Bits 31:7  Reserved, must be kept at reset value.

- Bit 6  **MUPDC**: Master update interrupt flag clear
  Writing 1 to this bit clears the MUPDC flag in HRTIM_MISR register.

- Bit 5  **SYNCC**: Sync input interrupt flag clear
  Writing 1 to this bit clears the SYNC flag in HRTIM_MISR register.

- Bit 4  **MREPC**: Repetition interrupt flag clear
  Writing 1 to this bit clears the MREP flag in HRTIM_MISR register.

- Bit 3  **MCMP4C**: Master compare 4 interrupt flag clear
  Writing 1 to this bit clears the MCMP4 flag in HRTIM_MISR register.

- Bit 2  **MCMP3C**: Master compare 3 interrupt flag clear
  Writing 1 to this bit clears the MCMP3 flag in HRTIM_MISR register.

- Bit 1  **MCMP2C**: Master compare 2 interrupt flag clear
  Writing 1 to this bit clears the MCMP2 flag in HRTIM_MISR register.

- Bit 0  **MCMP1C**: Master compare 1 interrupt flag clear
  Writing 1 to this bit clears the MCMP1 flag in HRTIM_MISR register.

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 MCNT[15:0]: Counter value

Holds the master timer counter value. This register can only be written when the master timer is stopped (MCEN = 0 in HRTIM_MCR).

Note: For HR clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be written and return 0 when read.

Note: The timer behavior is not guaranteed if the counter value is set above the HRTIM_MPER register value.

27.5.6 HRTIM master timer period register (HRTIM_MPER)

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 MPER[15:0]: Master timer period value

This register defines the counter overflow value.

The period value must be above or equal to 3 periods of the f_HRTIM clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2, ..., The maximum value is 0x0000 FFDF.

Bits 31:28 **UPDGAT[3:0]**: Update gating

These bits define how the update occurs relatively to the burst DMA transaction and the external update request on update enable inputs hrtim_upd_en[3:1] (see Table 210).

The update events, as mentioned below, can be: MSTU, TFU, TEU, TDU, TCU, TBU, TAU, TxRSTU, TxREP U.

0000: The update occurs independently from the DMA burst transfer
0001: The update occurs when the DMA burst transfer is completed
0010: The update occurs on the update event following the DMA burst transfer completion
0011: The update occurs on a rising edge on hrtim_upd_en1
0100: The update occurs on a rising edge on hrtim_upd_en2
0101: The update occurs on a rising edge on hrtim_upd_en3
0110: The update occurs on the update event following a rising edge on hrtim_upd_en1
0111: The update occurs on the update event following a rising edge on hrtim_upd_en2
1000: The update occurs on the update event following a rising edge on hrtim_upd_en3
Others: Reserved

*Note: This bitfield must be reset before programming a new value.*

For **UPDGAT[3:0]** values equal to 0001, 0011, 0100, 0101, it is possible to have multiple concurrent update source (for instance RSTU and DMA burst).

Bit 27 **PREEN**: Preload enable

This bit enables the registers preload mechanism and defines whether a write access into a preloadable register is done into the active or the preload register.

0: Preload disabled: the write access is directly done into the active register
1: Preload enabled: the write access is done into the preload register
Bits 26:25 **DACSYNC[1:0]**: DAC synchronization
A DAC synchronization event is generated when the timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to Section 27.3.21: DAC triggers for connections details).
00: No DAC trigger generated
01: Trigger generated on hrtim_dac_trg1
10: Trigger generated on hrtim_dac_trg2
11: Trigger generated on hrtim_dac_trg3

Bit 24 **MSTU**: Master timer update
Register update is triggered by the master timer update.
0: Update by master timer disabled
1: Update by master timer enabled

Bit 23 **TEU**: Timer E update
Register update is triggered by the timer E update
0: Update by timer E disabled
1: Update by timer E enabled

*Note: This bit is reserved for HRTIM_TIMECR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMFCR.*

Bit 22 **TDU**: Timer D update
Register update is triggered by the timer D update
0: Update by timer D disabled
1: Update by timer D enabled

*Note: This bit is reserved for HRTIM_TIMDCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMECR, HRTIM_TIMFCR.*

Bit 21 **TCU**: Timer C update
Register update is triggered by the timer C update
0: Update by timer C disabled
1: Update by timer C enabled

*Note: This bit is reserved for HRTIM_TIMCCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMDCR, HRTIM_TIMECR, HRTIM_TIMFCR.*

Bit 20 **TBU**: Timer B update
Register update is triggered by the timer B update
0: Update by timer B disabled
1: Update by timer B enabled

*Note: This bit is reserved for HRTIM_TIMBCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMECR, HRTIM_TIMFCR.*

Bit 19 **TAU**: Timer A update
Register update is triggered by the timer A update
0: Update by timer A disabled
1: Update by timer A enabled

*Note: This bit is reserved for HRTIM_TIMBCR. It is only available for HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR, HRTIM_TIMFCR.*

Bit 18 **TxRSTU**: Timer x reset update
Register update is triggered by timer x counter reset or roll-over to 0 after reaching the period value in continuous mode.
0: Update by timer x reset / roll-over disabled
1: Update by timer x reset / roll-over enabled
Bit 17 **TxREPU**: Timer x repetition update
Register update is triggered when the counter rolls over and HRTIM_REPx = 0
0: Update on repetition disabled
1: Update on repetition enabled

Bit 16 **TFU**: Timer F update
Register update is triggered by the timer F update
0: Update by timer F disabled
1: Update by timer F enabled

*Note: This bit is reserved for HRTIM_TIMFCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMESCR.*

Bits 15:14 **DELCMP4[1:0]**: CMP4 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see Section : Auto-delayed mode).
00: CMP4 register is always active (standard compare mode)
01: CMP4 value is recomputed and is active following a capture 2 event
10: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 1 match (timeout function if capture 2 event is missing)
11: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)

*Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).*

Bits 13:12 **DELCMP2[1:0]**: CMP2 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see Section : Auto-delayed mode).
00: CMP2 register is always active (standard compare mode)
01: CMP2 value is recomputed and is active following a capture 1 event
10: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after compare 1 match (timeout function if capture event is missing)
11: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after compare 3 match (timeout function if capture event is missing)

*Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).*

Bit 11 **SYNCSTRTx**: Synchronization starts timer x
This bit defines the timer x behavior following the synchronization event:
0: No effect on timer x
1: A synchronization input event starts the timer x

Bit 10 **SYNCRSTx**: Synchronization resets timer x
This bit defines the timer x behavior following the synchronization event:
0: No effect on timer x
1: A synchronization input event resets the timer x

Bit 9 **RSYNCU**: Re-synchronized update
This bit specifies whether update source coming outside from the timing unit must be synchronized:
0: The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) is taken into account immediately
1: The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) is taken into account on the following reset/roll-over event.

*Note: This bit is significant only when UPDGAT[3:0] = 0000, it is ignored otherwise.*
Bits 8:7 **INTLVD[1:0]**: Interleaved mode
   - This bitfield is significant only when the HALF bit is reset. It enables the interleaved mode.
   - 00: Interleaved mode disabled
   - 01: Triple interleaved mode: when HRTIM_PERxR register is written, the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/3 value, and the HRTIM_CMP2xR active register is automatically updated with 2x (HRTIM_PERxR/3) value.
   - 10: Quad interleaved mode: when HRTIM_PERxR register is written, the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/4 value, the HRTIM_CMP2xR active register is automatically updated with HRTIM_PERxR/2 value and the HRTIM_CMP3xR active register is automatically updated with 3x (HRTIM_PERxR/4) value.
   - 11: Interleaved mode disabled

Bit 6 **PSHPLL**: Push-pull mode enable
   - This bit enables the push-pull mode.
   - 0: Push-pull mode disabled
   - 1: Push-pull mode enabled
   
   **Note**: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 5 **HALF**: Half mode enable
   - This bit enables the half duty-cycle mode: the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/2 value when HRTIM_PERxR register is written.
   - 0: Half mode disabled
   - 1: Half mode enabled

Bit 4 **RETRIG**: Re-triggerable mode
   - This bit defines the counter behavior in single shot mode.
   - 0: The timer is not re-triggerable: a counter reset is done if the counter is stopped (period elapsed in single-shot mode or counter stopped in continuous mode)
   - 1: The timer is re-triggerable: a counter reset is done whatever the counter state.

Bit 3 **CONT**: Continuous mode
   - This bit defines the timer operating mode.
   - 0: The timer operates in single-shot mode and stops when it reaches TIMxPER value
   - 1: The timer operates in continuous mode and rolls over to zero when it reaches TIMxPER value

Bits 2:0 **CKPSCx[2:0]**: HRTIM timer x clock prescaler
   - These bits define the master timer high-resolution clock prescaler ratio.
   - The counter clock equivalent frequency \( f_{\text{COUNTER}} \) is equal to \( f_{\text{HRCK}} / 2^{\text{CKPSC}[2:0]} \)
   - The prescaling ratio cannot be modified once the timer is enabled.
27.5.13 HRTIM timer x interrupt status register (HRTIM_TIMxISR) (x = A to F)

Address offset: Block A: 0x084
Address offset: Block B: 0x104

Bits 31:22 Reserved, must be kept at reset value.

- **Bit 21** **O2CPY**: Output 2 copy
  - This status bit is a raw copy of the output 2 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.
  - 0: Output 2 is inactive
  - 1: Output 2 is active

- **Bit 20** **O1CPY**: Output 1 copy
  - This status bit is a raw copy of the output 1 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.
  - 0: Output 1 is inactive
  - 1: Output 1 is active

- **Bit 19** **O2STAT**: Output 2 status
  - This status bit indicates the output 2 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.
  - 0: Output 2 was inactive
  - 1: Output 2 was active

- **Bit 18** **O1STAT**: Output 1 status
  - This status bit indicates the output 1 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.
  - 0: Output 1 was inactive
  - 1: Output 1 was active

- **Bit 17** **IPPSTAT**: Idle push-pull Status
  - This status bit indicates on which output the signal was applied, in push-pull mode balanced fault mode or delayed idle mode, when the protection was triggered (whatever the output state, active or inactive).
  - 0: Protection occurred when the output 1 was active and output 2 forced inactive
  - 1: Protection occurred when the output 2 was active and output 1 forced inactive
Bit 16 **CPPSTAT**: Current push-pull status  
This status bit indicates on which output the signal is currently applied, in push-pull mode. It is only significant in this configuration.  
0: Signal applied on output 1 and output 2 forced inactive  
1: Signal applied on output 2 and output 1 forced inactive  

Bit 15 Reserved, must be kept at reset value.  

Bit 14 **DLYPRRT**: Delayed protection flag  
0: No delayed protection interrupt occurred  
1: Delayed Idle or balanced Idle mode entry occurred  

Bit 13 **RST**: Reset and/or roll-over interrupt flag  
This bit is set by hardware when the timer x counter is reset or rolls over in continuous mode.  
0: No TIMx counter reset/roll-over interrupt occurred  
1: TIMx counter reset/roll-over interrupt occurred  

Bit 12 **RSTx2**: Output 2 reset interrupt flag timer x  
Refer to RSTx1 description  

Bit 11 **SETx2**: Output 2 set interrupt flag timer x  
Refer to SETx1 description  

Bit 10 **RSTx1**: Output 1 reset interrupt flag timer x  
This bit is set by hardware when the Tx1 output is reset (goes from active to inactive mode).  
0: No Tx1 output reset interrupt occurred  
1: Tx1 output reset interrupt occurred  

Bit 9 **SETx1**: Output 1 set interrupt flag timer x  
This bit is set by hardware when the Tx1 output is set (goes from inactive to active mode).  
0: No Tx1 output set interrupt occurred  
1: Tx1 output set interrupt occurred  

Bit 8 **CPT2**: Capture 2 interrupt flag  
Refer to CPT1 description  

Bit 7 **CPT1**: Capture 1 interrupt flag  
This bit is set by hardware when the timer x capture 1 event occurs.  
0: No timer x capture 1 interrupt occurred  
1: Timer x capture 1 interrupt occurred  

Bit 6 **UPD**: Update interrupt flag  
This bit is set by hardware when the timer x update event occurs.  
0: No timer x update interrupt occurred  
1: Timer x update interrupt occurred  

Bit 5 Reserved, must be kept at reset value.  

Bit 4 **REP**: Repetition interrupt flag  
This bit is set by hardware when the timer x repetition period has elapsed.  
0: No timer x repetition interrupt occurred  
1: Timer x repetition interrupt occurred  

Bit 3 **CMP4**: Compare 4 interrupt flag  
Refer to CMP1 description
Bit 2 **CMP3**: Compare 3 interrupt flag
Refer to CMP1 description

Bit 1 **CMP2**: Compare 2 interrupt flag
Refer to CMP1 description

Bit 0 **CMP1**: Compare 1 interrupt flag
This bit is set by hardware when the timer x counter matches the value programmed in the compare 1 register.
0: No compare 1 interrupt occurred
1: Compare 1 interrupt occurred

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 CNTx[15:0]: Timer x counter value

- This register holds the timer x counter value. It can only be written when the timer is stopped (TxCEN = 0 in HRTIM_TIMxCR).
- **Note:** For HR clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be written and return 0 when read.
- **Note:** The timer behavior is not guaranteed if the counter value is above the HRTIM_PERxR register value.

### 27.5.17 HRTIM timer x period register (HRTIM_PERxR) (x = A to F)

CMP4x[15:0]

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 **CMP4x[15:0]:** Timer x compare 4 value

This register holds the compare 4 value.
This register holds either the content of the preload register or the content of the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the $f_{\text{HRTIM}}$ clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...
This register can behave as an auto-delayed compare register, if enabled with DELCMP4[1:0] bits in HRTIM_TIMxCR.
27.5.24  HRTIM timer x capture 1 register (HRTIM_CPT1xR) (x = A to F)

Address offset: Block A: 0x0B0
Address offset: Block B: 0x130
Address offset: Block C: 0x1B0
Address offset: Block D: 0x230
Address offset: Block E: 0x2B0
Address offset: Block F: 0x330
Reset value: 0x0000 0000

Note: In up/down mode (UDM bit set to 1), the capture value is referred to:
- counting reset, when up-counting
- the PER event when down counting

The DIR bit allows to discriminate the up-down phases when reading the captured value.

Note: This is a regular resolution register: for HR clock prescaling ratio below 32
(CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be
written and return 0 when read.
27.5.25 HRTIM timer x capture 2 register (HRTIM_CPT2xR)
(x = A to F)

Address offset: Block A: 0x0B4
Address offset: Block B: 0x134

</table>

Bit 31  **DTFLKx**: Deadtime falling lock timer x

This write-once bit prevents the deadtime (sign and value) to be modified, if enabled.
0: Deadtime falling value and sign is writable
1: Deadtime falling value and sign is read-only

*Note: This bit is not preloaded*

Bit 30  **DTFSLKx**: Deadtime falling sign lock timer x

This write-once bit prevents the sign of falling deadtime to be modified, if enabled.
0: Deadtime falling sign is writable
1: Deadtime falling sign is read-only

*Note: This bit is not preloaded.*

Bits 29:26  Reserved, must be kept at reset value.

Bit 25  **SDTFx**: Sign deadtime falling value timer x

This register determines whether the deadtime is positive (signals not overlapping) or negative (signals overlapping).
0: Positive deadtime on falling edge
1: Negative deadtime on falling edge

Bits 24:16  **DTFx[8:0]**: Deadtime falling value timer x

This register holds the value of the deadtime following a falling edge of reference PWM signal.
\[ t_{DTL} = DTFx[8:0] \times t_{DTG} \]

Bit 15  **DTRLKx**: Deadtime rising lock timer x

This write-once bit prevents the deadtime (sign and value) to be modified, if enabled.
0: Deadtime rising value and sign is writable
1: Deadtime rising value and sign is read-only

*Note: This bit is not preloaded.*
Bit 14 **DTRSLKx**: Deadtime rising sign lock timer x
- This write-once bit prevents the sign of deadtime to be modified, if enabled.
- 0: Deadtime rising sign is writable
- 1: Deadtime rising sign is read-only

**Note**: This bit is not preloaded.

Bit 13 Reserved, must be kept at reset value.

Bits 12:10 **DTPRSC[2:0]**: Deadtime prescaler
- This register holds the value of the deadtime clock prescaler determined by the following formula:
  \[ t_{DTG} = \left(2^{\text{DTPRSC}[2:0]}\right) \times (t_{\text{HRTIM}} / 8) \]
- (see **Table 222: Deadtime resolution and max absolute values**)
- This bitfield is read-only as soon as any of the lock bit is enabled (DTFLKs, DTFSLKx, DTRLKx, DTRSLKx).

Bit 9 **SDTRx**: Sign deadtime rising value timer x
- This register determines whether the deadtime is positive or negative (overlapping signals).
- 0: Positive deadtime on rising edge
- 1: Negative deadtime on rising edge

Bits 8:0 **DTRx[8:0]**: Deadtime rising value timer x
- This register holds the value of the deadtime following a rising edge of reference PWM signal.
  \[ t_{DTR} = DTRx[8:0] \times t_{DTG} \]

Bit 31 **UPDATE**: Registers update (transfer preload to active)
Register update event forces the output to its active state.

Bit 30 **EXTEVNT10**: External event 10
Refer to ExtEVNT1 description.

Bit 29 **EXTEVNT9**: External event 9
Refer to ExtEVNT1 description.

Bit 28 **EXTEVNT8**: External event 8
Refer to ExtEVNT1 description.

Bit 27 **EXTEVNT7**: External event 7
Refer to ExtEVNT1 description.

Bit 26 **EXTEVNT6**: External event 6
Refer to ExtEVNT1 description.

Bit 25 **EXTEVNT5**: External event 5
Refer to ExtEVNT1 description.

Bit 24 **EXTEVNT4**: External event 4
Refer to ExtEVNT1 description.

Bit 23 **EXTEVNT3**: External event 3
Refer to ExtEVNT1 description.

Bit 22 **EXTEVNT2**: External event 2
Refer to ExtEVNT1 description.

Bit 21 **EXTEVNT1**: External event 1
External event 1 forces the output to its active state.

Bit 20 **TIMEEVNT9**: Timer event 9
Refer to TimeEVNT1 description.
Bit 19  **TIMEVNT8**: Timer event 8
Refer to **TIMEVNT1** description.

Bit 18  **TIMEVNT7**: Timer event 7
Refer to **TIMEVNT1** description.

Bit 17  **TIMEVNT6**: Timer event 6
Refer to **TIMEVNT1** description.

Bit 16  **TIMEVNT5**: Timer event 5
Refer to **TIMEVNT1** description.

Bit 15  **TIMEVNT4**: Timer event 4
Refer to **TIMEVNT1** description.

Bit 14  **TIMEVNT3**: Timer event 3
Refer to **TIMEVNT1** description.

Bit 13  **TIMEVNT2**: Timer event 2
Refer to **TIMEVNT1** description.

Bit 12  **TIMEVNT1**: Timer event 1
Timers event 1 forces the output to its active state (refer to Table 219 for timer events assignments).

Bit 11  **MSTCMP4**: Master compare 4
Master timer compare 4 event forces the output to its active state.

Bit 10  **MSTCMP3**: Master compare 3
Master timer compare 3 event forces the output to its active state.

Bit 9  **MSTCMP2**: Master compare 2
Master timer compare 2 event forces the output to its active state.

Bit 8  **MSTCMP1**: Master compare 1
Master timer compare 1 event forces the output to its active state.

Bit 7  **MSTPER**: Master period
The master timer counter roll-over in continuous mode, or to the master timer reset in single-shot mode forces the output to its active state.

Bit 6  **CMP4**: Timer x compare 4
Timer A compare 4 event forces the output to its active state.

Bit 5  **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its active state.

Bit 4  **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its active state.

Bit 3  **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its active state.
Bit 2 **PER:** Timer x period
   Timer A period event forces the output to its active state.
   Note: *In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.*

Bit 1 **RESYNC:** Timer A resynchronization
   Timer A reset event coming solely from software or SYNC input forces the output to its active state.
   Note: *Other timer reset are not affecting the output when RESYNC=1.*

Bit 0 **SST:** Software set trigger
   This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
   Note: *This bit is not preloaded.*

   Refer to **TIMEVNT1** description.

