC Transmit Good Packet Counter Interrupt Status

This bit is set when the *Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

Bit 15  **TXMCOLGPIS**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Status

This bit is set when the *Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 14  **TXSCOLGPIS**: MMC Transmit Single Collision Good Packet Counter Interrupt Status

This bit is set when the *Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
MMC Rx interrupt mask register (ETH_MMC_RX_INTERRUPT_MASK)

Address offset: 0x070C
Reset value: 0x0000 0000

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  TXLPITRCIM: MMC Transmit LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR) counter reaches half of the maximum value or the maximum value.

Bit 26  TXLPUSCIM: MMC Transmit LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR) counter reaches half of the maximum value or the maximum value.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  TXGPKTIM: MMC Transmit Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD) counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

Bit 15  TXMCOLGPIM: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS) counter reaches half of the maximum value or the maximum value.

Bit 14  TXSCOLGPIM: MMC Transmit Single Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS) counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
Tx single collision good packets register
(ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)
Address offset: 0x074C
Reset value: 0x0000 0000
This register provides the number of successfully transmitted packets by Ethernet peripheral after a single collision in the Half-duplex mode.

Bits 31:0 TXSNGLCOLG[31:0]: Tx Single Collision Good Packets
This field indicates the number of successfully transmitted packets after a single collision in the Half-duplex mode.

Tx multiple collision good packets register
(ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)
Address offset: 0x0750
Reset value: 0x0000 0000
This register provides the number of successfully transmitted packets by Ethernet peripheral after multiple collisions in the Half-duplex mode.

Bits 31:0 TXMULTCOLG[31:0]: Tx Multiple Collision Good Packets
This field indicates the number of successfully transmitted packets after multiple collisions in the Half-duplex mode.
**Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)**

Address offset: 0x0768  
Reset value: 0x0000 0000  
This register provides the number of good packets transmitted by Ethernet peripheral.

**L3HDBM0[4:0]**  **L3HSBM0[4:0]**  **L3DAIM0**  **L3DAM0**  **L3SAIM0**  **L3SAM0**  **Res.**  **L3PEN0**  

Bits 31:22  Reserved, must be kept at reset value.

- **Bit 21** **L4DPIM0:** Layer 4 Destination Port Inverse Match Enable
  - When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching.
  - This bit is valid and applicable only when the L4DPM0 bit is set high.

- **Bit 20** **L4DPM0:** Layer 4 Destination Port Match Enable
  - When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

- **Bit 19** **L4SPIM0:** Layer 4 Source Port Inverse Match Enable
  - When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching.
  - This bit is valid and applicable only when the L4SPM0 bit is set high.

- **Bit 18** **L4SPM0:** Layer 4 Source Port Match Enable
  - When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.

- **Bit 17**  Reserved, must be kept at reset value.

- **Bit 16** **L4PEN0:** Layer 4 Protocol Enable
  - When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.
  - The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.
Bits 15:11 L3HDBM0[4:0]: Layer 3 IP DA higher bits match
    Condition: IPv4 packets
    This field contains the number of higher bits of IP Destination Address that are masked in the IPv4 packets:
    0: No bits are masked.
    1: LSb[0] is masked
    2: Two LSbs [1:0] are masked
    ..
    31: All bits except MSb are masked.
    Condition: IPv6 packets
    Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. Number of bits masked is given by concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits:
    0: No bits are masked.
    1: LSb[0] is masked
    2: Two LSbs [1:0] are masked
    ..
    31: All bits except MSb are masked.
    This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 L3HSBM0[4:0]: Layer 3 IP SA higher bits match
    Condition: IPv4 packets
    This field contains the number of lower bits of IP source address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
    0: No bits are masked.
    1: LSb[0] is masked
    2: Two LSbs [1:0] are masked
    ..
    31: All bits except MSb are masked.
    Condition: IPv6 packets:
    This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP source or destination address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bit 5 L3DAIM0: Layer 3 IP DA Inverse Match Enable
    When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.
    This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 L3DAM0: Layer 3 IP DA Match Enable
    When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.
    Note: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Bit 3 L3SAIM0: Layer 3 IP SA Inverse Match Enable
    When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.
    This bit is valid and applicable only when the L3SAM0 bit is set.
Bit 2 **L3SAM0**: Layer 3 IP SA Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **L3PEN0**: Layer 3 Protocol Enable
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.
The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

**Layer4 Address filter 0 register (ETH_MACL4A0R)**

Bits 31:16 **L4DP0[15:0]**: Layer 4 Destination Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.
When the L4PEN0 and L4DPM0 bits are set in L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

Bits 15:0 **L4SP0[15:0]**: Layer 4 Source Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.
When the L4PEN0 and L4DPM0 bits are set in L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer3 Address 0 filter 0 register (ETH_MACL3A00R)

Address offset: 0x0910  
Reset value: 0x0000 0000  
For IPv4 packets, the Layer 3 Address 0 filter 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Bits 31:22 Reserved, must be kept at reset value.

**Bit 21 L4DPIM1**: Layer 4 Destination Port Inverse Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching.
This bit is valid and applicable only when the L4DPM1 bit is set high.

**Bit 20 L4DPM1**: Layer 4 Destination Port Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

**Bit 19 L4SPIM1**: Layer 4 Source Port Inverse Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching.
This bit is valid and applicable only when the L4SPM1 bit is set high.

**Bit 18 L4SPM1**: Layer 4 Source Port Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.

**Bit 17** Reserved, must be kept at reset value.
Bit 16 **L4PEN1**: Layer 4 Protocol Enable

When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.

The Layer 4 matching is done only when the L4SPM1 or L4DPM1 bit is set.

**Bits 15:11** **L3HDBM1[4:0]**: Layer 3 IP DA higher bits match

Condition: IPv4 packets

This field contains the number of lower bits of IP Destination Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

- 0: No bits are masked.
- 1: LSb[0] is masked
- 2: Two LSbs [1:0] are masked
- ...
- 31: All bits except MSb are masked.

Condition: IPv6 packets

Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM1, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM1[1:0] and L3HSBM1 bits:

- 0: No bits are masked
- 1: LSb[0] is masked
- 2: Two LSbs [1:0] are masked
- ...
- 127: All bits except MSb are masked.

This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set.

**Bits 10:6** **L3HSBM1[4:0]**: Layer 3 IP SA Higher Bits Match

Condition: IPv4 packets

This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:

- 0: No bits are masked.
- 1: LSb[0] is masked
- 2: Two LSbs [1:0] are masked
- ...
- 31: All bits except MSb are masked.

Condition: IPv6 packets

This field contains Bits[4:0] of L3HSBM1. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set high.

**Bit 5** **L3DAIM1**: Layer 3 IP DA Inverse Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DAM1 bit is set high.

**Bit 4** **L3DAM1**: Layer 3 IP DA Match Enable

When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note:* When the L3PEN1 bit is set, you should set either this bit or the L3SAM1 bit because either IPv6 DA or SA can be checked for filtering.
Bit 3  **L3SAIM1**: Layer 3 IP SA Inverse Match Enable
   - When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.
   - This bit is valid and applicable only when the L3SAM1 bit is set.

Bit 2  **L3SAM1**: Layer 3 IP SA Match Enable
   - When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.
   - *Note*: When the L3PEN01 bit is set, you should set either this bit or the L3DAM1 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **L3PEN1**: Layer 3 Protocol Enable
   - When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.
   - The Layer 3 matching is done only when the L3SAM1 or L3DAM1 bit is set.

**Layer 4 address filter 1 register (ETH_MACL4A1R)**

Address offset: 0x0934

Reset value: 0x0000 0000

**Bits 31:16  L4DP1[15:0]**: Layer 4 Destination Port Number Field
   - When the L4PEN1 bit is set and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.
   - When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

**Bits 15:0  L4SP1[15:0]**: Layer 4 Source Port Number Field
   - When the L4PEN1 bit is reset and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.
   - When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer 3 address 0 filter 1 Register (ETH_MACL3A01R)

Address offset: 0x0940
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 1 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer 3 address 1 filter 1 register (ETH_MACL3A11R)

Address offset: 0x0944
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 1 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.
Bits 31:0  **L3A11[31:0]**: Layer 3 Address 1 Field

When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset and the L3SAM1 bit is set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

**Layer3 address 2 filter 1 Register (ETH_MACL3A21R)**

Address offset: 0x0948
Reset value: 0x0000 0000

The Layer 3 Address 2 filter 1 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

Bits 31:0  **L3A21[31:0]**: Layer 3 Address 2 Field

When the L3PEN1 and L3SAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[95:64] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset in the **L3 and L4 control 1 register (ETH_MACL3L4C1R)**, this field is not used.

**Layer3 address 3 filter 1 register (ETH_MACL3A31R)**

Address offset: 0x94C
Reset value: 0x0000 0000

The Layer 3 Address 3 filter 1 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.
**Timestamp control Register (ETH_MACTSCR)**

Address offset: 0xB00

Reset value: 0x0000 2000

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

**Bits 31:29** Reserved, must be kept at reset value.

**Bit 28** **AV8021ASMen**: AV 802.1AS Mode Enable

When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS operating mode.

When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit.

**Bits 27:25** Reserved, must be kept at reset value.

**Bit 24** **TXTSSTSM**: Transmit Timestamp Status Mode

When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) register.

When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

**Bits 23:19** Reserved, must be kept at reset value.

**Bits 18:16** Reserved, must be kept at reset value.

**Bits 15:12** Reserved, must be kept at reset value.

**Bits 11:8** Reserved, must be kept at reset value.

**Bits 7:4** Reserved, must be kept at reset value.

**Bits 3:0** Reserved, must be kept at reset value.
Bit 18 **TSENMACADDR**: Enable MAC Address for PTP Packet Filtering
When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet.
When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet.
For normal timestamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching.
For PTP offload, only MAC address register 0 is considered for unicast destination address matching.

Bits 17:16 **SNAPTYPSEL[1:0]**: Select PTP packets for Taking Snapshots
These bits, along with Bits 15 and 14, define the set of PTP packet types for which snapshot needs to be taken. The encoding is given in *Table 561: Timestamp Snapshot Dependency on ETH_MACTSCR bits*.

Bit 15 **TSMSTRENA**: Enable Snapshot for Messages Relevant to Master
When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Bit 14 **TSEVNTENA**: Enable Timestamp Snapshot for Event Messages
When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see *Table 561: Timestamp Snapshot Dependency on ETH_MACTSCR bits*.

Bit 13 **TSIPV4ENA**: Enable Processing of PTP Packets Sent over IPv4-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

Bit 12 **TSIPV6ENA**: Enable Processing of PTP Packets Sent over IPv6-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Bit 11 **TSIPENA**: Enable Processing of PTP over Ethernet Packets
When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.

Bit 10 **TSVER2ENA**: Enable PTP Packet Processing for Version 2 Format
When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.

Bit 9 **TSCTRLSSR**: Timestamp Digital or Binary Rollover Control
When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of subsecond register is 0x7FFF_FFFF. The subsecond increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Bit 8 **TSENALL**: Enable Timestamp for All Packets
When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **TSADDREG**: Update Addend Register
When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set.

Bit 4 **Reserved, must be kept at reset value.**

Bit 3 **TSUPDT**: Update Timestamp
When this bit is set, the system time is updated (added or subtracted) with the value specified in *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before updating it. This bit is reset when the update is complete in hardware.

Bit 2 **TSINIT**: Initialize Timestamp
When this bit is set, the system time is initialized (overwritten) with the value specified in the *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before it is updated. This bit is reset when the initialization is complete.

Bit 1 **TSCFUPDT**: Fine or Coarse Timestamp Update
When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.

Bit 0 **TSENA**: Enable Timestamp
When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode.
On the Receive side, the MAC processes the 1588 packets only if this bit is set.

**Subsecond increment register (ETH_MACSSIR)**

Address offset: 0x0B04
Reset value: 0x0000 0000

In Coarse Update mode (bit **TSCFUPDT** in *Timestamp control Register (ETH_MACTSCR)*), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **SSINC[7:0]**: Subsecond Increment Value

The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the subsecond register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [TSCTRLSR bit is set in Timestamp control Register (ETH_MACTSCR)]. When TSCTRLSR is cleared, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

Bits 15:0  Reserved, must be kept at reset value.
System time seconds register (ETH_MACSTSR)

Address offset: 0x0B08
Reset value: 0x0000 0000

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Bits 31:0 **TSS[31:0]:** Timestamp Second

The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

System time nanoseconds register (ETH_MACSTNR)

Address offset: 0x0B0C
Reset value: 0x0000 0000

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Bit 31 **Reserved,** must be kept at reset value.

Bits 30:0 **TSS[30:0]:** Timestamp subseconds

The value in this field has the subsecond representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set in **Timestamp control Register (ETH_MACTSCR),** each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.
System time seconds update register (ETH_MACSTSUR)

Address offset: 0x0B10
Reset value: 0x0000 0000

The System Time Seconds Update register, along with the System Time Nanoseconds update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in Timestamp control Register (ETH_MACTSCR).

<table>
<thead>
<tr>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0B10</td>
<td>0x0000 0000</td>
</tr>
</tbody>
</table>

**Bits 31:0 TSS[31:0]: Timestamp Seconds**

The value in this field is the seconds part of the update.

- When ADDSUB is reset, this field must be programmed with the seconds part of the update value.
- When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value.

For example, to subtract 2.000000001 seconds from the system time, the TSS field in the ETH_MACSTSUR register must be 0xFFFF_FFFE (that is, $2^{32} – 2$).

**Caution:** When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0 in System time nanoseconds update register (ETH_MACSTNUR). The TSSS bitfield must be programmed to 0x7FFF_FFFF (resulting in −0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF_FFFE (that is, $2^{32} – 1$) and the System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF_FFFF (ADDSUB = 1 and TSSS[30:0] field = 0x7FFF_FFFF)

System time nanoseconds update register (ETH_MACSTNUR)

Address offset: 0x0B14
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0B14</td>
<td>0x0000 0000</td>
</tr>
</tbody>
</table>

**Bits 31:0 TSSS[31:0]: Timestamp Nanoseconds**

The value in this field is the nanoseconds part of the update.

When ADDSUB is reset, this field must be programmed with the nanoseconds part of the update value.

- When ADDSUB is set, this field must be programmed with the complement of the nanoseconds part of the update value.

For example, to subtract 2.000000001 nanoseconds from the system time, the TSS field in the ETH_MACSTSUR register must be 0xFFFF_FFFE (that is, $2^{30} – 2$).

**Caution:** When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0 in System time nanoseconds update register (ETH_MACSTNUR). The TSSS bitfield must be programmed to 0x7FFF_FFFF (resulting in −0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 nanoseconds from the system time, the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF_FFFE (that is, $2^{30} – 1$) and the System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF_FFFF (ADDSUB = 1 and TSSS[30:0] field = 0x7FFF_FFFF)
Bit 31  **ADDSUB**: Add or Subtract Time  
When this bit is set, the time value is subtracted with the contents of the update register.  
When this bit is reset, the time value is added with the contents of the update register.

Bits 30:0  **TSSS[30:0]**: Timestamp subseconds  
The value in this field is the subseconds part of the update.  
- **ADDSUB** is 1: This field must be programmed with the complement of the subseconds part of the update value as described.  
- **ADDSUB** is 0: This field must be programmed with the subseconds part of the update value, with an accuracy based on the TSCTRLSSR bit in the **Timestamp control Register (ETH_MACTSCR)**.  

- **TSCTRLSSR** field in the **Timestamp control Register (ETH_MACTSCR)** is 1:  
  - The programmed value must be $10^{9} \times \text{<subsecond value>}$.  
  - Each bit represents 1 ns and the programmed value should not exceed $0x3B9A_{C9FF}$.  
- **TSCTRLSSR** field in the **Timestamp control Register (ETH_MACTSCR)** is 0:  
  - The programmed value must be $2^31 - \text{<subsecond value>}$.  
  - Each bit represents an accuracy of 0.46 ns.

For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the ETH_MACSTNUR register must be 0x7FFF_FFFF (that is, $2^31 - 1$), when TSCTRLSSR bit in **Timestamp control Register (ETH_MACTSCR)** is reset and 0x3B9A_C9FF (that is, $10^9 - 1$), when TSCTRLSSR bit in **Timestamp control Register (ETH_MACTSCR)** is set.

**Caution:**  
When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0. The TSSS bitfield must be programmed to 0x7FFF_FFFF (resulting in −0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, **System time nanoseconds update register (ETH_MACSTNUR)** must be 0xFFFF_FFFF (ADDSUB = 1 and TSSS[30:0] = 0) and the TSS field in the **System time seconds update register (ETH_MACSTSUR)** must be 0xFFFF_FFFE (that is, $2^32 - 1$).

**Timestamp addend register (ETH_MACTSAR)**

Address offset: 0x0B18  
Reset value: 0x0000 0000

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the **Timestamp control Register (ETH_MACTSCR)**). The content of this register is added to a 32-bit accumulator in every clock cycle of clk_ptp_ref_i and the system time is updated whenever the accumulator overflows.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:25 **ATSN[4:0]: Number of Auxiliary Timestamp Snapshots**

This field indicates the number of Snapshots available in the FIFO. A value equal to the depth of FIFO (4) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.

Bit 24 **ATSTM: Auxiliary Timestamp Snapshot Trigger Missed**

This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ATSTSTN[3:0]: Auxiliary Timestamp Snapshot Trigger Identifier**

These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list:

- Bit 16: Auxiliary trigger 0
- Bit 17: Auxiliary trigger 1
- Bit 18: Auxiliary trigger 2
- Bit 19: Auxiliary trigger 3

The software can read this register to find the triggers that are set when the timestamp is taken.

Bit 15 **TXTSSIS: Tx Timestamp Status Interrupt Status**

When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR).

When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) and Tx timestamp status seconds register (ETH_MACTXTSSSR), for PTO generated Delay Request and Pdelay request packets.

This bit is cleared when the Tx timestamp status seconds register (ETH_MACTXTSSSR) is read (or written to 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 14:4 Reserved, must be kept at reset value.
Bit 3 **TSTRGTER0**: Timestamp Target Time Error
This bit is set when the latest target time programmed in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR elapses (see **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTSNR)**).
This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSSRSWCR)** is set).

Bit 2 **AUXTSTRIG**: Auxiliary Timestamp Trigger Snapshot
This bit is set high when the auxiliary snapshot is written to the FIFO.
This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSSRSWCR)** is set).

Bit 1 **TSTARGT0**: Timestamp Target Time Reached
When set, this bit indicates that the value of system time is greater than or equal to the value specified in the ETH_MACPPSTTSR and ETH_MACPPSTTSNR registers (see **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTSNR)**).
This bit is cleared when the application reads this bit (or writes of 1 when RCWE bit in **CSR software control register (ETH_MACCSSRSWCR)** is set)

Bit 0 **TSSOVF**: Timestamp Seconds Overflow
When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF.
This bit is cleared when the application reads this bit (or writes it to 1 when RCWE bit in **CSR software control register (ETH_MACCSSRSWCR)** is set)

**Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**
Address offset: 0x0B30
Reset value: 0x0000 0000
This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

Bit 31 **TXTSSMIS**: Transmit Timestamp Status Missed
When this bit is set, it indicates one of the following:
- The timestamp of the current packet is ignored if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is reset
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is set.

Bits 30:0 **TXTSSLO[30:0]**: Transmit Timestamp Status Low
This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.
Rx timestamp status seconds register (ETH_MACTXTSSSR)

Address offset: 0x0B34
Reset value: 0x0000 0000

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

ATSEN3 ATSEN2 ATSEN1 ATSEN0

|     |     |     |     |     |
|-----|-----|-----|-----|
| rw  | rw  | rw  | rw  |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **ATSEN3**: Auxiliary Snapshot 3 Enable

- This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg3 input is enabled. When this bit is reset, the events on this input are ignored.

Bit 6 **ATSEN2**: Auxiliary Snapshot 2 Enable

- This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg2 input is enabled. When this bit is reset, the events on this input are ignored.

Bit 5 **ATSEN1**: Auxiliary Snapshot 1 Enable

- This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg1 input is enabled. When this bit is reset, the events on this input are ignored.
Bit 4 **ATSEN0**: Auxiliary Snapshot 0 Enable
This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg0 input is enabled. When this bit is reset, the events on this input are ignored.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ATSFC**: Auxiliary Snapshot FIFO Clear
When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO.

**Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**

Address offset: 0x0B48
Reset value: 0x0000 0000

The **Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**, along with **Auxiliary timestamp seconds register (ETH_MACATSSR)**, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4 words.

You can store multiple snapshots in this FIFO. Bits[29:25] in **Timestamp status register (ETH_MACTSSR)** indicate the fill-level of the FIFO. The top of the FIFO is removed only when **Auxiliary timestamp seconds register (ETH_MACATSSR)** is read.

```

Bits 31:0 **OSTIAC[31:0]**: One-Step Timestamp Ingress Asymmetry Correction
This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000.

The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

**Timestamp Egress asymmetric correction register (ETH_MACTSEACR)**

Address offset: 0x0B54
Reset value: 0x0000 0000

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

```

Bits 31:0 **OSTEAC[31:0]**: One-Step Timestamp Egress Asymmetry Correction
This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16.

For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFDF_8000, which is the 2's complement of 0x0002_8000(2.5 * 2^16). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 2^16).
**Timestamp Ingress correction nanosecond register (ETH_MACTSICNR)**

Address offset: 0x0B58

Reset value: 0x0000 0000

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Bits 31:7  Reserved, must be kept at reset value.

Bits 6:5  **TRGTMODSEL[1:0]**: Target Time Register Mode for PPS Output

This field indicates the Target Time registers (*PPS target time seconds register (ETH_MACPPSTTSR)* and *PPS target time nanoseconds register (ETH_MACPPSTTNR)*)) mode for PPS output signal:

- 00: Target Time registers are programmed only for generating the interrupt event.
- 01: Reserved, must not be used
- 10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
- 11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4  **PPSEN0**: Flexible PPS Output Mode Enable

When this bit is set, PPSCTRL[3:0] function as PPSCMD[3:0]. When this bit is reset, PPSCTRL[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0  **PPSCTRL[3:0]**: PPS Output Frequency Control

This field controls the frequency of the PPS output (*eth_ptp_pps_out*) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:

- 0000: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
- 0001: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
- 0010: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
- 0011: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.
- 0100: The binary rollover is 32 Hz, and the digital rollover is 16 Hz.
- 0101: The binary rollover is 64 Hz, and the digital rollover is 32 Hz.
- 0110: The binary rollover is 128 Hz, and the digital rollover is 64 Hz.
- 0111: The binary rollover is 256 Hz, and the digital rollover is 128 Hz.
- 1000: The binary rollover is 512 Hz, and the digital rollover is 256 Hz.
- 1001: The binary rollover is 1024 Hz, and the digital rollover is 512 Hz.
- 1010: The binary rollover is 2048 Hz, and the digital rollover is 1024 Hz.
- 1011: The binary rollover is 4096 Hz, and the digital rollover is 2048 Hz.
- 1100: The binary rollover is 8192 Hz, and the digital rollover is 4096 Hz.
- 1101: The binary rollover is 16384 Hz, and the digital rollover is 8192 Hz.
- 1110: The binary rollover is 32768 Hz, and the digital rollover is 16,384 Hz.
- 1111: The binary rollover is 65536 Hz, and the digital rollover is 32,768 Hz.

Note: *In the binary rollover mode, the PPS output (*eth_ptp_pps_out*) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:

- When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.
- When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of
  One clock of 50 percent duty cycle and 337 ms period
  Second clock of 463 ms period (268 ms low and 195 ms high).
- When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of
  Three clocks of 50 percent duty cycle and 268 ms period
  Fourth clock of 195 ms period (134 ms low and 61 ms high).

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the ETH_MACSTNR register.
**PPS control register [alternate] (ETH_MACPPSCR)**

Address offset: 0x0B70

</tbody>
</table>
Bits 3:0 **PPSCMD[3:0]:** Flexible PPS Output (eth_ptp_pps_out) Control

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all zero’. The following list describes the values of PPSCMD0:

- **0000:** No Command
- **0001:** START Single Pulse.
  This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS Width Register.
- **0010:** START Pulse Train.
  This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time’ or 'Stop Pulse Train immediately’ commands.
- **0011:** Cancel START.
  This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time.
- **0100:** STOP Pulse Train at time.
  This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010) after the time programmed in the Target Time registers elapses.
- **0101:** STOP Pulse Train immediately.
  This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010).
- **0110:** Cancel STOP Pulse train.
  This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
- **0111** to **1111:** Reserved, must not be used

**PPS target time seconds register (ETH_MACPPSTTSR)**

Address offset: 0x0B80
Reset value: 0x0000 0000

The PPS output Target Time Seconds register, along with **PPS target time nanoseconds register (ETH_MACPPSTTNR)**, is used to schedule an interrupt event (Bit TSSOVF of **Timestamp status register (ETH_MACTSSR)**) when the system time exceeds the value programmed in these registers.

Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:0 **TSTRH0[31:0]**: PPS Target Time Seconds Register
This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the **PPS control register (ETH_MACPPSCR)**.

**PPS target time nanoseconds register (ETH_MACPPSTTNR)**
Address offset: 0x0B84
Reset value: 0x0000 0000
The PPS Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

</tbody>
</table>

Bit 31 **TRGTBUSY0**: PPS Target Time Register Busy
The MAC sets this bit when the PPSCMD0 field in the **PPS control register (ETH_MACPPSCR)** is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers with the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

Bits 30:0 **TTSL0[30:0]**: Target Time Low for PPS Register
This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in **PPS control register (ETH_MACPPSCR)**.

When the TSCTRLSSR bit is set in the Timestamp control Register (ETH_MACTSCR), this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of subsecond increment value.

**PPS interval register (ETH_MACPPPSIR)**
Address offset: 0x0B88
Reset value: 0x0000 0000
The PPS Interval register contains the number of units of subsecond increment value between the rising edges of PPS output.
**PPS Width register (ETH_MACPPSWR)**

Address offset: 0x0B8C  
Reset value: 0x0000 0000  

The PPS Width register contains the number of units of subsecond increment value between the rising and corresponding falling edges of PPS output.

<table>
<thead>

<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td>PPSWIDTH0[15:0]</td>
</tr>
</tbody>
</table>

Bits 31:0 **PPSWIDTH0[31:0]:** PPS Output Signal Width  
These bits store the width between the rising edge and corresponding falling edge of PPS signal output. The width is stored in terms of number of units of subsecond increment value.  
You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS signal output is 80 ns (that is, four units of subsecond increment value), you should program value 3 (4-1) in this register.  

*Note: The value programmed in this register must be lesser than the value programmed in PPS interval register (ETH_MACPPSIR).*
**PTP Offload control register (ETH_MACPOCR)**

Address offset: 0x0BC0

Reset value: 0x0000 0000

This register controls the PTP Offload Engine operation.

- **DN[7:0]**: Domain Number
  - Bits 31:16: Reserved, must be kept at reset value.
  - Bits 15:8: Domain Number
  - This field indicates the domain Number in which the PTP node is operating.
  - Bit 7: Reserved, must be kept at reset value.
  - Bit 6: **DRRDIS**: Disable PTO Delay Request/Response response generation
    - When this bit is set, the Delay Request and Delay response are not generated for received SYNC and Delay request packet respectively, as required by the programmed mode.
  - Bit 5: **APDREQTRIG**: Automatic PTP Pdelay_Req message Trigger
    - When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the APDREQEN bit for this operation.
  - Bit 4: **ASYNCRIG**: Automatic PTP SYNC message Trigger
    - When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the ASYNCECN bit for this operation.
  - Bit 3: Reserved, must be kept at reset value.
  - Bit 2: **APDREQEN**: Automatic PTP Pdelay_Req message Enable
    - When this bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer Transparent mode.
  - Bit 1: **ASYNCEN**: Automatic PTP SYNC message Enable
    - When this bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Clock Master mode.
  - Bit 0: **PTOEN**: PTP Offload Enable
    - When this bit is set, the PTP Offload feature is enabled.

**PTP Source Port Identity 0 Register (ETH_MACSPI0R)**

Address offset: 0x0BC4

Reset value: 0x0000 0000

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node.
RM0399 Ethernet (ETH): media access control (MAC) with DMA controller

PTP Source port identity 1 register (ETH_MACSPI1R)
Address offset: 0x0BC8
Reset value: 0x0000 0000
This register contains Bits[63:32] of the 80-bit Source Port Identity of the PTP node.

PTP Source port identity 2 register (ETH_MACSPI2R)
Address offset: 0x0BCC
Reset value: 0x0000 0000
This register contains Bits[79:64] of the 80-bit Source Port Identity of the PTP node.
**Log message interval register (ETH_MACLMIR)**

Address offset: 0x0BD0  
Reset value: 0x0000 0000  
This register contains the periodic intervals for automatic PTP packet generation.

**Bits 31:24**  **LMPDR[7:0]**: Log Min Pdelay_Req Interval  
This field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

**Bits 23:11**  **Reserved, must be kept at reset value.**

**Bits 10:8**  **DRSYNCR[2:0]**:  
Delay_Req to SYNC Ratio  
In Slave mode, it is used for controlling frequency of Delay_Req messages transmitted.  
0: DelayReq generated for every received SYNC  
1: DelayReq generated every alternate reception of SYNC  
2: for every 4 SYNC messages  
3: for every 8 SYNC messages  
4: for every 16 SYNC messages  
5: for every 32 SYNC messages  
Others: Reserved, must not be used  
The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The reception processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay_Resp PTP message.

**Bits 7:0**  **LSI[7:0]**:  
Log Sync Interval  
This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2's-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

Refer to Section 2.3 on page 134 for the register boundary addresses.
62  HDMI-CEC controller (CEC)

62.1  HDMI-CEC introduction
Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

62.2  HDMI-CEC controller main features
- Complies with HDMI-CEC v1.4 specification
- Independent 32 kHz CEC kernel (refer to section RCC kernel clock distribution)
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - with automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)
62.3 HDMI-CEC functional description

62.3.1 HDMI-CEC pin and internal signals

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on Figure 860.

Table 610 lists the internal signals that are exchanged between the HDMI-CEC and other functional blocks (such as RCC and EXTI).

62.3.2 HDMI-CEC block diagram

Figure 860. HDMI-CEC block diagram

62.3.3 Message description

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.

All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to ‘ping’ other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

Figure 861. Message structure
62.3.4 Bit timing

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.

62.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time
starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the figure below.

**Figure 864. Signal free time**

![Signal free time](MS31007V1)

Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.

**Figure 865. Arbitration phase**

![Arbitration phase](MS31008V1)

*Figure 866* shows an example for a SFT of three nominal bit periods.

**Figure 866. SFT of three nominal bit periods**

![SFT of three nominal bit periods](MS31009V1)

A configurable time window is counted before starting the transmission.

In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission
This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission. Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

62.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM = 1).

In case of SFTOPT = 1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.

In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR = 1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACKE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncodified low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

62.5 Error handling

62.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period (3.6 ms nominally).

![Figure 867. Error bit timing](image-url)
62.5.2 Message error
A message is considered lost and therefore may be retransmitted under the following conditions:
- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

62.5.3 Bit rising error (BRE)
BRE (bit rising error) is set when a bit rising edge is detected outside the windows where it is expected (see Figure 868). BRE flag also generates a CEC interrupt if the BREIE = 1.
In the case of a BRE detection, the message reception can be stopped according to the BRESTP bit value and an error bit can be generated if BREGEN bit is set.
When BRE is detected in a broadcast message with BRESTP = 1 an error bit is generated even if BREGEN = 0 to enforce initiator's retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN = 0, BRDNOGEN = 1.

62.5.4 Short bit period error (SBPE)
SBPE is set when a bit falling edge is detected earlier than expected (see Figure 868). SBPE flag also generates a CEC interrupt if the SBPEIE = 1.
An error bit is always generated on the line in case of a SBPE error detection. An error bit is not generated upon SBPE detection only when Listen mode is set (LSTN = 1) and the following conditions are met:
- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN = 1

62.5.5 Long bit period error (LBPE)
LBPE is set when a bit falling edge is not detected in a valid window (see Figure 868). LBPE flag also generates a CEC interrupt if the LBPEIE = 1.
LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.
When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN = 0 to enforce initiator's retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN = 0, BRDNOGEN = 1.

Note: The BREGEN = 1, BRESTP = 0 configuration must be avoided.

</table>
62.5.6 Transmission error detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE = 1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to five times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

### 62.6 HDMI-CEC interrupts

An interrupt can be produced:
- during reception if a receive block transfer is finished or if a receive error occurs.
- during transmission if a transmit block transfer is finished or if a transmit error occurs.

62.7 HDMI-CEC registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions. The registers have to be accessed by words (32 bits).

62.7.1 CEC control register (CEC_CR)

Address offset: 0x00
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>2</td>
<td>TXEOM: Tx end of message</td>
</tr>
<tr>
<td></td>
<td>The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.</td>
</tr>
<tr>
<td>0:</td>
<td>TXDR data byte is transmitted with EOM = 0.</td>
</tr>
<tr>
<td>1:</td>
<td>TXDR data byte is transmitted with EOM = 1.</td>
</tr>
<tr>
<td>Note:</td>
<td>TXEOM must be set when CECEN = 1.</td>
</tr>
<tr>
<td></td>
<td>TXEOM must be set before writing transmission data to TXDR.</td>
</tr>
<tr>
<td></td>
<td>If TXEOM is set when TXSOM = 0, transmitted message consists of 1 byte (HEADER) only (PING message).</td>
</tr>
<tr>
<td>1</td>
<td>TXSOM: Tx start of message</td>
</tr>
<tr>
<td></td>
<td>TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.</td>
</tr>
<tr>
<td></td>
<td>Start-bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission starts after the end of reception.</td>
</tr>
<tr>
<td></td>
<td>TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND = 1), in case of transmission underrun (TXUDR = 1), negative acknowledge (TXACKE = 1), and transmission error (TXERR = 1). It is also cleared by CECEN = 0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST = 1).</td>
</tr>
<tr>
<td></td>
<td>TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.</td>
</tr>
<tr>
<td>0:</td>
<td>No CEC transmission is on-going.</td>
</tr>
<tr>
<td>1:</td>
<td>CEC transmission command</td>
</tr>
<tr>
<td>Note:</td>
<td>TXSOM must be set when CECEN = 1.</td>
</tr>
<tr>
<td></td>
<td>TXSOM must be set when transmission data is available into TXDR.</td>
</tr>
</tbody>
</table>
|  | HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC_CFGR.OAR that is used only for reception.
Bit 0 **CECEN**: CEC enable
The CECEN bit is set and cleared by software. CECEN = 1 starts message reception and enables the TXSOM control. CECEN = 0 disables the CEC peripheral, clears all bits of CEC_CR register and aborts any on-going reception or transmission.
0: CEC peripheral is off.
1: CEC peripheral is on.

62.7.2 **CEC configuration register (CEC_CFGR)**
This register is used to configure the HDMI-CEC controller.
Address offset: 0x04
Reset value: 0x0000 0000

**Caution:** It is mandatory to write CEC_CFGR only when CECEN = 0.

<table>
<thead>

</tbody>
</table>

**Example:**
OAR = 0b0000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5. Consequently, each message directed to one of these addresses is received.

Bits 15:9 **Reserved, must be kept at reset value.**

Bit 8 **SFTOP**: SFT option bit
The SFTOPT bit is set and cleared by software.
0: SFT timer starts when TXSOM is set by software.
1: SFT timer starts automatically at the end of message transmission/reception.
Bit 7  **BRDNOGEN**: Avoid error-bit generation in broadcast  
The BRDNOGEN bit is set and cleared by software.  
0: BRE detection with BRESTP = 1 and BREGEN = 0 on a broadcast message generates an error-bit on the CEC line. LBPE detection with LBPEGEN = 0 on a broadcast message generates an error-bit on the CEC line.  
1: Error-bit is not generated in the same condition as above. An error-bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

Bit 6  **LBPEGEN**: Generate error-bit on long bit period error  
The LBPEGEN bit is set and cleared by software.  
0: LBPE detection does not generate an error-bit on the CEC line.  
1: LBPE detection generates an error-bit on the CEC line.  
*Note: If BRDNOGEN = 0, an error-bit is generated upon LBPE detection in broadcast even if LBPEGEN = 0.*

Bit 5  **BREGEN**: Generate error-bit on bit rising error  
The BREGEN bit is set and cleared by software.  
0: BRE detection does not generate an error-bit on the CEC line.  
1: BRE detection generates an error-bit on the CEC line (if BRESTP is set).  
*Note: If BRDNOGEN = 0, an error-bit is generated upon BRE detection with BRESTP = 1 in broadcast even if BREGEN = 0.*

Bit 4  **BRESTP**: Rx-stop on bit rising error  
The BRESTP bit is set and cleared by software.  
0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.  
1: BRE detection stops message reception.

Bit 3  **RXTOL**: Rx-tolerance  
The RXTOL bit is set and cleared by software.  
0: Standard tolerance margin:  
  – Start-bit, +/- 200 µs rise, +/- 200 µs fall  
  – Data-bit: +/- 200 µs rise, +/- 350 µs fall  
1: Extended tolerance  
  – Start-bit: +/- 400 µs rise, +/- 400 µs fall  
  – Data-bit: +/- 300 µs rise, +/- 500 µs fall

Bits 2:0  **SFT[2:0]**: Signal free time  
SFT bits are set by software. In the SFT = 0x0 configuration, the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.  
0x0  
  – 2.5 data-bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST = 1, TXERR = 1, TXUDR = 1 or TXACKE = 1)  
  – 4 data-bit periods if CEC is the new bus initiator  
  – 6 data-bit periods if CEC is the last bus initiator with successful transmission (TXEOM = 1)  
0x1: 0.5 nominal data bit periods  
0x2: 1.5 nominal data bit periods  
0x3: 2.5 nominal data bit periods  
0x4: 3.5 nominal data bit periods  
0x5: 4.5 nominal data bit periods  
0x6: 5.5 nominal data bit periods  
0x7: 6.5 nominal data bit periods
### 62.7.3 CEC Tx data register (CEC_TXDR)

<td>rc_w1</td>
<td>rc_w1</td>
<td>rc_w1</td>
</tr>
</tbody>
</table>

Bits 31:13 Reserved, must be kept at reset value.
Bit 12 **TXACKE:** Tx-missing acknowledge error
In transmission mode, TXACKE is set by hardware to inform application that no acknowledge was received. In case of broadcast transmission, TXACKE informs application that a negative acknowledge was received. TXACKE aborts message transmission and clears TXSOM and TXEOM controls.
TXACKE is cleared by software write at 1.

Bit 11 **TXERR:** Tx-error
In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM controls.
TXERR is cleared by software write at 1.

Bit 10 **TXUDR:** Tx-buffer underrun
In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM control bits.
TXUDR is cleared by software write at 1

Bit 9 **TXEND:** End of transmission
TXEND is set by hardware to inform application that the last byte of the CEC message has been successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.
TXEND is cleared by software write at 1.

Bit 8 **TXBR:** Tx-byte request
TXBR is set by hardware to inform application that the next transmission data has to be written to TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the next byte to TXDR within six nominal data-bit periods before transmission underrun error occurs (TXUDR).
TXBR is cleared by software write at 1.

Bit 7 **ARBLST:** Arbitration lost
ARBLST is set by hardware to inform application that CEC device is switching to reception due to arbitration lost event following the TXSOM command. ARBLST can be due either to a contending CEC device starting earlier or starting at the same time but with higher HEADER priority. After ARBLST assertion TXSOM bit keeps pending for next transmission attempt.
ARBLST is cleared by software write at 1.

Bit 6 **RXACKE:** Rx-missing acknowledge
In receive mode, RXACKE is set by hardware to inform application that no acknowledge was seen on the CEC line. RXACKE applies only for broadcast messages and in listen mode also for not directly addressed messages (destination address not enabled in OAR). RXACKE aborts message reception.
RXACKE is cleared by software write at 1.

Bit 5 **LBPE:** Rx-long bit period error
LBPE is set by hardware in case a data-bit waveform is detected with long bit period error. LBPE is set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still longing. LBPE always stops reception of the CEC message. LBPE generates an error-bit on the CEC line if LBPEGEN = 1. In case of broadcast, error-bit is generated even in case of LBPEGEN = 0.
LBPE is cleared by software write at 1.

Bit 4 **SBPE:** Rx-short bit period error
SBPE is set by hardware in case a data-bit waveform is detected with short bit period error. SBPE is set at the time the anticipated falling edge occurs. SBPE generates an error-bit on the CEC line.
SBPE is cleared by software write at 1.
Bit 3  **BRE**: Rx-bit rising error
BRE is set by hardware in case a data-bit waveform is detected with bit rising error. BRE is set either at the time the misplaced rising edge occurs, or at the end of the maximum BRE tolerance allowed by RXTOL. In case rising edge is still longing, BRE stops message reception if BRESTP = 1. BRE generates an error-bit on the CEC line if BREGEN = 1.
BRE is cleared by software write at 1.

Bit 2  **RXOVR**: Rx-overrun
RXOVR is set by hardware if RXBR is not yet cleared at the time a new byte is received on the CEC line and stored into RXD. RXOVR assertion stops message reception so that no acknowledge is sent. In case of broadcast, a negative acknowledge is sent.
RXOVR is cleared by software write at 1.

Bit 1  **RXEND**: End of reception
RXEND is set by hardware to inform application that the last byte of a CEC message is received from the CEC line and stored into the RXD buffer. RXEND is set at the same time of RXBR.
RXEND is cleared by software write at 1.

Bit 0  **RXBR**: Rx-byte received
The RXBR bit is set by hardware to inform application that a new byte has been received from the CEC line and stored into the RXD buffer.
RXBR is cleared by software write at 1.

### 62.7.6 CEC interrupt enable register (CEC_IER)
Address offset: 0x14
Reset value: 0x0000 0000

**Caution**: It is mandatory to write CEC_IER only when CECEN = 0.

63 Debug infrastructure

63.1 Introduction

The debug infrastructure allows software designers to debug and trace their embedded software.

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port captures data for logging and analysis.

The trace and debug system is designed to support a variety of typical use cases:

- **Low cost trace**
  Limited trace capability is available over the single-wire debug output. This supports code instrumentation using "printf", tracing of data and address watchpoints, interrupt detection and program counter sampling. Single-wire trace can be maintained even when one or both processors are switched off or clock-stopped.

- **Breakpoint debugging of each core independently**
  Both processor cores can be simultaneously and independently debugged using equipment connected to the JTAG/SWD debug port. This allows breakpoint and watchpoint setting, code stepping, memory access, and so on.

- **Synchronous debugging of both cores**
  When one core stops due to a breakpoint or a debugger stop command, the other core can be stopped as well. Similarly, the cores can be restarted at the same time. This allows debugging of loosely coupled applications which require the processors to remain synchronized.

- **Tracing code execution from one or both cores via the trace port**
  Trace information from both cores is combined into a single trace stream and output to a real-time trace port analyzer. An ID embedded in the trace allows the analyzer to identify the source of each information packet.

- **Continuous trace capturing in a circular buffer**
  Instead of streaming it off-chip, the combined trace information can be stored on-chip in a circular buffer. The trace storage can be started and stopped by different means such as a debugger command, a software command, an external trigger signal or an internal event.

- **Draining the buffer to the trace port**
  The stored trace can be dumped off-chip to the trace port analyzer. The buffer draining can be initiated by different means such as debugger, software, external trigger or internal event.

- **Reading the buffer with the debugger**
  The debugger can read the contents of the trace buffer via the debug port. This is slower than the trace port, but allows basic trace functionality on the debugger without the cost of a trace port analyzer.

- **Analyzing stored trace in software**
  The trace buffer can be read by either processor core, or transferred into system memory by DMA. This powerful feature allows built-in test software to monitor real-time
code execution, analyze and identify faults, handle exceptions autonomously, and so on.

- **Uploading stored trace**
  The stored trace can also be uploaded to a host machine using one of the MCU’s many communications interfaces (such as USB, USART, SPI, I2C, Ethernet or CAN). This is especially useful if the trace port is not accessible, for example remote monitoring and failure analysis of a deployed product.

### 63.2 Debug infrastructure features

A comprehensive set of trace and debug features is provided to support software development and system integration:

- Independent breakpoint debugging of each CPU core in the system
- Code execution tracing
- Software instrumentation
- Cross-triggering
- JTAG debug port
- Serial-wire debug port
- Trigger input and output
- Serial-wire trace port
- Trace port
- Arm® CoreSight™ debug and trace components

The CoreSight components are described at high level in this document. Detailed information is available in the Arm® documents referenced in *Section 63.8.*

### 63.3 Debug infrastructure functional description

#### 63.3.1 Debug infrastructure block diagram

The block diagram shows the logical partitioning of the debug infrastructure.
63.3.2 Debug infrastructure pins and internal signals

</tbody>
</table>

1. TRGIO can be configured as an input or an output by the TRGOEN bit in the DBGMCU. If configured as an input, it is connected to TRGIN. If an output, it is connected to TRGOUT. This is because TRGIN and TRGOUT are not available on certain packages.
### 63.3.3 Debug infrastructure powering, clocking and reset

#### Power domains

The debug components are distributed across the power domains D1, D2 and D3. The D3 power domain is always considered to be on when the debugger is connected. It therefore contains the SWJ-DP, so that the debugger does not lose the connection with the SoC when one or both of the other power domains are switched off. In addition, it contains the timestamp generator, the DBGMCU and the serial wire trace features. This allows the Cortex-M7 core to be switched off while still allowing basic trace on the Cortex-M4.

The D1 power domain contains the Cortex-M7 core and the associated debug and trace components. It also contains the system trace components located on the APB-D that are common to both processors. This power domain therefore needs to be on whenever a debug access to the Cortex-M7 is required, or whenever a trace functionality is active on either processor.

The D2 domain contains only the debug and trace components dedicated to the Cortex-M4. This power domain can be switched off without any impact on Cortex-M7 debug and trace.
The debugger supplies the clock for the debug port, SWTCLK, via the debug interface pin, JTCK/SWCLK. This clock is used to register the serial input data in both serial wire and JTAG mode, as well as to operate the state machines and internal logic of the debug port. It must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the DAPCLK domain, which covers the rest of the SWJ-DP and the access ports. The DBGMCU, timestamp generator and System ROM table 1 are also in the DAPCLK domain.

CK_DBG_D3 clocks the SWO and serial wire trace funnel.

Both DAPCLK and CK_DBG_D3 are gated versions of the D3 domain system clock (rcc_hclk4).

CK_DBG_D1 clocks the trace components in the D1 power domain: System ROM table 2, CoreSight trace funnel, ETF, system CTI and TPIU. It is a gated version of the D1 domain system clock (rcc_hclk3).

CK_DBG_D2 is the clock for the D2 domain trace bus components. It is a gated version of the D2 domain system clock (rcc_hclk1).

TRACECLK is the trace port output clock. It is derived from the PLL1 R divider output (pll1_r_ck).
All the debug clocks (except DAPCLK) can be enabled and disabled by register bits in the DBGMCU. The DAPCLK domain is enabled by the debugger using the CDBGPWRUPREQ bit in the debug port CTRL/STAT register. The clock must be enabled before the debugger can access any of the debug features on the device. It should be disabled at power up and when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processors (such as ETM ITM, DWG and FPB) are clocked with the corresponding core clock (rcc_c1_ck and rcc_c2_ck).

**Debug with low-power modes**

The device includes power-saving features allowing individual power domains to be switched off or stopped when not required. If a power domain is switched off or not clocked, all debug components in that domain are inaccessible to the debugger. To avoid this, power saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power saving mode, while the debugger does not lose the connection.

The emulation mode is programmed in the MCU Debug (DBGMCU) unit. For more information, refer to Section 63.5.8

**Reset of debug infrastructure**

The debug components, except for the debug port and access ports, are reset by their respective power domain resets. The debug port (SWJ-DP) is reset by a power-on reset of the D3 domain only.

### 63.4 Debug access port functional description

The debug access port (DAP) is a debug subsystem comprising serial-wire and JTAG debug port (SWJ-DP) and four access ports.

#### 63.4.1 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight component that implements an external access port for connecting debugging equipment.