Bit 13 **TIMEVNT2**: Timer event 2
   Refer to **TIMEVNT1** description.

Bit 12 **TIMEVNT1**: Timer event 1
   Timers event 1 forces the output to its active state (refer to *Table 219* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4
   Master timer compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3**: Master compare 3
   Master timer compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2**: Master compare 2
   Master timer compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1**: Master compare 1
   Master timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER**: Master period
   The master timer counter roll-over in continuous mode, or to the master timer reset in single-shot mode forces the output to its active state.

Bit 6 **CMP4**: Timer x compare 4
   Timer A compare 4 event forces the output to its active state.

Bit 5 **CMP3**: Timer x compare 3
   Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2**: Timer x compare 2
   Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1**: Timer x compare 1
   Timer A compare 1 event forces the output to its active state.
**High-resolution timer (HRTIM)**

Bit 2 **PER**: Timer x period
    Timer A period event forces the output to its active state.
    
    *Note*: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

Bit 1 **RESYNC**: Timer A resynchronization
    Timer A reset event coming solely from software or SYNC input forces the output to its active state.
    
    *Note*: Other timer reset are not affecting the output when RESYNC=1.

Bit 0 **SST**: Software set trigger
    This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
    
    *Note*: This bit is not preloaded.

</tbody>
</table>

Bit 31 **UPDATE**: Registers update (transfer preload to active)
    Register update event forces the output to its active state.

Bit 30 **EXTEVNT10**: External event 10
    Refer to EXTEVNT1 description.

Bit 29 **EXTEVNT9**: External event 9
    Refer to EXTEVNT1 description.

Bit 28 **EXTEVNT8**: External event 8
    Refer to EXTEVNT1 description.

Bit 27 **EXTEVNT7**: External event 7
    Refer to EXTEVNT1 description.

Bit 26 **EXTEVNT6**: External event 6
    Refer to EXTEVNT1 description.
Bit 25 **EXTEVNT5**: External event 5  
Refer to EXTEVNT1 description.

Bit 24 **EXTEVNT4**: External event 4  
Refer to EXTEVNT1 description.

Bit 23 **EXTEVNT3**: External event 3  
Refer to EXTEVNT1 description.

Bit 22 **EXTEVNT2**: External event 2  
Refer to EXTEVNT1 description.

Bit 21 **EXTEVNT1**: External event 1  
External event 1 forces the output to its active state.

Bit 20 **TIMEVNT9**: Timer event 9  
Refer to TIMEVNT1 description.

Bit 19 **TIMEVNT8**: Timer event 8  
Refer to TIMEVNT1 description.

Bit 18 **TIMEVNT7**: Timer event 7  
Refer to TIMEVNT1 description.

Bit 17 **TIMEVNT6**: Timer event 6  
Refer to TIMEVNT1 description.

Bit 16 **TIMEVNT5**: Timer event 5  
Refer to TIMEVNT1 description.

Bit 15 **TIMEVNT4**: Timer event 4  
Refer to TIMEVNT1 description.

Bit 14 **TIMEVNT3**: Timer event 3  
Refer to TIMEVNT1 description.

Bit 13 **TIMEVNT2**: Timer event 2  
Refer to TIMEVNT1 description.

Bit 12 **TIMEVNT1**: Timer event 1  
Timers event 1 forces the output to its active state (refer to *Table 219* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4  
Master timer compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3**: Master compare 3  
Master timer compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2**: Master compare 2  
Master timer compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1**: Master compare 1  
Master timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER**: Master period  
The master timer counter roll-over in continuous mode, or to the master timer reset in single-shot mode forces the output to its active state.

Bit 6 **CMP4**: Timer x compare 4  
Timer A compare 4 event forces the output to its active state.
Bit 5 **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its active state.

Bit 2 **PER**: Timer x period
Timer A period event forces the output to its active state.
Note: *In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.*

Bit 1 **RESYNC**: Timer A resynchronization
Timer A reset event coming solely from software or SYNC input forces the output to its active state.
Note: *Other timer reset are not affecting the output when RESYNC=1.*

Bit 0 **SST**: Software set trigger
This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
Note: *This bit is not preloaded.*

Refer to EE1LTCH description

Bit 11  Reserved, must be kept at reset value.

Bits 10:7  **EE2FLTR[3:0]**: External event 2 filter
Refer to EE1FLTR[3:0] description.

Bit 6  **EE2LTCH**: External event 2 latch
Refer to EE1LTCH description.
Bit 5  Reserved, must be kept at reset value.

Bits 4:1  **EE1FLTR[3:0]:** External event 1 filter  
0000: No filtering  
0001: Blanking from counter reset/roll-over to compare 1  
0010: Blanking from counter reset/roll-over to compare 2 in up-counting mode (UDM bit reset)  
In up-down counting mode (UDM bit set): blanking from compare 1 to compare 2, only during the up-counting phase.  
0011: Blanking from counter reset/roll-over to compare 3  
0100: Blanking from counter reset/roll-over to compare 4  
0100: Blanking from counter reset/roll-over to compare 4 in up-counting mode (UDM bit reset)  
In up-down counting mode (UDM bit set): blanking from compare 3 to compare 4, only during the up-counting phase.  
0101: Blanking from another timing unit: TIMFLTR1 source (see Table 227 for details)  
0110: Blanking from another timing unit: TIMFLTR2 source (see Table 227 for details)  
0111: Blanking from another timing unit: TIMFLTR3 source (see Table 227 for details)  
1000: Blanking from another timing unit: TIMFLTR4 source (see Table 227 for details)  
1001: Blanking from another timing unit: TIMFLTR5 source (see Table 227 for details)  
1010: Blanking from another timing unit: TIMFLTR6 source (see Table 227 for details)  
1011: Blanking from another timing unit: TIMFLTR7 source (see Table 227 for details)  
1100: Blanking from another timing unit: TIMFLTR8 source (see Table 227 for details)  
1101: Windowing from counter reset/roll-over to compare 2 in up-counting mode (UDM bit reset)  
In up-down counting mode (UDM bit set): windowing from compare 2 to compare 3, only during the up-counting phase.  
1110: Windowing from counter reset/roll-over to compare 3 in up-counting mode (UDM bit reset)  
In up-down counting mode (UDM bit set): windowing from compare 2 to compare 3, only during the down-counting phase.  
1111: Windowing from another timing unit: TIMWIN source (see Table 228 for details) in up-counting mode (UDM bit reset)  
In up-down counting mode (UDM bit set): windowing from compare 2 during the up-counting phase to compare 3 during the down-counting phase.  

*Note:* Whenever a compare register is used for filtering, the value must be strictly above 0.  
This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 0  **EE1LTCH:** External event 1 latch  
0: Event 1 is ignored if it happens during a blank, or passed through during a window.  
1: Event 1 is latched and delayed till the end of the blanking or windowing period.  

*Note:* A timeout event is generated in window mode (EE1FLTR[3:0]=1101, 1110, 1111) if EE1LTCH = 0, except if the external event is programmed in fast mode (EExFAST = 1).  
This bitfield must not be modified once the counter is enabled (TxCEN bit set).

The timer A counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer A counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer A counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer A compare 4 reset
The timer A counter is reset upon timer A compare 4 event.

Bit 2 **CMP2**: Timer A compare 2 reset
The timer A counter is reset upon timer A compare 2 event.

Bit 1 **UPDT**: Timer A update reset
The timer A counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer A counter is reset upon timer F compare 1 event.
27.5.34 HRTIM timer B reset register (HRTIM_RSTBR)

Address offset: 0x154
Reset value: 0x0000 0000

Bit 31 TIMFCMP2: Timer F compare 2
The timer B counter is reset upon timer F Compare 2 event.

Bit 30 TIMECMP4: Timer E compare 4
The timer B counter is reset upon timer E compare 4 event.

Bit 29 TIMECMP2: Timer E compare 2
The timer B counter is reset upon timer E compare 2 event.

Bit 28 TIMECMP1: Timer E compare 1
The timer B counter is reset upon timer E compare 1 event.

Bit 27 TIMDCMP4: Timer D compare 4
The timer B counter is reset upon timer D compare 4 event.

Bit 26 TIMDCMP2: Timer D compare 2
The timer B counter is reset upon timer D compare 2 event.

Bit 25 TIMDCMP1: Timer D compare 1
The timer B counter is reset upon timer D compare 1 event.

Bit 24 TIMCCMP4: Timer C compare 4
The timer B counter is reset upon timer C compare 4 event.

Bit 23 TIMCCMP2: Timer C compare 2
The timer B counter is reset upon timer C compare 2 event.

Bit 22 TIMCCMP1: Timer C compare 1
The timer B counter is reset upon timer C compare 1 event.

Bit 21 TIMACMP4: Timer A compare 4
The timer B counter is reset upon timer A compare 4 event.

Bit 20 TIMACMP2: Timer A compare 2
The timer B counter is reset upon timer A compare 2 event.

Bit 19 TIMACMP1: Timer A compare 1
The timer B counter is reset upon timer A compare 1 event.

Bit 18 EXTEVNT10: External event
The timer B counter is reset upon external event 10.

Bit 17 EXTEVNT9: External event 9
The timer B counter is reset upon external event 9.
Bit 16 **EXTEVNT8**: External event 8
The timer B counter is reset upon external event 8.

Bit 15 **EXTEVNT7**: External event 7
The timer B counter is reset upon external event 7.

Bit 14 **EXTEVNT6**: External event 6
The timer B counter is reset upon external event 6.

Bit 13 **EXTEVNT5**: External event 5
The timer B counter is reset upon external event 5.

Bit 12 **EXTEVNT4**: External event 4
The timer B counter is reset upon external event 4.

Bit 11 **EXTEVNT3**: External event 3
The timer B counter is reset upon external event 3.

Bit 10 **EXTEVNT2**: External event 2
The timer B counter is reset upon external event 2.

Bit 9 **EXTEVNT1**: External event 1
The timer B counter is reset upon external event 1.

Bit 8 **MSTCMP4**: Master compare 4
The timer B counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer B counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer B counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer B counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer B counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer B compare 4 reset
The timer B counter is reset upon timer B compare 4 event.

Bit 2 **CMP2**: Timer B compare 2 reset
The timer B counter is reset upon timer B compare 2 event.

Bit 1 **UPDT**: Timer B update reset
The timer B counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer B counter is reset upon timer F compare 1 event.

The timer D counter is reset upon timer C compare 1 event. |
| Bit 24 | TIMBCMP4: Timer B compare 4  
The timer D counter is reset upon timer B compare 4 event. |
| Bit 23 | TIMBCMP2: Timer B compare 2  
The timer D counter is reset upon timer B compare 2 event. |
| Bit 22 | TIMBCMP1: Timer B compare 1  
The timer D counter is reset upon timer B compare 1 event. |
| Bit 21 | TIMACMP4: Timer A compare 4  
The timer D counter is reset upon timer A compare 4 event. |
| Bit 20 | TIMACMP2: Timer A compare 2  
The timer D counter is reset upon timer A compare 2 event. |
| Bit 19 | TIMACMP1: Timer A compare 1  
The timer D counter is reset upon timer A compare 1 event. |
| Bit 18 | EXTEVNT10: External event  
The timer D counter is reset upon external event 10. |
| Bit 17 | EXTEVNT9: External event 9  
The timer D counter is reset upon external event 9. |
Bit 16 **EXTEVNT8**: External event 8
The timer D counter is reset upon external event 8.

Bit 15 **EXTEVNT7**: External event 7
The timer D counter is reset upon external event 7.

Bit 14 **EXTEVNT6**: External event 6
The timer D counter is reset upon external event 6.

Bit 13 **EXTEVNT5**: External event 5
The timer D counter is reset upon external event 5.

Bit 12 **EXTEVNT4**: External event 4
The timer D counter is reset upon external event 4.

Bit 11 **EXTEVNT3**: External event 3
The timer D counter is reset upon external event 3.

Bit 10 **EXTEVNT2**: External event 2
The timer D counter is reset upon external event 2.

Bit 9 **EXTEVNT1**: External event 1
The timer D counter is reset upon external event 1.

Bit 8 **MSTCMP4**: Master compare 4
The timer D counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer D counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer D counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer D counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer D counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer D compare 4 reset
The timer D counter is reset upon timer D compare 4 event.

Bit 2 **CMP2**: Timer D compare 2 reset
The timer D counter is reset upon timer D compare 2 event.

Bit 1 **UPDT**: Timer D update reset
The timer D counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer D counter is reset upon timer F compare 1 event.
27.5.37  HRTIM timer E reset register (HRTIM_RSTER)

Address offset: 0x2D4
Reset value: 0x0000 0000

Bit 31  TIMFCMP2: Timer F compare 2
The timer E counter is reset upon timer F Compare 2 event.

Bit 30  TIMDCMP4: Timer D compare 4
The timer E counter is reset upon timer D compare 4 event.

Bit 29  TIMDCMP2: Timer D compare 2
The timer E counter is reset upon timer D compare 2 event.

Bit 28  TIMDCMP1: Timer D compare 1
The timer E counter is reset upon timer D compare 1 event.

Bit 27  TIMCCMP4: Timer C compare 4
The timer E counter is reset upon timer C compare 4 event.

Bit 26  TIMCCMP2: Timer C compare 2
The timer E counter is reset upon timer C compare 2 event.

Bit 25  TIMCCMP1: Timer C compare 1
The timer E counter is reset upon timer C compare 1 event.

Bit 24  TIMBCMP4: Timer B compare 4
The timer E counter is reset upon timer B compare 4 event.

Bit 23  TIMBCMP2: Timer B compare 2
The timer E counter is reset upon timer B compare 2 event.

Bit 22  TIMBCMP1: Timer B compare 1
The timer E counter is reset upon timer B compare 1 event.

Bit 21  TIMACMP4: Timer A compare 4
The timer E counter is reset upon timer A compare 4 event.

Bit 20  TIMACMP2: Timer A compare 2
The timer E counter is reset upon timer A compare 2 event.

Bit 19  TIMACMP1: Timer A compare 1
The timer E counter is reset upon timer A compare 1 event.

Bit 18  EXTEVNT10: External event
The timer E counter is reset upon external event 10.

Bit 17  EXTEVNT9: External event 9
The timer E counter is reset upon external event 9.
Bit 16 **EXTEVNT8**: External event 8
The timer E counter is reset upon external event 8.

Bit 15 **EXTEVNT7**: External event 7
The timer E counter is reset upon external event 7.

Bit 14 **EXTEVNT6**: External event 6
The timer E counter is reset upon external event 6.

Bit 13 **EXTEVNT5**: External event 5
The timer E counter is reset upon external event 5.

Bit 12 **EXTEVNT4**: External event 4
The timer E counter is reset upon external event 4.

Bit 11 **EXTEVNT3**: External event 3
The timer E counter is reset upon external event 3.

Bit 10 **EXTEVNT2**: External event 2
The timer E counter is reset upon external event 2.

Bit 9 **EXTEVNT1**: External event 1
The timer E counter is reset upon external event 1.

Bit 8 **MSTCMP4**: Master compare 4
The timer E counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer E counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer E counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer E counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer E counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer E compare 4 reset
The timer E counter is reset upon timer E compare 4 event.

Bit 2 **CMP2**: Timer E compare 2 reset
The timer E counter is reset upon timer E compare 2 event.

Bit 1 **UPDT**: Timer E update reset
The timer E counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer E counter is reset upon timer F compare 1 event.

The timer F counter is reset upon timer E compare 1 event.
27.5.39 HRTIM timer x chopper register (HRTIM_CHPxR) (x = A to F)

Address offset: Block A: 0x0D8
Address offset: Block B: 0x158
Address offset: Block C: 0x1D8
Address offset: Block D: 0x258
Address offset: Block E: 0x2D8
Address offset: Block F: 0x358
Reset value: 0x0000 0000

| Bits 31:11 | Reserved, must be kept at reset value. |
| Bits 10:7  | \textbf{STRTPW}[3:0]: Timer x start pulsewidth |
|           | This register defines the initial pulsewidth following a rising edge on output signal. |
|           | This bitfield cannot be modified when one of the CHPx bits is set. |
|           | \( t_{\text{STPW}} = (\text{STRPW}[3:0]+1) \times 16 \times \frac{1}{f_{\text{HRTIM}}} \). |
|           | 0000: 94.1 ns (1/10.625 MHz) |
|           | 1111: 1.51 \( \mu \)s (16/10.625 MHz) |
| Bits 6:4  | \textbf{CARDTY}[2:0]: Timer x chopper duty cycle value |
|           | This register defines the duty cycle of the carrier signal. This bitfield cannot be modified when one of the CHPx bits is set. |
|           | 000: 0/8 (i.e. only 1st pulse is present) |
|           | 111: 7/8 |
| Bits 3:0  | \textbf{CARFRQ}[3:0]: Timer x carrier frequency value |
|           | This register defines the carrier frequency \( F_{\text{CHFRQ}} = \frac{f_{\text{HRTIM}}}{(16 \times (\text{CARFRQ}[3:0]+1))} \). |
|           | This bitfield cannot be modified when one of the CHPx bits is set. |
|           | 0000: 10.625 MHz (\( f_{\text{HRTIM}}/16 \)) |
|           | 1111: 664 kHz (\( f_{\text{HRTIM}}/256 \)) |

Bit 9 **EXEV8CPT**: External event 8 capture  
Refer to EXEV1CPT description.

Bit 8 **EXEV7CPT**: External event 7 capture  
Refer to EXEV1CPT description.

Bit 7 **EXEV6CPT**: External event 6 capture  
Refer to EXEV1CPT description.

Bit 6 **EXEV5CPT**: External event 5 capture  
Refer to EXEV1CPT description.

Bit 5 **EXEV4CPT**: External event 4 capture  
Refer to EXEV1CPT description.

Bit 4 **EXEV3CPT**: External event 3 capture  
Refer to EXEV1CPT description.

Bit 3 **EXEV2CPT**: External event 2 capture  
Refer to EXEV1CPT description.

Bit 2 **EXEV1CPT**: External event 1 capture  
0: No action  
1: The external event 1 triggers the capture 2

Bit 1 **UPDCPT**: Update capture  
0: No action  
1: The update event triggers the capture 2

Bit 0 **SWCPT**: Software capture  
0: No action  
1: This bit forces the capture 2 by software. This bit is set only, reset by hardware.

Bit 31  **TECMP2**: Timer E compare 2
Refer to TACMP2 description.

Bit 30  **TECMP1**: Timer E compare 1
Refer to TACMP1 description.

Bit 29  **TE1RST**: Timer E output 1 reset
Refer to TA1RST description.

Bit 28  **TE1SET**: Timer E output 1 set
Refer to TA1SET description.

Bit 27  **TDCMP2**: Timer D compare 2
Refer to TACMP2 description.

Bit 26  **TDCMP1**: Timer D compare 1
Refer to TACMP1 description.

Bit 25  **TD1RST**: Timer D output 1 reset
Refer to TA1RST description.

Bit 24  **TD1SET**: Timer D output 1 set
Refer to TA1SET description.

Bit 23  **TCCMP2**: Timer C compare 2
Refer to TACMP2 description.

Bit 22  **TCCMP1**: Timer C compare 1
Refer to TACMP1 description.

Bit 21  **TC1RST**: Timer C output 1 reset
Refer to TA1RST description.

Bit 20  **TC1SET**: Timer C output 1 set
Refer to TA1SET description.

Bit 19  **TBCMP2**: Timer B compare 2
Refer to TACMP2 description.

Bit 18  **TBCMP1**: Timer B compare 1
Refer to TACMP1 description.

Bit 17  **TB1RST**: Timer B output 1 reset
Refer to TA1RST description.
Bit 16 **TB1SET**: Timer B output 1 set
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2
0: No action
1: Timer A compare 2 triggers capture 2

Bit 14 **TACMP1**: Timer A compare 1
0: No action
1: Timer A compare 1 triggers capture 2

Bit 13 **TA1RST**: Timer B output 1 reset
0: No action
1: Capture 2 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set
0: No action
1: Capture 2 is triggered by TA1 output inactive to active transition

Bit 11 **EXEV10CPT**: External event 10 capture
Refer to EXEV1CPT description

Bit 10 **EXEV9CPT**: External event 9 capture
Refer to EXEV1CPT description.

Bit 31  **TFCMP2**: Timer F compare 2  
Refer to **TACMP2** description.

Bit 30  **TFCMP1**: Timer F compare 1  
Refer to **TACMP1** description.

Bit 29  **TF1RST**: Timer F output 1 reset  
Refer to **TA1RST** description.

Bit 28  **TF1SET**: Timer F output 1 set  
Refer to **TA1SET** description.

Bit 27  **TDCMP2**: Timer D compare 2  
Refer to **TACMP2** description.

Bit 26  **TDCMP1**: Timer D compare 1  
Refer to **TACMP1** description.

Bit 25  **TD1RST**: Timer D output 1 reset  
Refer to **TA1RST** description.

Bit 24  **TD1SET**: Timer D output 1 set  
Refer to **TA1SET** description.

Bit 23  **TCCMP2**: Timer C compare 2  
Refer to **TACMP2** description.

Bit 22  **TCCMP1**: Timer C compare 1  
Refer to **TACMP1** description.

Bit 21  **TC1RST**: Timer C output 1 reset  
Refer to **TA1RST** description.

Bit 20  **TC1SET**: Timer C output 1 set  
Refer to **TA1SET** description.

Bit 19  **TBCMP2**: Timer B compare 2  
Refer to **TACMP2** description.

Bit 18  **TBCMP1**: Timer B compare 1  
Refer to **TACMP1** description.

Bit 17  **TB1RST**: Timer B output 1 reset  
Refer to **TA1RST** description.
Bit 16 **TB1SET**: Timer B output 1 set  
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2  
0: No action  
1: Timer A compare 2 triggers capture 2

Bit 14 **TACMP1**: Timer A compare 1  
0: No action  
1: Timer A compare 1 triggers capture 2

Bit 13 **TA1RST**: Timer B output 1 reset  
0: No action  
1: Capture 2 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set  
0: No action  
1: Capture 2 is triggered by TA1 output inactive to active transition

Bit 11 **EXEV10CPT**: External event 10 capture  
Refer to EXEV1CPT description

Bit 10 **EXEV9CPT**: External event 9 capture  
Refer to EXEV1CPT description.

Bit 9 **EXEV8CPT**: External event 8 capture  
Refer to EXEV1CPT description.

Bit 8 **EXEV7CPT**: External event 7 capture  
Refer to EXEV1CPT description.

Bit 7 **EXEV6CPT**: External event 6 capture  
Refer to EXEV1CPT description.

Bit 6 **EXEV5CPT**: External event 5 capture  
Refer to EXEV1CPT description.

Bit 5 **EXEV4CPT**: External event 4 capture  
Refer to EXEV1CPT description.

Bit 4 **EXEV3CPT**: External event 3 capture  
Refer to EXEV1CPT description.

Bit 3 **EXEV2CPT**: External event 2 capture  
Refer to EXEV1CPT description.

Bit 2 **EXEV1CPT**: External event 1 capture  
0: No action  
1: The external event 1 triggers the capture 2

Bit 1 **UPDCPT**: Update capture  
0: No action  
1: The update event triggers the capture 2

Bit 0 **SWCPT**: Software capture  
0: No action  
1: This bit forces the capture 2 by software. This bit is set only, reset by hardware.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 DIDL2: Output 2 deadtime upon burst mode Idle entry
This bit delays the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering in idle state during a burst mode operation.
0: The programmed Idle state is applied immediately to the output 2
1: Deadtime (inactive level) is inserted on output 2 before entering the idle mode. The deadtime value is set by DTFx[8:0].

Note: This parameter cannot be changed once the timer x is enabled.
DIDL=1 is set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).

Bit 22 CHP2: Output 2 chopper enable
This bit enables the chopper on output 2.
0: Output signal is not altered
1: Output signal is chopped by a carrier signal

Note: This parameter cannot be changed once the timer x is enabled.

Bits 21:20 FAULT2[1:0]: Output 2 fault state
These bits select the output 2 state after a fault event.
00: No action: the output is not affected by the fault input and stays in run mode.
01: Active
10: Inactive
11: High-Z

Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.

Bit 19 IDLES2: Output 2 idle state
This bit selects the output 2 idle state.
0: Inactive
1: Active

Note: This parameter must be set prior to have the HRTIM controlling the outputs.
Bit 18 **IDLEM2**: Output 2 idle mode
This bit selects the output 2 idle mode.
0: No action: the output is not affected by the burst mode operation.
1: The output is in idle state when requested by the burst mode controller.
*Note: This bit is preloaded and is changed during run-time, but must not be changed while the burst mode is active.*

Bit 17 **POL2**: Output 2 polarity
This bit selects the output 2 polarity.
0: Positive polarity (output active high)
1: Negative polarity (output active low)
*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **BIAR**: Balanced Idle Automatic Resume
This bit selects if the outputs are automatically re-enabled after a balanced idle event.
This bit is only significant if DLYPRT[2:0] = 011 or 111, it is ignored otherwise.
0: Disabled
1: Enabled
*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 13 Reserved, must be kept at reset value.

Bits 12:10 **DLYPRT[2:0]**: Delayed protection
These bits define the source and outputs on which the delayed protection schemes are applied.

*In HRTIM_OUTAR, HRTIM_OUTBR, HRTIM_OUTCR:*
000: Output 1 delayed idle on external event 6
001: Output 2 delayed idle on external event 6
010: Output 1 and output 2 delayed idle on external event 6
011: Balanced idle on external event 6
100: Output 1 delayed idle on external event 7
101: Output 2 delayed idle on external event 7
110: Output 1 and output 2 delayed idle on external event 7
111: Balanced idle on external event 7

*In HRTIM_OUTDR, HRTIM_OUTER, HRTIM_OUTFR:*
000: Output 1 delayed idle on external event 8
001: Output 2 delayed idle on external event 8
010: Output 1 and output 2 delayed idle on external event 8
011: Balanced idle on external event 8
100: Output 1 delayed idle on external event 9
101: Output 2 delayed idle on external event 9
110: Output 1 and output 2 delayed idle on external event 9
111: Balanced idle on external event 9

*Note: This bitfield must not be modified once the delayed protection is enabled (DLYPRTEN bit set).*

Bit 9 **DLYPRTEN**: Delayed protection enable
This bit enables the delayed protection scheme.
0: No action
1: Delayed protection is enabled, as per DLYPRT[2:0] bits
*Note: This parameter cannot be changed once the timer x is enabled (TxEN bit set).*
Bit 8 **DTEN**: Deadtime enable
- This bit enables the deadtime insertion on output 1 and output 2.
  - 0: Output 1 and output 2 signals are independent.
  - 1: Deadtime is inserted between output 1 and output 2 (reference signal is output 1 signal generator)

  *Note: This parameter cannot be changed once the timer is operating (TxEN bit set) or if its outputs are enabled and set/reset by another timer.*

Bit 7 **DIDL1**: Output 1 deadtime upon burst mode idle entry
- This bit delays the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering the idle state during a burst mode operation.
  - 0: The programmed idle state is applied immediately to the output 1
  - 1: Deadtime (inactive level) is inserted on output 1 before entering the idle mode. The deadtime value is set by DTRx[8:0].

  *Note: This parameter cannot be changed once the timer x is enabled.*

  *DIDL=1 is set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).*

Bit 6 **CHP1**: Output 1 chopper enable
- This bit enables the chopper on output 1.
  - 0: Output signal is not altered
  - 1: Output signal is chopped by a carrier signal

  *Note: This parameter cannot be changed once the timer x is enabled.*

Bits 5:4 **FAULT[1:0]**: Output 1 fault state
- These bits select the output 1 state after a fault event
  - 00: No action: the output is not affected by the fault input and stays in run mode.
  - 01: Active
  - 10: Inactive
  - 11: High-Z

  *Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.*

Bit 3 **IDLES1**: Output 1 Idle State
- This bit selects the output 1 idle state.
  - 0: Inactive
  - 1: Active

  *Note: This parameter must be set prior to HRTIM controlling the outputs.*

Bit 2 **IDLEM1**: Output 1 Idle mode
- This bit selects the output 1 idle mode.
  - 0: No action: the output is not affected by the burst mode operation.
  - 1: The output is in idle state when requested by the burst mode controller.

  *Note: This bit is preloaded and is changed during runtime, but must not be changed while burst mode is active.*

Bit 1 **POL1**: Output 1 polarity
- This bit selects the output 1 polarity.
  - 0: Positive polarity (output active high)
  - 1: Negative polarity (output active low)

  *Note: This parameter cannot be changed once the timer x is enabled.*

Bit 0 **Reserved**: must be kept at reset value.

**Bits 31:21** Reserved, must be kept at reset value.

**Bit 20 TRG HLF:** Triggered-half mode

This bitfield defines whether the compare 2 register is behaving in standard mode (compare match issued as soon as counter equal compare), or in triggered-half mode (see Section: Triggered-half mode).

- **0:** CMP2 register is written by the user only (standard compare mode)
- **1:** CMP2 value is set by hardware as soon as a capture 1 event occurs. It is loaded with the (capture 1 divided by 2) value. The initial value can be written by the user (as long as TRG HLF is reset), but is ignored once the first capture has been triggered (the preload mechanism is disabled for CMP2 when the TRG HLF bit is set).

*Note:* This bitfield must not be modified once the counter is enabled (TxCEN bit set).

**Bits 19:18** Reserved, must be kept at reset value.

**Bit 17 GT CMP3:** Greater than compare 3 PWM mode

This bit defines the compare 3 operating mode.

- **0:** The compare 3 event is generated when the counter is equal to the compare value (compare match mode)
- **1:** The compare 3 event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.

**Bit 16 GT CMP1:** Greater than compare 1 PWM mode

This bit defines the compare 1 operating mode.

- **0:** The compare 1 event is generated when the counter is equal to the compare value (compare match mode)
- **1:** The compare 1 event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.
Bits 15:14 **FEROM[1:0]:** Fault and event roll-over mode
This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the Roll-over event used by the fault and event counters.
00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value
01: Event generated when the counter is equal to 0
10: Event generated when the counter is equal to HRTIM_PERxR
11: Reserved

*Note: This setting only applies when the UDM bit is set. It is not significant otherwise.*

*Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).*

Bits 13:12 **BMROM[1:0]:** Burst mode roll-over mode
This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event used in the burst mode controller, as clock as burst mode trigger.
00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value
01: Event generated when the counter is equal to 0
10: Event generated when the counter is equal to HRTIM_PERxR
11: Reserved

*Note: This setting only applies when the UDM bit is set. It is not significant otherwise.*

*Note: This parameter cannot be changed once the timer is operating (TxEN bit set).*

Bits 11:10 **ADROM[1:0]:** ADC roll-over mode
This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event which triggers the ADC.
00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value
01: Event generated when the counter is equal to 0
10: Event generated when the counter is equal to HRTIM_PERxR
11: Reserved

*Note: This setting only applies when the UDM bit is set. It is not significant otherwise.*

*Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).*

Bits 9:8 **OUTROM[1:0]:** Output roll-over mode
This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event which sets and/or resets the outputs, as per HRTIM_SETxyR and HRTIM_RSTxyR settings.
00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value
01: Event generated when the counter is equal to 0
10: Event generated when the counter is equal to HRTIM_PERxR
11: Reserved

*Note: This setting only applies when the UDM bit is set. It is not significant otherwise.*

*Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).*

Bits 7:6 **ROM[1:0]:** Roll-over mode
This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event with the following destinations: update trigger (to transfer content from preload to active registers), IRQ and DMA requests, repetition counter decrement and external event filtering.
00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value
01: Event generated when the counter is equal to 0
10: Event generated when the counter is equal to HRTIM_PERxR
11: Reserved

*Note: This setting only applies when the UDM bit is set. It is not significant otherwise.*

*Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).*

Bit 5 Reserved, must be kept at reset value.
Bit 4 **UDM**: Up-Down mode
   This bit defines if the counter is operating in up or up-down counting mode.
   0: The counter is operating in up-counting mode
   1: The counter is operating in up-down counting mode
   Note: This bit cannot be changed once the timer is operating (TxEN bit set).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCDR**: Dual channel DAC reset trigger
   This bit defines when the hrtim_dac_reset_trgx trigger is generated.
   0: The trigger is generated on counter reset or roll-over event
   1: The trigger is generated on output 1 set event
   Note: The DCSR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

Bit 1 **DCDS**: Dual channel DAC Step trigger
   This bit defines when the hrtim_dac_step_trgx trigger is generated.
   0: The trigger is generated on compare 2 event
   1: The trigger is generated on output 1 reset event
   Note: The DCSR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

Bit 0 **DCDE**: Dual channel DAC trigger enable
   This bit enables the dual channel DAC triggering mechanism.
   0: Dual channel DAC trigger disabled
   1: Dual channel DAC trigger enabled
   Note: This bit cannot be changed once the timer is operating (TxEN bit set).
### 27.5.55  HRTIM timer x external event filtering register 3 (HRTIM(TIMxEEFR3)) (x = A to F)

- **Bits 31:14**: Reserved, must be kept at reset value.
- **Bits 13:8** **EEVACNT[5:0]**: External event A counter
  
  This bitfield selects the external event A counter threshold. An event is considered valid when the number of events is equal to the \( \text{EEVACNT}[5:0]+1 \) value.

- **Bits 7:4** **EEVASEL[3:0]**: External event A Selection

  This bit selects the external event A source.
  
  0: External event 1 is used as external event A source
  1: External event 2 is used as external event A source
  ...
  9: External event 10 is used as external event A source
  Others: Reserved

- **Bit 3**: Reserved, must be kept at reset value.

- **Bit 2** **EEVARSTM**: External event A reset mode

  This bit selects the external event x counter reset mode.
  
  0: External event counter A is reset on each reset / roll-over event
  1: External event counter A is reset on each reset / roll-over event only if no event occurs during last counting period

- **Bit 1** **EEVACRES**: External event A counter reset

  This bit resets the external event A counter. It is set by software and reset by hardware.
  
  0: No action
  1: External event counter A is reset

- **Bit 0** **EEVACE**: External event A counter enable

  This bit enables the external event x counter.
  
  0: External event A counter disabled
  1: External event A counter enabled
27.5.56  **HRTIM control register 1 (HRTIM_CR1)**

Bit 2 **TBUDIS**: Timer B update disable
Refer to TAUDIS description.

Bit 1 **TAUDIS**: Timer A update disable
This bit is set and cleared by software to enable/disable an update event generation temporarily on timer A.
0: Update enabled. The update occurs upon generation of the selected source.
1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bit 0 **MUDIS**: Master update disable
This bit is set and cleared by software to enable/disable an update event generation temporarily.
0: Update enabled.
1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bits 31:22 Reserved, must be kept at reset value.

- **Bit 21 SWPF**: Swap timer F outputs  
  Refer to SWPA description.  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 20 SWPE**: Swap timer E outputs  
  Refer to SWPA description.  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 19 SWPD**: Swap timer D outputs  
  Refer to SWPA description.  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 18 SWPC**: Swap timer C outputs  
  Refer to SWPA description.  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 17 SWPB**: Swap timer B outputs  
  Refer to SWPA description.  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 16 SWPA**: Swap timer A outputs  
  This bit allows to swap the timer A outputs.  
  0: HRTIM_SETA1R and HRTIM_RSTA1R are coding for the output A1, HRTIM_SETA2R and HRTIM_RSTA2R are coding for the output A2  
  1: HRTIM_SETA1R and HRTIM_RSTA1R are coding for the output A2, HRTIM_SETA2R and HRTIM_RSTA2R are coding for the output A1  
  *Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).*

- **Bit 15 Reserved, must be kept at reset value.**

- **Bit 14 TFRST**: Timer F counter software reset  
  Refer to TARST description.

- **Bit 13 TERST**: Timer E counter software reset  
  Refer to TARST description.

- **Bit 12 TDRST**: Timer D counter software reset  
  Refer to TARST description.

- **Bit 11 TCRST**: Timer C counter software reset  
  Refer to TARST description.
Bit 10 **TBRST**: Timer B counter software reset  
Refer to TARST description.

Bit 9 **TARST**: Timer A counter software reset  
Setting this bit resets the timer A counter.  
The bit is automatically reset by hardware.

Bit 8 **MRST**: Master counter software reset  
Setting this bit resets the master timer counter.  
The bit is automatically reset by hardware.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TFSWU**: Timer F software update  
Refer to TASWU description.

Bit 5 **TESWU**: Timer E software update  
Refer to TASWU description.

Bit 4 **TDSWU**: Timer D software update  
Refer to TASWU description.

Bit 3 **TCSWU**: Timer C software update  
Refer to TASWU description.

Bit 2 **TBSWU**: Timer B software update  
Refer to TASWU description.

Bit 1 **TASWU**: Timer A software update  
This bit is set by software and automatically reset by hardware. It forces an immediate transfer from  
the preload to the active register and any pending update request is canceled.

Bit 0 **MSWU**: Master timer software update  
This bit is set by software and automatically reset by hardware. It forces an immediate transfer from  
the preload to the active register in the master timer and any pending update request is canceled.

Notes:  
- Res. = Reserved, must be kept at reset value.
- BMPE = Bit Master Preload Enable
- DLL = Double Load
- TDY = Transfer Data Ready
- FLT6, FLT5, FLT4, FLT3, FLT2, FLT1: Flags for interrupt status.
Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **BMPER**: Burst mode period interrupt flag
   This bit is set by hardware when a single-shot burst mode operation is completed or at the end of a burst mode period in continuous mode. It is cleared by software writing it at 1.
   0: No burst mode period interrupt occurred
   1: Burst mode period interrupt occurred

Bit 16  **DLLRDY**: DLL Ready Interrupt Flag
   This bit is set by hardware when the DLL calibration is completed. It is cleared by software writing it at 1.
   0: No DLL calibration ready interrupt occurred
   1: DLL calibration ready interrupt occurred

Bits 15:7  Reserved, must be kept at reset value.

Bit 6  **FLT6**: Fault 6 interrupt flag
   Refer to FLT1 description.

Bit 5  **SYSFLT**: System fault interrupt flag
   Refer to FLT1 description.

Bit 4  **FLT5**: Fault 5 interrupt flag
   Refer to FLT1 description.

Bit 3  **FLT4**: Fault 4 interrupt flag
   Refer to FLT1 description.

Bit 2  **FLT3**: Fault 3 interrupt flag
   Refer to FLT1 description.

Bit 1  **FLT2**: Fault 2 interrupt flag
   Refer to FLT1 description.

Bit 0  **FLT1**: Fault 1 interrupt flag
   This bit is set by hardware when fault 1 event occurs. It is cleared by software writing it at 1.
   0: No fault 1 interrupt occurred
   1: Fault 1 interrupt occurred

Bits 31:12 Reserved, must be kept at reset value.

- **Bit 11 TF2DIS:** Timer F output 2 disable
  - Refer to TA1DIS description.

- **Bit 10 TF1DIS:** Timer F output 1 disable
  - Refer to TA1DIS description.

- **Bit 9 TE2DIS:** Timer E output 2 disable
  - Refer to TA1DIS description.

- **Bit 8 TE1DIS:** Timer E output 1 disable
  - Refer to TA1DIS description.

- **Bit 7 TD2DIS:** Timer D output 2 disable
  - Refer to TA1DIS description.

- **Bit 6 TD1DIS:** Timer D output 1 disable
  - Refer to TA1DIS description.

- **Bit 5 TC2DIS:** Timer C output 2 disable
  - Refer to TA1DIS description.

- **Bit 4 TC1DIS:** Timer C output 1 disable
  - Refer to TA1DIS description.

- **Bit 3 TB2DIS:** Timer B output 2 disable
  - Refer to TA1DIS description.

- **Bit 2 TB1DIS:** Timer B output 1 disable
  - Refer to TA1DIS description.

- **Bit 1 TA2DIS:** Timer A output 2 disable
  - Refer to TA1DIS description.