The port can be configured as:
- a 5-pin standard JTAG debug port (JTAG-DP)
- a 2-pin (clock + data) “serial-wire” debug port (SW-DP)

The two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected on system or power-on reset. The five IOs are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on the JTDI, JTMS/SWDIO, and nJTRST lines, as well as a pull-down resistor on the JTCK/SWCLK line.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO:

```
...(50 or more ones)....0,1,1,1,1,0,0,1,1,1,0,0,1,1,1,...(50 or more ones)...
```

JTCK/SWCLK must be cycled for each data bit.
In SW-DP mode, the unused JTAG lines JTDI, JTDO and nJTRST can be used for other functions.

All SWJ port IOs can be reconfigured to other functions by software, in which case debugging is no longer possible.

**Serial wire debug port**

The Serial wire debug protocol uses two pins:

- **SWCLK**: clock from host to target
- **SWDIO**: bi-directional serial data (100kΩ pull-up required)

Serial data is transferred LSB first, synchronously with the clock. A transfer comprises three phases:

1. packet request (8 bits) transmitted by the host
2. acknowledge response (3 bits) transmitted by the target
3. data transfer (33 bits) transmitted by the host (in the case of a write) or target (in the case of a read)

The data transfer only occurs if the acknowledge response is OK.

If the direction of the data is reversed between each phase, a single clock cycle turn-around time is inserted.

<table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2:0</td>
<td>ACK</td>
<td>000b: FAULT 010b: WAIT 100b: OK</td>
</tr>
</tbody>
</table>
Figure 873 shows successful write and read transfers.

For any FAULT or WAIT ACK response from the target, the data transfer phase is canceled, unless overrun detection is enabled, in which case the data will be ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists of 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the Serial Wire debug protocol, refer to the Arm® Debug Interface Architecture Specification [1].

Note: The SWJ-DP implements SWD protocol version 2.
The JTAG-DP implements a TAP state machine (TAPSM) based on IEEE 1149.1-1990. The state machine is shown in Figure 874. It controls two scan chains, one associated with an instruction register (IR) and one with a number of data registers (DR).

When the TAPSM goes through the Capture-IR state, 0b0001 is transferred to the IR scan chain. The IR scan chain is connected between JTDI and JTDO.

While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:
- The LSB of the IR scan chain is output on JTDO.
- Bit [n] of the IR scan chain is transferred to bit [n-1].
- The value on JTDI is transferred to the MSB of the IR scan chain.

When the TAPSM goes through the Update-IR state, the value scanned in the IR scan chain is transferred to the instruction register.

When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers onto one of the DR scan chains, connected between JTDI and JTDO.
The value held in the instruction register determines which data register, and associated DR scan chain, is selected.

This data is then shifted while the TAPSM is in the Shift-DR state, in the same way as the IR shift in the Shift-IR state.

When the TAPSM goes through the Update-DR state, the value scanned in the DR scan chain is transferred to the selected data register.

When the TAPSM is in the Run-Test/Idle state, no special actions occur. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the Test-Logic-Reset state.

The data registers corresponding to the 4-bit IR instructions are listed in Table 622.

The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification [1].

**Debug port registers**

The SW-DP and JTAG-DP both access the debug port (DP) registers. These are listed in Table 623.

The debugger can access the DP registers as follows:

1. Program the SELECT register DPBANKSEL field in the DP to select the register bank to be accessed (see Table 623).
2. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the R/W bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and R/W fields are part of the Packet Request word sent to the SW-DP with the APnDP bit reset (see Table 619). The write data is sent in the data phase.

The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification [1].

**Debug port registers**

The SW-DP and JTAG-DP both access the debug port (DP) registers. These are listed in Table 623.

The debugger can access the DP registers as follows:

1. Program the SELECT register DPBANKSEL field in the DP to select the register bank to be accessed (see Table 623).
2. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the R/W bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and R/W fields are part of the Packet Request word sent to the SW-DP with the APnDP bit reset (see Table 619). The write data is sent in the data phase.

| Bit 27 | CDBGWRUPACK | Debug domain power-up status bit
This bit is read-only. It returns the status of the debug domain power-up acknowledge signal from the power controller.
0: domain powered down
1: domain powered up

| Bit 26 | CDBGWRUPREQ | Debug domain power-up/down control bit
This bit controls the debug domain power-up/down request signal to the power controller.
0: power-down requested
1: power-up requested

| Bit 23 | CSYSPWRUPACK: System domain power-up status bit - not used in this device
| Bit 22 | CSYSPWRUPREQ: System domain power-up control bit - not used in this device
| Bit 19 | CDBGWRUPACK: Debug domain power-up status bit
This bit is read-only. It returns the status of the debug domain power-up acknowledge signal from the power controller.
0: domain powered down
1: domain powered up

| Bit 18 | CSYSPWRUPREQ: System domain power-up control bit - not used in this device
| Bit 17 | CDBGWRUPACK: Debug domain power-up status bit
This bit is read-only. It returns the status of the debug domain power-up acknowledge signal from the power controller.
0: domain powered down
1: domain powered up

| Bit 16 | CDBGWRUPREQ: Debug domain power-up/down control bit
This bit controls the debug domain power-up/down request signal to the power controller.
0: power-down requested
1: power-up requested

Bit 27  **CDBGWRSTACK**: Debug domain reset status bit - not used in this device
Bit 26 **CDBGRSTREQ**: Debug domain reset control bit - not used in this device

Bits 25:24 Reserved, must be kept at reset value.

Bits 23:12 **TRNCNT[11:0]**: Transaction counter

To program a sequence of transactions to incremental addresses via an AP, TRNCNT bits are loaded with the number of transactions to perform. It is decremented on successful completion of each transaction.

Bits 11:8 **MASKLANE[3:0]**: Pushed-compare and pushed-verify masking bits

The field indicates the bytes to be masked in pushed-compare and pushed-verify operations (DP_CTRL/STAT register’s field TRNMODE = 1 or 2). In the pushed operations, the word supplied in an AP write transaction is compared with the current value at the target AP address.

- 0b1XXX: include byte lane 3 in comparisons
- 0bX1XX: include byte lane 2 in comparisons
- 0bXX1X: include byte lane 1 in comparisons
- 0bXXX1: include byte lane 0 in comparisons

Bit 7 **WDATAERR**: Write data error in SW-DP

The bit indicates

- a parity or a framing error on the data phase of a write operation, or
- a write operation that had been accepted by the DP has then been discarded without being submitted to the AP

This bit is read-only. It is reset by writing 1 to the WDERRCLR bit of the DP_ABORT register.

0: No error
1: Error has occurred

This bit is reserved in JTAG-DP.

Bit 6 **READOK**: AP read response in SW-DP

This bit indicates the response to the last AP read access. It is read-only.

0: Read not OK
1: Read OK

This bit is Reserved in JTAG-DP.

Bit 5 **STICKYERR**: Transaction error (read-only in SW-DP, R/W in JTAG-DP)

This bit indicates that an error occurred during an AP transaction.

0: No error
1: Error has occurred

In the SW-DP, this bit is reset by writing 1 to the STKERRCLR bit of the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.
Bit 4 **STICKYCMP**: Compare match (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that a match occurred in a pushed operation.

- 0: Match if TRNMODE = 0x1; no match if TRNMODE = 0x2
- 1: No match if TRNMODE = 0x1; match if TRNMODE = 0x2

In the SW-DP, this bit is reset by writing 1 to the STKCMPCLR bit in the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.

Bits 3:2 **TRNMODE[1:0]**: Transfer mode for AP write operations
For read operations, this field must be set to 0x0.

- 0x0: Normal operation - AP transactions are passed directly to the AP.
- 0x1: Pushed-verify operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read operation is compared with the stored data. If they do not match, the STICKYCMP bit is set.
- 0x2: Pushed-compare operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read is compared with the stored data. If they match, the STICKYCMP bit is set.
- 0x3: Reserved

In pushed operations, only the data bytes indicated by the MASKLANE field are included in the comparison.

Bit 1 **STICKYORUN**: Overrun (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that an overrun occurred (new transaction received before previous transaction completed). This bit is only set if the ORUNDETECT bit is set.

- 0: No overrun
- 1: Overrun occurred

In the SW-DP, this bit is reset by writing 1 to the ABORT register’s ORUNERRCLR bit. In the JTAG-DP, this bit is reset by writing a 1 to it.

Bit 0 **ORUNDETECT**: Overrun detection mode enable

- 0: Overrun detection disabled
- 1: Overrun detection enabled. In the event of an overrun, the STICKYORUN bit is set and subsequent transactions are blocked until the STICKYORUN bit is cleared.

Bits 31:28 **TINSTANCE[3:0]**: Target instance number
The field defines the instance number for the target device in a multi-drop system. It must be programmed with the same value as TINSTANCE field of DP_DLPIDR register, in order to select this device.

Bits 27:12 **TPARTNO[15:4]**: Target part number
The field defines the part number for the target device. It must be programmed with the same value as TPARTNO field of DP_TARGETID register, in order to select this device.

Bits 11:1 **TDESIGNER[10:0]**: Target designer JEDEC code
The field defines the JEDEC code for the target device. It must be programmed with the same value as TDESIGNER field of DP_TARGETID register, in order to select this device.

Bit 0 Reserved, must be kept at reset value.

### 63.4.2 Access ports

**Figure 875. Debug and access port connections**
The access ports (AP) attached to the DP as the following:

1. **AP0**: Cortex-M7 access port (AHB-AP). Allows access to the debug and trace features integrated in the Cortex-M7 processor core via an AHB-Lite bus connected to the AHBD port of the processor.

2. **AP1**: D3 access port (AHB-AP). Allows access to the bus matrix in the D3 domain. This gives visibility of the D3 domain memory and peripherals when the D1 and D2 domains are switched off. No CoreSight components are accessible via this port.

3. **AP2**: System access port (APB-AP). Allows access to the debug and trace features on the system APB debug bus, that is, all components not included in one of the processor cores.

4. **AP3**: Cortex-M4 access port (AHB-AP). Allows access to the debug and trace features integrated in the Cortex-M4 processor core via its internal AHB bus.

All access ports are of MEM-AP type, that is, the debug and trace component registers are mapped in the address space of the associated debug bus. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 624.

The address of the AP registers is composed of:

- bits [7:4]: content of the DP_SELECT register’s APBANKSEL field
- bits [3:2]: content of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 622) or of the SW-DP Packet Request (see Table 619), depending on the debug interface used
- bits [1:0]: Always set to 0

The content of the SELECT register APSEL field in the DP define which MEM-AP is being accessed.

The debugger can access the AP registers as follows:

1. Program the DP_SELECT register’s APSEL field to choose one of the APs, and the APBANKSEL field to select the register bank to be accessed.

2. Program the A(3:2) field in the APACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the Packet Request word sent to the SW-DP with the APnDP bit set (see Table 619). The write data is sent in the data phase.

The debugger can access the memory mapped debug component registers through the MEM-AP registers (using the AP register access procedure described above) as follows:

1. Program the transaction target address in the TAR register.

2. Program the CSW register, if necessary, with the transfer parameters (AddrInc for example).

3. Write to or read from the DRW register to initiate a bus transaction at the address held in the TAR register. Alternatively, a read or write to banked data register BDn triggers an access to address TAR[31:4] + n (this allows accessing up to four consecutive addresses without changing the address in the TAR register).

For more detailed information on the MEM-AP, refer to the Arm® Debug Interface Architecture Specification [1]. To use the MEM-AP to connect the debug port to the debug components (in the example, a processor, an ETM and a ROM table), go to Section 63.6.2:
**Cortex-M7 data watchpoint and trace unit (DWT) and Section 63.7.2: Cortex-M4 data watchpoint and trace unit (DWT).**

Bit 31  Reserved, must be kept at reset value.

Bit 30  **SPROT**: Secure transfer request bit
In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attribute HPROT[6] of the bus transfer.
0: If SPIDEN is high, secure transfer. If SPIDEN is low, non-secure transfer.
1: Non-secure transfer.

Bit 29  Reserved, must be kept at reset value.

Bits 28:24  **PROT[4:0]** Bus transfer protection bits
In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attributes HPROT[4:0] of the bus transfer.
0bXXXX0: Instruction fetch
0bXXXX1: Data access
0bXXXXX: User mode
0bXXX1X: Privileged mode
0bXX0XX: Non-bufferable
0bXX1XX: Bufferable
0bX0XXX: Non-cacheable
0bX1XXX: Cacheable
0b0XXXX: Non-exclusive
0b1XXXX: Exclusive

Bit 23  **SPISTATUS**: Status of SPIDEN option bit
This bit determines whether the debugger can access secure memory. This field is reserved in the APB-AP.
0: Secure AHB transfers are blocked
1: Secure AHB transfers are allowed

Bits 22:12  Reserved, must be kept at reset value.

Bits 11:8  **MODE[3:0]**: Barrier support enabled bit
These bits define if the memory barrier operation is supported.
0x0: Not supported

Bit 7  **TRINPROG**: Transfer in progress
This bit indicates that an AP bus transfer is in progress.
0: No transfer in progress.
1: Bus transfer in progress.
Bit 6 DEVICEEN: Device Enable bit
This bit defines whether the AP can be accessed or not.

1: AP access enabled.

Bits 5:4 ADDRINC[1:0]: Auto-increment mode bits
These bits define whether the TAR address is automatically incremented after a transaction.

0x0: no auto-increment
0x1: Address is incremented by the size in bytes of the transaction (SIZE field).
0x2: Packed transfers enabled (Only in AHB-APs - reserved in APB-AP). A 32-bit AP access generates a 1 x 32-bit, 2 x 16-bit or 4 x 8-bit bus transaction corresponding to the programmed transaction size. The data is packed or unpacked accordingly.
0x3: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 SIZE[2:0]: Size of next memory access transaction (only for AHB-APs)

0x0: Byte (8-bit)
0x1: Half-word (16-bit)
0x2: Word (32-bit)
0x3-0x7: Reserved

For APB-AP, this field is read-only and fixed at 0x2 (32-bit).

Access port base address register (AP_BASE)

Address offset: 0xF8
Reset value: 0xE00F E003 (AP0), 0x0000 0002 (AP1), 0xE00E 0003 (AP2), 0xE00F F003 (AP3)

   0x02: APB-AP (AP2)
   0x11: Cortex-M4 AHB-AP (AP3)
63.5 Trace and debug subsystem functional description

The trace and debug subsystem features the following CoreSight components:

- System ROM tables
- Global timestamp generator (TSG)
- System cross-trigger interface (CTI)
- Cross-trigger matrix (CTM)
- Trace port interface unit (TPIU)
- Trace bus funnel (CSTF)
- Embedded trace FIFO (ETF)
- Serial wire output (SWO)
- Serial wire output trace funnel (SWTF)

These components are accessible by the debugger via the system APB-AP and its associated APB-D debug bus. They are also accessible by the Cortex-M7 and Cortex-M4 processors.

The MCU debug unit (DBGMCU) is also accessed via the APB-D. This non-CoreSight component contains registers for configuring the device behavior in Debug mode.

Trace bus replicators branch the trace bus from the CPU’s ITM CoreSight component to ETF and SWO, through trace bus funnels.

63.5.1 System ROM tables

There are two ROM tables on the APB-D bus. The ROM table is a CoreSight component that contains the base addresses of all the CoreSight components on the APB-D bus. These tables allow a debugger to access the topology of the CoreSight components automatically.

The first table points to the second table, and to the CoreSight components located in D3 power domain: SWO, SWTF, TSG. The DBGMCU is not referenced by the table as it is not a standard CoreSight component. The table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00E0000 to 0xE00E0FFC when accessed by the debugger, and from 0x5C000000 to 0x5C000FFC when accessed from the system bus.

Table 625. System ROM table 1

<table>
<thead>
<tr>
<th>Address offset in ROM table</th>

<td>0x00005003</td>
</tr>
</tbody>
</table>
The second table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00F0000 to 0xE00F0FFC when accessed by the debugger, and from 0x5C010000 to 0x5C010FFC when accessed from the system bus.

<td>See System ROM registers</td>
</tr>
</tbody>
</table>

The top of each ROM table contains a number of read-only registers, including the standard CoreSight component and peripheral identity registers, see section System ROM registers.

Each debug component occupies one or more 4 Kbyte blocks of address space. This block of address space is referred to as the debug register file for the component.

The component address offset field of a ROM Table entry points to the start of the last 4 Kbyte block of the address space of the component. This block always contains the component and peripheral ID registers for the component, starting at offset 0xFD0 from the start of the block. The 4 Kbyte count field PIDR4 [7:4], specifies the number of 4 Kbyte blocks for the component. Therefore, the process for finding the start of the address space for a component is:
1. Read the ROM-table entry for the component and extract its Address_Offset[18:0] from bits [31:12] of the ROM-table entry.

2. Use the address offset, together with the base address of the ROM table, ROM_Base_Address, to calculate the base address of the component:
   
   \[ \text{Component Base Address} = \text{ROM Base Address} + \text{Address Offset} \]

   The Component Base Address is the start address of the 4 Kbyte block of the address space for the component.

3. Read the peripheral ID4 register for the component. The address of this register is:
   
   \[ \text{Peripheral ID4 address} = \text{Component Base Address} + 0xFD0 \]

4. Extract the 4 Kbyte count field [7:4] from the value of the Peripheral ID4 Register.

5. Use the 4 Kbyte count field value to calculate the start address of the address space for the component. If the field value is 0b0000, which corresponds to a count value of 1, the address space for the component starts at Component Base Address obtained at stage 2.

The topology for the CoreSight components on the APB-D is shown in Figure 876.
For more information on the use of the ROM table, refer to the Arm® Debug Interface Architecture Specification [1].

63.5.2 **Global timestamp generator (TSG)**

The global timestamp generator contains a 64-bit counter that provides a common timing reference for all of the trace sources in the system, namely the ETM and ITM in each processor core. These components insert timestamps in the trace streams that allow the trace analyzer to recover the chronological order of trace packets, which can be lost when multiple trace sources are multiplexed into one stream at the funnels.

The TSG registers are accessible over the APB-D. This allows the debugger or debug software to:
- start and stop the timestamp incrementing
- read the current timestamp value
- change the current timestamp value
  - The timestamp counter must be halted while it is changed. When the timestamp value is changed, the timestamp generator resynchronizes all the trace sources.
- change the reported timestamp increment

For more information on the global timestamp generator CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

The timestamp generator is located in the D3 power domain, and the timestamp is distributed to the Cortex-M7 and Cortex-M4. To simplify the distribution over power domain
boundaries, the 64-bit timestamp is encoded in seven bits, then decoded in the destination power domain, and interpolated to increase its resolution if the processor clock is significantly faster than the generator clock. The timestamp distribution is shown in Figure 877.

Figure 877. Global timestamp distribution

Bits 31:0 **CNTCVU[15:0]**: TSG current counter value field, bits[63:32]  
To change the current timestamp value, write the lower 32 bits of the new value to CNTCVUL before writing the upper 32 bits to this register. The 64-bit timestamp value is updated with the value from both writes when this register is written to. Note: The TSG_CNTCR register’s EN bit must be cleared before writing to this register.

### 63.5.3 Cross trigger interfaces (CTI) and matrix (CTM)

The cross trigger interfaces (CTI) and cross trigger matrix (CTM) together form the CoreSight embedded cross trigger feature. There are three CTI components, one at system level, one dedicated to the Cortex-M7 and one dedicated to the Cortex-M4. The three CTIs are connected to each other via the CTM. The system-level CTI and the Cortex M4 CTI are accessible to the debugger via the system access port and associated APB-D. The Cortex-M7 CTI is physically integrated in the Cortex-M7 core, and is accessible via the Cortex-M7 access port and associated AHBD.
The CTIs allow events from various sources to trigger debug and/or trace activity. For example, a breakpoint reached in one of the processor cores can stop the other processor, or a transition detected on an external trigger input can start code trace.

Each CTI has up to 8 trigger inputs and 8 trigger outputs. Any input can be connected to any output, on the same CTI, or on another CTI via the CTM.
The trigger input and output signals for each CTI are listed in Table 630 to Table 635.

</table>
There are four event channels in the cross trigger matrix, which allows up to four parallel bidirectional connections between trigger inputs and outputs on different CTIs. To connect input number \( m \) on CTI \( x \) to output number \( n \) on CTI \( y \), the input must be connected to an event channel \( p \) using the CTIINEN\( m \) register of CTI \( x \). The same channel \( p \) must be connected to the output using the CTIOUTEN\( n \) register of CTI \( y \). Note: this applies even if the input and output belong to the same CTI.

An input can be connected to more than one channel (up to four), so an input can be routed to several outputs. Similarly, an output can be connected to several inputs. It is also possible to connect several inputs/outputs to the same channel.

Example configurations:

When either CPU core hits a breakpoint, stop the other core. Restart the two cores synchronously.

To stop both cores when either core stops requires the HALTED output of each core to be connected to the EDBGRQ input of the opposite core.

As shown in Table 632 and Table 634, the HALTED signal from the Cortex-M7 core is connected to input 0 of the Cortex-M7 CTI, and the same signal from the Cortex-M4 core is connected to the same input on the Cortex-M4 CTI. Hence the CTIINEN0 register on each CTI is programmed such as to connect these inputs to a CTM channel (for example channel 0).
As shown in Table 633 and Table 635, the EDBGRQ signals to the CPUs are connected to output 0 of the respective CTIs. Therefore, the CTIOUTEN0 register of each CTI should be programmed such as to connect these outputs to the same CTM channel.

To restart both cores simultaneously the debugger must use the APPPULSE register in either of the CTIs. This allows the debugger to generate a pulse on any of the four ETM channels. The channel must be connected to the DBGRESTART signal of both cores.

As shown in Table 633 and Table 635, the DBGRESTART signals to the CPUs is are connected to output 1 of the respective CTIs. Therefore, the CTIOUTEN1 register of each CTI should be programmed such as to connect these outputs to an unused CTM channel (for example channel 1).

The above configuration is illustrated in Figure 880.

Figure 880. Cross trigger configuration example

To force the processors to restart simultaneously, the debugger should use the following procedure:

1. Clear the debug request by writing 0x01, then 0x00, to the CTIINTACK register in each CTI.
2. Cause a pulse on channel 1 by writing 0x02 to the APPPULSE register in either CTI. This will generate a restart request to both processors. Note that the debugger can also force both cores to stop simultaneously by writing 0x01 to the APPPULSE register in either CTI, which generates a pulse on channel 0.

For more information on the cross-trigger interface CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].
**CTI registers**

The register file base address for each CTI is defined by the ROM table for the bus to which it is connected. The registers are the same for each CTI.

**CTI control register (CTI_CONTROL)**

Address offset: 0x000

Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **CLAIMSET[3:0]**
Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0 **CLAIMSET[3:0]**: Set claim tag bits

Write:
- 0000: No effect
- xxx1: Set bit 0
- xx1x: Set bit 1
- x1xx: Set bit 2
- 1xxx: Set bit 3

Read:
- 0xF: Indicates there are four bits in claim tag

**CTI claim tag clear register (CTI_CLAIMCLR)**

Address offset: 0xFA4
Reset value: 0x0000 0000

3290/3556 RM0399 Rev 4
63.5.4 Trace funnel (CSTF)

The trace funnel is a CoreSight component that combines the ATB buses from four trace sources into one single ATB. The CSTF has four ATB slave ports, and one ATB master port. An arbiter selects the slave ports according to a programmable priority.

The slave ports are connected as follows:
- S0: Cortex-M7 ETM
- S1: Cortex-M7 ITM
- S2: Cortex-M4 ETM
- S3: Cortex-M4 ITM

The CSTF registers allow the slave ports to be individually enabled, and their priority settings to be configured. The priorities can be modified only when trace is disabled. The arbitration works as follows:
- The arbiter selects the slave port with the highest assigned priority that has data valid
- Up to min_hold_time transfers are passed from the selected slave to the master port, where min_hold_time is programmable in the CONTROL register.
- A new arbitration is then performed

High priority should be assigned to slave ports connected to sources with a small amount of buffering, or where data loss can not be tolerated. Low priority should be assigned to less critical sources or those with large buffers.

For more information on the ATB Funnel CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

Trace funnel registers

CSTF control register (CSTF_CTRL)

</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 LOCKTYPE: Size of the CSTF_LAR register
0: 32-bit

Bit 1 LOCKGRANT: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 LOCKEXIST: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented
CSTF authentication status register (CSTF_AUTHSTAT)

63.5.5 Embedded trace FIFO (ETF)

The ETF is a 4 Kbyte memory that captures trace data from four trace sources, namely the ETM and ITM of each CPU core. The ETF is a design configuration of the CoreSight™ trace memory controller component.