- **Bit 0 TA1DIS:** Timer A output 1 disable
  - Setting this bit disables the timer A output 1. The output enters the idle state, either from the run state or from the fault state.
  - Writing "0" has no effect.

</tbody>
</table>
Bits 9:6 **BMPRSC[3:0]**: Burst mode prescaler

Defines the prescaling ratio of the f\textsubscript{HRTIM} clock for the burst mode controller. This bitfield cannot be changed while the burst mode is enabled.

- 0000: Clock not divided
- 0001: Division by 2
- 0010: Division by 4
- 0011: Division by 8
- 0100: Division by 16
- 0101: Division by 32
- 0110: Division by 64
- 0111: Division by 128
- 1000: Division by 256
- 1001: Division by 512
- 1010: Division by 1024
- 1011: Division by 2048
- 1100: Division by 4096
- 1101: Division by 8192
- 1110: Division by 16384
- 1111: Division by 32768

Bits 5:2 **BMCLK[3:0]**: Burst mode clock source

This bitfield defines the clock source for the burst mode counter. It cannot be changed while the burst mode is enabled (refer to Table 211 for on-chip events 1..4 connections details).

- 0000: Master timer counter reset/roll-over
- 0001: Timer A counter reset/roll-over
- 0010: Timer B counter reset/roll-over
- 0011: Timer C counter reset/roll-over
- 0100: Timer D counter reset/roll-over
- 0101: Timer E counter reset/roll-over
- 0110: On-chip event 1 (hrtim\_bm\_ck1), acting as a burst mode counter clock
- 0111: On-chip event 2 (hrtim\_bm\_ck2) acting as a burst mode counter clock
- 1000: On-chip event 3 (hrtim\_bm\_ck3) acting as a burst mode counter clock
- 1001: On-chip event 4 (hrtim\_bm\_ck4) acting as a burst mode counter clock
- 1010: Prescaled f\textsubscript{HRTIM} clock (as per BMPRSC[3:0] setting)
- 1011: Timer F counter reset/roll-over
- Others: Reserved

Bit 1 **BMOM**: Burst mode operating mode

This bit defines if the burst mode is entered once or if it is continuously operating.

- 0: Single-shot mode
- 1: Continuous operation

Bit 0 **BME**: Burst mode enable

This bit starts the burst mode controller which becomes ready to receive the start trigger.

Writing this bit to 0 causes a burst mode early termination.

- 0: Burst mode disabled
- 1: Burst mode enabled

</tbody>
</table>

Bit 31  OCHPEV: On-chip event
A rising edge on the hrtim_bm_trg input (connected to general purpose timer TRGO output) triggers a burst mode entry (see Table 208 for details).

Bit 30  EEV8: External event 8 (TIMD filters applied)
The external event 8 conditioned by TIMD filters is starting the burst mode operation.

Bit 29  EEV7: External event 7 (TIMA filters applied)
The external event 7 conditioned by TIMA filters is starting the burst mode operation.

Bit 28  TDEEV8: Timer D period following external event 8
The timer D period following an external event 8 (conditioned by TIMD filters) is starting the burst mode operation.

Bit 27  TAEEV7: Timer A period following external event 7
The timer A period following an external event 7 (conditioned by TIMA filters) is starting the burst mode operation.

Bit 26  TECMP2: Timer E compare 2 event
Refer to TACMP1 description.

Bit 25  TECMP1: Timer E compare 1 event
Refer to TACMP1 description.

Bit 24  TEREP: Timer E repetition
Refer to TAREP description.

Bit 23  TFCMP1: Timer F compare 1 event
Refer to TACMP1 description.

Bit 22  TDCMP2: Timer D compare 2 event
Refer to TACMP1 description.

Bit 21  TFREP: Timer F repetition
Refer to TAREP description.

Bit 20  TDREP: Timer D repetition
Refer to TAREP description.

Bit 19  TDRST: Timer D reset or roll-over
Refer to TARST description.

Bit 18  TFRST: Timer F reset
Refer to TARST description.
Bit 17 **TCCMP1**: Timer C compare 1 event
Refer to TACMP1 description.

Bit 16 **TCREP**: Timer C repetition
Refer to TAREP description.

Bit 15 **TCRST**: Timer C reset or roll-over
Refer to TARST description.

Bit 14 **TBCMP2**: Timer B compare 2 event
Refer to TACMP1 description.

Bit 13 **TBCMP1**: Timer B compare 1 event
Refer to TACMP1 description.

Bit 12 **TBREP**: Timer B repetition
Refer to TAREP description.

Bit 11 **TBRST**: Timer B reset or roll-over
Refer to TARST description.

Bit 10 **TACMP2**: Timer A compare 2 event
Refer to TACMP1 description.

Bit 9 **TACMP1**: Timer A compare 1 event
The timer A compare 1 event is starting the burst mode operation.

Bit 8 **TAREP**: Timer A repetition
The Timer A repetition event is starting the burst mode operation.

Bit 7 **TARST**: Timer A reset or roll-over
The Timer A reset or roll-over event is starting the burst mode operation.

Bit 6 **MSTCMP4**: Master compare 4
Refer to MSTCMP1 description.

Bit 5 **MSTCMP3**: Master compare 3
Refer to MSTCMP1 description.

Bit 4 **MSTCMP2**: Master compare 2
Refer to MSTCMP1 description.

Bit 3 **MSTCMP1**: Master compare 1
The master timer compare 1 event is starting the burst mode operation.

Bit 2 **MSTREP**: Master repetition
The master timer repetition event is starting the burst mode operation.

Bit 1 **MSTRST**: Master reset or roll-over
The master timer reset and roll-over event is starting the burst mode operation.

Bit 0 **SW**: Software start
This bit is set by software and automatically reset by hardware.
When set, it starts the burst mode operation immediately.
This bit is not active if the burst mode is not enabled (BME bit is reset).

Bits 31:16  **Reserved, must be kept at reset value.**

Bits 15:0  **BMPER[15:0]: Burst mode period**

- Defines the burst mode repetition period.
- This register holds either the content of the preload register or the content of the active register if preload is disabled.

**Note:**  **The BMPER[15:0] must not be null when the burst mode is enabled.**
27.5.68  HRTIM timer external event control register 1 (HRTIM_EECR1)

Address offset: 0x3B0
Reset value: 0x0000 0000

Bit 31:30 Reserved, must be kept at reset value.

Bit 29  **EE5FAST**: External event 5 fast mode
Refer to EE1FAST description.

Bits 28:27  **EE5SNS[1:0]**: External event 5 sensitivity
Refer to EE1SNS[1:0] description.

Bit 26  **EE5POL**: External event 5 polarity
Refer to EE1POL description.

Bits 25:24  **EE5SRC[1:0]**: External event 5 source
Refer to EE1SRC[1:0] description.

Bit 23  **EE4FAST**: External event 4 fast mode
Refer to EE1FAST description.

Bits 22:21  **EE4SNS[1:0]**: External event 4 sensitivity
Refer to EE1SNS[1:0] description.

Bit 20  **EE4POL**: External event 4 polarity
Refer to EE1POL description.

Bits 19:18  **EE4SRC[1:0]**: External event 4 source
Refer to EE1SRC[1:0] description.

Bit 17  **EE3FAST**: External event 3 fast mode
Refer to EE1FAST description.

Bits 16:15  **EE3SNS[1:0]**: External event 3 sensitivity
Refer to EE1SNS[1:0] description.

Bit 14  **EE3POL**: External event 3 polarity
Refer to EE1POL description.

Bits 13:12  **EE3SRC[1:0]**: External event 3 source
Refer to EE1SRC[1:0] description.

Bit 11  **EE2FAST**: External event 2 fast mode
Refer to EE1FAST description.

Bits 10:9  **EE2SNS[1:0]**: External event 2 sensitivity
Refer to EE1SNS[1:0] description.
Bit 8 **EE2POL**: External event 2 polarity
Refer to **EE1POL** description.

Bits 7:6 **EE2SRC[1:0]**: External event 2 source
Refer to **EE1SRC[1:0]** description.

Bit 5 **EE1FAST**: External event 1 fast mode
0: External event 1 is re-synchronized by the HRTIM logic before acting on outputs, which adds a
f_{HRTIM} clock-related latency
1: External event 1 is acting asynchronously on outputs (low latency mode)

*Note: This bit must not be modified once the counter in which the event is used is enabled (TxCEN bit set).*

Bits 4:3 **EE1SNS[1:0]**: External event 1 sensitivity
00: On active level defined by EE1POL bit
01: Rising edge, whatever EE1POL bit value
10: Falling edge, whatever EE1POL bit value
11: Both edges, whatever EE1POL bit value

Bit 2 **EE1POL**: External event 1 polarity
This bit is only significant if **EE1SNS[1:0]** = 00.
0: External event is active high
1: External event is active low

*Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting **EE1FAST** bit.*

Bits 1:0 **EE1SRC[1:0]**: External event 1 source
This bitfield selects the External event 1 source. See Table 209 for details.
00: hrtim_eev1_1
01: hrtim_eev1_2
10: hrtim_eev1_3
11: hrtim_eev1_4

*Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting **EE1FAST** bit.*

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:27  **EE10SNS[1:0]**: External event 10 sensitivity
Refer to EE1SNS[1:0] description.

Bit 26  **EE10POL**: External event 10 polarity
Refer to EE1POL description.

Bits 25:24  **EE10SRC[1:0]**: External event 10 source
Refer to EE1SRC[1:0] description.

Bit 23 Reserved, must be kept at reset value.

Bits 22:21  **EE9SNS[1:0]**: External event 9 sensitivity
Refer to EE1SNS[1:0] description.

Bit 20  **EE9POL**: External event 9 polarity
Refer to EE1POL description.

Bits 19:18  **EE9SRC[1:0]**: External event 9 source
Refer to EE1SRC[1:0] description.

Bit 17 Reserved, must be kept at reset value.

Bits 16:15  **EE8SNS[1:0]**: External event 8 sensitivity
Refer to EE1SNS[1:0] description.

Bit 14  **EE8POL**: External event 8 polarity
Refer to EE1POL description.

Bits 13:12  **EE8SRC[1:0]**: External event 8 source
Refer to EE1SRC[1:0] description.

Bit 11 Reserved, must be kept at reset value.

Bits 10:9  **EE7SNS[1:0]**: External event 7 sensitivity
Refer to EE1SNS[1:0] description.

Bit 8  **EE7POL**: External event 7 polarity
Refer to EE1POL description.

Bits 7:6  **EE7SRC[1:0]**: External event 7 source
Refer to EE1SRC[1:0] description.

Bit 5 Reserved, must be kept at reset value.
**RM0440**  
**High-resolution timer (HRTIM)**

Bits 4:3 **EE6NS[1:0]**: External event 6 sensitivity  
Refer to EE1NS[1:0] description.

Bit 2 **EE6POL**: External event 6 polarity  
Refer to EE1POL description.

Bits 1:0 **EE6SRC[1:0]**: External event 6 source  
Refer to EE1SRC[1:0] description.

| rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:30 **EEVSD[1:0]**: External event sampling clock division  
This bitfield indicates the division ratio between the timer clock frequency \((f_{HRTIM})\) and the external event signal sampling clock \((f_{EEVS})\) used by the digital filters.  
00: \(f_{EEVS}=f_{HRTIM}\)  
01: \(f_{EEVS}=f_{HRTIM}/2\)  
10: \(f_{EEVS}=f_{HRTIM}/4\)  
11: \(f_{EEVS}=f_{HRTIM}/8\)

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:24 **EE10F[3:0]**: External event 10 filter  
Refer to EE6F[3:0] description.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:18 **EE9F[3:0]**: External event 9 filter  
Refer to EE6F[3:0] description.

Bits 17:16 Reserved, must be kept at reset value.

Bits 15:12 **EE8F[3:0]**: External event 8 filter  
Refer to EE6F[3:0] description.

Bits 11:10 Reserved, must be kept at reset value.
Bits 9:6  **EE7F[3:0]**: External event 7 filter
Refer to EE6F[3:0] description.

Bits 5:4  Reserved, must be kept at reset value.

Bits 3:0  **EE6F[3:0]**: External event 6 filter
This bitfield defines the frequency used to sample external event 6 input and the length of the digital filter applied to EEV6. The digital filter is made of a counter in which N valid samples are needed to validate a transition on the output.
0000: Filter disabled
0001: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}}, N=2 \)
0010: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}}, N=4 \)
0011: \( f_{\text{SAMPLING}} = f_{\text{HRTIM}}, N=8 \)
0100: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/2, N=6 \)
0101: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/2, N=8 \)
0110: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/4, N=6 \)
0111: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/4, N=8 \)
1000: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/8, N=6 \)
1001: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/8, N=8 \)
1010: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/16, N=5 \)
1011: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/16, N=6 \)
1100: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/32, N=6 \)
1101: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/32, N=8 \)
1110: \( f_{\text{SAMPLING}} = f_{\text{EEVS}}/32, N=8 \)

Bit 31  **ADC1TEPER**: ADC trigger 1 on timer E period
Refer to ADC1TAPFR description.

Bit 30  **ADC1TEC4**: ADC trigger 1 on timer E compare 4
Refer to ADC1TFCC2 description.

Bit 29  **ADC1TEC3**: ADC trigger 1 on timer E compare 3
Refer to ADC1TFCC2 description.

Bit 28  **ADC1TFRST**: ADC trigger 1 on timer F reset and counter roll-over(1)
Refer to ADC1TARST description.

Bit 27  **ADC1TDPER**: ADC trigger 1 on timer D period
Refer to ADC1TAPFR description.
Bit 26  **ADC1TDC4**: ADC trigger 1 on timer D compare 4  
Refer to ADC1TFC2 description.

Bit 25  **ADC1TDC3**: ADC trigger 1 on timer D compare 3  
Refer to ADC1TFC2 description.

Bit 24  **ADC1TFPER**: ADC trigger 1 on timer F period  
Refer to ADC1TAPER description.

Bit 23  **ADC1TCPER**: ADC trigger 1 on timer C period  
Refer to ADC1TAPER description.

Bit 22  **ADC1TCC4**: ADC trigger 1 on timer C compare 4  
Refer to ADC1TFC2 description.

Bit 21  **ADC1TCC3**: ADC trigger 1 on timer C compare 3  
Refer to ADC1TFC2 description.

Bit 20  **ADC1TFC4**: ADC trigger 1 on timer F compare 4  
Refer to ADC1TAC2 description.

Bit 19  **ADC1TBRST**: ADC trigger 1 on timer B reset and counter roll-over\(^{(1)}\)  
This bit enables the generation of an ADC trigger upon timer B reset and roll-over event, on ADC  
trigger 1 output.

Bit 18  **ADC1TBPER**: ADC trigger 1 on timer B period  
Refer to ADC1TAPER description.

Bit 17  **ADC1TBC4**: ADC trigger 1 on timer B compare 4  
Refer to ADC1TFC2 description.

Bit 16  **ADC1TBC3**: ADC trigger 1 on timer B compare 3  
Refer to ADC1TFC2 description.

Bit 15  **ADC1TFC3**: ADC trigger 1 on timer F compare 3  
Refer to ADC1TFC2 description.

Bit 14  **ADC1TARST**: ADC trigger 1 on timer A reset and counter roll-over\(^{(1)}\)  
This bit enables the generation of an ADC trigger upon timer A reset and roll-over event, on ADC  
trigger 1 output.

Bit 13  **ADC1TAPER**: ADC trigger 1 on timer A period  
This bit enables the generation of an ADC trigger upon timer A period event, on ADC trigger 1  
output.

Bit 12  **ADC1TAC4**: ADC trigger 1 on timer A compare 4  
Refer to ADC1TFC2 description.

Bit 11  **ADC1TAC3**: ADC trigger 1 on timer A compare 3  
Refer to ADC1TFC2 description.

Bit 10  **ADC1TFC2**: ADC trigger 1 on timer F compare 2  
This bit enables the generation of an ADC trigger upon timer F compare 2 event, on ADC trigger 1  
output.

Bit 9   **ADC1EEV5**: ADC trigger 1 on external event 5\(^{(1)}\)  
Refer to ADC1EEV1 description.

Bit 8   **ADC1EEV4**: ADC trigger 1 on external event 4\(^{(1)}\)  
Refer to ADC1EEV1 description.
Bit 7 **ADC1EEV3**: ADC trigger 1 on external event 3\(^{(1)}\)
Refer to ADC1EEV1 description.

Bit 6 **ADC1EEV2**: ADC trigger 1 on external event 2\(^{(1)}\)
Refer to ADC1EEV1 description.

Bit 5 **ADC1EEV1**: ADC trigger 1 on external event 1\(^{(1)}\)
This bit enables the generation of an ADC trigger upon external event 1, on ADC trigger 1 output.

Bit 4 **ADC1MPER**: ADC trigger 1 on master period
This bit enables the generation of an ADC trigger upon master timer period event, on ADC trigger 1 output.

Bit 3 **ADC1MC4**: ADC trigger 1 on master compare 4
Refer to ADC1MC1 description.

Bit 2 **ADC1MC3**: ADC trigger 1 on master compare 3
Refer to ADC1MC1 description.

Bit 1 **ADC1MC2**: ADC trigger 1 on master compare 2
Refer to ADC1MC1 description.

Bit 0 **ADC1MC1**: ADC trigger 1 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 1 output.

Bit 31  **ADC4TERST**: ADC trigger 4 on timer E reset and counter roll-over(1)
Refer to ADC4TCRST description.

Bit 30  **ADC4TEC4**: ADC trigger 4 on timer E compare 4
Refer to ADC4TAC2 description.

Bit 29  **ADC4TEC3**: ADC trigger 4 on timer E compare 3
Refer to ADC4TAC2 description.

Bit 28  **ADC4TEC2**: ADC trigger 4 on timer E compare 2
Refer to ADC4TAC2 description.

Bit 27  **ADC4TDRST**: ADC trigger 4 on timer D reset and counter roll-over(1)
Refer to ADC4TCRST description.

Bit 26  **ADC4TDPER**: ADC trigger 4 on timer D period
Refer to ADC4TAPER description.

Bit 25  **ADC4TDC4**: ADC trigger 4 on timer D compare 4
Refer to ADC4TAC2 description.

Bit 24  **ADC4TFPER**: ADC trigger 4 on timer F period
Refer to ADC4TAPER description.

Bit 23  **ADC4TDC2**: ADC trigger 2 on timer D compare 2
Refer to ADC4TAC2 description.

Bit 22  **ADC4TCRST**: ADC trigger 4 on timer C reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer C reset and roll-over event, on ADC trigger 1 output.

Bit 21  **ADC4TCPER**: ADC trigger 4 on timer C period
Refer to ADC4TAPER description.

Bit 20  **ADC4TCC4**: ADC trigger 4 on timer C compare 4
Refer to ADC4TAC2 description.

Bit 19  **ADC4TFC4**: ADC trigger 4 on timer F compare 4
Refer to ADC4TAC2 description.

Bit 18  **ADC4TCC2**: ADC trigger 4 on timer C compare 2
Refer to ADC4TAC2 description.

Bit 17  **ADC4TBPER**: ADC trigger 4 on timer B period
Refer to ADC4TAPER description.
Bit 16 **ADC4TBC4**: ADC trigger 4 on timer B compare 4
Refer to ADC4TAC2 description.

Bit 15 **ADC4TFC3**: ADC trigger 4 on timer F compare 3
Refer to ADC4TAC2 description.

Bit 14 **ADC4TBC2**: ADC trigger 4 on timer B compare 2
Refer to ADC4TAC2 description.

Bit 13 **ADC4TAPER**: ADC trigger 4 on timer A period
This bit enables the generation of an ADC trigger upon timer A event, on ADC trigger 2 output.

Bit 12 **ADC4TAC4**: ADC trigger 4 on timer A compare 4
Refer to ADC4TAC2 description.

Bit 11 **ADC4TFC2**: ADC trigger 4 on timer F compare 2
Refer to ADC4TAC2 description.

Bit 10 **ADC4TAC2**: ADC trigger 4 on timer A compare 2
This bit enables the generation of an ADC trigger upon timer A compare 2, on ADC trigger 2 output.

Bit 9 **ADC4EEV10**: ADC trigger 4 on external event 10\(^{(1)}\)
Refer to ADC4EEV6 description.

Bit 8 **ADC4EEV9**: ADC trigger 4 on external event 9\(^{(1)}\)
Refer to ADC4EEV6 description.

Bit 7 **ADC4EEV8**: ADC trigger 4 on external event 8\(^{(1)}\)
Refer to ADC4EEV6 description.

Bit 6 **ADC4EEV7**: ADC trigger 4 on external event 7\(^{(1)}\)
Refer to ADC4EEV6 description.

Bit 5 **ADC4EEV6**: ADC trigger 4 on external event 6\(^{(1)}\)
This bit enables the generation of an ADC trigger upon external event 6, on ADC trigger 2 output.

Bit 4 **ADC4MPER**: ADC trigger 4 on master period
This bit enables the generation of an ADC trigger upon master period event, on ADC trigger 2 output.

Bit 3 **ADC4MC4**: ADC trigger 4 on master compare 4
Refer to ADC4MC1 description.

Bit 2 **ADC4MC3**: ADC trigger 4 on master compare 3
Refer to ADC4MC1 description.

Bit 1 **ADC4MC2**: ADC trigger 4 on master compare 2
Refer to ADC4MC1 description.

Bit 0 **ADC4MC1**: ADC trigger 4 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 2 output.

1. These triggers are differing from HRTIM_ADC1R/HRTIM_ADC3R to HRTIM_ADC2R/HRTIM_ADC4R.

- **Bits 31:4** Res. Reserved, must be kept at reset value.
- **Bits 3:2** CALRTE[1:0]: DLL Calibration rate  
  This defines the DLL calibration periodicity.  
  00: 1048576 * t\textsubscript{HRTIM} (6.168 ms for f\textsubscript{HRTIM} = 170 MHz)  
  01: 131072 * t\textsubscript{HRTIM} (771 µs for f\textsubscript{HRTIM} = 170 MHz)  
  10: 16384 * t\textsubscript{HRTIM} (96 µs for f\textsubscript{HRTIM} = 170 MHz)  
  11: 2048 * t\textsubscript{HRTIM} (12 µs for f\textsubscript{HRTIM} = 170 MHz)
- **Bit 1** CALEN: DLL Calibration Enable  
  This bit enables the periodic DLL calibration, as per CALRTE[1:0] bit setting. When CALEN bit is reset, the calibration can be started in single-shot mode with CAL bit.  
  0: Periodic calibration disabled  
  1: Calibration is performed periodically, as per CALRTE[1:0] setting  
  *Note: CALEN must not be set simultaneously with CAL bit*
- **Bit 0** CAL: DLL Calibration Start  
  This bit starts the DLL calibration process. It is write-only.  
  0: No calibration request  
  1: Calibration start  
  *Note: CAL must not be set simultaneously with CALEN bit*

</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FLTSD[1:0]:** Fault sampling clock division  
This bitfield indicates the division ratio between the timer clock frequency (f\_{HRTIM}) and the fault signal sampling clock (f\_{FLTS}) used by the digital filters.  
00: f\_{FLTS} = f\_{HRTIM}  
01: f\_{FLTS} = f\_{HRTIM} / 2  
10: f\_{FLTS} = f\_{HRTIM} / 4  
11: f\_{FLTS} = f\_{HRTIM} / 8  

*Note: This bitfield must be written prior to any of the FLTxE enable bits.*

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **FLT6SRC[1]:** Fault 6 source bit 1  
Refer to FLT5SRC[0] description.

Bit 20 **FLT5SRC[1]:** Fault 5 source bit 1  
Refer to FLT5SRC[0] description.

Bit 19 **FLT4SRC[1]:** Fault 4 source bit 1  
Refer to FLT5SRC[0] description.

Bit 18 **FLT3SRC[1]:** Fault 3 source bit 1  
Refer to FLT5SRC[0] description.

Bit 17 **FLT2SRC[1]:** Fault 2 source bit 1  
Refer to FLT5SRC[0] description.

Bit 16 **FLT1SRC[1]:** Fault 1 source bit 1  
Refer to FLT5SRC[0] description.

Bit 15 **FLT6LCK:** Fault 6 lock  
Refer to FLT5LCK description.

Bits 14:11 **FLT6F[3:0]:** Fault 6 filter  
Refer to FLT5F[3:0] description.

Bit 10 **FLT6SRC[0]:** Fault 6 source bit 0  
Refer to FLT5SRC[0] description.

Bit 9 **FLT6P:** Fault 6 polarity  
Refer to FLT5P description.
Bit 8  **FLT6E**: Fault 6 enable  
Refer to FLT5E description.

Bit 7  **FLT5LCK**: Fault 5 lock  
The FLT5LCK bit modifies the write attributes of the fault programming bit, so that they are protected against spurious write accesses.  
This bit is write-once. Once it has been set, it cannot be modified till the next system reset.  
0: FLT5E, FLT5P, FLT5SRC[1:0], FLT5F[3:0] and FLT5BLK bits are read/write.  
1: FLT5E, FLT5P, FLT5SRC[1:0], FLT5F[3:0] and FLT5BLK bits cannot be written (read-only mode)

Bits 6:3  **FLT5F[3:0]**: Fault 5 filter  
This bitfield defines the frequency used to sample FLT5 input and the length of the digital filter applied to FLT5. The digital filter is made of an event counter in which N events are needed to validate a transition on the output.  
0000: No filter, FLT5 acts asynchronously  
0001: \( f_{\text{sampling}} = f_{\text{HRTIM}} \cdot N = 2 \)  
0010: \( f_{\text{sampling}} = f_{\text{HRTIM}} \cdot N = 4 \)  
0011: \( f_{\text{sampling}} = f_{\text{HRTIM}} \cdot N = 8 \)  
0100: \( f_{\text{sampling}} = f_{\text{FLTS}}/2, N = 6 \)  
0101: \( f_{\text{sampling}} = f_{\text{FLTS}}/2, N = 8 \)  
0110: \( f_{\text{sampling}} = f_{\text{FLTS}}/4, N = 6 \)  
0111: \( f_{\text{sampling}} = f_{\text{FLTS}}/4, N = 8 \)  
1000: \( f_{\text{sampling}} = f_{\text{FLTS}}/8, N = 6 \)  
1001: \( f_{\text{sampling}} = f_{\text{FLTS}}/8, N = 8 \)  
1010: \( f_{\text{sampling}} = f_{\text{FLTS}}/16, N = 5 \)  
1011: \( f_{\text{sampling}} = f_{\text{FLTS}}/16, N = 6 \)  
1100: \( f_{\text{sampling}} = f_{\text{FLTS}}/16, N = 8 \)  
1101: \( f_{\text{sampling}} = f_{\text{FLTS}}/32, N = 5 \)  
1110: \( f_{\text{sampling}} = f_{\text{FLTS}}/32, N = 6 \)  
1111: \( f_{\text{sampling}} = f_{\text{FLTS}}/32, N = 8 \)  

*Note:* This bitfield is written only when FLT5E enable bit is reset.  
This bitfield is modified when FLT5LOCK has been programmed.

Bit 2  **FLT5SRC[0]**: Fault 5 source bit 0  
The FLT5SRC[1:0] bitfield selects the FAULT5 input source (refer to *Table 208* for connection details).  
00: Fault 5 input is HRTIM_FLT5 input pin  
01: Fault 5 input is connected to a COMPx output  
10: Fault 5 input is EEV5_muxout input pin  
01: Reserved  

*Note:* This bitfield is written only when FLT5E enable bit is reset.

Bit 1  **FLT5P**: Fault 5 polarity  
This bit selects the FAULT5 input polarity.  
0: Fault 5 input is active low  
1: Fault 5 input is active high  

*Note:* This bitfield is written only when FLT5E enable bit is reset.

Bit 0  **FLT5E**: Fault 5 enable  
This bit enables the global FAULT5 input circuitry.  
0: Fault 5 input disabled  
1: Fault 5 input enabled

   Refer to `TIMxCR` description.

Bit 9 `TIMxCMP4`: HRTIM_CMP4xR register update enable timer x
   Refer to `TIMxCR` description.

Bit 8 `TIMxCMP3`: HRTIM_CMP3xR register update enable timer x
   Refer to `TIMxCR` description.

Bit 7 `TIMxCMP2`: HRTIM_CMP2xR register update enable timer x
   Refer to `TIMxCR` description.

Bit 6 `TIMxCMP1`: HRTIM_CMP1xR register update enable timer x
   Refer to `TIMxCR` description.

Bit 5 `TIMxREP`: HRTIM_REPxR register update enable timer x
   Refer to `TIMxCR` description.

Bit 4 `TIMxPER`: HRTIM_PERxR register update enable timer x
   Refer to `TIMxCR` description.

Bit 3 `TIMxCNT`: HRTIM_CNTxR register update enable timer x
   Refer to `TIMxCR` description.

Bit 2 `TIMxDIER`: HRTIM_TIMxDIER register update enable timer x
   Refer to `TIMxCR` description.

Bit 1 `TIMxICR`: HRTIM_TIMxICR register update enable timer x
   Refer to `TIMxCR` description.

Bit 0 `TIMxCR`: HRTIM_TIMxCR register update enable timer x
   This bit defines if the master timer MCR register is part of the list of registers to be updated by the burst DMA.
   0: HRTIM_TIMxCR register is not updated by burst DMA accesses
   1: HRTIM_TIMxCR register is updated by burst DMA accesses

### 27.5.80 HRTIM burst DMA data register (HRTIM_BDMADR)

Bits 31:0 **BDMADR[31:0]**: Burst DMA data register
Write accesses to this register triggers:
- the copy of the data value into the registers enabled in BDTxUPR and BDMUPR register bits
- the increment of the register pointer to the next location to be filled
27.5.81 HRTIM ADC extended trigger register (HRTIM_ADCER)

  Refer to **AD5USRC[2:0]** description.
- **Bit 3**: Reserved, must be kept at reset value.
- **Bits 2:0**: **AD5USRC[2:0]**: ADC trigger 5 update source  
  These bits define the source which triggers the update of the ADC5TRG[4:0] bitfield in the 
  HRTIM_ADCER register (transfer from preload to active register). It only defines the source timer. 
  The precise condition is defined within the timer itself, with the BRSTDMA[1:0] bitfield in 
  HRTIM_MCR or the UPDGAT[3:0] bitfield in HRTIM_TIMxCR register.

</tr>
<tr>
<td></td>
<td>1: Fault 5 counter is reset</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Bits 5:2  **FLT5CNT[3:0]**: Fault 5 counter

This bitfield selects the FAULT5 counter threshold. A fault is considered valid when the number of events is equal to the (FLT5CNT[3:0]+1) value.

Bit 1  **FLT5BLKS**: Fault 5 blanking source

The FLT5BLKS bit selects the FAULT5 blanking source (refer to Table 237 for details).

0: Fault 5 reset-aligned blanking window
1: Fault 5 Moving blanking window

*Note:* This bitfield is written only when FLT5E enable bit is reset.

Bit 0  **FLT5BLKE**: Fault 5 blanking enable

The FLT5BLKE bit selects the FAULT5 blanking mode. The blanking source is defined by the FLT5BLKS bit.

0: No blanking on fault 5
1: Fault 5 blanking mode

*Note:* This bitfield is written only when FLT5E enable bit is reset

Table 245. HRTIM register map and reset values – common functions (continued)
Refer to Section 2.2 on page 81 for the register boundary addresses.
28 Advanced-control timers (TIM1/TIM8/TIM20)

28.1 TIM1/TIM8/TIM20 introduction

The advanced-control timers (TIM1/TIM8/TIM20) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8/TIM20) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 28.3.30: Timer synchronization.

28.2 TIM1/TIM8/TIM20 main features

TIM1/TIM8/TIM20 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (Edge and Center-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
28.3 TIM1/TIM8/TIM20 functional description

28.3.1 Block diagram

Figure 269. Advanced-control timer block diagram

1. This feature is not available on all timers, refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals.
2. See Figure 316: Break and Break2 circuitry overview for details.
28.3.2 TIM1/TIM8/TIM20 pins and internal signals

The tables in this section summarize the TIM inputs and outputs.

### Table 246. TIM input/output pins

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIM_CH1</td>
<td>Input/Output</td>
<td>Timer multi-purpose channels. Each channel can be used for capture, compare or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock), external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.</td>
</tr>
<tr>

28.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

*Note:* *The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.*

Prescaler description

The prescaler divides the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 270* and *Figure 271* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 270. Counter timing diagram with prescaler division change from 1 to 2

Figure 271. Counter timing diagram with prescaler division change from 1 to 4
28.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

- **Update interrupt flag (UIF)**
Figure 276. Counter timing diagram, update event when ARPE = 0
(TIMx_ARR not preloaded)
Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

**Figure 278. Counter timing diagram, internal clock divided by 1**
Figure 279. Counter timing diagram, internal clock divided by 2

Figure 280. Counter timing diagram, internal clock divided by 4
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to 00. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = 01), the counter counts up (Center aligned mode 2, CMS = 10) the counter counts up and down (Center aligned mode 3, CMS = 11).

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

28.3.5 Repetition counter

Section 28.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 289). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

- **Update Event** if the repetition counter underflow occurs when the counter is equal to the auto-reload value

---

### 28.3.6 External trigger input

The timer features an external trigger input tim_etr_in. It can be used as:
- external clock (external clock mode 2, see Section 28.3.7)
- trigger for the slave mode (see Section 28.3.30)
- PWM reset input for cycle-by-cycle current regulation (see Section 28.3.9)

**Figure 290** below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition...
the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

**Figure 290. External trigger input block**

The `tim_eti_in` input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for the list of sources connected to the etr_in input in the product.

### 28.3.7 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (`tim_ker_ck`)
- External clock mode1: external input pin (`tim_ti1` or `tim_ti2`)
- External clock mode2: external trigger input (`tim_eti_in`)
- Encoder mode

**Internal clock source (tim_ker_ck)**

If the slave mode controller is disabled (SMS = 000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock `tim_ker_ck`.

**Figure 291** shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS = 111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 0100 to 1111 are reserved.
For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = 01 in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F = 0000).
3. Select rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIMx_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS = 00110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN = 1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set. The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

**Figure 293. Control circuit in external clock mode 1**

External clock source mode 2

This mode is selected by writing ECE = 1 in the TIMx_SMCR register. The counter counts at each rising or falling edge on the external trigger input tim_etr_in. The **Figure 294** gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim\_etr\_in, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0] = 0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0] = 01 in the TIMx\_SMCR register.
3. Select rising edge detection on the tim\_etr\_in input by writing ETP = 0 in the TIMx\_SMCR register.
4. Enable external clock mode 2 by writing ECE = 1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN = 1 in the TIMx\_CR1 register.

The counter counts once each 2 tim\_etr\_in rising edges.

The delay between the rising edge on tim\_etr\_in and the actual clock of the counter is due to the resynchronization circuit on the tim\_etrp signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of tim\_ker\_ck frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.
28.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

Figure 296 to Figure 299 give an overview of one capture/compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 296. Capture/compare channel (example: channel 1 input stage)
The output stage generates an intermediate waveform which is then used for reference: `tim_ocxref` (active high). The polarity acts at the end of the chain.

**Figure 297. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.
In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 28.3.9 Input capture mode

In Input capture mode, the capture/compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the tim_ti1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.
Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

28.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges).

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_t1 can be measured using the following procedure:

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to 0 (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
- Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP = 10 (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to 1 in the TIMx_CCER register.
28.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

28.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM = 0000), be
set active (OCxM = 0001), be set inactive (OCxM = 0010) or can toggle (OCxM = 0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 301.
28.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 0110 (PWM mode 1) or 0111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Upcounting mode.

In the following example, the mode is PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at 1. If the compare value is 0 then tim_ocxref is held at 0. Figure 302 shows some edge-aligned PWM waveforms in an example where TIMx_ARR = 8.

Figure 302. Edge-aligned PWM waveforms (ARR = 8)

- Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at 1. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting).

Figure 303 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR = 8
- PWM mode is the PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. Figure 304 presents the dithering principle applied to 4 consecutive PWM cycles.

**Figure 304. Dithering principle**

When the dithering mode is enabled, the register coding is changed as follows (see Figure 305 for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The ARR and CCR values will be updated automatically if the DITHEN bit is set / reset (for instance, if ARR= 0x05 with DITHEN = 0, it will be updated to ARR = 0x50 with DITHEN =
The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset.
2. The ARR[3:0] bits must be reset.
3. The DITTHEN bit must be reset.
4. The CCIF flags must be cleared.
5. The CEN bit can be set (eventually with ARPE = 1).

Base compare value is 20 during 16 periods Additional 6 cycles are spread over the 16 periods

The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}$$

Dithering mode disabled: $$F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536}$$

Dithering mode enabled: $$F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}}$$

**Note:** The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on Figure 306, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.
The duty cycle and/or period changes are spread over 16 consecutive periods, as described in Figure 307.
The auto-reload and compare values increments are spread following specific patterns described in Table 258. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Figure 308. Dithering effect on duty cycle in center-aligned PWM mode

No dithering  Dithering up  Dithering down
28.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- `tim_oc1refc (or tim_oc2refc)` is controlled by TIMx_CCR1 and TIMx_CCR2
- `tim_oc3refc (or tim_oc4refc)` is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one `tim_ocx` output per pair of CCR registers) by writing 1110 (Asymmetric PWM mode 1) or 1111 (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an `tim_oc1refc` signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the `tim_oc2ref` signal on channel 2, or an `tim_oc2refc` signal resulting from asymmetric PWM mode 1.

*Figure 309* represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

Table 259. CCR register change dithering pattern in center-aligned PWM mode (continued)
28.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 1100 (Combined PWM mode 1) or 1101 (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bitfield is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 310** represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
- Channel 3 is configured in Combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.
28.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The \text{tim\_oc5\_ref} signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx\_CCR5 allow selection on which reference signal the \text{tim\_oc5\_ref} is combined. The resulting signals, \text{tim\_oc\_x\_refc}, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, \text{tim\_oc1\_refc} is controlled by TIMx\_CCR1 and TIMx\_CCR5.
- If GC5C2 is set, \text{tim\_oc2\_refc} is controlled by TIMx\_CCR2 and TIMx\_CCR5.
- If GC5C3 is set, \text{tim\_oc3\_refc} is controlled by TIMx\_CCR3 and TIMx\_CCR5.

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
The tim_trgo2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to Section 28.3.31: ADC triggers for more details.

28.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8/TIM20) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (such as intrinsic delays of level-shifters, or delays due to power switches).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 267: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref considering CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1 in these examples.

**Figure 312. Complementary output with symmetrical dead-time insertion**

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on **Figure 313**.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMx_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 28.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8, 20) for delay calculation.
Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only tim_ocxn is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP = 0 then tim_ocxn = tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE = CCxNE = 1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

28.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- The MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- The OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 267: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous
and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation)
  - coming from a system break request (refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation)

The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per Figure 316 below.
Figure 316. Break and Break2 circuitry overview

Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE = 0. If OSSI = 0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to
their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 \( \text{tim\_ker\_ck} \) clock cycles).

- If OSSI = 0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, \( \text{tim\_ocx}/\text{tim\_ocxn} \) polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 28.6.20: TIMx break and dead-time register (TIMx_BDTR)\((x = 1, 8, 20)\). The LOCK bits can be written only once after an MCU reset.

Figure 317 shows an example of behavior of the outputs in response to a break.
Figure 317. Various output behavior in response to a break event on tim_brk (OSSI = 1)

The two break inputs have different behaviors on timer outputs:

- The tim_brk input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- tim_brk2 can only disable (inactive state) the PWM outputs.
The tim_brk has a higher priority than tim_brk2 input, as described in Table 260.

Note: *tim_brk2 must only be used with OSSR = OSSI = 1.*

**Figure 318** gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

**Figure 318. PWM output state following tim_brk and tim_brk2 assertion (OSSI = 1)**
28.3.19 Bidirectional break inputs

The TIM1/TIM8/TIM20 feature bidirectional break I/Os, as represented on Figure 320.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to 0 to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKIN and TIMx_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 261).
## Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control.
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming).
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears).