The ETF can be used in three modes (selected in the mode register):
1. Hardware FIFO mode

   The trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured into the trace RAM and when full, the incoming trace stream is
 stalled. When the Trace buffer is not empty, trace data is drained out through the ATB master interface to the TPIU.
In this mode, the role of the FIFO is to smooth the flow of trace information arriving at the trace port. Since the trace data can be very irregular by nature, the peak data rate can easily exceed the port capability, resulting in an overflow. The ETF allows a steady data rate at the trace port, which can then be sized according to the average rate rather than the peak. The trace is stored off-chip in real time by the trace port analyzer tool, and so the trace log can be very big.

2. Software FIFO mode
The trace memory is used as a FIFO that can be read through the RRD Register while trace is being captured. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled.
This mode allows the trace to be transferred by DMA into the system memory, or to a high speed interface (such as SPI or USB), or even monitored by software running on one of the cores. Note that unlike the hardware FIFO mode, this mode is invasive, since it uses system resources which are shared by the processors.

3. Circular buffer mode
The trace memory is used as a circular buffer. Trace data is captured into the Trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten to the trace memory until a stop condition occurs.
In this mode, the ETF stores the trace data on-chip, so the trace log size is limited to that of the ETF SRAM, 4 Kbytes in this case. Being a circular buffer, when the FIFO becomes full, incoming trace data overwrites the oldest stored data and the oldest stored data is lost. Therefore the content of the trace buffer represents the most recent activity of the processor(s), before the buffer was stopped, rather than all the activity since the trace was started.
There are three possible methods to read out the buffer contents once the trace stops:
– via the Trace port - with the TPIU enabled, the content of the buffer is output over the Trace port. This can be done by setting the DRAINBUF bit in the ETF_FFCR register.
– via the Debug port - the debugger can read the buffer via the RRD register that is accessible over the system APB-D.
– by software - either processor can read the buffer via the RRD register, since the APB-D is accessible from the system bus.
The ETF can be moved to any one of the following states:

- **Disabled**
  This state is entered after a reset, or when trace capture is disabled. The ETF must only be programmed in this state.

- **Running**
  Trace capture is performed in this state. It is entered by enabling trace capture while in disabled state.

- **Stopped**
  Trace capture is stopped in this state, but the contents of the buffer can be read out or drained. This state is entered after a stop event (trigger or flush).

- **Disabling**
  This is a transition state while disabling trace capture.

- **Stopping**
  This is a transition state while stopping trace capture.

- **Draining**
  This state is entered while draining the buffer in Stopped state.

The state transition diagram is shown in Figure 881.

For more information on the CoreSight™ trace memory controller component, refer to the Arm® CoreSight™ trace memory controller technical reference manual [3].

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 EMPTY: Trace FIFO empty  
This bit is valid only when the TCEN bit of the ETF_CTL register is high. This bit reads as zero when TCEN is low.

0: Trace FIFO contains data  
1: Trace FIFO is empty.

Note: Empty trace FIFO does not mean that the ETF pipeline is empty. The latter is indicated by the FTEMPY bit.

Bit 3 FTEMPY: Formatter empty  
This bit is set when trace capture has stopped, and all internal pipelines and buffers have been drained. Unlike READY, it is not affected by buffer drains. The ACQCOMP output reflects the value of this bit.
Bit 2  **READY**: ETF ready  
This bit is set when trace capture has stopped and all internal pipelines and buffers have been drained (Stopped or Disabled state)

Bit 1  **TRIGD**: Triggered  
The Triggered bit is set when trace capture is in progress and the TMC has detected a Trigger Event. This bit is cleared when leaving Disabled state.  
This bit is operational only in the Circular buffer mode. In all other modes, this bit is always low.  
This bit does not indicate that a trigger has been embedded in the formatted output trace data from the TMC. Trigger indication on the output trace stream is determined by the programming of the Formatter and Flush Control Register, ETF_FFCR.

Bit 0  **FULL**: Trace buffer full  
In circular buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer, and remains set until the TCEN bit of the ETF_CTL register is cleared and set.  
In software and hardware FIFO modes, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the ETF_BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM.  
This bit is cleared when leaving Disabled state. The FULL output reflects the value of this register bit.

**ETF RAM read data register (ETF_RRD)**

Address offset: 0x010  
Reset value: Unknown

**Bits 31:0**  **RRD[31:0]**: RAM Read Data.  
Circular buffer mode:  
When in Stopped state and the buffer is not empty, reading this register returns the next word of data from the trace buffer. When the whole trace buffer has been read, the Empty bit in the ETF_STS Register is set, and subsequent reads return 0xFFFFFFFF. Reading this register when not in Stopped state returns 0xFFFFFFFF.

Software FIFO mode:  
Reading this register returns data from the FIFO. If this register is read when the FIFO is empty, the data returned is 0xFFFFFFFF.

Hardware FIFO mode:  
Reading this register returns 0xFFFFFFFF.
ETF RAM read pointer register (ETF_RRP)

Address offset: 0x014
Reset value: 0x0000 0000

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **RRP[12:0]:** RAM Read Pointer

The RAM Read Pointer Register contains the value of the read pointer that is used to read entries from the trace memory over the APB interface via the ETF_RRD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been written. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.

ETF RAM write pointer register (ETF_RWP)

Address offset: 0x018
Reset value: 0x0000 0000

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:0  **RWP[12:0]:** RAM write pointer

The RAM write pointer register contains the value of the write pointer that is used to write entries into the trace memory over the APB interface via the ETF_RWD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been read. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.
ETF trigger counter register (ETF_TRG)

<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:0  TRG[10:0]: Trigger counter

In Circular buffer mode, specifies the number of 32-bit words to capture in the trace RAM following the detection of either a rising edge on the TRIGIN input or a trigger packet in the incoming trace stream, ATID =7’h7D. On capturing the specified number of data words, a trigger event occurs. The effect of a trigger event on the ETF behavior is controlled by the FFCR Register.

The number of 32-bit words written into the trace RAM following the trigger is the value stored in this register, plus one. This register is ignored when the ETF is in Software FIFO mode or Hardware FIFO mode. When the trigger counter starts counting, any additional triggers, either on TRIGIN or in the incoming trace stream, are ignored until the counter reaches zero. When the trigger counter has reached zero, it remains at zero until it is re-programmed with a write to this register.

This register is cleared when READY goes high, so that the state of the counter when trace capture has stopped does not affect a subsequent trace capture session. Writing to this register when not in Disabled state results in unpredictable behavior.

A read access to this register is permitted at any time when in Disabled state, or in Circular buffer mode. A read access returns the current value of the trigger counter.

Bits 31:1  Reserved, must be kept at reset value.

Bit 0  **TCEN:** Trace capture enable
When writing:
0: Disable trace capture (moves from Running, Stopping or Stopped state into Disabling or Disabled state)
1: Enable trace capture (moves from Disabled state to Running state)

When reading, this bit is low when in Disabling or Disabled states, and high otherwise.
Bits 1:2 Reserved, must be kept at reset value.

Bits 1:0 MODE[1:0]: Operation mode
- 00b: Circular buffer mode
  In this mode, the trace memory is used as a circular buffer. Trace data is captured into the Trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten into the trace memory until a stop condition has occurred.
- 01b: Software FIFO mode
  In this mode, the trace memory is used as a FIFO that can be read through the RRD Register while trace is being captured. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled.
- 10b: Hardware FIFO mode
  In this mode, the trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled. When the trace buffer is non-empty, trace data is drained out through the ATB master interface to the TPIU.
- 11b: Reserved

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 LBÚFLEVEL[11:0]: Latched buffer fill level
Reading this register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level.
When entering Disabled state, this register retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL register is cleared.
This register is used for performance analysis of the trace system.

RM0399 Rev 4 3309/3556
ETF buffer level watermark register (ETF_BUFWM)

Address offset: 0x034
Reset value: 0x0000 0000

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **CBUFLEVEL[11:0]**: Current buffer fill level

Reading this register returns the current fill level of the trace memory in 32-bit words.
This register is cleared when TCEN is low.

ETF formatter and flush status register (ETF_FFSR)

Address offset: 0x300
Reset value: 0x0000 0002

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **BUFWM[10:0]**: Buffer level watermark

The value programmed into this register indicates the required threshold vacancy level in the trace memory in 32-bit words. When the space in the FIFO is less than or equal to this value, that is, Fill level >= MEM_SIZE - BUFWM, the FULL output is pulled high and the FULL bit in the STS Register is set.

This register is used only in Software FIFO and Hardware FIFO modes. In Circular buffer mode, this functionality can be obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the FULL bit is set indicating that the vacancy level has fallen below the required level.

The maximum value that can be written into this register is MEM_SIZE - 1. In this case, the FULL bit output is asserted after the first 32-bit word is written to trace memory.
Writing to this register other than when in disabled state results in unpredictable behavior.
Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **FTSTOPPED**: Formatter stopped
This bit behaves in the same way as the FTEMPTY bit in the ETF_STS register.

Bit 0  **FLINPROG**: Flush in progress
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the ETF_FFCR register, or requested by the ATB master port.

0: No flush in progress
1: Flush in progress

**ETF formatter and flush control register (ETF_FFCR)**

Address offset: 0x304
Reset value: 0x0000 0000

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     | rw     |

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **DRAINBUF**: Drain buffer
This bit is used to enable draining of the trace data through the ATB master interface after the formatter has stopped. This is useful in Circular buffer mode to capture trace data into trace memory and then to drain the captured trace through the ATB master interface.
Writing a one to this bit when in Stopped state starts the drain of the trace buffer content through the ATB Master interface. This bit always reads as zero. The READY bit in the ETF_STS register goes low while the drain is in progress.
This bit is only functional when the ETF is in Circular buffer mode and formatting is enabled, that is, the ENFT bit in the ETF_FFCR register is set. Setting this bit when the ETF is in any other mode, or when not in Stopped state, results in Unpredictable behavior.
When trace capture is complete in Circular buffer mode, all of the captured trace must be retrieved from the trace memory through the same mechanism, either read all trace data out through RRD reads, or drain all trace data by setting the DRAINBUF bit. Setting the DRAINBUF bit after some of the captured trace has been read out through RRD results in unpredictable behavior.

Bit 13  **STPONTRGEV**: Stop on trigger event
0: No effect
1: Stop trace capture when a trigger event occurs

Enabling the ETF in Software FIFO mode or Hardware FIFO mode with this bit set results in unpredictable behavior.
Bit 12 **STOPONFL**: Stop on flush  
0: No effect  
1: Stop trace capture when flush is completed

If a flush is initiated by the ATB master interface, its completion does not lead to a formatter stop regardless of the value programmed in this bit.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **TRIGONFL**: Trigger on flush  
0: No effect  
1: Indicate a trigger in the trace stream when flush is completed

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.  
If a flush is initiated by the ATB master interface, its completion does not lead to a trigger indication regardless of the value programmed in this bit.

Bit 9 **TRGONTRGEV**: Trigger on trigger event  
0: No effect  
1: Indicate a trigger in the trace stream when trigger event occurs

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.  
This bit is not supported in Software FIFO mode or Hardware FIFO mode.

Bit 8 **TRGONTRGIN**: Trigger on trigger in  
0: No effect  
1: Indicate a trigger in the trace stream when a rising edge is detected on the TRIGIN input.

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FLUSHMAN**: Manual flush  
0: No effect  
1: Flush the trace FIFO and pipeline

This bit is cleared automatically when the flush completes. If the TCEN bit in the ETF_CTL register is 0, writes to this bit are ignored.

Bit 5 **FONTRGEV**: Flush on trigger event  
0: No effect  
1: Flush the trace FIFO and pipeline if a trigger event occurs

This bit is not supported in Software FIFO mode or Hardware FIFO mode. If STPONTRGEV is set, this bit is ignored.

Bit 4 **FONFLIN**: Flush on flush in  
0: No effect  
1: Flush the trace FIFO and pipeline if when a rising edge is detected on the FLUSHIN input
ETF periodic synchronization counter register (ETF_PSCR)

Address offset: 0x308
Reset value: 0x0000 000A

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **PSCOUNT[4:0]**: Synchronization counter reload value

Determines the reload value of the Synchronization Counter. The reload value takes effect the next time the counter reaches zero. Reads from this register return the reload value programmed into this register. This register is set to 0xA on reset, corresponding to a synchronization period of 1024 bytes.

0x0: Synchronization disabled
0x1-0x6: Reserved
0x7-0x1B: Synchronization period is \(2^{\text{PSCOUNT}}\) bytes
0x1C-0x1F: Reserved
ETF claim tag set register (ETFCLAIMSET)

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the ETF_LAR register
- 0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
- This bit always returns zero when read by an external debugger.
  - 0: Write access is permitted
  - 1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
- The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  - 0: No lock control mechanism exists
  - 1: Lock control mechanism is implemented

Table 638. ETF register map and reset values (continued)
63.5.6 Trace port interface unit (TPIU)

The TPIU is a CoreSight™ component that formats the trace stream and outputs it on the external trace port signals. The TPIU has a single ATB slave port for incoming trace data. The trace port is a synchronous parallel port, comprising a clock output, TRACECK, and four data outputs, TRACED(7:0). The trace port width is programmable in the range 1 to 8. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes. However it restricts the bandwidth of the trace port and hence the quantity of trace information that can be output in real time. The TRACECK output must be enabled by setting the TRACECLKEN bit in the DBGMCU_CR register before trace is sent to the TPIU. Furthermore, the TRACECK frequency can be programmed in the RCC.

For more information on the Trace port interface CoreSight™ component, refer to the Arm® CoreSight™ SoC-400 technical reference manual [2].
TPIU registers

**TPIU supported port size register (TPIU_SUPPSIZE)**

Address offset: 0x000

Reset value: 0x0000 000F

**Bits 31:8** Reserved, must be kept at reset value.

**Bits 7:0 ** **TRIGCOUNT[7:0]**: Enable trigger delay indication

Enables delaying trigger flagging to any external connected trace capture or storage devices. This counter is only eight bits wide and is intended to be used only with the counter multipliers in the Trigger multiplier register, 0x108. When a trigger is started, this value, in conjunction with the multiplier, specifies the number of words before the trigger is indicated. When the trigger counter reaches 0, the value written here is reloaded. Writing to this register causes the trigger counter value to reset but does not reset any value on the multiplier. Reading this register returns the preset value, not the current count.
TPIU trigger multiplier register (TPIU_TRGMULT)

Address offset: 0x108
Reset value: 0x0000 0000

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  MULT64K: Multiply the trigger counter by 65536
0: Disabled
1: Enabled

Bit 3  MULT256: Multiply the trigger counter by 256
0: Disabled
1: Enabled

Bit 2  MULT16: Multiply the trigger counter by 16
0: Disabled
1: Enabled

Bit 1  MULT4: Multiply the trigger counter by 4
0: Disabled
1: Enabled

Bit 0  MULT2: Multiply the trigger counter by 2
0: Disabled
1: Enabled

TPIU supported test patterns/modes register (TPIU_SUPTPM)

Address offset: 0x200
Reset value: 0x0003 000F
Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **PCONTEN**: Continuous mode support
1: Supported

Bit 16  **PTIMEEN**: Timed mode support
1: Supported

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **PATF0**: Support of FF/00 pattern
Indicates whether the FF/00 pattern is supported as output over the trace port.
1: Supported

Bit 2  **PATA5**: Support of AA/55 pattern
Indicates whether the AA/55 pattern is supported as output over the trace port.
1: Supported

Bit 1  **PATW0**: Support of walking 0’s pattern
Indicates whether the walking 0’s pattern is supported as output over the trace port.
1: Supported

Bit 0  **PATW1**: Support of walking 1’s pattern
Indicates whether the walking 1’s pattern is supported as output over the trace port.
1: Supported

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **TCPRESENT**: TRACECTL output pin availability
Indicates whether the optional TRACECTL output pin is available for use.

0: TRACECTL pin is not present in this device.

Bit 1 **FTSTOPPED**: Formatter stopped
The formatter has received a stop request signal and all trace data and post-amble is sent. Any additional trace data on the ATB interface is ignored.

0: Formatter has not stopped
1: Formatter has stopped

Bit 0 **FLINPROG**: Flush in progress
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.

0: No flush in progress
1: Flush in progress

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **STOPTRIG**: Stop on trigger event
0: No effect
1: Stop formatter when a trigger event occurs

Bit 12 **STOPFL**: Stop on flush
0: No effect
1: Stop formatter when flush is completed

Bit 11 Reserved, must be kept at reset value.

Bit 10 **TRIGFL**: Trigger on flush
0: No effect
1: Indicate a trigger in the trace stream when flush is completed

Bit 9 **TRIGEVT**: Trigger on trigger event
0: No effect
1: Indicate a trigger in the trace stream when trigger event occurs
Bit 8 **TRIGIN**: Trigger on trigger in
0: No effect
1: Indicate a trigger in the trace stream when the TRIGIN input from the system CTI is asserted.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FONMAN**: Generate a manual flush
0: No effect
1: Flush the trace

This bit is cleared automatically when the flush completes.

Bit 5 **FONTRIG**: Flush on trigger event
A trigger event occurs when the trigger counter reaches 0, or, if the trigger counter is 0, when the TRIGIN input from the system CTI is high.

0: No effect
1: Flush the trace if a trigger event occurs

Bit 4 **FONFLIN**: Flush on flush in
0: No effect
1: Flush the trace if the FLUSHIN input from the system CTI is asserted

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ENFCONT**: Enable continuous formatting
0: Continuous formatting is disabled
1: Continuous formatting is enabled

Bit 0 **ENFTC**: Enable the embedding of triggers in formatted trace
0: Formatting is disabled
1: Formatting is enabled

rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  CYCCOUNT[11:0]: Enables effective use of TPAs
    Enables effective use of different-sized TPAs without wasting large amounts of storage
capacity of the capture device. This counter contains the number of formatter frames since
the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value
of 4096. This equates to synchronization every 65536 bytes, that is, 4096 packets x 16 bytes
per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every
64 formatter frames. If the formatter is configured for continuous mode, full and half-word
sync frames are inserted during normal operation. Under these circumstances, the count
value is the maximum number of complete frames between full synchronization packets.

CLAIMCLR[3:0]

St
TPIU lock access register (TPIU_LAR)
Address offset: 0xFB0
Reset value: 0xFFFF XXXX

Bits 31:4 Reserved, must be kept at reset value.
Bits 3:0 CLAIMCLR[3:0]: Reset claim tag bits
Write:
0000: No effect
xxx1: Clear bit 0
xx1x: Clear bit 1
x1xx: Clear bit 2
1xxx: Clear bit 3
Read: Returns current value of claim tag

TPIU lock status register (TPIU_LSR)
Address offset: 0xFB4
Reset value: 0x0000 0003

Bits 31:0 ACCESS_W[31:0]: TPIU register access enable
Enables write access to some TPIU registers by processor cores (debuggers do not need to unlock the component)
0xC5ACCE55: Enable write access
Other values: Disable write access
Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the TPIU_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.
0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Implementation of a lock control mechanism
The bit indicates whether a lock control mechanism is implemented. It always returns zero when read by an external debugger.
0: No lock control mechanism is available
1: Lock control mechanism is implemented

**TPIU authentication status register (TPIU_AUTHSTAT)**

Address offset: 0xFB8

63.5.7 Serial wire output (SWO) and SWO trace funnel (SWTF)

The SWO is a CoreSight component that formats the trace stream from the processor ITM and outputs it on the single wire TRACESWO output. The trace source identity is not handled by the SWO, so only one processor can use the SWO at a time. The SWO trace funnel (SWTF) must be programmed to select which processor ITM will use it before trace is enabled. Port 0 is connected to the Cortex-M7 and Port 1 to the Cortex-M4. The SWTF registers are listed in Table 641.

Compared to the TPIU, the SWO contains:

- no formatter
- no pattern generator
- an 8-bit ATB input
- no synchronous trace output, that is, no TRACEDATA or TRACECLK pins
- no support for flush, because this is not required
- no support for triggering
The SWO output supports Manchester encoded and UART NRZ formats. For more information about the serial wire output CoreSight™ component, refer to the Arm® CoreSight™ Components Technical Reference Manual [4].

**SWO registers**

**SWO current output divisor register (SWO_CODR)**

Bits 31:13 Reserved, must be kept at reset value.  

Bits 12:0 **PRESCALER[12:0]**: SWO baud rate scaling  
The baud rate is the trace clock frequency divided by (PRESCALER + 1). The baud rate changes instantly, so it is recommended to stop the trace source and wait until the port is idle before writing to this register.

**SWO selected pin protocol register (SWO_SPPR)**

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **FTNONSTOP**: Change of settings without stopping formatter
1: Change of settings is allowed with formatter running

Bit 2 **TCPRESENT**: TRACECTL pin present on SWO
0: TRACECTL pin not present

Bit 1 **FTSTOPPED**: Formatter stopped
0: Formatter running
The bit always returns 0 as the SWO formatter cannot be stopped in this device.

Bit 0 **FLINPROG**: Flush in progress
0: Flush is not in progress
The bit always returns 0 as SWO flushing is not supported in this device.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the SWTF_LAR register

0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock

This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked - only read access is permitted

Bit 0 **LOCKEXIST**: Existence of lock control mechanism

The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

**SWTF authentication status register (SWTF_AUTHSTAT)**

Address offset: 0xFB8

Reset value: 0x0000 000A

63.5.8 Microcontroller debug unit (DBGMCU)

The DBGMCU component contains a number of registers that control the power and clock behavior in Debug mode. Specifically it allows the debugger, or debug software, to:

- maintain the clock and power to the processor cores when in low-power modes (sleep, stop or standby)
- maintain the clock and power to the system debug and trace components when in low power modes
- stop the clock to certain peripherals (CAN, SMBUS timeout, Watchdogs, Timers, RTC) when either the processor core is stopped in Debug mode. For timers having complementary outputs, these outputs are disabled (as if the MOE bit was reset) for safety purposes when the counter is stopped (TIM1/8/15/16/17 = 1 in DBGMCU_APB2FZ1).

The DBGMCU registers are not reset by a system reset, only by a power on reset. They are accessible to the debugger via the APB-D bus at base address 0xE00E1000. They are also accessible by both processor cores at base address 0x5C001000.

Note: the DBGMCU is not a standard CoreSight component. Therefore, it does not appear in the system ROM table.

DBGMCU registers

DBGMCU identity code register (DBGMCU_IDC)

Bits 31:29  Reserved, must be kept at reset value.

Bit 28 **TRGOEN**: External trigger output enable  
This bit controls the direction of the bi-directional trigger pin, TRGIO.

0: Input - TRGIO is connected to TRGIN  
1: Output - TRGIO is connected to TRGOUT

Bits 27:23  Reserved, must be kept at reset value.

Bit 22 **D3DBGCKEN**: D3 debug clock enable  
This bit allows the debug components in the D3 domain (excluding the DAPCLK domain) to be switched off if they are not needed.

0: Disabled - D3 domain debug components are disabled and their clocks gated  
1: Enabled - D3 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D3) is active

Bit 21 **D1DBGCKEN**: D1 debug clock enable  
This bit allows the debug components in the D1 domain (excluding those in the processor core) to be switched off if they are not needed.

0: Disabled - D1 domain debug components are disabled and their clocks gated  
1: Enabled - D1 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D1) is active

Bit 20 **TRACECLKEN**: Trace port clock enable  
This bit enables the trace port clock, TRACECLK.

0: Disabled - TRACECLK is disabled  
1: Enabled - TRACECLK is active

Bits 19:6  Reserved, must be kept at reset value.

Bit 5 **DBGSTBY_D2**: D2 domain debug in Standby mode enable  
0: Normal operation - all clocks is disabled and the domain powered down automatically in Standby mode  
1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the domain supply is maintained, allowing full debug capability. On exit from Standby mode, a domain reset is performed.
Bit 4 **DBGSTOP_D2**: D2 domain debug in Stop mode enable
0: Normal operation - all clocks is disabled automatically in Stop mode
1: Automatic clock stop disabled - all active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings is set to the Stop mode exit state.