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

### 28.3.20 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM
This function can only be used in Output compare and PWM modes. It does not work in Forced mode. `tim_ocref_clr_int` input can be selected between the `tim_ocref_clr` input and `tim_etrf (tim_etrf_in after the filter)` by configuring the OCCS bit in the TIMx_SMCR register.

The `tim_ocref_clr` input can be selected among several inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown on the Figure 321 below. Refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for a list of sources available in the product.

**Figure 321. tim_ocref_clr input selection multiplexer**

When `tim_etrf` is chosen, `tim_etrf_in` must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to 00.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

**Figure 322** shows the behavior of the `tim_ocxref` signal when the `tim_etrf Input` becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.
**28.3.21 6-step PWM generation**

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on \texttt{tim\_trgi} rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

*Figure 323* describes the behavior of the tim\_ocx and tim\_ocxn outputs when a COM event occurs, in three different examples of programmed configurations.
28.3.22 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: \( CNT < CCRx \leq ARR \) (in particular, \( 0 < CCRx \))
- In downcounting: \( CNT > CCRx \)
In the following example, the user wants to generate a positive pulse on \texttt{tim\_oc1} with a length of \(t_{\text{PULSE}}\) and after a delay of \(t_{\text{DELAY}}\) as soon as a positive edge is detected on the \texttt{tim\_ti2} input pin.

Use \texttt{tim\_ti2fp2} as trigger 1:

- Map \texttt{tim\_ti2fp2} to \texttt{tim\_ti2} by writing \texttt{CC2S = 01} in the TIMx\_CCMR1 register.
- \texttt{tim\_ti2fp2} must detect a rising edge, write \texttt{CC2P = 0} and \texttt{CC2NP = 0} in the TIMx\_CCER register.
- Configure \texttt{tim\_ti2fp2} as trigger for the slave mode controller (\texttt{tim\_trgi}) by writing \texttt{TS = 00110} in the TIMx\_SMCR register.
- \texttt{tim\_ti2fp2} is used to start the counter by writing \texttt{SMS to 110} in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \(t_{\text{DELAY}}\) is defined by the value written in the TIMx\_CCR1 register.
- The \(t_{\text{PULSE}}\) is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).

Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the auto-reload value. This is achieved by enabling PWM mode 2 (OC1M = 111 in TIMx\_CCMR1). Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case one has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on \texttt{tim\_ti2}. CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIMx\_CR1 register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over.
from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to 0, so the Repetitive mode is selected.

Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY \min}}$ that can be achieved.

To output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 28.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 28.3.22:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.

The timer must be in Slave mode, with the bits SMS[3:0] = 1000 (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to 1000 or 1001 for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bitfields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

![Figure 325. Retriggerable one-pulse mode](image-url)
### 28.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on Figure 326.

**Figure 326. Pulse generator circuitry**

*Figure 327* shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIMx_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{(2 \times PWPRSC[2:0])}) \times t_{tim\_ker\_ck} \)

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 328).
28.3.25 Encoder interface mode

**Quadrature encoder**

To select Encoder Interface mode write SMS = 0001 in the TIMx_SMCR register if the counter is counting on tim_t1 edges only, SMS = 0010 if it is counting on tim_t2 edges only and SMS = 0011 if it is counting on both tim_t1 and tim_t2 edges.

Select the tim_t1 and tim_t2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_t1 and tim_t2 are used to interface to an quadrature encoder. Refer to *Table 262*. The counter is clocked by each valid transition on tim_t1fp1 or tim_t2fp2 (tim_t1 and tim_t2 after input filter and polarity selection, tim_t1fp1 = tim_t1 if not filtered and not inverted, tim_t2fp2 = tim_t2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_t1 or tim_t2), whatever the counter is counting on tim_t1 only, tim_t2 only or both tim_t1 and tim_t2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_t1 and tim_t2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 329 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIMx_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P = 0 and CC1NP = 0 (TIMx_CCER register, tim_ti1fp1 non-inverted, tim_ti1fp1 = tim_ti1).
- CC2P = 0 and CC2NP = 0 (TIMx_CCER register, tim_ti1fp2 non-inverted, tim_ti1fp2= tim_ti2).
- SMS = 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIMx_CR1 register, Counter enabled).
**Figure 329.** Example of counter operation in encoder interface mode.

**Figure 330** gives an example of counter behavior when `tim_ti1fp1` polarity is inverted (same configuration as above except `CC1P = 1`).

**Figure 330.** Example of encoder interface mode with `tim_ti1fp1` polarity inverted.

**Figure 331** shows the timer counter value during a speed reversal, for various counting modes.
The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the clock plus direction mode shown on Figure 332, the clock is provided on a single line, on tim_t2, while the direction is forced using the tim_t1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity
The polarity of the direction signal on `tim_ti1` is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when `tim_ti1` is high and down-counting when `tim_ti1` is low) and CC1P = 1 corresponds to negative polarity (up-counting when `tim_ti1` is low).

**Figure 332. Direction plus clock encoder mode**

![Directional clock encoder mode](MSv62352V1)

**Directional clock encoder mode**

In the directional clock mode on **Figure 333**, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1100**: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to **Figure 333**) and CCxP = 1 corresponds to low-level idle state (refer to **Figure 334**).

- **1101**: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to **Figure 333**), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to **Figure 334**).

**Figure 333. Directional clock encoder mode (CC1P = CC2P = 0)**

Index input

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 101, 1011, 1100, 1101, 1110, 1111.
Available encoders are proposed with several options for index pulse conditioning, as per Figure 335:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

**Figure 335. Index gating options**

The circuitry tolerates jitter on index signal, whatever the gating mode, as show on Figure 336.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulsewidth is greater or equal to 2 encoder period, the counter is reset multiple times.

**Figure 336. Jittered Index signals**

The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and
channel B state combination) the index must be synchronized, using the \text{IPOS}[1:0] bitfield in the \text{TIMx\_ECR} register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:
- The counter is reset during up-counting (\text{DIR} bit = 0).
- The counter is set to \text{TIMx\_ARR} when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. Figure 337 shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).

**Figure 337. Index generation for \text{IPOS}[1:0] = 11**

![Figure 337](MSv45767V1)

Figure 338 presents waveforms and corresponding values for \text{IPOS}[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:
- Counter set to 0 when encoder state is 11 (\text{ChA} = 1, \text{ChB} = 1), when up-counting (\text{DIR} bit = 0).
- Counter set to \text{TIMx\_ARR} when exiting the 11 state, when down-counting (\text{DIR} bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

**Figure 338. Counter reading with index gated on channel A (IPOS[1:0] = 11)**

![Figure 338](MSv45768V1)
Figure 339. presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 339. Counter reading with index ungated (IPOS[1:0] = 00)

Figure 340. shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

Figure 340. Counter reading with index gated on channel A and B

Figure 341 and Figure 342 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 342. Counter reset Narrow index pulse (closer view, ARR = 0x07)
Figure 343 shows how the index is managed in x1 and x2 modes.

**Figure 343. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)**

Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

Figure 344 shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

**Note:** The IDR[1:0] bitfield must be written when IE bit is reset (index mode disabled).

**Note:** The directional index sensitivity is not supported in clock + direction mode. When SMS[3:0] = 1010 or 1011, the IDIR[1:0] must be set to 00.
Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on Figure 345. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Note: When FIDX = 1, the index can be issued twice (IDXF flag set) if the direction changes at position 0 (index active).

Index management in non-quadrature mode

Figure 346 and Figure 347 detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.
For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

**Figure 346. Index behavior in clock + direction mode, IPOS[0] = 1**

**Figure 347. Index behavior in directional clock mode, IPOS[0] = 1**

**Encoder error management**

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on **Figure 348.** A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.
For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with $N$ pulses per revolution provides $4N$ counts per revolution. The Index signal resets the counter every $4N$ clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 349.

**Figure 349. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 350, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 350. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder interrupts**

The following interrupts are also available in encoder mode:

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- Index event: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
**Slave mode selection preload for run-time encoder mode update**

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on Figure 351.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMPS bit in the TIMx_SMCR register.

- **SMSPS = 0**: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting. This mode must be used only when index is disabled (bit IE = 0).
- **SMSPS = 1**: the transfer is triggered by the Index event.

**Figure 351. Encoder mode change with preload transferred on update (SMPS = 0)**

![Encoder mode change with preload transferred on update](MSv45781V1)

**Encoder clock output**

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the timer output signals. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

**28.3.26 Direction bit output**

It is possible to output a direction signal out of the timer, on the timer output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

### 28.3.27 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

### 28.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 352.

![Figure 352. Measuring time interval between edges on three signals](MSv62358V2)

### 28.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in Figure 353. The “interfacing timer” captures the 3 timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See Figure 296). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.
The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

In this example the user wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to 1.
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors.
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to 01. The digital filter can also be programmed if needed.
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to 111 and the CC2S bits to 00 in the TIMx_CCMR1 register.
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to 101.

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC = 1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS = 1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

*Figure 353* describes this example.
28.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 29.4.23: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS = 100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.
- Start the counter by writing CEN = 1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

![Control circuit in reset mode](image)

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIMx_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS = 101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.
- Enable the counter by writing CEN = 1 in the TIMx_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).
The counter starts counting on the internal clock as long as `tim_ti1` is low and stops as soon as `tim_ti1` becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on `tim_ti1` and the actual stop of the counter is due to the resynchronization circuit on `tim_ti1` input.

### Figure 355. Control circuit in Gated mode

![Figure 355. Control circuit in Gated mode](image-url)

#### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on `tim_ti2` input:

- Configure the channel 2 to detect rising edges on `tim_ti2`. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S = 01 in TIMx_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS = 110 in TIMx_SMCR register. Select `tim_ti2` as the input source by writing TS = 00110 in TIMx_SMCR register.

When a rising edge occurs on `tim_ti2`, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on `tim_ti2` and the actual start of the counter is due to the resynchronization circuit on `tim_ti2` input.
Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.
In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS = 110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

**Figure 357. Control circuit in external clock mode 2 + trigger mode**

**Note:** The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
28.3.31 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 311.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

28.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.
This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (see note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bitfields as follows:
   - DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let’s take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

### 28.3.33 TIM1/TIM8/TIM20 DMA requests

The TIM1/TIM8/TIM20 can generate a DMA request, as shown in the table below.

<table>

### 28.3.34 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 with FPU core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.
For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).

<tr>
<td></td>
<td><strong>Note:</strong> It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)</td>
</tr>
</tbody>
</table>
Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
   These events can be:
   - Counter overflow/underflow
   - Setting the UG bit
   - Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   - Counter overflow/underflow
   - Setting the UG bit
   - Update generation through the slave mode controller
   Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

**RM0440**
Bits 31:26  Reserved, must be kept at reset value.

Bit 24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]: Master mode selection 2**

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

- **0000: Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

- **0001: Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

- **0010: Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

- **0011: Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

- **0100: Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

- **0101: Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

- **0110: Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

- **0111: Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

- **1000: Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

- **1001: Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

- **1010: Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

- **1011: Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

- **1100: Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

- **1101: Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

- **1110: Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

- **1111: Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

**Bit 19**  Reserved, must be kept at reset value.

**Bit 18  OIS6:** Output idle state 6 (tim_oc6 output)

Refer to OIS1 bit

**Bit 17**  Reserved, must be kept at reset value.

**Bit 16  OIS5:** Output idle state 5 (tim_oc5 output)

Refer to OIS1 bit

**Bit 15  OIS4N:** Output idle state 4 (tim_oc4n output)

Refer to OIS1N bit

**Bit 14  OIS4:** Output idle state 4 (tim_oc4 output)

Refer to OIS1 bit
Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n = 0 after a dead-time when MOE = 0
1: tim_oc1n = 1 after a dead-time when MOE = 0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1 = 0 (after a dead-time) when MOE = 0
1: tim_oc1 = 1 (after a dead-time) when MOE = 0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input
Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit only
1: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
### 28.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8, 20)

Bits 31:26 Reserved, must be kept at reset value.

**Bit 25 SMSPS:** SMS preload source

This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active

- 0: The transfer is triggered by the Timer’s Update event
- 1: The transfer is triggered by the Index event

**Bit 24 SMSPE:** SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded

- 0: SMS[3:0] bitfield is not preloaded
- 1: SMS[3:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

**Bits 21:20 TS[4:3]:** Trigger selection - bit 4:3

Refer to TS[2:0] description - bits 6:4

**Bits 19:17** Reserved, must be kept at reset value.

**Bit 15 ETP:** External trigger polarity

This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations

- 0: tim_etr_in is non-inverted, active at high level or rising edge.
- 1: tim_etr_in is inverted, active at low level or falling edge.

**Bit 14 ECE:** External clock enable

This bit enables External clock mode 2.

- 0: External clock mode 2 disabled
- 1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

**Note:** Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111).

It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).

If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etr.
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

- **00**: Prescaler OFF
- **01**: tim_etr_in frequency divided by 2
- **10**: tim_etr_in frequency divided by 4
- **11**: tim_etr_in frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at fDTS
- **0001**: $f_{SAMPLING} = f_{tim_ker_ck}$, $N = 2$
- **0010**: $f_{SAMPLING} = f_{tim_ker_ck}$, $N = 4$
- **0011**: $f_{SAMPLING} = f_{tim_ker_ck}$, $N = 8$
- **0100**: $f_{SAMPLING} = f_{DTS}/2$, $N = 6$
- **0101**: $f_{SAMPLING} = f_{DTS}/2$, $N = 8$
- **0110**: $f_{SAMPLING} = f_{DTS}/4$, $N = 6$
- **0111**: $f_{SAMPLING} = f_{DTS}/4$, $N = 8$
- **1000**: $f_{SAMPLING} = f_{DTS}/8$, $N = 6$
- **1001**: $f_{SAMPLING} = f_{DTS}/8$, $N = 8$
- **1010**: $f_{SAMPLING} = f_{DTS}/16$, $N = 5$
- **1011**: $f_{SAMPLING} = f_{DTS}/16$, $N = 6$
- **1100**: $f_{SAMPLING} = f_{DTS}/16$, $N = 8$
- **1101**: $f_{SAMPLING} = f_{DTS}/32$, $N = 5$
- **1110**: $f_{SAMPLING} = f_{DTS}/32$, $N = 6$
- **1111**: $f_{SAMPLING} = f_{DTS}/32$, $N = 8$

Bit 7 **MSM**: Master/slave mode

- **0**: No action
- **1**: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 6:4  **TS[2:0]:** Trigger selection  
This bitfield is combined with TS[4:3] bits.  
This bitfield selects the trigger input to be used to synchronize the counter.  
00000: Internal Trigger 0 (tim_itr0)  
00001: Internal Trigger 1 (tim_itr1)  
00010: Internal Trigger 2 (tim_itr2)  
00011: Internal Trigger 3 (tim_itr3)  
00100: tim_ti1 Edge Detector (tim_ti1f_ed)  
00101: Filtered Timer Input 1 (tim_ti1fp1)  
00110: Filtered Timer Input 2 (tim_ti2fp2)  
00111: External Trigger input (tim_etrf)  
01000: Internal Trigger 4 (tim_itr4)  
01001: Internal Trigger 5 (tim_itr5)  
01010: Internal Trigger 6 (tim_itr6)  
01011: Internal Trigger 7 (tim_itr7)  
01100: Internal Trigger 8 (tim_itr8)  
01101: Internal Trigger 9 (tim_itr9)  
01110: Internal Trigger 10 (tim_itr10)  
01111: Internal trigger 11 (tim_itr11)  
10000: Internal trigger 12 (tim_itr12)  
10001: Internal trigger 13 (tim_itr13)  
10010: Internal trigger 14 (tim_itr14)  
10011: Internal trigger 15 (tim_itr15)  
Others: Reserved  
See Table 252: Internal trigger connection for more details on tim_itrx meaning for each Timer.  

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3  **OCCS:** OCREF clear selection  
This bit is used to select the OCREF clear source.  
0: tim_ocref_clr_int is connected to the tim_ocref_clr input  
1: tim_ocref_clr_int is connected to tim_etrf
Bits 16, 2:0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIMx_SMCR for tim_etr_in and CCxP/CCxNP bits in TIMx_CCER register for tim_ti1fp1 and tim_ti2fp2).

0000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.
0001: Quadrature encoder mode 1, x2 mode - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.
0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.
0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.
0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
1010: Encoder mode: Clock plus direction, x2 mode.
1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.
1100: Encoder mode: Directional Clock, x2 mode.
1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.
1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.
1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

**Bit 8 UDE:** Update DMA request enable  
0: Update DMA request disabled  
1: Update DMA request enabled

**Bit 7 BIE:** Break interrupt enable  
0: Break interrupt disabled  
1: Break interrupt enabled

**Bit 6 TIE:** Trigger interrupt enable  
0: Trigger interrupt disabled  
1: Trigger interrupt enabled

**Bit 5 COMIE:** COM interrupt enable  
0: COM interrupt disabled  
1: COM interrupt enabled

**Bit 4 CC4IE:** Capture/compare 4 interrupt enable  
0: CC4 interrupt disabled  
1: CC4 interrupt enabled

**Bit 3 CC3IE:** Capture/compare 3 interrupt enable  
0: CC3 interrupt disabled  
1: CC3 interrupt enabled

**Bit 2 CC2IE:** Capture/compare 2 interrupt enable  
0: CC2 interrupt disabled  
1: CC2 interrupt enabled

**Bit 1 CC1IE:** Capture/compare 1 interrupt enable  
0: CC1 interrupt disabled  
1: CC1 interrupt enabled

**Bit 0 UIE:** Update interrupt enable  
0: Update interrupt disabled  
1: Update interrupt enabled
Bits 31:24  Reserved, must be kept at reset value.

Bit 23  \textbf{TERRF}: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22  \textbf{IERRF}: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.
0: No index error has been detected.
1: An index error has been detected

Bit 21  \textbf{DIRF}: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to 0.
0: No direction change
1: Direction change

Bit 20  \textbf{IDXIF}: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
0: No index event occurred.
1: An index event has occurred

Bits 19:18  Reserved, must be kept at reset value.

Bit 17  \textbf{CC6IF}: Compare 6 interrupt flag
Refer to CC1IF description
\textit{Note}: Channel 6 can only be configured as output.

Bit 16  \textbf{CC5IF}: Compare 5 interrupt flag
Refer to CC1IF description
\textit{Note}: Channel 5 can only be configured as output.

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  \textbf{SBIF}: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 12  \textbf{CC4OF}: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11  \textbf{CC3OF}: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10  \textbf{CC2OF}: Capture/compare 2 overcapture flag
Refer to CC1OF description
Bit 9  **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bit 8  **B2IF**: Break 2 interrupt flag
This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 7  **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE = 1 in the TIMx_DIER register.

Bit 6  **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5  **COMIF**: COM interrupt flag
This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
0: No COM event occurred.
1: COM interrupt pending.

Bit 4  **CC4IF**: Capture/compare 4 interrupt flag
Refer to CC1IF description

Bit 3  **CC3IF**: Capture/compare 3 interrupt flag
Refer to CC1IF description
Bit 2  **CC2IF**: Capture/compare 2 interrupt flag  
Refer to CC1IF description

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred  

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.  

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
– At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS = 0 in the TIMx_CR1 register.  
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.  
– When CNT is reinitialized by a trigger event (refer to Section 28.6.3: TIMx slave mode control register (TIMx_SMCR)(x = 1, 8, 20)), if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 28.6.6  TIMx event generation register (TIMx_EGR)(x = 1, 8, 20)

**Address offset**: 0x014  
**Reset value**: 0x0000

Bits 15:9  **Reserved**, must be kept at reset value.