Bit 3 **DBGSLEEP_D2**: D2 domain debug in Sleep mode enable
0: Normal operation - processor clock is stopped automatically in Sleep mode
1: Automatic clock stop disabled - processor clock continues to run, allowing full debug capability

Bit 2 **DBGSTBY_D1**: D1 domain debug in Standby mode enable
0: Normal operation - all clocks is disabled and the domain powered down automatically in Standby mode.
1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the domain supply is maintained, allowing full debug capability. On exit from Standby mode, a domain reset is performed.

Bit 1 **DBGSTOP_D1**: D1 domain debug in Stop mode enable
0: Normal operation - all clocks are disabled automatically in Stop mode
1: Automatic clock stop disabled - all active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings is set to the Stop mode exit state.

Bit 0 **DBGSLEEP_D1**: D1 domain debug in Sleep mode enable
0: Normal operation - processor clock is stopped automatically in Sleep mode
1: Automatic clock stop disabled - processor clock continues to run, allowing full debug capability

**DBGMCU APB3 peripheral freeze register CPU1 (DBGMCU_APB3FZ1)**

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **WWDG1**: WWDG1 stop in debug
0: Normal operation - WWDG1 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - WWDG1 is frozen while the Cortex-M7 core is in Debug mode

Bits 5:0 Reserved, must be kept at reset value.
DBGMCU APB3 peripheral freeze register CPU2 (DBGMCU_APB3FZ2)

Address offset: 0x038
Reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **WWDG1**: WWDG1 stop in debug
- 0: Normal operation - WWDG1 continues operating while Cortex-M4 is in Debug mode
- 1: Stop in debug - WWDG1 is frozen while Cortex-M4 is in Debug mode

Bits 5:0 Reserved, must be kept at reset value.

DBGMCU APB1L peripheral freeze register CPU1 (DBGMCU_APB1LFZ1)

Address offset: 0x03C
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **DBG_I2C3**: I2C3 SMBUS timeout stop in debug
- 0: Normal operation - I2C3 SMBUS timeout continues operating while the Cortex-M7 core is in Debug mode
- 1: Stop in debug - I2C3 SMBUS timeout is frozen while Cortex-M7 is in Debug mode

Bit 22 **DBG_I2C2**: I2C2 SMBUS timeout stop in debug
- 0: Normal operation - I2C2 SMBUS timeout continues operating while the Cortex-M7 core is in Debug mode
- 1: Stop in debug - I2C2 SMBUS timeout is frozen while Cortex-M7 is in Debug mode

Bit 21 **DBG_I2C1**: I2C1 SMBUS timeout stop in debug
- 0: Normal operation - I2C1 SMBUS timeout continues operating while the Cortex-M7 core is in Debug mode
- 1: Stop in debug - I2C1 SMBUS timeout is frozen while the Cortex-M7 core is in Debug mode

Bits 20:12 Reserved, must be kept at reset value.
Bit 11 **DBG_WWDG2**: WWDG2 stop in debug
0: Normal operation - WWDG2 continues operating while Cortex-M7 is in Debug mode
1: Stop in debug - WWDG2 is frozen while Cortex-M7 is in Debug mode

Bit 10 Reserved, must be kept at reset value.

Bit 9 **DBG_LPTIM1**: LPTIM1 stop in debug
0: Normal operation - LPTIM1 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - LPTIM1 is frozen while Cortex-M7 is in Debug mode

Bit 8 **DBG_TIM14**: TIM14 stop in debug
0: Normal operation - TIM14 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM14 is frozen while Cortex-M7 is in Debug mode

Bit 7 **DBG_TIM13**: TIM13 stop in debug
0: Normal operation - TIM13 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM13 is frozen while Cortex-M7 is in Debug mode

Bit 6 **DBG_TIM12**: TIM12 stop in debug
0: Normal operation - TIM12 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM12 is frozen while Cortex-M7 is in Debug mode

Bit 5 **DBG_TIM7**: TIM7 stop in debug
0: Normal operation - TIM7 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM7 is frozen while Cortex-M7 is in Debug mode

Bit 4 **DBG_TIM6**: TIM6 stop in debug
0: Normal operation - TIM6 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM6 is frozen while Cortex-M7 is in Debug mode

Bit 3 **DBG_TIM5**: TIM5 stop in debug
0: Normal operation - TIM5 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM5 is frozen while Cortex-M7 is in Debug mode

Bit 2 **DBG_TIM4**: TIM4 stop in debug
0: Normal operation - TIM4 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM4 is frozen while Cortex-M7 is in Debug mode

Bit 1 **DBG_TIM3**: TIM3 stop in debug
0: Normal operation - TIM3 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM3 is frozen while Cortex-M7 is in Debug mode

Bit 0 **DBG_TIM2**: TIM2 stop in debug
0: Normal operation - TIM2 continues operating while the Cortex-M7 core is in Debug mode
1: Stop in debug - TIM2 is frozen while Cortex-M7 is in Debug mode

63.6 Cortex-M7 debug functional description

The Cortex-M7 subsystem features the following CoreSight™ components:

- ROM tables
- System control space (SCS)
- Breakpoint unit (FPB)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded trace macrocell (ETM)
- Cross trigger interface (CTI)

These components are accessible by the debugger via the Cortex-M7 AHB-AP and its associated AHBD bus.

63.6.1 Cortex-M7 ROM tables

The ROM table is a CoreSight™ component that contains the base addresses of all the CoreSight debug components accessible via the AHBD. These tables enable a debugger to access the topology of the CoreSight system automatically.

There are two ROM tables in the Cortex-M7 sub-system:

- Cortex-M7 processor ROM table
  
  This table is pointed to by the BASE register in the Cortex-M7 AHB-AP. It contains the base address pointers for the ETM and CTI, as well as for the Cortex-M7 PPB ROM table.

- Cortex-M7 PPB (private peripheral bus) ROM table

  This table contains pointers to the Cortex-M7 System Control Space registers allowing the debugger to identify the CPU core, as well as to the remaining CoreSight components in the Cortex-M7 subsystem: FPB, DWT and ITM.

The processor ROM table occupies a 4-Kbyte, 32-bit wide chunk of AHBD address space, from 0xE00FE000 to 0xE00FEFFC.
The Cortex-M7 PPB ROM table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00FF000 to 0xE00FFFFC.

Table 646. Cortex-M7 PPB ROM table register map and reset values
The DWT provides four comparators that can be used as:

- **watchpoint**
- **ETM trigger**
- **PC sampling trigger**
- **data address sampling trigger**
- **data comparator (comparator 1 only)**
- **clock cycle counter comparator (comparator 0 only)**

It also contains counters for:

- **clock cycles**
- **folded instructions**
- **load store unit (LSU) operations**
- **sleep cycles**
- **number of cycles per instruction**
- **interrupt overhead**
A DWT comparator compares one of the following with the value held in its DWT_COMP register:

- a data address
- an instruction address
- a data value
- the cycle count value, for comparator 0 only.

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:

- one or more DWT data trace packets, containing one or more of:
  - the address of the instruction that caused a data access
  - an address offset, bits[15:0] of the data access address
  - the matched data value
- a watchpoint debug event, on either the PC value or the accessed data address
- a CMPMATCH[N] event that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter Debug state.

For more details on how to use the DWT, refer to the Arm®v7-M Architecture Reference Manual [5].

DWT mask register x (M7_DWT_MASKx)
Address offset: 0x024 + x * 0x10 (for x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:0  COMP[31:0]: Reference value for comparison.

DWT function register x (M7_DWT_FUNCTx)
Address offset: 0x028 + x * 0x10 (for x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:5  Reserved, must be kept at reset value.

Bits 4:0  MASK[4:0]: Comparator mask size
Provides the size of the ignore mask applied to the access address for address range matching by comparator n. A debugger can write 0b11111 to this field and then read the register back to determine the maximum mask size supported.

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  MATCHED: Comparator match (read-only)
Indicates if a comparator match has occurred since the register was last read.

0: No match
1: Match occurred

Bits 23:20  Reserved, must be kept at reset value.
Bits 19:16 **DATAVADDR1[3:0]**: Comparator number of a second comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a second comparator to use for linked address comparison.

Bits 15:12 **DATAVADDR0[3:0]**: Comparator number of a comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a comparator to use for linked address comparison.

Bits 11:10 **DATAFSIZE[1:0]**: Size of required data comparison
For data value matching, specifies the size of the required data comparison.

0x0: Byte
0x1: Half word
0x2: Word
0x3: Reserved

Bit 9 **LNK1ENA**: Support of a second linked comparator (read-only)
Indicates whether the use of a second linked comparator is supported (read-only).

1: Supported

Bit 8 **DATAVMATCH**: Cycle comparison enable
0: Perform address comparison
1: Perform data value comparison

Bit 7 **CYCMATCH**: Cycle count comparison enable on comparator 0
This field is reserved for other comparators.

0: No cycle count comparison
1: Compare DWT_COMP0 with the cycle counter, DWT_CYCCNT

Bit 6 Reserved, must be kept at reset value.

Bit 5 **EMITRANGE**: Data trace address offset packet enable
Enables generation of data trace address offset packets (containing data address bits 0 to 15)

0: Disabled
1: Enabled

Bit 4 Reserved, must be kept at reset value.

Bits 3:0 **FUNCTION[3:0]**: Action on comparator match
The meaning of this bit field depends on the setting of the DATAVMATCH and CYCMATCH fields. See [5].

### 63.6.3 Cortex-M7 instrumentation trace macrocell (ITM)

The ITM generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. **Software trace**
   
   Software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access, and the data written, into a packet that it writes to a FIFO. The ITM
outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

2. Hardware trace

The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

3. Local timestamping

The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

4. Global system timestamping

Timestamps can also be generated using the system-wide 64-bit count value coming from the Timestamp Generator component.

Cortex-M7 ITM registers

**ITM stimulus register x (M7_ITM_STIMx)**

Address offset: 0x000 + x * 0x4 (x = 0 to 31)

Reset value: Undefined

<table>
<thead>
<tr>
<th>Bit 31:0</th>
<th>Description</th>
</tr>
</thead>
</table>
| STIMULUS[31:16] | Bits 31:0: STIMULUS[31:0]: Software event packet / FIFOREADY  
Write data is output on the trace bus as a software event packet. When reading, bit 0 is a FIFOREADY indicator:  
0: Stimulus port buffer is full (or port is disabled)  
1: Stimulus port can accept new write data |

**ITM trace enable register (M7_ITM_TER)**

Address offset: 0xE00

Reset value: 0x00000000

**GTSFREQ[1:0]**

**TSPRESCALE[1:0]**

**SWOEN**

**TXENA**

**SYNC**

**TSEN**

**ITM**

**ENA**
Bits 31:24 Reserved, must be kept at reset value.

Bit 23 BUSY: ITM busy
Indicates whether the ITM is currently processing events (read-only):

0: Not busy
1: Busy

Bits 22:16 TRACEBUSID[6:0]: Identifier for multi-source trace stream formatting
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note: different IDs must be used for each trace source in the system.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 GTSFREQ[1:0]: Global timestamp frequency
Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps. The possible values are:

0x0: Disable generation of global timestamps
0x1: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:7]; this is approximately every 128 cycles
0x2: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:13]; this is approximately every 8192 cycles
0x3: Generate a timestamp after every packet, if the output FIFO is empty

Bits 9:8 TSPRESCALE[1:0]: Local timestamp prescale
Prescale used with the trace packet reference clock. The possible values are:

0x0: No prescaling
0x1: Divide by 4
0x2: Divide by 16
0x3: Divide by 64

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 SWOENA: Asynchronous clocking enable for the timestamp counter (read-only)
0: Timestamp counter uses processor clock

Bit 3 TXENA: Hardware event packet forwarding enable
Enables forwarding of hardware event packets from the DWT unit to the trace port.

0: Disabled
1: Enabled

Bit 2 SYNCENA: Synchronization packet transmission enable
If a debugger sets this bit it must also configure the DWT_CTRL register SYNCTAP field in the DWT for the correct synchronization speed.

0: Disabled
1: Enabled

Bit 1 TSENA: Local timestamp generation enable
0: Disabled
1: Enabled

Bit 0 ITMENA: ITM enable
0: Disabled
1: Enabled
ITM CoreSight peripheral identity register 4 (M7_ITM_PIDR4)

Cortex-M7 FPB registers

FPB control register (M7_FPB_CTRL)

Address offset: 0x000
Reset value: 0x0000 0080

Table 648. Cortex-M7 ITM register map and reset values (continued)
Bits 31:15  Reserved, must be kept at reset value.

Bits 14:12  **NUM_CODE[6:4]**: Instruction address comparator number field, three MSBs
           This read-only field holds the three MSBs of the number of instruction address comparators supported.
           0x0: the MSBs of the number are all 0

Bits 11:8  **NUM_LIT[3:0]**: Number of literal address comparators supported (read-only).
           0x0: No literal comparators supported.

Bits 7:4  **NUM_CODE[3:0]**: Instruction address comparator number field, four LSBs
           This read-only field holds the four LSBs of the number of instruction address comparators supported.
           0x8: 8 instruction comparators supported

Bit 1  **KEY**: Write protect key
       A write to M7_FPB_CTRL register is ignored if this bit is not set to 1.

Bits 0  **ENABLE**: FPB enable
       0: Disable
       1: Enable

**FPB remap register (M7_FPB_REMAP)**

Address offset: 0x004

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:30 REaPLaCE[1:0]: Behavior upon COMP versus instruction fetch address match

Defines the behavior when a match occurs between the COMP field and the instruction fetch address:

0x0: Reserved
0x1: Breakpoint on lower half-word, upper half-word is unaffected.
0x2: Breakpoint on upper half-word, lower half-word is unaffected.
0x3: Breakpoint on both upper and lower half-words.

Bit 29 Reserved, must be kept at reset value.

Bits 28:2 COMPaR[26:0]: Value to compare with code memory access address

Value to compare with address bits 28:2 of accesses to instruction code memory (0x00000000 to 0x1FFFFFFF). If a match occurs, the action to take is defined by the REaPLaCE field.

Bit 1 Reserved, must be kept at reset value.

Bit 0 ENaBLaE: Comparator enable

The comparator is only enabled if both this bit and the FPB ENABLE bit in the M7_FPB_CTRL register are set.

0: Disabled
1: Enabled

FPB CoreSight peripheral identity register 4 (M7_FPB_PIDR4)

**Note:** Values that are not specified in the table are reserved and should be considered as such.
63.6.5 Cortex-M7 embedded trace macrocell (ETM)

The Cortex-M7 ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M7 core to be traced. In the STM32H7, the ETM is configured for instruction trace only, so data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:
- The number of instructions executed in the same cycle
- Changes in program flow
- The current processor instruction state
- The addresses of memory locations accessed by load and store instructions
- The type, direction and size of a transfer
- Condition code information
- Exception information
- Wait for interrupt state information

For more information, refer to the Arm® CoreSight™ ETM™-M7 technical reference manual [6].

Cortex-M7 ETM registers

ETM programming control register (M7_ETM_PRGCTL)

Address offset: 0x004
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PMSTABLE**: Programmers model stable

Indicates whether the ETM registers are stable and can be read.

0: Registers are not stable
1: Registers are stable

Bit 0 **IDLE**: Trace unit inactive

0: ETM is not idle
1: ETM is idle
ETM trace configuration register (M7_ETM_CONFIG)

Address offset: 0x010
Reset value: 0x0000 0000

<table>

<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

#### Bits 31:16
Reserved, must be kept at reset value.

- **Bit 15** **TYPE1**: Resource type for event 1
  - 0: Single selected resource
  - 1: Boolean combined resource pair

#### Bits 14:12
Reserved, must be kept at reset value.

#### Bits 11:8
**SEL1[3:0]**: Resource / Boolean combined resource pair, for event 1
- When TYPE1 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
- When TYPE1 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

#### Bit 7
**TYPE0**: Resource type for event 0
- 0: Single selected resource
- 1: Boolean combined resource pair

#### Bits 6:4
Reserved, must be kept at reset value.

#### Bits 3:0
**SEL0[3:0]**: Resource / Boolean combined resource pair for event 0
- When TYPE0 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
- When TYPE0 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

### ETM event control 1 register (M7_ETM_EVENTCTL1)

Only accepts writes when trace unit is disabled

Address offset: 0x024

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

#### Bits 31:16
Reserved, must be kept at reset value.

- **Bit 15** **LPOVE**: Resource
- **Bit 14** **RRIDE**: Resource
- **ATB**: Resource
- **INSTEN[3:0]**: Resource

#### Bits 11:8
**SEL1[3:0]**: Resource

#### Bits 6:4
**SEL0[3:0]**: Resource

#### Bits 3:0
**SEL0[3:0]**: Resource
Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LPOVERRIDE**: Low power state behavior override
- 0: Low power state normal behavior
- 1: Entry to low power state does not affect resources and event trace generation

Bit 11 **ATB**: ATB trigger enable
- 0: Disabled
- 1: Enabled

Bits 10:4 Reserved, must be kept at reset value.

Bits 3:0 **INSTEN[3:0]**: Instruction trace event element enable
Each bit corresponds to an event:
- 0bXXX0: Event 0 does not cause an event element
- 0bXXX1: Event 0 causes an event element
- 0bXX0X: Event 1 does not cause an event element
- 0bXX1X: Event 1 causes an event element
- 0bX0XX: Event 2 does not cause an event element
- 0bX1XX: Event 2 causes an event element
- 0b0XXX: Event 3 does not cause an event element
- 0b1XXX: Event 3 causes an event element

**ETM stall control register (M7_ETM_STALLCTL)**

Only accepts writes when trace unit is disabled

Address offset: 0x02C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>

<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **DSTALL**: Stall processor based on data trace buffer space
- 0: Do not stall processor
- 1: Stall processor

Bit 8 **ISTALL**: Stall processor based on instruction trace buffer space
- 0: Do not stall processor
- 1: Stall processor
ETM global timestamp control register (M7_ETM_TSCTL)

Only accepts writes when trace unit is disabled
Address offset: 0x030
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:8 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 7:4 Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bits 3:2 LEVEL[1:0]: Stalling threshold level</td>
</tr>
<tr>
<td>A low level minimizes the amount of processor stalling, with a higher risk of FIFO overflow. A high level minimizes the risk of FIFO overflow but increases the amount of processor stalling.</td>
</tr>
<tr>
<td>Bits 1:0 Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

| Bits 31:8 Reserved, must be kept at reset value. |
| Bit 7 TYPE: Resource type for time stamp insertion |
| 0: Single selected resource |
| 1: Boolean combined resource pair |
| Bits 6:4 Reserved, must be kept at reset value.  |
| Bits 3:0 SEL[3:0]: Resource / Boolean combined resource pair |
| When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0] |
| When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0] |

ETM synchronization period register (M7_ETM_SYNCP)

Address offset: 0x034
Reset value: 0x0000 000A

<table>
<thead>
<tr>
<th>Bits 31:5 Reserved, must be kept at reset value.</th>

Bits 31:20  Reserved, must be kept at reset value.

Bit 19  **EXLEVEL_S3**: Trace disable, exception level 3  
Disables tracing in the specified exception level in Secure state for exception level 3.  
0: Enable ViewInst in this exception level  
1: Disable ViewInst in this exception level

Bits 18:17  Reserved, must be kept at reset value.

Bit 16  **EXLEVEL_S0**: Trace disable, exception level 0  
Disables tracing in the specified exception level in Secure state for exception level 0.  
0: Enable ViewInst in this exception level  
1: Disable ViewInst in this exception level

Bits 15:12  Reserved, must be kept at reset value.

Bit 11  **TRCERR**: Tracing of system error exception  
Selects whether a system error exception must always be traced.  
0: System error exception is traced only if the instruction or exception immediately before the system error exception is traced  
1: System error exception is always traced regardless of the value of ViewInst

Bit 10  **TRCRESET**: Tracing of reset exception  
Selects whether a reset exception must always be traced.  
0: Reset exception is traced only if the instruction or exception immediately before the reset exception is traced  
1: Reset exception is always traced regardless of the value of ViewInst

Bit 9  **SSSTATUS**: Current status of the start/stop logic  
0: Stop state  
1: Started state

Bit 8  Reserved, must be kept at reset value.
Bit 7  **TYPE**: Resource type  
0: Single selected resource  
1: Boolean combined resource pair  

Bits 6:4  Reserved, must be kept at reset value.  

Bits 3:0  **SEL[3:0]**: Resource / Boolean combined resource pair  
When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0]  
When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

| 0: Not inverted  
| 1: Inverted |
| Bit 19 Reserved, must be kept at reset value. |

**Bits 18:16 GROUP[2:0]:** Selects a group of resources  
**Bits 15:8 Reserved, must be kept at reset value.**

**Bits 7:0 SELECT[7:0]:** Selector of resources from desired group  
Selects one or more resources from the desired group. One bit is provided per resource from the group.

### ETM single-shot comparator control register 0 (M7_ETM_SSCC0)

**Address offset:** 0x280  
**Reset value:** 0x0000 0000

---

---
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **RST**: Single-shot comparator resource reset enable
Enables the single-shot comparator resource to be reset when it occurs, then enables another comparator match to be detected.
0: Disabled
1: Reset enabled; multiple matches can occur

Bits 23:0  Reserved, must be kept at reset value.

**ETM single-shot comparator status register 0 (M7_ETM_SSCS0)**

Address offset: 0x2A0
Reset value: 0x0000 0001

<table>
<thead>

</tr>
</tbody>
</table>

Bit 31  **STATUS**: Single-shot status
This indicates whether any of the selected comparators have matched. If SSCC0.RST is set to 0, the STATUS bit must be written with 0 in order to enable single-shot comparator control.

0: No match occurred
1: Match has occurred at least once.

Bits 30:3  Reserved, must be kept at reset value.

Bit 2  **DV**: Data value comparator support
0: Single-shot data value comparisons not supported

Bit 1  **DA**: Data address comparator support
0: Single-shot data address comparisons not supported

Bit 0  **INST**: Instruction address comparator support
1: Single-shot instruction address comparisons supported
ETM single-shot processor comparator input control register (M7_ETM_SSPCIC0)

</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1** **STICKYPD**: Sticky power-down state
- This bit is set to 1 when power to the ETM registers is removed, to indicate that programming state has been lost. It is cleared after a read of the TRCPDSR.
  - 0: Trace register power uninterrupted since the last read of PDS register
  - 1: Trace register power interrupted since the last read of PDS register

**Bit 0** **POWER**: ETM powered up
- 1: ETM is powered up; all registers are accessible

ETM lock status register (M7_ETM_LSR)

Address offset: 0xFB4
Reset value: 0x0000 0003

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the M7_ETM_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

ETM authentication status register (M7_ETM_AUTHSTAT)

Address offset: 0xFB8
Reset value: 0x0000 000A

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:6 **SNID[1:0]**: Security level for secure non-invasive debug
0x0: Not implemented
RM0399  Debug infrastructure

ETM CoreSight device architecture register (M7_ETM_DEVARCH)

Address offset: 0xFBC
Reset value: 0x4770 4A13

Table 650. Cortex-M7 ETM register map and reset values (continued)
63.6.6 Cortex-M7 cross trigger interface (CTI)

See Section 63.5.3.

63.7 Cortex-M4 debug functional description

The Cortex-M4 subsystem features the following CoreSight™ components:
- Cortex-M4 ROM table
- Cortex-M4 system control space (SCS)
- Breakpoint unit (FPB)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded trace macrocell (ETM)
- Cross trigger interface (CTI)

These components are accessible by the debugger via the Cortex-M4 AHB-AP.
63.7.1 Cortex-M4 ROM table

The Cortex-M4 ROM table is a CoreSight™ component that contains the base addresses of all the CoreSight debug components accessible via the AHB-AP. These tables allow a debugger to discover the topology of the CoreSight system automatically.

There is one ROM table in the Cortex-M4 sub-system. This table is pointed to by the BASE register in the Cortex-M4 AHB-AP. It contains the base address pointer for the System Control Space registers, which allow the debugger to identify the CPU core, as well as for the FPB, DWT, ITM, ETM and CTI.

The Cortex-M4 ROM table occupies a 4kbyte, 32-bit wide chunk of address space, from 0xE00FF000 to 0xE00FFFFC.