Bit 8  **B2G**: Break 2 generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7  **BG**: Break generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
### TIMx capture/compare mode register 1 (TIMx_CCMR1)

**Address offset:** 0x018  
**Reset value:** 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

</tr>
</tbody>
</table>
Input capture mode:

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  IC2F[3:0]: Input capture 2 filter

Bits 11:10  IC2PSC[1:0]: Input capture 2 prescaler

Bits 9:8   CC2S[1:0]: Capture/compare 2 selection
  This bitfield defines the direction of the channel (input/output) as well as the used input.
  00: CC2 channel is configured as output
  01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
  10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
  11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an
      internal trigger input is selected through TS bit (TIMx_SMCR register)

Note:  CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter
This bitfield defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at fDTS
- 0001: fsampling = ftim_ker_ck, N = 2
- 0010: fsampling = ftim_ker_ck, N = 4
- 0011: fsampling = ftim_ker_ck, N = 8
- 0100: fsampling = fDTS/2, N = 6
- 0101: fsampling = fDTS/2, N = 8
- 0110: fsampling = fDTS/4, N = 6
- 0111: fsampling = fDTS/4, N = 8
- 1000: fsampling = fDTS/8, N = 6
- 1001: fsampling = fDTS/8, N = 8
- 1010: fsampling = fDTS/16, N = 5
- 1011: fsampling = fDTS/16, N = 6
- 1100: fsampling = fDTS/16, N = 8
- 1101: fsampling = fDTS/32, N = 5
- 1110: fsampling = fDTS/32, N = 6
- 1111: fsampling = fDTS/32, N = 8

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler
This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/compare 1 Selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

28.6.8  **TIMx capture/compare mode register 1 [alternate]**
(TIMx_CCMR1)(x = 1, 8, 20)
Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
### Output compare mode:

- **Bits 31:25**  Reserved, must be kept at reset value.
- **Bits 23:17**  Reserved, must be kept at reset value.
- **Bit 15**  **OC2CE**: Output compare 2 clear enable
- **Bits 24, 14:12**  **OC2M[3:0]**: Output compare 2 mode
- **Bit 11**  **OC2PE**: Output compare 2 preload enable
- **Bit 10**  **OC2FE**: Output compare 2 fast enable
- **Bits 9:8**  **CC2S[1:0]**: Capture/compare 2 selection
  
  This bitfield defines the direction of the channel (input/output) as well as the used input.
  - 00: CC2 channel is configured as output
  - 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
  - 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
  - 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

  **Note**: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).**

- **Bit 7**  **OC1CE**: Output compare 1 clear enable
  - 0: tim_oc1ref is not affected by the tim_ocref_clr_int signal
  - 1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref = 0) as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref = 1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

**Note:** On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
28.6.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)
(x = 1, 8, 20)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

| 0: | Input capture mode

Input capture mode
Advanced-control timers (TIM1/TIM8/TIM20)

Output compare mode

Bits 31:25  Reserved, must be kept at reset value.
Bits 23:17  Reserved, must be kept at reset value.
Bit 15  OC4CE: Output compare 4 clear enable
Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode  
Refer to **OC3M[3:0]** bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection  
This bitfield defines the direction of the channel (input/output) as well as the used input.  
00: CC4 channel is configured as output  
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_t4  
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_t3  
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)  

*Note*: **CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).**

Bit 7 **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4 **OC3M[3:0]:** Output compare 3 mode

These bits define the behavior of the output reference signal tim\_oc3ref from which tim\_oc3 and tim\_oc3n are derived. tim\_oc3ref is active high whereas tim\_oc3 and tim\_oc3n active level depends on CC3P and CC3NP bits.

- **0000:** Frozen - The comparison between the output compare register TIMx\_CCR3 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).
- **0001:** Set channel 3 to active level on match. tim\_oc3ref signal is forced high when the counter TIMx\_CNT matches the capture/compare register 3 (TIMx\_CCR3).
- **0010:** Set channel 3 to inactive level on match. tim\_oc3ref signal is forced low when the counter TIMx\_CNT matches the capture/compare register 3 (TIMx\_CCR3).
- **0011:** Toggle - tim\_oc3ref toggles when TIMx\_CNT = TIMx\_CCR3.
- **0100:** Force inactive level - tim\_oc3ref is forced low.
- **0101:** Force active level - tim\_oc3ref is forced high.
- **0110:** PWM mode 1 - In upcounting, channel 3 is active as long as TIMx\_CNT<TIMx\_CCR3 else inactive. In downcounting, channel 3 is inactive (tim\_oc3ref = 0) as long as TIMx\_CNT> TIMx\_CCR3 else active (tim\_oc3ref = 1).
- **0111:** PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx\_CNT<TIMx\_CCR3 else active. In downcounting, channel 3 is active as long as TIMx\_CNT> TIMx\_CCR3 else inactive.
- **1000:** Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim\_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim\_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.
- **1001:** Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim\_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim\_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1010:** Pulse on compare: a pulse is generated on tim\_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.
- **1011:** Direction output. The tim\_oc3ref signal is overridden by a copy of the DIR bit.
- **1100:** Combined PWM mode 1 - tim\_oc3ref has the same behavior as in PWM mode 1. tim\_oc3refc is the logical OR between tim\_oc3ref and tim\_oc4ref.
- **1101:** Combined PWM mode 2 - tim\_oc3ref has the same behavior as in PWM mode 2. tim\_oc3refc is the logical AND between tim\_oc3ref and tim\_oc4ref.
- **1110:** Asymmetric PWM mode 1 - tim\_oc3ref has the same behavior as in PWM mode 1. tim\_oc3refc outputs tim\_oc3ref when the counter is counting up, tim\_oc4ref when it is counting down.
- **1111:** Asymmetric PWM mode 2 - tim\_oc3ref has the same behavior as in PWM mode 2. tim\_oc3refc outputs tim\_oc3ref when the counter is counting up, tim\_oc4ref when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S = 00 (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
**28.6.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8, 20)**

Address offset: 0x020  
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

- **Bit 21 CC6P**: Capture/compare 6 output polarity  
  Refer to CC1P description
- **Bit 20 CC6E**: Capture/compare 6 output enable  
  Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.

- **Bit 17 CC5P**: Capture/compare 5 output polarity  
  Refer to CC1P description
- **Bit 16 CC5E**: Capture/compare 5 output enable  
  Refer to CC1E description
- **Bit 15 CC4NP**: Capture/compare 4 complementary output polarity  
  Refer to CC1NP description
- **Bit 14 CC4NE**: Capture/compare 4 complementary output enable  
  Refer to CC1NE description
- **Bit 13 CC4P**: Capture/compare 4 output polarity  
  Refer to CC1P description
- **Bit 12 CC4E**: Capture/compare 4 output enable  
  Refer to CC1E description
- **Bit 11 CC3NP**: Capture/compare 3 complementary output polarity  
  Refer to CC1NP description
Bit 10  **CC3NE**: Capture/compare 3 complementary output enable
Refer to CC1NE description

Bit 9  **CC3P**: Capture/compare 3 output polarity
Refer to CC1P description

Bit 8  **CC3E**: Capture/compare 3 output enable
Refer to CC1E description

Bit 7  **CC2NP**: Capture/compare 2 complementary output polarity
Refer to CC1NP description

Bit 6  **CC2NE**: Capture/compare 2 complementary output enable
Refer to CC1NE description

Bit 5  **CC2P**: Capture/compare 2 output polarity
Refer to CC1P description

Bit 4  **CC2E**: Capture/compare 2 output enable
Refer to CC1E description

Bit 3  **CC1NP**: Capture/compare 1 complementary output polarity

**CC1 channel configured as output:**
0: tim_oc1n active high.
1: tim_oc1n active low.

**CC1 channel configured as input:**
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.
Refer to CC1P description.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S = 00 (channel configured as output).*

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 2  **CC1NE**: Capture/compare 1 complementary output enable
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.*
Bit 1  **CC1P**: Capture/compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

**CC1NP = 0, CC1P = 0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

**CC1NP = 0, CC1P = 1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

**CC1NP = 1, CC1P = 1**: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

**CC1NP = 1, CC1P = 0**: the configuration is reserved, it must not be used.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 0  **CC1E**: Capture/compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

*When CC1 channel is configured as output*, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 267* for details.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*
### Table 267. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature

<table>
<thead>
<tr>
<th>Control bits</th>
<th>Output states(1)</th>
</tr>

Bit 31 **UIFCPY**: UIF copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value
- Non-dithering mode (DITHEN = 0)
  The register holds the counter value.
- Dithering mode (DITHEN = 1)
  The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

28.6.13 TIMx prescaler (TIMx_PSC)(x = 1, 8, 20)

Address offset: 0x028
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>PSC[15:0]: Prescaler value</td>
</tr>
<tr>
<td>14</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency \(f_{\text{tim_cnt_ck}}\) is equal to \(f_{\text{tim_psc_ck}} / (\text{PSC[15:0]} + 1)\).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").
28.6.14  TIMx auto-reload register (TIMx_ARR)(x = 1, 8, 20)

Address offset: 0x02C
Reset value: 0x0000 FFFF

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>

<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **ARR[19:0]: Auto-reload value**

ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 28.3.3: Time-base unit on page 1100 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

28.6.15  TIMx repetition counter register (TIMx_RCR)(x = 1, 8, 20)

Address offset: 0x030
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0  **REP[15:0]: Repetition counter reload value**

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reload with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to:
– the number of PWM periods in edge-aligned mode
– the number of half PWM period in center-aligned mode.
### 28.6.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8, 20)

#### Bits 31:20: Reserved, must be kept at reset value.

#### Bits 19:0 CCR1[19:0]: Capture/compare 1 value

**If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

**Non-dithering mode (DITHEN = 0):**

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1):**

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0):**

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1):**

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]**: Capture/compare 2 value

*If channel CC2 is configured as output:* CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

*If channel CC2 is configured as input:* CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR3[19:0]: Capture/compare value**

- **If channel CC3 is configured as output:** CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
  - It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
  - The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.
  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.

- **If channel CC3 is configured as input:** CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.
  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the capture value in CCR3[15:0]. The CCR3[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the capture in CCR3[19:4]. The CCR3[3:0] bits are reset.

### 28.6.19  TIMx capture/compare register 4 (TIMx_CCR4)(x = 1, 8, 20)

**Address offset:** 0x040

**Reset value:** 0x0000 0000

**Note:** As the bits BKBID/BK2BID/BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSR, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **BK2BID**: Break2 bidirectional
  Refer to BK2BID description

Bit 28  **BK2BID**: Break bidirectional
  0: Break input tim_brk in input mode
  1: Break input tim_brk in bidirectional mode
  In the bidirectional mode (BK2BID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

  **Note**: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  **Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  **BK2DSRM**: Break2 disarm
  Refer to BK2DSRM description

Bit 26  **BKDSRM**: Break disarm
  0: Break input tim_brk is armed
  1: Break input tim_brk is disarmed
  This bit is cleared by hardware when no break source is active.
  The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

  **Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25  **BK2P**: Break 2 polarity
  0: Break input tim_brk2 is active low
  1: Break input tim_brk2 is active high

  **Note**: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  **Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24  **BK2E**: Break 2 enable
  This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 316: Break and Break2 circuitry overview).
  0: Break2 function disabled
  1: Break2 function enabled

  **Note**: The BKIN2 must only be used with OSSR = OSSI = 1.

  **Note**: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  **Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bitfield defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk2 acts asynchronously
0001: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{2}, N = 2 \)
0010: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{4}, N = 4 \)
0011: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{8}, N = 8 \)
0100: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{2}, N = 6 \)
0101: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{4}, N = 8 \)
0110: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 6 \)
0111: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{6}, N = 8 \)
1000: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 6 \)
1001: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 8 \)
1010: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{16}, N = 5 \)
1011: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{16}, N = 6 \)
1100: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 5 \)
1101: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 6 \)
1110: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 8 \)
1111: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 8 \)

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 19:16 **BKF[3:0]**: Break filter

This bitfield defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{2}, N = 2 \)
0010: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{4}, N = 4 \)
0011: \( f_{\text{sampling}} = \frac{f_{\text{tim_ker_ck}}}{8}, N = 8 \)
0100: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{2}, N = 6 \)
0101: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{4}, N = 8 \)
0110: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 6 \)
0111: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{6}, N = 8 \)
1000: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 6 \)
1001: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{8}, N = 8 \)
1010: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{16}, N = 5 \)
1011: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{16}, N = 6 \)
1100: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 5 \)
1101: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 6 \)
1110: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 8 \)
1111: \( f_{\text{sampling}} = \frac{f_{\text{DTS}}}{32}, N = 8 \)

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- **0**: In response to a break 2 event. OC and OCN outputs are disabled
  - In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
  - 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

  See OC/OCN enable description for more details (Section 28.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8, 20)).

Bit 14 **AOE**: Automatic output enable

- **0**: MOE can be set only by software
- **1**: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

  *Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

- **0**: Break input tim_brk is active low
- **1**: Break input tim_brk is active high

  *Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per Figure 316: Break and Break2 circuitry overview).

- **0**: Break function disabled
- **1**: Break function enabled

  *Note*: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

  *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE = 1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 28.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8, 20)).

- **0**: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
- **1**: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE = 1 or CCxNE = 1 (the output is still controlled by the timer).

  *Note*: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for idle mode

This bit is used when MOE = 0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 28.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8, 20)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).
1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

**Bits 9:8** **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKBID/BK2BID/BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note:** The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

**Bits 7:0** **DTG[7:0]**: Dead-time generator setup

This bitfield defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5] = 0xx => DT = DTG[7:0]x t_{DTS} with t_{DTS} = t_{DTS}.
DTG[7:5] = 10x => DT = (64+DTG[5:0])x t_{DTS} with t_{DTS} = 2x t_{DTS}.
DTG[7:5] = 110 => DT = (32+DTG[4:0])x t_{DTS} with t_{DTS} = 8x t_{DTS}.
DTG[7:5] = 111 => DT = (32+DTG[4:0])x t_{DTS} with t_{DTS} = 16x t_{DTS}.

Example if T_{DTS} = 125 ns (8 MHz), dead-time possible values are:
- 0 to 15875 ns by 125 ns steps,
- 16 μs to 31750 ns by 250 ns steps,
- 32 μs to 63 μs by 1 μs steps,
- 64 μs to 126 μs by 2 μs steps

**Note:** This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

1220/2138 RM0440 Rev 8
Bit 31  **GC5C3**: Group channel 5 and channel 3
Distortion on channel 3 output:
0: No effect of tim_oc5ref on tim_oc3refc
1: tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).
*Note:* it is also possible to apply this distortion on combined PWM signals.

Bit 30  **GC5C2**: Group channel 5 and channel 2
Distortion on channel 2 output:
0: No effect of tim_oc5ref on tim_oc2refc
1: tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
*Note:* it is also possible to apply this distortion on combined PWM signals.

Bit 29  **GC5C1**: Group channel 5 and channel 1
Distortion on channel 1 output:
0: No effect of oc5ref on oc1refc
1: oc1refc is the logical AND of oc1ref and oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
*Note:* it is also possible to apply this distortion on combined PWM signals.

Bits 28:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR5[19:0]**: Capture/compare 5 value
CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc5 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.

28.6.23  TIMx capture/compare mode register 3 (TIMx_CCMR3)  
(x = 1, 8, 20)

Address offset: 0x050
Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR6[19:0]: Capture/compare 6 value**  
CCR6 is the value to be loaded in the actual capture/compare 6 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC6PE). Else the preload value is copied in the active capture/compare 6 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc6 output.

- **Non-dithering mode (DITHEN = 0)**  
The register holds the compare value in CCR6[15:0]. The CCR6[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**  
The register holds the integer part in CCR6[19:4]. The CCR6[3:0] bitfield contains the dithered part.

- **OC6CE**: Output compare 6 clear enable
- **OC6M[3:0]**: Output compare 6 mode
- **OC6FE**: Output compare 6 fast enable
- **OC5CE**: Output compare 5 clear enable
- **OC5M[3:0]**: Output compare 5 mode
- **OC5PE**: Output compare 5 preload enable
- **OC5FE**: Output compare 5 fast enable

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC6CE**: Output compare 6 clear enable

Bits 24, 14:12  **OC6M[3:0]**: Output compare 6 mode

Bit 11  **OC6PE**: Output compare 6 preload enable

Bit 10  **OC6FE**: Output compare 6 fast enable

Bits 9:8  Reserved, must be kept at reset value.

Bit 7  **OC5CE**: Output compare 5 clear enable

Bits 16, 6:4  **OC5M[3:0]**: Output compare 5 mode

Bit 3  **OC5PE**: Output compare 5 preload enable

Bit 2  **OC5FE**: Output compare 5 fast enable

Bits 1:0  Reserved, must be kept at reset value.
### 28.6.24 TIMx timer deadtime register 2 (TIMx_DTR2)(x = 1, 8, 20)

**Bits 31:18** Reserved, must be kept at reset value.

**Bit 17 DTPE:** Deadtime preload enable  
0: Deadtime value is not preloaded  
1: Deadtime value preload is enabled  

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 16 DTAE:** Deadtime asymmetric enable  
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register  
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.  

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bits 15:8** Reserved, must be kept at reset value.

**Bits 7:0 DTGF[7:0]:** Dead-time falling edge generator setup  
This bitfield defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.  

- DTGF[7:5] = 0xx => DTF = DTGF[7:0]x t_{dtg} with t_{dtg} = T_DTS.  
- DTGF[7:5] = 10x => DTF = (64+DTGF[5:0])x t_{dtg} with T_{dtg} = 2xT_DTS.  
- DTGF[7:5] = 110 => DTF = (32+DTGF[4:0])x t_{dtg} with T_{dtg} = 8xT_DTS.  
- DTGF[7:5] = 111 => DTF = (32+DTGF[4:0])x t_{dtg} with T_{dtg} = 16xT_DTS.

Example if T_DTS = 125 ns (8 MHz), dead-time possible values are:  
0 to 15875 ns by 125 ns steps,  
16 µs to 31750 ns by 250 ns steps,  
32 µs to 63 µs by 1 µs steps,  
64 µs to 126 µs by 2 µs steps

*Note: This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*
28.6.25 TIMx timer encoder control register (TIMx_ECR)(x = 1, 8, 20)

Address offset: 0x058
Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 PWPRSC[2:0]: Pulse width prescaler
This bitfield sets the clock prescaler for the pulse generator, as following:
\[ t_{PWG} = (2^{PWPRSC[2:0]}) \times t_{tim\_ker\_ck} \]

Bits 23:16 PW[7:0]: Pulse width
This bitfield defines the pulse duration, as following:
\[ t_{PW} = PW[7:0] \times t_{PWG} \]

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 IPOS[1:0]: Index positioning
In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicate on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

Note: IPOS[1] bit is not significant

Bit 5 FIDX: First index
This bit indicates if the first Index only is taken into account
0: Index is always active
1: the first Index only resets the counter
**Advanced-control timers (TIM1/TIM8/TIM20)**

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKMP4P**: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12  **BKCMP3P**: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 11  **BKCMP2P**: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10  **BKCMP1P**: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9  **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: TIMx_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8  **BKCMP8E**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. tim_brk_cmp8 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7  **BKCMP7E**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 6  **BKCMP6E**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Advanced-control timers (TIM1/TIM8/TIM20) RM0440

Bit 5 \textbf{BKCMP5E}: tim\_brk\_cmp5 enable
This bit enables the tim\_brk\_cmp5 for the timer's tim\_brk input. tim\_brk\_cmp5 output is 'ORed' with the other tim\_brk sources.
0: tim\_brk\_cmp5 input disabled
1: tim\_brk\_cmp5 input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 4 \textbf{BKCMP4E}: tim\_brk\_cmp4 enable
This bit enables the tim\_brk\_cmp4 for the timer's tim\_brk input. tim\_brk\_cmp4 output is 'ORed' with the other tim\_brk sources.
0: tim\_brk\_cmp4 input disabled
1: tim\_brk\_cmp4 input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 3 \textbf{BKCMP3E}: tim\_brk\_cmp3 enable
This bit enables the tim\_brk\_cmp3 for the timer's tim\_brk input. tim\_brk\_cmp3 output is 'ORed' with the other tim\_brk sources.
0: tim\_brk\_cmp3 input disabled
1: tim\_brk\_cmp3 input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 2 \textbf{BKCMP2E}: tim\_brk\_cmp2 enable
This bit enables the tim\_brk\_cmp2 for the timer's tim\_brk input. tim\_brk\_cmp2 output is 'ORed' with the other tim\_brk sources.
0: tim\_brk\_cmp2 input disabled
1: tim\_brk\_cmp2 input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 1 \textbf{BKCMP1E}: tim\_brk\_cmp1 enable
This bit enables the tim\_brk\_cmp1 for the timer's tim\_brk input. tim\_brk\_cmp1 output is 'ORed' with the other tim\_brk sources.
0: tim\_brk\_cmp1 input disabled
1: tim\_brk\_cmp1 input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 0 \textbf{BKINE}: TIMx\_BKIN input enable
This bit enables the TIMx\_BKIN alternate function input for the timer's tim\_brk input. TIMx\_BKIN input is 'ORed' with the other tim\_brk sources.
0: TIMx\_BKIN input disabled
1: TIMx\_BKIN input enabled

\textit{Note}: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

\textit{Note}: Refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation.