1. The TPIU is included in this table by default, but bit 0 is reset to indicate that it is not present.

The Topology for the CoreSight components in the Cortex-M4 subsystem is shown in Figure 883.
Cortex-M4 ROM table registers

ROM memory type register (M4_ROM_MEMTYPE)

Address offset: 0xFCC
Reset value: 0x0000 0001
Bits 31:1  Reserved, must be kept at reset value.

Bit 0  **SYSMEM**: System memory
1: System memory is present on this bus

**ROM CoreSight peripheral identity register 4 (M4_ROM_PIDR4)**

Address offset: 0xFD0
Reset value: 0x0000 0000

### 63.7.2 Cortex-M4 data watchpoint and trace unit (DWT)

The DWT provides four comparators that can be used as:
- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (comparator 1 only)
- clock cycle counter comparator (comparator 0 only)

</table>
It also contains counters for:
• clock cycles
• folded instructions
• load store unit (LSU) operations
• sleep cycles
• number of cycles per instruction
• interrupt overhead

A DWT comparator compares one of the following with the value held in its DWT_COMP register:
• a data address
• an instruction address
• a data value
• the cycle count value, for comparator 0 only.

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:
• one or more DWT Data trace packets, containing one or more of:
  – the address of the instruction that caused a data access
  – an address offset, bits[15:0] of the data access address
  – the matched data value
• a watchpoint debug event, on either the PC value or the accessed data address
• a CMPMATCH[N] event, that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter Debug state.

For more details on how to use the DWT, refer to the Arm®v7-M Architecture Reference Manual [5].

Bits 31:28  **NUMCOMP[3:0]**: Number of comparators implemented (read-only)
0x4: Four comparators

Bit 27  **NOTRCPKT**: Trace sampling and exception tracing support (read-only)
0: Supported

Bit 26  **NOEXTRIG**: External match signal, CMPMATCH support (read-only)
0: Supported

Bit 25  **NOCYCCNT**: Cycle counter support (read-only)
0: Supported

Bit 24  **NOPRFCNT**: Profiling counter support (read-only)
0: Supported

Bit 23 Reserved, must be kept at reset value.

Bit 22  **CYCEVTENA**: Enable for POSTCNT underflow event counter packet generation
0: Disabled
1: Enabled

Bit 21  **FOLDEVTENA**: Enable for folded instruction counter overflow event generation
0: Disabled
1: Enabled

Bit 20  **LSUEVTENA**: Enable for LSU counter overflow event generation
0: Disabled
1: Enabled

Bit 19  **SLEEPEVTENA**: Enable for sleep counter overflow event generation
0: Disabled
1: Enabled

Bit 18  **EXCEVTENA**: Enable for exception overhead counter overflow event generation
0: Disabled
1: Enabled

Bit 17  **CPIEVTENA**: Enable for CPI counter overflow event generation
0: Disabled
1: Enabled

Bit 16  **EXCTRCENA**: Enable for exception trace generation
0: Disabled
1: Enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12  **PCSAMPLENA**: Enable for POSTCNT use as sample timer
Enables use of POSTCNT counter as a timer for Periodic PC sample packet generation.
0: Disabled
1: Enabled
Debug infrastructure

DWT cycle count register (M4_DWT_CYCCNT)

Address offset: 0x004
Reset value: 0x0000 0000

Bits 11:10 SYNCTAP[1:0]: Position of sync packet counter tap on CYCCNT
Selects the position of the synchronization packet counter tap on the CYCCNT counter. This determines the synchronization packet rate.

0x0: Disabled. No synchronization packets
0x1: Tap at CYCCNT[24]
0x2: Tap at CYCCNT[26]
0x3: Tap at CYCCNT[28]

Bit 9 CYCTAP: Position of POSTCNT tap on CYCCNT
Selects the position of the POSTCNT tap on the CYCCNT counter.

0: Tap at CYCCNT[6]
1: Tap at CYCCNT[10]

Bits 8:5 POSTINIT[3:0]: Initial value of POSTCNT
Writes to this field are ignored if POSTCNT counter is enabled (that is, CYCEVTENA or PCSAMPLENA must be reset prior to writing POSTINIT).

Bits 4:1 POSTRESET[3:0]: Reload value of the POSTCNT counter

Bit 0 CYCCNTENA: CYCCNT counter enable
0: Disabled
1: Enabled

DWT CPI count register (M4_DWT_CPICNT)

Address offset: 0x008
Reset value: 0x0000 0000

Bits 31:0 CYCCNT[31:0]: Processor clock cycle counter

3460/3556
Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **CPICNT[7:0]**: CPI counter
Counts additional cycles required to execute multi-cycle instructions, except those recorded by M4_DWT_LSUCNT, and counts any instruction fetch stalls.

### DWT exception count register (M4_DWT_EXCCNT)

Address offset: 0x00C
Reset value: 0x0000 0000

<td>9</td>
<td>8</td>
<td>7</td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **MASK[4:0]**: Comparator mask size

Provides the size of the ignore mask applied to the access address for address range matching by comparator n. A debugger can write 0b11111 to this field and then read the register back to determine the maximum mask size supported.
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **MATCHED**: Comparator match (read-only)
Indicates if a comparator match has occurred since the register was last read.

0: No match
1: Match occurred

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **DATAVADDR1[3:0]**: Comparator number of a second comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a second comparator to use for linked address comparison.

Bits 15:12  **DATAVADDR0[3:0]**: Comparator number of a comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a comparator to use for linked address comparison.

Bits 11:10  **DATAVSIZE[1:0]**: Size of required data comparison
For data value matching, specifies the size of the required data comparison.

0x0: Byte
0x1: Half word
0x2: Word
0x3: Reserved

Bit 9  **LNK1ENA**: Support of a second linked comparator (read-only)
Indicates whether use of a second linked comparator is supported (read-only).

1: Supported

Bit 8  **DATAVMATCH**: Cycle comparison enable
0: Perform address comparison
1: Perform data value comparison

Bit 7  **CYCMATCH**: Enables cycle count comparison on comparator 0. This field is reserved for other comparators.
0: No cycle count comparison
1: Compare M4_DWT_COMP0 with the cycle counter, M4_DWT_CYCCNT

Bit 6  Reserved, must be kept at reset value

Bit 5  **EMITRANGE**: Data trace address offset packet enable
Enables generation of data trace address offset packets (containing data address bits 0 to 15)
0: Disabled
1: Enabled

Bit 4  Reserved, must be kept at reset value.

Bits 3:0  **FUNCTION[3:0]**: Action on comparator match
The meaning of this bit field depends on the setting of the DATAVMATCH and CYCMATCH fields. See [5].

63.7.3 Cortex-M4 instrumentation trace macrocell (ITM)

The ITM generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace
   Software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access, and the data written, into a packet that it writes to a FIFO. The ITM outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

2. Hardware trace
   The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

3. Local timestamping
   The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

4. Global system timestamping
   Timestamps can also be generated using the system-wide 64-bit count value coming from the Timestamp generator component.

Cortex-M4 ITM registers

ITM stimulus register x (M4_ITM_STIMx)

Address offset: 0x000 + x * 0x4 (x = 0 to 31)

Reset value: Unknown

</table>
| 23    | BUSY                      | Indicates whether the ITM is currently processing events (read-only):  
0: Not busy  
1: Busy                                            |
| 22:16 | TRACEBUSID[6:0]           | Identifier for multi-source trace stream formatting  
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note: different IDs must be used for each trace source in the system. |
| 15:12 | Reserved, must be kept at reset value. |                                                                                                |
| 11:10 | GTSFREQ[1:0]              | Global timestamp frequency  
Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps. The possible values are:  
0x0: Disable generation of global timestamps  
0x1: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [47:7]; this is approximately every 128 cycles  
0x2: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [47:13]; this is approximately every 8192 cycles  
0x3: Generate a timestamp after every packet, if the output FIFO is empty |
| 9:8   | TSPRESCALE[1:0]           | Local timestamp prescale  
Prescale used with the trace packet reference clock The possible values are:  
0x0: No prescaling  
0x1: Divide by 4  
0x2: Divide by 16  
0x3: Divide by 64 |
| 7:5   | Reserved, must be kept at reset value. |                                                                                                |
| 4     | SWOENA                    | Asynchronous clocking enable for the timestamp counter (read-only)  
0: Timestamp counter uses processor clock |

Bits 31:24: Reserved, must be kept at reset value.  
Bit 23 **BUSY**: ITM busy  
Indicates whether the ITM is currently processing events (read-only):  
0: Not busy  
1: Busy

Bits 22:16 **TRACEBUSID[6:0]**: Identifier for multi-source trace stream formatting  
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note: different IDs must be used for each trace source in the system.

Bits 15:12: Reserved, must be kept at reset value.

Bits 11:10 **GTSFREQ[1:0]**: Global timestamp frequency  
Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps. The possible values are:  
0x0: Disable generation of global timestamps  
0x1: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [47:7]; this is approximately every 128 cycles  
0x2: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [47:13]; this is approximately every 8192 cycles  
0x3: Generate a timestamp after every packet, if the output FIFO is empty

Bits 9:8 **TSPRESCALE[1:0]**: Local timestamp prescale  
Prescale used with the trace packet reference clock The possible values are:  
0x0: No prescaling  
0x1: Divide by 4  
0x2: Divide by 16  
0x3: Divide by 64

Bits 7:5: Reserved, must be kept at reset value.

Bit 4 **SWOENA**: Asynchronous clocking enable for the timestamp counter (read-only)  
0: Timestamp counter uses processor clock
Bit 3 **TXENA**: Hardware event packet forwarding enable  
   Enables forwarding of hardware event packets from the DWT unit to the trace port.  
   
   0: Disabled  
   1: Enabled

Bit 2 **SYNCENA**: Synchronization packet transmission enable  
   If a debugger sets this bit it must also configure the DWT_CTRL register SYNCTAP field in the DWT for the correct synchronization speed.  
   
   0: Disabled  
   1: Enabled

Bit 1 **TSENA**: Local timestamp generation enable  
   0: Disabled  
   1: Enabled

Bit 0 **ITMENA**: ITM enable  
   0: Disabled  
   1: Enabled

0xB1: Common ID value
### Cortex-M4 breakpoint unit (FPB)

The FPB allows hardware breakpoints to be set. It contains six comparators which monitor the instruction fetch address and two literal address comparators. If a match occurs, the address is remapped to an address in system memory, defined by the M4_FPB_REMAP register plus an offset corresponding to the matching comparator. Alternatively, the instruction comparators can be configured to generate a breakpoint instruction.

### Cortex-M4 FPB registers

FPB remap register (M4_FPB_REMAP)

Address offset: 0x004

Reset value: 0x000

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:12  **NUM_CODE[6:4]**: Instruction address comparator number field, three MSBs
            This read-only field holds the three MSBs of the number of instruction address comparators supported.

            0x0: the MSBs of the number are all 0

Bits 11:8  **NUM_LIT[3:0]**: Number of literal address comparators supported (read-only).
            0x0: No literal comparators supported.

Bits 7:4  **NUM_CODE[3:0]**: Instruction address comparator number field, four LSBs
            This read-only field holds the four LSBs of the number of instruction address comparators supported.

            0x8: 8 instruction comparators supported

Bit 1  **KEY**: Write protect key
            A write to M4_FPB_CTRL register will be ignored if this bit is not set to 1.

Bits 0  **ENABLE**: FPB enable
            0: Disable
            1: Enable

Bits 31:28  RMPSPT: Flash patch remap support (read-only)
            0: Remapping not supported

Bits 27:20  REMAP[23:11]: Remap target address
            Bits [28:5] of the base address in SRAM to which the FPB remaps the address. The remap base address must be aligned to the number of words required to support the implemented comparators, that is to (NUM_CODE+NUM_LIT) words, with a minimum alignment of 8 words. Because remap is into the SRAM memory region, 0x20000000-0x3FFFFFFF, bits [31:29] of the remap address are 0b001.

Bits 19:16  Reserved, must be kept at reset value.
### FPB comparator registers (M4_FPB_COMPx)

Bits 31:30 REPLAY[1:0]: Behavior upon COMP versus instruction fetch address match

Defines the behavior when a match occurs between the COMP field and the instruction fetch address:

- 0x0: Reserved
- 0x1: Breakpoint on lower half-word, upper half-word is unaffected.
- 0x2: Breakpoint on upper half-word, lower half-word is unaffected.
- 0x3: Breakpoint on both upper and lower half-words.

Bit 29 Reserved, must be kept at reset value.

Bits 28:2 COMP[26:0]: Value to compare with code memory access address

Value to compare with address bits 28:2 of accesses to instruction code memory ($0x00000000$ to $0xFFFFFFFF$). If a match occurs, the action to take is defined by the REPLACE field.

Bit 1 Reserved, must be kept at reset value.

Bit 0 ENABLE: Comparator enable

The comparator is only enabled if both this bit and the FPB ENABLE bit in the M4_FPB_CTRL register are set.

0: Disabled
1: Enabled

63.7.5 Cortex-M4 embedded trace macrocell (ETM)

The Cortex-M4 ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M4 core to be traced. In the STM32H7, the ETM is configured for instruction trace only, that is, data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:

- the number of instructions executed in the same cycle
- changes in program flow
- the current processor instruction state
- the addresses of memory locations accessed by load and store instructions
- the type, direction and size of a transfer
- condition code information
- exception information
- wait for interrupt state information
For more information, refer to the Arm® CoreSight™ ETM™-M4 technical reference manual [7].

Cortex-M4 ETM registers

ETM control register (M4_ETM_CR)

Address offset: 0x000
Reset value: 0x0000 0411

<table>
<thead>
<tr>
<th>31</th>

<th>16</th>
</tr>
</thead>
</table>

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **TSEN**: Timestamp enable
0: Timestamping disabled  
1: Timestamping enabled

Bits 26:12 Reserved, must be kept at reset value.

Bit 11 **ETMEN**: ETM enable
0: Trace output disabled  
1: Trace output enabled

Bit 10 **PROG**: ETM programming
This bit must be set to 1 before programming the ETM. Tracing is prevented while this bit is set to 1.

0: ETM operational  
1: ETM in programming state

Bit 9 **BO**: Branch output
When set to 1 all branch addresses are output, even if the branch was because of a direct branch instruction. Setting this bit enables reconstruction of the program flow without having access to the memory image of the code being executed.
When this bit is set to 1, more trace data is generated, and this may affect the performance of the trace system. Information about the execution of a branch is traced regardless of the state of this bit.
Bit 8 **STALL**: Stall processor
The FIFOFULL output can be used to stall the processor to prevent overflow. The FIFOFULL output is only enabled when the stall processor bit is set to 1. When the bit is 0 the FIFOFULL output remains low at all times and the FIFO overflows if there are too many trace packets. Trace resumes without corruption once the FIFO has drained, if overflow does occur.

Bits 6:1 **Reserved, must be kept at reset value.**

Bit 0 **PDN**: ETM power down
This bit can be used by an implementation to control if the ETM is in a low power state. This bit must be cleared by the trace software tools at the beginning of a debug session.
When this bit is set to 1, writes to some registers and fields might be ignored. The following registers and fields are still write-accessible:
- ETMCR bit [0]
- ETMLAR
- ETMCLAIMSET register
- ETMCLAIMCLR register
When the ETMCR is written with this bit set to 1, bits other than bit [0] might be ignored.

**ETM configuration code register (M4_ETM_CCR)**
Address offset: 0x004
Reset value: 0x8C80 2000

Bit 16 **SEQPRES**: Sequencer present

0: The sequencer is not present in the ETM.

Bits 15:13 **NCNT[2:0]**: Number of counters

0x1: One counter is implemented

Bits 12:8 **NMMDEC[4:0]**: Number of memory map decoders

0x0: No memory map decoder inputs are implemented.

Bits 7:4 **NDVCMP[3:0]**: Number of data value comparators

0x0: No data value comparators are implemented.

Bits 3:0 **NADCMP[3:0]**: Number of address comparator pairs

0x0: No address comparator pairs are implemented.

**Bits 31:17** Reserved, must be kept at reset value.

**Bits 16:14** **FCN[2:0]**: Boolean function

- 0x0: A
- 0x1: NOT A
- 0x2: A AND B
- 0x3: NOT A AND B
- 0x4: NOT A AND NOT B
- 0x5: A OR B
- 0x6: NOT A OR B
- 0x7: NOT A OR NOT B

**Bits 13:7** **RESOURCEB[6:0]**: Second resource identifier

See **RESOURCEA[6:0]** field for bit description.

**Bits 6:0** **RESOURCEA[6:0]**: First resource identifier

Bits [6:4] defines the resource type and bits [3:0] the index. The supported resource identifiers are listed below. Programming any other values may result in unpredictable behavior.

- Type (bits [6:4])
- Index (bits [3:0])
0x2  0-3  Embedded-ICE watchpoint comparators 1-4 (from DWT)
0x4  0  Counter 1 at zero
0x5  15  Trace start/stop resource
0x6  0-1  External inputs 1-2
         15  Hard-wired input, always true

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  TRIGFL: Trigger flag
Set when the trigger occurs, and prevents the trigger from being output until the ETM is programmed again.

Bit 2  TSSRSTAT: Trigger start/stop resource status
Holds the current status of the trace start/stop resource. If set to 1, it indicates that a trace on address has been matched, without a corresponding trace off address match.

Bit 1  PROGVAL: Programming bit value (read-only)
The current effective value of the ETM Programming bit, bit [10] of the M4_ETM_CR. Set the programming bit to 1 and wait for this bit to go to 1 before programming the ETM. This bit remains at 0 until the FIFO is empty, or if OS lock is set in the M4_ETM_OSLSR register.

Bit 0  UOVFL: Untraced overflow (read-only)
If set to 1, there is an overflow that has not yet been traced. This bit is cleared to 0 when trace is restarted, or when the ETM power-down bit (bit [0] of the M4_ETM_CR register) is set to 1.

Bits 31:24  **DESIGNER[7:0]**: Implementer code
0x41: Arm®

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **ABPE**: Alternative ranch packet encoding
1: ABPE is implemented.

Bit 19  **SXSUPP**: Security extensions support
0: ETM behaves as if the processor is in secure mode at all times

Bit 18  **T32SUPP**: 32-bit Thumb instruction tracing
1: 32-bit Thumb instructions are traced as single instructions

Bit 17  Reserved, must be kept at reset value.

Bit 16  **LDPCF**: Load PC first
0: Data tracing is not supported

Bits 15:12  **PROCFAM[3:0]**: Processor family
0xF: Processor family is not identified in this register

Bits 11:8  **ETMARCHMAJ[3:0]**: Major ETM architecture version
0x2: Version 3

Bits 7:4  **ETMARCHMIN[3:0]**: Minor ETM architecture version
0x5: Version 5

Bits 3:0  **REVISION[3:0]**: Implementation revision
0x0: Revision 0
**ETM configuration code extension register (M4_ETM_CCER)**

Address offset: 0x1E8

ETM trace enable start/stop embedded ICE control register (M4_ETM_TESSEICR)

Address offset: 0x1F0
Reset value: 0x0000 0000

| Bits 31:20 | Reserved, must be kept at reset value. |
| Bits 19:16 | STOPRS[3:0]: Stop resource selection |
| Setting any of these bits to 1 selects the corresponding EmbeddedICE watchpoint input as a TraceEnable stop resource. Bit [16] corresponds to input 1, bit [17] corresponds to input 2, bit [18] corresponds to input 3, and bit [19] corresponds to input 4. |
| Bits 15:4 | Reserved, must be kept at reset value. |
| Bits 3:0 | STARTRS[3:0]: Start resource selection |
| Setting any of these bits to 1 selects the corresponding EmbeddedICE watchpoint input as a TraceEnable start resource. Bit [0] corresponds to input 1, bit [1] corresponds to input 2, bit [2] corresponds to input 3, and bit [3] corresponds to input 4. |

ETM timestamp event register (M4_ETM_TSEVR)

Address offset: 0x1F8
Reset value: 0x0000 0000

| Bits 31:20 | Reserved, must be kept at reset value. |
| Bits 19:16 | FCN[2]: |
| Setting any of these bits to 1 selects the corresponding EmbeddedICE watchpoint input as a TraceEnable stop resource. Bit [16] corresponds to input 1, bit [17] corresponds to input 2, bit [18] corresponds to input 3, and bit [19] corresponds to input 4. |
| Bits 15:4 | RESOURCEB[6:0]: |
| Setting any of these bits to 1 selects the corresponding EmbeddedICE watchpoint input as a TraceEnable start resource. Bit [0] corresponds to input 1, bit [1] corresponds to input 2, bit [2] corresponds to input 3, and bit [3] corresponds to input 4. |
ETM trace ID register (M4_ETM_TRACEIDR)

Address offset: 0x200

Reset value: 0x0000 0000

| Bits 31:7 | Reserved, must be kept at reset value.
| Bits 6:0 | TRACEID[6:0]: Trace ID to output onto the trace bus
This should be programmed with a unique value to differentiate it from other trace sources in the system.
### ETM ID register 2 (M4_ETM_IDR2)

Bits 31:2 Reserved, must be kept at reset value.

- **Bit 1** **SWPTO**: SWP or SWPB instruction order  
  Identifies the order for a SWP or SWPB instruction.
  
  0: The Load transfer is traced before the Store transfer

- **Bit 0** **RFETO**: RFE instruction order  
  Identifies the order for a RFE instruction.
  
  0: The PC transfer is traced before the CPSR transfer

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the ETM_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented
**ETM authentication status register (M4_ETM_AUTHSTAT)**

64 **Device electronic signature**

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32H745/755 and STM32H747/757 microcontrollers.

64.1 **Unique device ID register (96 bits)**

The unique device identifier is ideally suited:
- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

**Base address: 0x1FF1 E800**

</tbody>
</table>

Bits 31:0 L_ID[31:0]: Line identifier
This bitfield indicates the device line expressed in ASCII. As an example, STM32H747 corresponds to 0x4837 3437:
0x48 = 'H'
0x37 = '7'
0x34 = '4'
0x37 = '7'

64.4 Package data register

Refer to SYSCFG package register (SYSCFG_PKGR) for package identification. The SYSCFG clock should be enabled first in the RCC_APB4ENR register.
Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.

- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.

- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.

- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.

- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

### Table 657. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019| 2 (continued) | **Section 7: Power control (PWR)**  
Renamed SD converter into SMPS step-down converter in the whole section.  
Added case of device startup with VCORE supplied in Bypass mode in Section 7.4.1: System supply startup.  
Added VOS0 in Section 7.4.2: Core domain, Section 7.4.3: PWR external supply and Section 7.6.2: Voltage scaling. Added Section 7.4.2: VOS0 activation/deactivation sequence.  
Updated Section 7.5.5: Battery voltage thresholds.  
Updated Section 7.5.6: Temperature thresholds to indicate that the thresholds are available only when the backup regulator is enabled.  
Added note related to VOS0 activation in Section 7.4.2: Exiting Stop mode and Section 7.4.3: Entering Standby mode.  

**Section 9: Reset and Clock Control (RCC)**  
Updated Section 9.1: HSE oscillator, Section 9.2: LSE oscillator and Figure 52: HSE/LSE clock source.  
Changed maximum frequency to 480 MHz in Figure 55: Core and bus clock generation.  
Updated Table 60: Kernel clock distribution overview.  
Updated DIVP[16:0] in Section 9.7.12: RCC PLL1 dividers configuration register (RCC_PLL1DIVR).  
Renamed BKPSRAMAMEN into BKPRAMAMEN in Section 9.7.37: RCC D3 Autonomous mode register (RCC_D3AMR) register.  
Added USB2OTGHSULP1EN in Section 9.7.40: RCC AHB1 clock register (RCC_AHB1ENR), and USB2OTGHSULP1L1PEN in Section 9.7.49: RCC AHB1 Sleep clock register (RCC_AHB1LPENR).  
Renamed HDMICECRST into CECRST in Section 9.7.32: RCC APB1 peripheral reset register (RCC_APB1RSTR), and HDMICECEN to CECEN in Section 7.7.45: RCC APB1 Clock Register (RCC_APB1LENR).  

**Section 9: General-purpose I/Os (GPIO)**  
Updated Figure 82: Analog inputs connected to ADC inputs to specify that the analog switch status depends on PxysO reset value in SYS CFG_PMCR.  
MODER reset state changed to analog mode in Section 9.4.1: GPIO port mode register (GPIOx_MODER) (x=A to C and E, H).  

**Section 13: System configuration controller (SYSCFG)**  
Added note related to CSI clock required for setting READY bit in SYS CFG configuration register (SYS CFG_CFGR).  
Added SYSCFG power control register (SYS CFG_PWRCR).  

**Section 17: Basic direct memory access controller (BDMA)**  
Updated Section 7: Channel state and disabling a channel. |
### Section 12: DMA request multiplexer (DMAMUX)
Removed references to security and privileged/unprivileged access control in Section 18.6.4: DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2_CSR), Section 18.6.6: DMAMUX2 request line multiplexer interrupt clear flag register (DMAMUX2_CFR) and Section 18.6.8: DMAMUX2 request generator channel x configuration register (DMAMUX2_RGxCR).

### Section 19: Chrom-Art Accelerator™ controller (DMA2D)
Replaced DMA2D_FGPFCR by DMA2D_FGPFCCR in Section : Memory-to-memory with PFC, blending and fixed color FG.
Replaced DMA2D_BGPFCR by DMA2D_BGPFCCR in Section : Memory-to-memory with PFC, blending and fixed color BG.
Updated Section 19.6.9: DMA2D foreground color register (DMA2D_FGCOLR). Added Section 19.6.21: DMA2D foreground CLUT (DMA2D_FGCLUT[y]) and Section 19.6.22: DMA2D background CLUT (DMA2D_BGCLUT[y]).
Table 145: DMA2D register map and reset values:
Changed APLHA[7:0] to reserved for DMA2D_FGCOLR
Changed APLHA[7:0] to reserved for DMA2D_BGCOLR

### Section 23: Flexible memory controller (FMC)
Replaced BCH8 by Hamming in Section 23.8.6: Computation of the error correction code (ECC) in NAND Flash memory.
Updated Figure 115: Mode D write access waveforms.

### Section 25: Delay block (DLYB)
Updated Section 25.1: Introduction to specify that the DLYB output clock can be used to clock the data received by Quad-SPI interface.

### Section 26: Analog-to-digital converters (ADC)
Renamed OVSR into OVR, OSR into OSVR[9:0] and AUTODLY into AUTDLY. Added Section 26.3: ADC implementation.
For all ADC internal channels connected to VBAT, VSENSE, VREFINT, and DAC internal channels, changed ADC channel name from ADCx_INPy/INMy to ADCx VINP[y]/VINM[y].
Updated Table 213: Offset computation versus data resolution, Section : 16-bit and 8-bit signed format management: RSHIFTx, SSATE and Table 217: Analog watchdog 1,2,3 comparison.
Removed reference to ALIGN bit in the note related to data alignment in Section : Single ADC operating modes support when oversampling.
Updated Section 26.6.4: ADC configuration register (ADC_CFGR) to change RES[2:0] value corresponding to 8-bit format.

### Section 30: Operational amplifiers (OPAMP)
Removed references to OPAMODE in Section 30.6.1: OPAMP1 control/status register (OPAMP1_CSR). Changed OPAMODE bitfield to reserved in Section 30.6.1: OPAMP1 control/status register (OPAMP1_CSR).
### Table 657. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019| 2 (continued) | Section 35: JPEG codec (JPEG)  
Table 290: JPEG codec register map and reset values:  
JPEG_CR: added HPDIE (bit 6)  
Renamed JPEG_HWCFR1/2 into JPEG_HWCFGR1/2  

Section 33: LCD-TFT display controller (LTDC)  
Section 33.4.1: LTDC global configuration parameters / Synchronous timing updated.  

Section 19: True random number generator (RNG)  
Updated Section 19.2: RNG main features.  
Updated Section 19.4: RNG interrupts.  
Updated Section 19.6: RNG entropy source validation.  
Updated Table 97: RNG internal input/output signals.  

Section 37: Cryptographic processor (CRYP)  
Section 37.6.21: CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR): renamed CRYP_CSGCMCCMxR[31:0] bitfield into CSGCMCCMx[31:0] and updated bitfield description.  
Section 37.6.22: CRYP context swap GCM registers (CRYP_CSGCMxR): renamed CRYP_CSGCMx[31:0] bitfield into CSGCMx[31:0] and updated bitfield description.  
Table 308: CRYP register map and reset values:  
Added bitfield ranges for CRYP_K0LR/RR to CRYP_K3LR/RR.  
Updated CRYP_IV0LR/RR to CRYP_IV1LR/RR.  
Renamed CRYP_KxLR bitfields into Kx.  

Section 38: Hash processor (HASH)  
Changed CSRn into CSn for all HASH_CRSx registers in Table 313: HASH1 register map and reset values.  

Section 22: Advanced-control timers (TIM1)  
Replaced BKEx, BKPx by BKE, BK2E, BKP, BK2P.  
Updated Figure 134: Advanced-control timer block diagram.  
Updated Figure 177: Break and Break2 circuitry overview.  
Updated Figure 164: Output stage of capture/compare channel (channel 1, idem ch. 2 and 3), Figure 165: Output stage of capture/compare channel (channel 4) and Figure 420: Output stage of capture/compare channel (channel 5, idem ch. 6).  
Updated TIM1_CCMR1, TIM1_CCMR2, TIM1_CCMR3, TIM1_CCR2, TIM1_CCR4.  
Added 00010 configuration for TS[4:0] in TIMx_SMCR register.  
Table 347: TIM8 register map and reset values: extended DMAB bitfield to 32 bits for TIM8_DMAR.
Table 657. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019 | 2 (continued) | **Section 23: General-purpose timer (TIM2)**  
Updated Figure 194: General-purpose timer block diagram.  
Updated Section 23.3.3: Clock selection.  
Removed all information related to BDTR register and MOE and OSSSI bits.  

**Section 42: General-purpose timers (TIM12/TIM13/TIM14)**  
Updated Figure 497: General-purpose timer block diagram (TIM12).  

**Section 24: General-purpose timers (TIM16/TIM17)**  
Updated Figure 523: TIM15 block diagram.  
Updated Figure 256: Capture/compare channel 1 main circuit? Figure 257: Output stage of capture/compare channel (channel 1) and Figure 540: Output stage of capture/compare channel (channel 2 for TIM15).  
Updated Section 24.3.11: Using the break function.  
Removed bit COMDE for TIM16/17.  
Table 156: TIM16/TIM17 register map and reset values: changed TISEL[3:0] into TI1SEL[3:0] for TIM16_TISEL and TIM17_TISEL registers.  

**Section 29: Inter-integrated circuit (I2C) interface**  
Updated Section 29.3: I2C implementation.  
Updated Section 29.7.2: I2C control register 2 (I2C_CR2), Section 29.7.3: I2C own address 1 register (I2C_OAR1), and Section 29.7.8: I2C interrupt clear register (I2C_ICR).  

**Section 25: Low-power timer (LPTIM)**  
Updated Section 25.4.8: Timeout function.  
Updated WAVE bit description in Section 25.7.4: LPTIM configuration register (LPTIM_CFGR).  

**Section 30: Universal synchronous/asynchronous receiver transmitter (USART/UART)**  
Replaced DSI_NSS by DIS_NSS in USART_CR1.  
Changed USART_TDR into USART_RDR in Figure 328: Reception using DMA.  
Updated Section 30.5.4: USART FIFOs and thresholds.  
Updated RTO bitfield description in Section 30.7.7: USART receiver timeout register (USART_RTOR).  
Section 30.7.9: USART interrupt and status register [alternate] (USART_ISR):  
Updated ABRF, IDLE bit descriptions  
For FIFO disabled only: updated RXNE and ORE bit descriptions  
Changed NFCF to NECF in Section 30.7.11: USART interrupt flag clear register (USART_ICR).  
Table 193: USART register map and reset values:  
USART_CR1: bit 12 changed to M0, bit 7 changed to TXEIE/TXFNFIE, bit 5 changed to RXNEIE/RXFNEIE.  
USART_ISR: changed TXE bit to TXE/TXFNF and RXNE into RXNE/RXFNE.  
Corrected USART_ISR/TCGBIT reset value for FIFO disabled.

</table>
| 04-Apr-2019 | 2 (continued) | Section 31: Low-power universal asynchronous receiver transmitter (LPUART)
Changed LPUART_TDR into LPUART_RDR in Figure 342: Reception using DMA.
Updated Section 30.5.4: USART FIFOs and thresholds.
Updated Section 31.5.1: LPUART control register 1 [alternate] (LPUART_CR1).
Corrected WUS bitfield length and changed RXFTCFG to TXFTCFG (bit 31 to 29) in
Section 31.5.4: LPUART control register 3 (LPUART_CR3).
Section 31.5.8: LPUART interrupt and status register [alternate] (LPUART_ISR):
Updated IDLE bit descriptions
FIFO enabled only: updated reset value
Changed NFCF to NECF in Section 31.5.9: LPUART interrupt flag clear register
(LPUART_ICR).
Table 199: LPUART register map and reset values
LPUART_CR1: bit 12 changed to M0, bit 5 changed to RXNEIE/RXFNEIE.
LPUART_ISR: changed TXE bit to TXE/TXFNF
Corrected LPUART_ISR reset value and bits 7 and 5 names.

Section 53: Serial peripheral interface (SPI)
Table 438: SPI register map and reset values:
SPI2S_SR: Changed bit 7 to CRCE.
SPI2S_I2SCFGR: added DATFMT (bit 14)

Section 57: Management data input/output (MDIOS)
In Table 459: MDIOS register map and reset values, for MDIOS_CR register,
changed bit 3 to EIE and added DPC (bit 7).

Section 58: Secure digital input/output MultiMediaCard interface (SDMMC)
Replaced HOLD by DHOLD in the whole document.
Updated Figure 746: SDMMC block diagram and Table 464: SDMMC pins.
Updated Figure 755: CLKMUX unit.
Updated Wait_S in Section : Data path and Table 474: Data path status flags and
clear bits.
Updated Section 58.5.3: General description.
Updated Section : Stream operation and CMD12.
Added Section 58.8: SDMMC interrupts.
Updated Section 58.9.10: SDMMC data counter register (SDMMC_DCNTR),
Section 58.9.11: SDMMC status register (SDMMC_STAR) and Section 58.9.15:
SDMMC data FIFO registers x (SDMMC_FIFORx).
Updated Table 486: SDMMC register map.
Table 657. Document revision history (continued)

</table>
| 04-Apr-2019| 2        | Section 59: Controller area network with flexible data rate (FDCAN)  
Updated Section 59.4.7: FDCAN nominal bit timing and prescaler register (FDCAN_NBTP), Section 59.4.12: FDCAN error counter register (FDCAN_ECR), Section 59.4.15: FDCAN interrupt register (FDCAN_IR), Section 59.4.37: FDCAN Tx buffer request pending register (FDCAN_TXBRP) and Section 59.4.64: FDCAN TT trigger select register (FDCAN_TTTS).  
Updated Section Table 513.: FDCAN register map and reset values.  
Updated FCCAN_CCU_CCFG in Section Table 514.: CCU register map and reset values.  

Section 61: Ethernet (ETH): media access control (MAC) with DMA controller  
Added Figure 833: Supported PHY interfaces.  
Removed reference to AV standard in Section 61.1: Ethernet introduction.  

Section 63: Debug infrastructure  
Changed ETF RAM size to 4 Kbytes in Section 63.5.5: Embedded trace FIFO (ETF) and Section : ETF RAM size register (ETF_RSZ).  
Added revision V and updated reset value in Section : DBGMCU identity code register (DBGMCU_IDC).  
Renamed WDGLSD1/2 into DBG_IWDG1/2 in Section : DBGMCU APB4 peripheral freeze register CPU1 (DBGMCU_APB4FZ1) and Section : DBGMCU APB4 peripheral freeze register CPU2 (DBGMCU_APB4FZ2).  
Prefixed all bits names in Section : DBGMCU APB1L peripheral freeze register CPU1 (DBGMCU_APB1LFZ1), Section : DBGMCU APB1L peripheral freeze register CPU2 (DBGMCU_APB1LFZ2), Section : DBGMCU APB2 peripheral freeze register CPU1 (DBGMCU_APB2FZ1), Section : DBGMCU APB2 peripheral freeze register CPU2 (DBGMCU_APB2FZ2), Section : DBGMCU APB4 peripheral freeze register CPU1 (DBGMCU_APB4FZ1) and Section : DBGMCU APB4 peripheral freeze register CPU2 (DBGMCU_APB4FZ2) by 'DBG_'.

</tbody>
</table>

**Section 3: RAM ECC monitoring (RAMECC)**

Changed ECCEN bit of RAMECC_MxCR to reserved.

*Table 12: RAMECC register map and reset values:* updated RAMECC_MxCR, RAMECC_MxSR, replaced by RAMECC_MxFAR at address offset 0x28+0x20*(x-1) and RAMECC_MxDFRLH replaced by RAMECC_MxDFR.

**Section 4: Embedded flash memory (FLASH)**

Restricted Table 15 to STM32H745xl/747xl/755xl/757xl and added Table 15. Added VOS0 range to Table 17.

**Section 5: Secure memory management (SMM) (former Secure internal Flash memory)**

Updated exitSecureArea in Section 5.4.2: Secure area exiting service.

**Section 7: Power control (PWR)**

Moved LSI from backup to VDD domain in Figure 21: Power supply overview.

Added Figure 36: Switching VCORE from VOS1 to VOS0 in Section: VOS0 activation/deactivation sequence.

Updated list of GPIOs which use is restricted in Section 7.4.4: Backup domain.

Updated Section 7.4.8: DSI regulator.

Updated CStop mode exit in Section Table 42: CStop mode.

Updated ACTVOSRDY bit definition in Section 7.8.2: PWR control status register 1 (PWR_CSR).

Updated VOSRDY bit definition in Section 7.8.7: PWR D3 domain control register (PWR_D3CR).

**Section 8: Low-power D3 domain application example**

Replaced LINUART1 by LPUART1.

Updated Figure 45: Timing diagram of SRAM4-to-LPUART1 transfer with BDMA and D3 domain in Autonomous mode.

Updated section Section: EXTI programming.

Updated DMAMUX2_C0CR value for DMAMUX2 SYNC0 in Table 51: BDMA and DMAMUX2 initialization sequence (DMAMUX2_INIT).

Renamed Table 52 into “LPUART1 start programming.

**Section 9: Reset and Clock Control (RCC)**

Renamed adc_ker_ck into adc_ker_ck_inputs.

Added note on RTC/AWU and updated USB1ULPI and ADC1/2/3 maximum allowed frequency for VOS0/1/2/3 in Table 66: Kernel clock distribution overview.

Updated introductory sentence of Section 9.4.2: System reset.

**Section 10: Clock recovery system (CRS)**

Added Section 10.3: CRS implementation. Updated Section 10.8.1: CRS control register (CRS_CR). Updated Table 93: CRS register map and reset values.
**Table 657. Document revision history (continued)**

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>27-Feb-2020</td>
<td>3 (continued)</td>
<td></td>
</tr>
</tbody>
</table>

**Section 12: General-purpose I/Os (GPIO)**
Changed to analog the mode in which most of the I/O ports are configured during and just after reset.

**Section 16: Direct memory access controller (DMA)**
Change Bit 20 to TRBUFF instead of reserved in Section 16.5.5: DMA stream x configuration register (DMA_SxCR).

**Section 21: Extended interrupt and event controller (EXTI)**
Added note to event 80 in Table 152: EXTI Event input mapping.

**Section 23: Flexible memory controller (FMC)**
Updated Section : General transaction rules to clarify the behavior of the FMC when AXI transaction data size is different from the device data width and add the case of unaligned addresses.
Replaced FMC_CLK by fmc_ker_ck in the formulas of Section : WAIT management in asynchronous accesses.

**Section 24: Quad-SPI interface (QUADSPI)**
Updated Section 24.3.4: QUADSPI signal interface protocol modes.
Updated Section 24.3.11: QUADSPI configuration and Section 24.5.1: QUADSPI control register (QUADSPI_CR) adding 'when setting QUADSPI interface in DDR mode, the prescaler must be set with a division ratio of 2 or more' paragraph.
Updated FTHRES[4:0] bits description of Section 24.5.1: QUADSPI control register (QUADSPI_CR) for IP_XACT compliance.

**Section 26: Analog-to-digital converters (ADC)**
Removed note related to connection to DFSDM limited to ADC1 and ADC2, and added adc_sclk in Figure 141: ADC block diagram. Removed VREF+ and VREF-ranges and added adc_sclk in Table 209: ADC input/output pins.
Added reference to LDORDY bit in the whole section.
Updated Section 26.4.3: ADC clocks and renamed adc_ker_ck into adc_ker_ck_inputs. Updated Section : BOOST control.
Replaced SMPPLUS control by Extended sample time option (SMPPLUS control) and added LDO voltage regulator in Section 26.3: ADC implementation.
Updated Section 26.4.11: Channel selection (SQRx, JSQRx)
Removed RES[2:0] configuration in Table 217: Offset computation versus data resolution and Table 221: Analog watchdog 1,2,3 comparison.
Updated Section : ADC overrun (OVR, OVRMOD). Added case of FIFO overflow in Section : Managing a sequence of conversion without using the DMA.
Updated Section : Single ADC operating modes support when oversampling to remove the mention that the offset correction is not supported in oversampling mode.

| 27-Feb-2020| 3 (continued) | Section 35: JPEG codec (JPEG)  
Updated Section 35.5.5: JPEG codec configuration register 4-7 (JPEG_CONFR4-7). bit 1 and bit 0 description.  
Section 36: True random number generator (RNG)  
Updated Section 36.1: Introduction and Section 36.2: RNG main features.  
Updated Section 36.3.3: Random number generation and Figure 295: RNG initialization overview.  
Updated note in Section 36.3.5: RNG operation.  
Updated Section 36.5: RNG processing time and Section 36.6: RNG entropy source validation.  
Updated Section 36.7.3: RNG data register (RNG_DR).  
Section 37: Cryptographic processor (CRYP)  
Updated number of clock cycles for TDES in Section 37.2: CRYP main features.  
Removed flowcharts (Nonuser) in Section 37.4.5: CRYP procedure to perform a cipher operation.  
Updated Section 37.4.17: CRYP key registers.  
Updated Table 312: Cryptographic processor configuration for memory-to-peripheral DMA transfers and Table 313: Cryptographic processor configuration for peripheral-to-memory DMA transfers.  
Section 37.5: CRYP interrupts: removed Figure CRYP interrupt mapping diagram and updated Table 314: CRYP interrupt requests.  
Section 37.6: CRYP processing time: updated Table 315: Processing latency for ECB, CBC and CTR and Table 315: Processing latency for ECB, CBC and CTR.  
Section 38: Hash processor (HASH)  
Message size changed to $2^{64}$-1 in Section 38.1: Introduction and Section 38.4.3: About secure hash algorithms.  
Added Section 38.3: HASH implementation.  
Updated Figure 320: HASH block diagram.  
Updated Figure 321: Message data swapping feature.  
Updated Section 38.4.8: HASH suspend/resume operations.  
Renamed HASH_HRx registers located at address offset 0x0C into Section : HASH aliased digest register x (HASH_HRAx).  
Updated ALGO description in Section 38.7.1: HASH control register (HASH_CR).  
Specified value returned by reading Section 38.7.2: HASH data input register (HASH_DIN). |
Section 40: Advanced-control timers (TIM1/TIM8)
Updated Figure 386: Advanced-control timer block diagram.
Updated Section 40.3.3: Repetition counter.
Updated Section 40.3.16: Using the break function.
Updated Section 40.4.2: TIMx control register 2 (TIMx_CR2)(x = 1, 8). Aligned TS[2:0] field in Section 40.4.3: TIMx slave mode control register (TIMx_SMCR)(x = 1, 8). Updated Section 40.4.5: TIMx status register (TIMx_SR)(x = 1, 8). Updated Section 40.4.6: TIMx event generation register (TIMx_EGR)(x = 1, 8). Updated Table 355: TIM1 register map and reset values, Table 356: TIM8 register map and reset values.
Updated Section 40.3.29: Debug mode.

Section 41: General-purpose timers (TIM2/TIM3/TIM4/TIM5)
Updated Section 41.4.12: TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5).
Updated Table 360: TIM2/TIM3/TIM4/TIM5 register map and reset values.

Section 42: General-purpose timers (TIM12/TIM13/TIM14)
Updated Figure 496: General-purpose timer block diagram (TIM12).
Updated Figure 510: Capture/compare channel 1 main circuit.
Updated Figure 511: Output stage of capture/compare channel (channel 1).
Updated Section 42.4.1: TIM12 control register 1 (TIM12_CR1), Section 42.4.5: TIM12 status register (TIM12_SR) and Section 42.5.5: TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13 to 14).

Section 43: General-purpose timers (TIM15/TIM16/TIM17)
Updated Figure 522: TIM15 block diagram.
Updated Figure 537: Capture/compare channel 1 main circuit.
Updated Section 43.5.2: TIM15 control register 2 (TIM15_CR2), Section 43.5.5: TIM15 status register (TIM15_SR), Section 43.5.9: TIM15 capture/compare enable register (TIM15_CCER), Section 43.6.2: TIMx control register 2 (TIMx_CR2)(x = 16 to 17), Section 43.6.4: TIMx status register (TIMx_SR)(x = 16 to 17), Section 43.6.7: TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17) and Section 43.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17).Replaced DT[7:0] by DTG[7:0] in Table 368: TIM15 register map and reset values and Table 370: TIM16/TIM17 register map and reset values.

Section 45: Low-power timer (LPTIM)
Updated Section 45.4.5: Glitch filter.

Section 47: System window watchdog (WWDG)
Updated Section 47.5.1: WWDG control register (WWDG_CR).

Section 49: Real-time clock (RTC)
Updated Figure 580: Detailed RTC block diagram and Figure 581: Tamper detection. Updated Section 49.4: RTC low-power modes.
Updated Section 49.5: RTC interrupts.

| 27-Feb-2020  | 3 (continued) | Section 51: Universal synchronous/asynchronous receiver transmitter (USART/UART)  
Section 51.8.10: USART interrupt and status register [alternate] (USART_ISR):  
– FIFO enabled: changed reset value to 0x0000 00C0 in and Table 426: USART register map and reset values.  
– FIFO disabled: changed reset value to 0x0000 0000 in and Table 426: USART register map and reset values.  
Changed reset value to 0x0000 0000 in Section 51.8.12: USART receive data register (USART_RDR) and Section 51.8.13: USART transmit data register (USART_TDR).  
Updated Section 51.8: USART registers to indicate that USART and LPUART registers are accessed by words.  
Section 52: Low-power universal asynchronous receiver transmitter (LPUART)  
Added Section 51.4: USART implementation.  
Section 52.7: LPUART interrupt and status register (LPUART_ISR):  
– FIFO enabled: changed reset value to 0x0080 00C0 in Table 434: LPUART register map and reset values.  
– FIFO disabled: changed reset value to 0x0000 00C0 in Table 434: LPUART register map and reset values.  
Updated Section 52.7: LPUART registers to indicate that USART and LPUART registers are accessed by words.  
Section 54: Serial audio interface (SAI)  
Figure 689: SAI functional block diagram: number of Dn and CKn lines made generic, added note to indicate that all Dn and CKn might not be available on all SAI instances.  
Added Section 54.3: SAI implementation.  
Updated Table 445: SAI input/output pins to indicate the number of Dn/CKn available on each SAI instance.  
Updated Figure 698: Start-up sequence.  
Updated Section 54.6: SAI registers to indicate that SAI registers are accessed by words.  
Section 56: Single wire protocol master interface (SWPMI)  
Updated Section 56: Single wire protocol master interface (SWPMI).  
Section 59: Controller area network with flexible data rate (FDCAN)  
Updated Section 59.1: Introduction and Section 59.2: FDCAN main features. Added Section 59.3: FDCAN implementation.  
Section 59.4.1: Operating modes: updated Section : Software initialization, Section : CAN FD operation, and Section : Transceiver delay compensation.  
Section 59.4.2: Message RAM: updated Acceptance filter, Figure 781: Standard message ID filter path and Figure 782: Extended message ID filter path.  
Updated Section 59.4.4: Bit timing and Section 59.4.5: Clock calibration on CAN.  
Section 59.4.6: Application: updated Section : Software calibration, Section : Clock calibration active and Section : Timing of interface signals. |

</table>
| 27-Feb-2020| 3 (continued) | **Section 59: Controller area network with flexible data rate (FDCAN) (continued)**  
Section 59.4.8: TTCAN configuration: updated Section : Timing of interface signals.  
Updated Table 521: Standard message ID filter element field description, Table 523: Extended message ID filter element field description, Table 525: Trigger memory element description. Updated Table 525: Trigger memory element description and Table 780: Extended message ID filter path.  
Updated Section 59.5.6: FDCAN CC control register (FDCAN_CCCR), Section 59.5.15: FDCAN interrupt register (FDCAN_IR), Section 59.5.18: FDCAN interrupt line enable register (FDCAN_ILE), Section 59.5.21: FDCAN extended ID filter configuration register (FDCAN_XIDFC), Section 59.5.31: FDCAN Rx FIFO 1 status register (FDCAN_RXF1S), Section 59.5.32: FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) and Section 59.7.2: Calibration configuration register (FDCAN_CCU_CCFG). Updated Table 528: CCU register map and reset values.  
**Section 60: USB on-the-go high-speed (OTG_HS)**  
Updated Section 60.2: OTG_HS main features, Section 60.14.2: OTG interrupt register (OTG_GOTGINT), Section 60.14.5: OTG reset register (OTG_GRSTCTL), Section 60.14.6: OTG core interrupt register (OTG_GINTSTS), Section 60.14.18: OTG host periodic transmit FIFO size register (OTG_HPTXFSIZ), Section 60.14.22: OTG host frame interval register (OTG_HFIR), Section 60.14.33: OTG host channel x transfer size register (OTG_HCTSIZx), Section 60.14.39: OTG device configuration register (OTG_DCFG), Section 60.14.40: OTG device control register (OTG_DCTL), Section 60.14.41: OTG device status register (OTG_DSTS), Section 60.14.42: OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK), Section 60.14.43: OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK), Section 60.14.54: OTG device IN endpoint x control register (OTG_DIEPCTLx) and Section 60.14.61: OTG device OUT endpoint x interrupt register (OTG_DOEPINTx).  
Updated Section 60.10: OTG_HS Dynamic update of the OTG_HFIR register.  
Updated Section 60.15.3: Device initialization.  
Updated Section 60.15.5: Host programming model.  
**Section 61: Ethernet (ETH): media access control (MAC) with DMA controller**  
Replaced ptp_pps_o internal signal by eth_ptp_pps_out, and ptp_aux_ts_trig_i by eth_ptp_trg (where x = 0 to 3) and ptp_aux_trg_i[x] by eth_ptp_trgx.  
Update ARPEN bit description in Section : Operating mode configuration register (ETH_MACCR).  
Reintroduced EIPG enumerated values in Section : Extended operating mode configuration register (ETH_MACECR).  
Removed sentence "This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input" from Section : System time nanoseconds register (ETH_MACSTNR), and Section : System time nanoseconds update register (ETH_MACSTNUR) register descriptions. |

| 27-Feb-2020| 3 (continued) | **Section 63: Debug infrastructure**  
Updated Figure 870: Block diagram of debug infrastructure, Figure 871: Power domains of debug infrastructure and Figure 872: Clock domains of debug infrastructure.  
Updated Section : Clock domains.  
Changed ID code for Instruction register = 1110 in Table 622: JTAG-DP data registers.  
Updated notes in Table 623: Debug port registers.  
Modified Section : Debug port target identification register (DP_TARGETID) reset value as well as bit descriptions.  
Modified Section : Access port identification register (AP_IDR) reset value as well as description of REVISION bitfield.  
Updated Table 625: System ROM table 1.  
Modified Section : SYSROM CoreSight peripheral identity register 0 (SYSROM_PIDR0), Section : SYSROM CoreSight peripheral identity register 1 (SYSROM_PIDR1) and Section : SYSROM CoreSight peripheral identity register 2 (SYSROM_PIDR2).  
Added Table 626: System ROM table 2.  
Modified Section : CTI CoreSight peripheral identity register 0 (CTI_PIDR0) and Section : CTI CoreSight peripheral identity register 2 (CTI_PIDR2). Updated bitfield description for Section : CTI application trigger set register (CTI_APPSET), Section : CTI application trigger clear register (CTI_APPCLEAR), Section : CTI application pulse register (CTI_APPPULSE), Section : CTI trigger IN x enable register (CTI_INENx), Section : CTI trigger OUT x enable register (CTI_OUTENx) and Section : CTI channel gate register (CTI_GATE).  
Updated Section : ETF CoreSight peripheral identity register 2 (ETF_PIDR2) reset value.  
Modified Section : TPIU CoreSight peripheral identity register 2 (TPIU_PIDR2), and Section : SWTF CoreSight peripheral identity register 2 (SWTF_PIDR2).  
Changed DBGSTBY_D3 and DBGSTOP_D3 to reserved in Section : SWTF CoreSight peripheral identity register 2 (SWTF_PIDR2).  
Updated Table 641: Cortex-M7 processor ROM table and Table 656: Cortex-M4 ROM table. Updated Table 651: Cortex-M4 ROM table.  
Updated Section : Processor ROM CoreSight peripheral identity register 0 (M7_CPUROM_PIDR0), Section : Processor ROM CoreSight peripheral identity register 1 (M7_CPUROM_PIDR1) and Section : Processor ROM CoreSight peripheral identity register 2 (M7_CPUROM_PIDR2).  
Updated Section : DWT CoreSight peripheral identity register 0 (M7_DWT_PIDR0), Section : DWT CoreSight peripheral identity register 1 (M7_DWT_PIDR1), Section : DWT CoreSight peripheral identity register 2 (M7_DWT_PIDR2) reset value.  
Updated Section : ITM CoreSight peripheral identity register 0 (M7_ITM_PIDR0), Section : ITM CoreSight peripheral identity register 1 (M7_ITM_PIDR1), Section : ITM CoreSight peripheral identity register 2 (M7_ITM_PIDR2).  
Updated Table 648: Cortex-M7 ETM register map and reset values.  
Updated Section : ITM CoreSight peripheral identity register 0 (M7_ITM_PIDR0), Section : ITM CoreSight peripheral identity register 1 (M7_ITM_PIDR1) and Section : ITM CoreSight peripheral identity register 2 (M7_ITM_PIDR2). |
### Table 657. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
**Section 2: Memory and bus architecture**  
Updated Table 2: Bus-master-to-bus-slave interconnect.  
Updated Figure 1: System architecture for STM32H745/55/47/57xx devices.  
**Section 3: RAM ECC monitoring (RAMECC)**  
Added note to Section 3.1: Introduction.  
**Section 4: Embedded flash memory (FLASH)**  
Removed bootloader extension from Figure 8: Embedded flash memory usage.  
Added option byte area (bank 1) in Table 14: Flash memory organization on STM32H745xI/747xI/755xI/757xI devices.  
**Section : Erase operation overview**: added note related to the case where data cache is enabled after erase operations, removed the mention that Bank 2 can be erased with ST secure firmware.  
Updated FLASH registers:  
– Modified number of wait states in description of LATENCY bits in FLASH access control register (FLASH_ACR).  
– Updated FLASH option status register (FLASH_OPTSR_CUR) and FLASH option status register (FLASH_OPTSR_PRG).  
– Added note providing non-secure Flash area start address in SEC_AREA_END1 of FLASH secure address for bank 1 (FLASH_SCAR_CUR1).  
– Added formula to FAIL_ECC_ADDR1/2 in FLASH ECC fail address for bank 1 (FLASH_ECC_FA1R) and FLASH ECC fail address for bank 2 (FLASH_ECC_FA2R), respectively.  
**Section 5: Secure memory management (SMM)**  
Added note below Figure 16: Bootloader state machine in Secure access mode.  
**Section 5.4: Root secure services (RSS)**: added introduction and RSS API addresses.  
**Section 5.5.2: Setting secure user memory areas**: modified name of the service used to initialize the option bytes.  
**Section 6: ART accelerator**  
Added note to PCACHEADDR[11:0] in ART accelerator - control register (ART_CTR).  
**Section 7: Power control (PWR)**  
Modified Section 7.4: Power supplies, Section : VCORE supplied in Bypass mode (LDO and SMPS OFF) and Section 7.4.4: Backup domain.  
Updated Section 7.4.8: DSI regulator.  
Replaced WKUPn+1 with WKUPn, WKUPCn+1 with WKUPCn and WKUPFn+1 with WKUPFn in PWR wakeup clear register (PWR_WKUPCR), PWR wakeup flag register (PWR_WKUPFR) and PWR wakeup enable and polarity register (PWR_WKUPEPR).

</tr>
</thead>
</table>
| 16-Jun-2023| 4 (continued) | **Section 13: System configuration controller (SYSCFG)**  
SYSCFG peripheral mode configuration register (SYSCFG_PMCR): updated reset value, added note indicating that it depends on the package, modified BOOSTVDDSEL bit description in (VDDA instead of VDD).  
Added P[x] pin in SYSCFG external interrupt configuration register 4 (SYSCFG_EXTICR4).  
Added SYSCFG system register (SYSCFG_SR0).  

**Section 16: Direct memory access controller (DMA)**  
Updated number of DMA streams in Section 16.1: DMA introduction  

**Section 18: DMA request multiplexer (DMAMUX)**  
Updated caution note in Section 18.4.3: DMAMUX channels.  

**Section 19: Chrom-ART Accelerator controller (DMA2D)**  
Updated Section 19.3.1: General description, Figure 93: DMA2D block diagram, and Section 19.3.2: DMA2D internal signals.  
Updated Section 19.3.9: DMA2D output FIFO, Section 19.3.12: DMA2D transactions, and Section 19.3.13: DMA2D configuration.  
Updated DMA2D registers: DMA2D output color register (DMA2D_OCOLR), DMA2D foreground CLUT (DMA2D_FGCLUTx) and DMA2D background CLUT (DMA2D_BGCLUTx).  

**Section 22: Cyclic redundancy check calculation unit (CRC)**  
Added CRC register access granularity in Section 22.2: CRC main features and Section 22.4: CRC registers.  
Updated Figure 102: CRC calculation unit block diagram.  
Added note in Section : Polynomial programmability to clarify what are even and odd polynomials.  

**Section 23: Flexible memory controller (FMC)**  
Updated SRAM/NOR-flash chip-select control registers for bank x (FMC_BCRx) reset value.  

**Section 24: Quad-SPI interface (QUADSPI)**  
Changed status polling mode to Automatic status-polling.  
Updated Section : Triggering the start of a command.  

**Section 25: Delay block (DLYB)**  
Updated Section 25.3.4: Delay line length configuration procedure and Section 25.3.5: Output clock phase configuration procedure.

</tbody>
</table>
Section 40: Advanced-control timers (TIM1/TIM8)

Updated Figure 409: Control circuit in normal mode, internal clock divided by 1, Figure 413: Control circuit in external clock mode 2, Figure 415: Capture/compare channel 1 main circuit.

Updated Section 40.3.16: Using the break function, Section 40.3.18: Clearing the OCxREF signal on an external event, and Section 40.3.22: Encoder interface mode.

Section 40.4: TIM1/TIM8 registers:
- Updated TIMx control register 1 (TIMx_CR1)(x = 1, 8) and TIMx control register 2 (TIMx_CR2)(x = 1, 8).
- Updated TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8).
- Updated Table 354: Output control bits for complementary OCx and OCxN channels with break feature.
- Updated TIM1 alternate function option register 1 (TIM1_AF1), TIM1 Alternate function register 2 (TIM1_AF2), TIM8 Alternate function option register 1 (TIM8_AF1) and TIM8 Alternate function option register 2 (TIM8_AF2).

Section 41: General-purpose timers (TIM2/TIM3/TIM4/TIM5)

Updated Figure 470: Control circuit in external clock mode 2, Figure 472: Capture/Compare channel 1 main circuit, and Figure 473: Output stage of Capture/Compare channel (channel 1).

Updated Section 41.3.12: Clearing the OCxREF signal on an external event.

Update note below Figure 490: Master/slave connection example with 1 channel only timers.

Section 41.4: TIM2/TIM3/TIM4/TIM5 registers: updated TIMx control register 2 (TIMx_CR2)(x = 2 to 5), and TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 2 to 5).

Section 42: General-purpose timers (TIM12/TIM13/TIM14)

Updated Figure 497: General-purpose timer block diagram (TIM13/TIM14), Figure 510: Capture/compare channel 1 main circuit, and Figure 511: Output stage of capture/compare channel (channel 1).

Updated Section 42.3.6: PWM input mode (only for TIM12).

Added Section 42.3.18: Using timer output as trigger for other timers (TIM13/TIM14).

Section 42.4: TIM12 registers: updated TIM12 control register 2 (TIM12_CR2), TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1), TIM12 capture/compare enable register (TIM12_CCER).

Section 42.5: TIM13/TIM14 registers: updated TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13 to 14), TIMx capture/compare enable register (TIMx_CCER)(x = 13 to 14)

| 16-Jun-2023| 4        | **Section 51: Universal synchronous/asynchronous receiver transmitter (USART/UART)**  
|            |          | Renamed SCLK pin to CK in the whole section.  
|            |          | Added wakeup from Stop in Section 51.2: USART main features.  
|            |          | Updated Figure 636: RS232 RTS flow control and Figure 637: RS232 CTS flow control to replace RTS and CTS by nRTS and nCTS respectively.  
|            |          | Added Section 51.6: USART in low-power modes. Updated Section 51.7: USART interrupts.  
|            |          | **Section 51.8: USART registers**  
|            |          | – Updated ADD[7:0] bitfield descriptions in USART control register 2 (USART_CR2)  
|            |          | – Updated PSC bitfield description in USART guard time and prescaler register (USART_GTPR)  
|            |          | – Updated ABRRQ bit description in USART request register (USART_RQR) register.  
|            |          | – Updated SBKF bit description in USART interrupt and status register [alternate] (USART_ISR).  
|            |          | **Section 52: Low-power universal asynchronous receiver transmitter (LPUART)**  
|            |          | Renamed SCLK pin to CK in the whole section.  
|            |          | Updated Table 428: Error calculation for programmed baud rates at lpuart_ker_ck_pres = 32.768 kHz.  
|            |          | Replaced 88.36 Kaud by 88.36 kbaud in the example provided in Section: Determining the maximum LPUART baud rate that enables to correctly wake up the MCU from low-power mode.  
|            |          | Added Section 52.5: LPUART in low-power modes and updated Section 52.6: LPUART interrupts.  
|            |          | Section 52.7: LPUART registers: updated LPUART control register 2 (LPUART_CR2), and LPUART interrupt and status register [alternate] (LPUART_ISR).  
|            |          | **Section 53: Serial peripheral interface (SPI)**  
|            |          | Updated Section 53.2: SPI main features, Figure 654: SPI2S block diagram, Section 53.4.2: SPI signals, Section 53.4.3: SPI communication general aspects, note below Figure 655: Full-duplex single master/ single slave application, Figure 656: Half-duplex single master/ single slave application, notes below Figure 657: Simplex single master/ single slave application (master in transmit-only/ slave in receive-only mode), Figure 658: Master and three independent slaves at star topology, Section 53.4.7: Slave select (SS) pin management, Section 53.4.8: Communication formats, Section 53.4.9: Configuration of SPI, Section 53.4.10: Procedure for enabling SPI, Section 53.4.11: SPI data transmission and reception procedures, Section 53.4.12: Procedure for disabling the SPI, and Section 53.4.14: Communication using DMA (direct memory addressing).  
|            |          | Updated Section 53.5.1: TI mode, Section 53.5.2: SPI error flags and Section 53.5.3: CRC computation.  
|            |          | Updated Section 53.6: Low-power mode management and Section 53.7: SPI wakeup and interrupts.  
|            |          | Updated Section 53.8: I2S main features and Section 53.9.2: Pin sharing with SPI function.

|            |          | Added note on 24- and 32-bit data width availability in **Section 53.9.5: Supported audio protocols**, below **Figure 671: Master I2S Philips protocol waveforms (16/32-bit full accuracy)** to Figure 679: Slave PCM waveforms, and **Section 53.9.10: Internal FIFOs**. Updated note below **Table 438: WS and CK level before SPI/I2S is enabled when AFCNTR = 1**, **Section 53.9.7: Startup sequence**, **Section 53.9.9: Clock generator**, **Section 53.9.12: Handling of underrun situation**, and **Section 53.9.13: Handling of overrun situation**. Suppressed section Master I2S MSB Aligned, full-duplex. Updated **Section : Slave I2S Philips standard, receive procedure**. **Section 53.11: SPI/I2S registers:**
|            |          | – Updated SPI/I2S control register 1 (SPI_CR1).
|            |          | – Updated SPI configuration register 1 (SPI_CFG1) and SPI configuration register 2 (SPI_CFG2).
|            |          | – Updated SPI/I2S status register (SPI_SR).
|            |          | – Updated SPI/I2S transmit data register (SPI_TXDR) and SPI/I2S receive data register (SPI_RXDR).
|            |          | – Updated SPI polynomial register (SPI_CRCPOLY).
|            |          | – Updated SPI transmitter CRC register (SPI_TXCRC) and SPI receiver CRC register (SPI_RXCRC).
|            |          | – Updated SPI underrun data register (SPI_UDRDR).
|            |          | – Updated WSINV, CHLEN and DATLEN[1:0] of SPI/I2S configuration register (SPI_I2SCFGR)
|            |          | **Section 54: Serial audio interface (SAI)**
|            |          | **Section 54.4.10: PDM interface:** added reference to implementation section and note 2 in **Table 450: TDM frame configuration examples**.
|            |          | In **Section 54.4.12: SPDIF output**, replaced $F_{SAI\_CK\_x}$ by $F_{\text{FSAI}_x\_ker\_ck}$ in the formula enabling to compute the bit rate.
|            |          | Added note related to bitfield usage depending on Dx line availability in **SAI PDM delay register (SAI_PDMDLY)**.
|            |          | **Section 55: SPDIF receiver interface (SPDIFRX)**
|            |          | Added note in about RCC capabilities in **Section 55.2: SPDIFRX main features** and **Table 459: Minimum spdifrx_ker_ck frequency versus audio sampling rate**.
|            |          | Updated **Section 55.3: SPDIFRX functional description, Figure 711: SPDIFRX block diagram, Figure 716: SPDIFRX decoder, Figure 717: Noise filtering and edge detection and Section 55.5.1: SPDIFRX control register (SPDIFRX_CR)**.
|            |          | **Section 58: Secure digital input/output MultiMediaCard interface (SDMMC)**
|            |          | Updated **Section : Data path, Section : Data FIFO, Section : Stream operation and CMD12, Section : Block operation and CMD12, Section : Normal boot operation, and Section : Alternative boot operation**.
|            |          | **Section 58.10: SDMMC registers:** updated DBLOCKSIZE[3:0] in **SDMMC data control register (SDMMC_DCTRL)**, **SDMMC IDMA buffer 0 base address register (SDMMC_IDMABASE0R)** and **SDMMC IDMA buffer 1 base address register (SDMMC_IDMABASE1R)**.

</tr>
</thead>
</table>
| 16-Jun-2023| 4 (continued) | **Section 59: Controller area network with flexible data rate (FDCAN)**<br>Updated Section 59.4.6: Application. Modified Section Figure 777.: Transceiver delay measurement.  
Updated FDCAN data bit timing and prescaler register (FDCAN_DBTP), and FDCAN CC control register (FDCAN_CCCR).  
Added Section 59.5.47: FDCAN register map and Section 59.5: FDCAN registers.  

**Section 60: USB on-the-go high-speed (OTG_HS)**<br>Updated Section 60.4.3: OTG_HS core, Section 60.4.4: Embedded full-speed OTG PHY connected to OTG_HS.  
Added Section 60.4.5: OTG detections.  
Updated Section 60.4.6: High-speed OTG PHY connected to OTG_HS and Section 60.5: OTG_HS dual role device (DRD).  
Added Figure 795: OTG_HS peripheral-only connection and Figure 796: OTG_HS host-only connection.  
Section 60.14: OTG_HS registers:  
– Updated Table 540: TRDT values.  
– Added ODDFRM bit in OTG host channel x characteristics register (OTG_HCCHARx).  

**Section 61: Ethernet (ETH): media access control (MAC) with DMA controller**<br>Updated Section 61.1: Ethernet introduction, Section 61.2: Ethernet main features, Section 61.3: Ethernet pins and internal signals, Figure 824: Ethernet high-level block diagram.  
Updated step 9 of DMA reception sequence in Section : DMA reception. Added Section : Priority scheme for Tx DMA and Rx DMA.  
Updated Section 61.5.1: Double VLAN processing, Section 61.5.2: Source address and VLAN insertion, replacement, or deletion, Section 61.5.3: Packet filtering, Section 61.5.4: IEEE 1588 timestamp support, Section 61.5.5: Checksum offload engine, Section 61.5.6: TCP segmentation offload, Section 61.5.7: IPv4 ARP offload, Section 61.5.8: Loopback, Section 61.5.9: Flow control and Section 61.5.10: MAC management counters.  
Updated Section : SMA functional overview, Section : MII management write operations, Section : MII management read operation, and Section : Preamble suppression.  
Updated Section 61.6.2: Media independent interface (MII) and Section 61.6.3: Reduced media independent interface (RMII).  
Updated Section 61.7: Ethernet low-power modes.  
Updated Section 61.9.1: DMA initialization, Section 61.9.3: MAC initialization, Section 61.9.5: Stopping and starting transmission. Added Section 61.9.6: Programming guidelines for switching to new descriptor list in RxDMA, Section 61.9.7: Programming guidelines for switching the AHB clock frequency, and Section 61.9.10: Programming guidelines for PTP offload feature. Updated Section 61.9.11: Programming guidelines for Energy Efficient Ethernet (EEE), Section 61.9.12: Programming guidelines for flexible pulse-per-second (PPS) output, Section 61.9.13: Programming guidelines for TSO and Section 61.9.14: Programming guidelines to perform VLAN filtering on the receive. |

</tr>
</thead>
</table>
| 16-Jun-2023| 4 (continued) | **Section 61: Ethernet (ETH): media access control (MAC) with DMA controller (continued)**

**Section 61.10: Descriptors:**
- **Section 61.10.3: Transmit descriptor:** updated TDES2 normal descriptor (read format), TDES3 normal descriptor (read format), TDES3 normal descriptor (write-back format), TDES3 context descriptor (read format).
- **Section 61.10.4: Receive descriptor:** RDES0 normal descriptor (read format), RDES0 normal descriptor (write-back format), RDES3 normal descriptor (read format), RDES3 normal descriptor (write-back format).

**Section 61.11.2: Ethernet DMA registers:**
- **DMA mode register (ETH_DMAMR):** changed DA bit access type to rw.
- Updated System bus mode register (ETH_DMASBMR) reset value.
- Updated Channel transmit control register (ETH_DMACTXCR) and Channel receive control register (ETH_DMACRXCR).
- Updated TDES.LA and RDES.LA bitfield descriptions of Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR), respectively.
- Updated TDT and RDT bitfield descriptions in Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) and Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR), respectively.
- Updated TDESLA and RDESLA bitfield descriptions of Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR), respectively.
- Updated TDRL bitfield descriptions in Channel Tx descriptor ring length register (ETH_DMACTXRRL). Updated Channel Rx descriptor ring length register (ETH_DMACRXRRL).
- **Channel interrupt enable register (ETH_DMACIER):** removed MMCIE/MMCRSIPIS and GPIIS/GPIIE from Figure 859: Generation of ETH_DMAISR flags; updated AIE bit description.
- Added RWU bitfield in Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR).
- **Channel status register (ETH_DMACSR):** changed bit 15:10, 8:6 and 2:0 access type to rc_w1; updated REB, TEB, AIS, CDE and TBU bit descriptions.
- **Channel missed frame count register (ETH_DMACMFCR):** changed all bit access type to rc_r.

**Section 61.11.3: Ethernet MTL registers**
- **Operating mode Register (ETH_MTLOMR):** updated CNTPRST and RAA and DTXSTS bit descriptions.
- Updated Tx queue operating mode Register (ETH_MTLTXQOMR).
- Updated Tx queue underflow register (ETH_MTLTXQUR) bit access type.
- Updated Rx queue operating mode register (ETH_MTLRXQOMR).
- Updated Rx queue missed packet and overflow counter register (ETH_MTLRXQMPOCR) access type.