**Bit 3 BK2CMP3E: tim_brk2_cmp3 enable**

This bit enables the tim_brk2_cmp3 for the timer’s tim_brk2 input. tim_brk2_cmp3 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp3 input disabled
- 1: tim_brk2_cmp3 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 2 BK2CMP2E: tim_brk2_cmp2 enable**

This bit enables the tim_brk2_cmp2 for the timer’s tim_brk2 input. tim_brk2_cmp2 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp2 input disabled
- 1: tim_brk2_cmp2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 1 BK2CMP1E: tim_brk2_cmp1 enable**

This bit enables the tim_brk2_cmp1 for the timer’s tim_brk2 input. tim_brk2_cmp1 output is 'ORed' with the other tim_brk2 sources.

- 0: tim_brk2_cmp1 input disabled
- 1: tim_brk2_cmp1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 0 BK2INE: TIMx_BKIN2 input enable**

This bit enables the TIMx_BKIN2 alternate function input for the timer’s tim_brk2 input. TIMx_BKIN2 input is ‘ORed’ with the other tim_brk2 sources.

- 0: TIMx_BKIN2 input disabled
- 1: TIMx_BKIN2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

*Note: Refer to Section 28.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation.*
Advanced-control timers (TIM1/TIM8/TIM20)

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:
  
  \[(TIMx\_CR1\ \text{address}) + DBA + (\text{DMA index})\]

  In this example, 7 bytes are added to \((TIMx\_CR1\ \text{address}) + DBA\), which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: \((TIMx\_CR1\ \text{address}) + DBA\)

  According to the configuration of the DMA Data Size, several cases may occur:
  
  - If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
  - If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

  So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**

- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
- ...

**28.6.30  TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8, 20)**

Address offset: 0x3E0

Reset value: 0x0000 0000

DMAB[15:0]
Bits 31:0  **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

### 28.6.31 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

Refer to Section 2.2 on page 81 for the register boundary addresses.
29 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

29.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 29.4.23: Timer synchronization.

29.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit or 32-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
## 29.3 TIM2/TIM3/TIM4/TIM5 implementation

#### 29.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC):
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.
Figure 359 and Figure 360 give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 359. Counter timing diagram with prescaler division change from 1 to 2**

![Counter timing diagram with prescaler division change from 1 to 2](image-url)
29.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 361. Counter timing diagram, internal clock divided by 1

- **CEN**: Counter register
- **tim_cnt_ck**: Counter overflow
- **Update event (UEV)**
- **Update interrupt flag (UIF)**
- **Auto-reload preload register**: Write a new value in TIMx_ARR

Counter register:

```
31 32 33 34 35 36 00 01 02 03 04 05 06 07
```

Auto-reload preload register: FF 36
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

```
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
1. Here, center-aligned mode 1 is used (for more details refer to Section 29.5.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1315).

1. Center-aligned mode 2 or 3 is used with an UIF on overflow.

Figure 375. Counter timing diagram, internal clock divided by N
Figure 376. Counter timing diagram, Update event with ARPE=1 (counter underflow)
### 29.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to: Using one timer as prescaler for another timer on page 1307 for more details.

#### Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 378 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.*
Figure 378. Control circuit in normal mode, internal clock divided by 1

Exponential clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 379. tim_ti2 external clock connection example

1. Codes ranging from 01000 to 11111: tim_itr[15:0].

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S= ‘01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.
The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 380. Control circuit in external clock mode 1

External clock source mode 2
This mode is selected by writing ECE=1 in the TIMx_SMCR register.
The counter can count at each rising or falling edge on the external trigger input tim_etr_in.
Figure 381 gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the tim_etr_in by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etp signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPR prescaler setting.
29.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfp) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 383. Capture/compare channel (example: channel 1 input stage)
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

**Figure 384. Capture/compare channel 1 main circuit**

1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocref_clr_int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.
In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 29.4.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

**Note:** *IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.*
29.4.8 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_t1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
3. Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
5. Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx_CCER register.
29.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

29.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP...
General-purpose timers (TIM2/TIM3/TIM4/TIM5)

The output pin can keep its level (OCXM=000), be set active (OCXM=001), be set inactive (OCXM=010) or can toggle (OCXM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   b) Write OCxPE = 0 to disable preload register
   c) Write CCxP = 0 to select active high polarity
   d) Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 387.
29.4.11 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etn_in or the tim_ocref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ’111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
**PWM edge-aligned mode**

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to [Upcounting mode on page 1245](#).

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1. If the compare value is 0 then tim_ocxref is held at ‘0. Figure 388 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

![Figure 388. Edge-aligned PWM waveforms (ARR=8)](image)

**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to [Downcounting mode on page 1249](#).

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting) on page 1252.

Figure 389 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 390 below presents the dithering principle applied to 4 consecutive PWM cycles.

![Figure 390. Dithering principle](image)

When the dithering mode is enabled, the register coding is changed as following (see Figure 391 for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by 4 places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.
Note: The ARR and CCR values will be updated automatically if the DITHEN bit is set / reset (for instance, if ARR= 0x05 with DITHEN=0, it will be updated to ARR = 0x50 with DITHEN=1). The following sequence must be followed when resetting the DITHEN bit:

1. CEN and ARPE bits must be reset.
2. The ARR[3:0] bits must be reset.
3. The DITHEN bit must be reset.
4. The CCIF flags must be cleared.
5. The CEN bit can be set (eventually with ARPE = 1).

Figure 391. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{Max}_{\text{Resolution}}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode (16-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Dithering mode (32-bit timer): \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{268435454 + \frac{15}{16}} \)
**Note:** For 16-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part). For 32-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFFFFFEF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on the Figure 392 and Figure 393 below, the dithering mode is used to increase the PWM resolution.

**Figure 392. PWM resolution vs frequency (16-bit mode)**

![Figure 392](image1)

**Figure 393. PWM resolution vs frequency (32-bit mode)**

![Figure 393](image2)

The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the Figure 394 below.

</table>

The auto-reload and compare values increments are spread following specific patterns described in the Table 279 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to '00'). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 395 below.

*Table 280* below shows how the dithering pattern is added in center-aligned PWM mode.
### Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 2.

Figure 396 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2).

Figure 396. Generation of 2 phase-shifted PWM signals with 50% duty cycle

29.4.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, \text{tim\_ocxrefc}, are made of an OR or AND logical combination of two reference PWMs:

- \text{tim\_oc1refc} (or \text{tim\_oc2refc}) is controlled by TIMx\_CCR1 and TIMx\_CCR2
- \text{tim\_oc3refc} (or \text{tim\_oc4refc}) is controlled by TIMx\_CCR3 and TIMx\_CCR4

Combined PWM mode can be selected independently on two channels (one \text{tim\_ocx} output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 397 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
29.4.14 Clearing the \texttt{tim\_ocxref} signal on an external event

The \texttt{tim\_ocxref} signal of a given channel can be cleared when a high level is applied on the \texttt{tim\_ocref\_clr\_int} input (OCxCE enable bit in the corresponding TIMx\_CCMRx register set to 1). \texttt{tim\_ocxref} remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The \texttt{tim\_ocref\_clr\_int} source depends on the OCR\textit{E}F clear selection feature implementation, refer to Section 29.3: TIM2/TIM3/TIM4/TIM5 implementation.

If the OCR\textit{E}F clear selection feature is implemented, the \texttt{tim\_ocref\_clr\_int} can be selected between the \texttt{tim\_ocref\_clr} input and the \texttt{tim\_etrf\_input} (\texttt{tim\_etrf\_in\_after\_the\_filter}) by configuring the OCCS bit in the TIMx\_SMCR register. The \texttt{tim\_ocref\_clr} input can be selected among several \texttt{tim\_ocref\_clr[7:0]} inputs, using the OCRSEL[2:0] bitfield in the TIMx\_AF2 register, as shown in Figure 398 below.
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etrf_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application’s needs.

Figure 399 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

29.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT<CCRx ≤ ARR (in particular, 0<CCRx),

![Figure 400. Example of One-pulse mode](image)

For example one may want to generate a positive pulse on tim_oc1 with a length of t\text{PULSE} and after a delay of t\text{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Let’s use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register must be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: tim_ocx fast enable:**

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}}\text{min}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

**29.4.16 Retriggerable one-pulse mode**

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 29.4.15:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

*Note: In Retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
29.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 402 below.

The Figure 403 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim\_ker\_ck} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 404 below).
29.4.18 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS=’0001 in the TIMx_SMCR register if the counter is counting on tim_t1 edges only, SMS=’0010 if it is counting on tim_t2 edges only and SMS=’0011 if it is counting on both tim_t1 and tim_t2 edges.

Select the tim_t1 and tim_t2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_t1 and tim_t2 are used to interface to an incremental encoder. Refer to Table 281. The counter is clocked by each valid transition on tim_t1fp1 or tim_t2fp2 (tim_t1 and tim_t2 after input filter and polarity selection, tim_t1fp1=tim_t1 if not filtered and not inverted, tim_t2fp2=tim_t2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_t1 or tim_t2), whatever the counter is counting on tim_t1 only, tim_t2 only or both tim_t1 and tim_t2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction corresponds to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_t1 and tim_t2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 405 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1)
- CC2S = 01 (TIMx_CCMR1 register, tim_ti2fp2 mapped on tim_ti2)
- CC1P and CC1NP = ‘0’ (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1)
- CC2P and CC2NP = ‘0’ (TIMx_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2 = tim_ti2)
- SMS = 0011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN = 1 (TIMx_CR1 register, Counter is enabled)

Figure 405. Example of counter operation in encoder interface mode

Figure 406 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P=1).

Figure 406. Example of encoder interface mode with tim_ti1fp1 polarity inverted
The Figure 407 below shows the timer counter value during a speed reversal, for various counting modes.

**Figure 407. Quadrature encoder counting modes**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 408, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.
This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:
- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value:
  CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

### Directional Clock encoder mode

In the “directional clock” mode on Figure 409, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:
- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 409 below) and CCxP = 1 corresponds to low-level idle state (refer to Figure 410 below).
- 1101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 409 below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 410 below).
The Table 282 here-below details how the directional clock mode operates, for any input transition.
Index Input

The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim__etr__in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 411 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges

Table 282. Counting direction versus encoder signals and polarity settings
The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 412 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulse width is greater or equal to 2 encoder period, the counter is reset multiple times.

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0)
- The counter is set to TIMx_ARR when down counting

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 413 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).
The Figure 413 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

The Figure 414 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

The Figure 415 below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.
The Figure 416 below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

The Figure 417 and Figure 418 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 417. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)
The Figure 419 below shows how the index is managed in x1 and x2 modes.
Figure 419. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The Figure 420 below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

Note: The IDR[1:0] bitfield must be written when IE bit is reset (index mode disabled).

Note: The directional index sensitivity is not supported in clock + direction mode. When SMS[3:0] = 1010 or 1011, the IDIR[1:0] must be set to 00.
**Special first index event management**

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the **Figure 421** below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

*Note:* When FIDX = 1, the index can be issued twice (IDXF flag set) if the direction changes at position 0 (index active).

**Index management in non-quadrature mode**

The **Figure 422** and **Figure 423** below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.
For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

**Figure 422. Index behavior in clock + direction mode, IPOS[0] = 1**

**Figure 423. Index behavior in directional clock mode, IPOS[0] = 1**

**Encoder error management**

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the **Figure 424.** below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.
For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 425 below.

**Figure 425. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 426 below, to avoid any false error detection in case the encoder dithers between TIMx.ARR and 0 immediately after the index detection.

**Figure 426. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder Interrupts**

The following interrupts are also available in encoder mode:

- **Direction change:** any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- **Index event:** the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on the Figure 427 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting. This mode must be used only when index is disabled (bit IE = 0).
- SMSPS = 1: the transfer is triggered by the Index event.

Figure 427. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

29.4.19 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

### 29.4.20 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

### 29.4.21 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 28.3.29: Interfacing with Hall sensors on page 1174.

### 29.4.22 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 428. Control circuit in reset mode**

<table>
<thead>
<tr>
<th>tim_ti1</th>
<th>UG</th>
<th>tim_cnt_ck, tim_psc_ck</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
**Note:** The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TIM2 input:

1. Configure the channel 2 to detect rising edges on TIM2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCRER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TIM2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TIM2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TIM2 and the actual start of the counter is due to the resynchronization circuit on TIM2 input.
Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etra_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select tim_etra_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etra_in signal as soon as a rising edge of tim_t1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etra_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_t1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_t1 enables the counter and sets the TIF flag. The counter then counts on tim_etra_in rising edges.

The delay between the rising edge of the tim_etra_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etra_in input.
29.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 432* and *Figure 433* show examples of master/slave timer connections.

*Figure 432. Master/Slave timer example*

</tr>
</tbody>
</table>

**Note:** The timers with one channel only (see Figure 433) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 29.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

**Using one timer as prescaler for another timer**

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to Figure 432. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

**Note:** If tim_ocx is selected on TIM_mstr as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM_slv.

**Using one timer to enable another timer**

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to Figure 432 for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck (f_{tim_cnt_ck} = f_{tim_ker_ck}/3).
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Enable TIM_slv by writing ‘1’ in the CEN bit (TIM_slv_CR1 register).
6. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).

**Note:** The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

![Figure 434. Gating TIM_slv with tim_oc1ref of TIM_mstr](MSv62376V1)

In the example in **Figure 434**, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to **Figure 435**), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing ‘0’ to the CEN bit in the TIM_mstr_CR1 register:
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing ‘1’ in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing ‘1’ in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing ‘0xE7’ in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing ‘1’ in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing ‘0’ in the CEN bit (TIM_mstr_CR1 register).

**Figure 435. Gating TIM_slv with Enable of TIM_mstr**

Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to Figure 432 for connections. TIM_slv starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0’ to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck (f_{tim_cnt_ck} = f_{tim_ker_ck}/3).

1. Configure TIM_mstr master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS=110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing ‘1’ in the CEN bit (TIM_mstr_CR1 register).
As in the previous example, both counters can be initialized before starting counting. *Figure 437* shows the behavior with the same configuration as in *Figure 436* but in trigger mode (SMS=110 in the TIM_slv_SMCR register) instead of gated mode.

**Starting 2 timers synchronously in response to an external trigger**

In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to *Figure 432* for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):
1. Configure TIM_mstr master mode to send its Enable as trigger output (MMS=001 in the TIM_mstr_CR2 register).

2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS=00100 in the TIM_mstr_SMCR register).

3. Configure TIM_mstr in trigger mode (SMS=110 in the TIM_mstr_SMCR register).

4. Configure the TIM_mstr in Master/Slave mode by writing MSM=1 (TIM_mstr_SMCR register).

5. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00000 in the TIM_slv_SMCR register).

6. Configure TIM_slv in trigger mode (SMS=110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters start counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters start from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM_mstr.

Figure 438. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

29.4.24 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
29.4.25 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.
29.4.26 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in Table 283.

<table>
<thead>
<tr>
<th>DMA request signal</th>

</tbody>
</table>

Note: Some timer’s DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

29.4.27 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 with FPU core halted), the TIMx counter can either continues to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

29.4.28 TIM2/TIM3/TIM4/TIM5 low-power modes

<table>
<thead>
<tr>

29.5 TIM2/TIM3/TIM4/TIM5 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

29.5.1 TIMx control register 1 (TIMx_CR1) (x = 2 to 5)

Address offset: 0x000
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:13 Reserved</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10 Reserved</th>
<th>Bit 9:8</th>
<th>Bit 7</th>
<th>Bit 6:5</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering Enable

0: Dithering disabled
1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_etr_in, tim_tix),

00: \( t_{DTS} = t_{\text{tim_ker_ck}} \)
01: \( t_{DTS} = 2 \times t_{\text{tim_ker_ck}} \)
10: \( t_{DTS} = 4 \times t_{\text{tim_ker_ck}} \)
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*
29.5.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 5)

</table>
Bits 31:26  Reserved, must be kept at reset value.

Bits 24:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: tim_t1 selection  
0: The tim_t1_in[15:0] multiplexer output is to tim_t1 input  
1: The tim_t1_in[15:0], tim_t2_in[15:0] and tim_t3_in[15:0] multiplexers outputs are XORed and connected to the tim_t1 input. See also **Section 28.3.29: Interfacing with Hall sensors** on page 1174.

Bits 25, 6, 5, 4  **MMS[3:0]**: Master mode selection  
These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Others: Reserved

*Note:* The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3  **CCDS**: Capture/compare DMA selection  
0: CCx DMA request sent when CCx event occurs  
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
### 29.5.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5)

Address offset: 0x008  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 25 | **SMSPS**: SMS preload source  
This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active  
0: The transfer is triggered by the Timer’s Update event  
1: The transfer is triggered by the Index event |
| Bit 24 | **SMSPE**: SMS preload enable  
This bit selects whether the SMS[3:0] bitfield is preloaded  
0: SMS[3:0] bitfield is not preloaded  
1: SMS[3:0] preload is enabled |
| Bits 23:22 | Reserved, must be kept at reset value. |
| Bits 19:17 | Reserved, must be kept at reset value. |
| Bit 15 | **ETP**: External trigger polarity  
This bit selects whether tim_etr_in or tim_etr_in is used for trigger operations  
0: tim_etr_in is non-inverted, active at high level or rising edge  
1: tim_etr_in is inverted, active at low level or falling edge |
| Bit 14 | **ECE**: External clock enable  
This bit enables External clock mode 2.  
0: External clock mode 2 disabled  
1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal. |
| Note: | Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111).  
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111). If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf. |
| Bits 13:12 | **ETPS[1:0]**: External trigger prescaler  
External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etrp_in.  
00: Prescaler OFF  
01: tim_etrp frequency divided by 2  
10: tim_etrp frequency divided by 4  
11: tim_etrp frequency divided by 8 |
Bits 11:8 **ETF[3:0]:** External trigger filter

This bit-field then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at $f_{DTS}$
- 0001: \( f_{SAMPLING} = f_{tim\_ker\_ck}, N=2 \)
- 0010: \( f_{SAMPLING} = f_{tim\_ker\_ck}, N=4 \)
- 0011: \( f_{SAMPLING} = f_{tim\_ker\_ck}, N=8 \)
- 0100: \( f_{SAMPLING} = f_{DTS}/2, N=6 \)
- 0101: \( f_{SAMPLING} = f_{DTS}/2, N=8 \)
- 0110: \( f_{SAMPLING} = f_{DTS}/4, N=6 \)
- 0111: \( f_{SAMPLING} = f_{DTS}/4, N=8 \)
- 1000: \( f_{SAMPLING} = f_{DTS}/8, N=6 \)
- 1001: \( f_{SAMPLING} = f_{DTS}/8, N=8 \)
- 1010: \( f_{SAMPLING} = f_{DTS}/16, N=5 \)
- 1011: \( f_{SAMPLING} = f_{DTS}/16, N=6 \)
- 1100: \( f_{SAMPLING} = f_{DTS}/32, N=5 \)
- 1101: \( f_{SAMPLING} = f_{DTS}/32, N=6 \)
- 1110: \( f_{SAMPLING} = f_{DTS}/32, N=8 \)
- 1111: \( f_{SAMPLING} = f_{DTS}/32, N=8 \)

Bit 7 **MSM:** Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]: Trigger selection**

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal trigger 0 (tim_itr0)
- 00001: Internal trigger 1 (tim_itr1)
- 00010: Internal trigger 2 (tim_itr2)
- 00011: Internal trigger 3 (tim_itr3)
- 00100: tim_ti1 edge detector (tim_ti1f_ed)
- 00101: Filtered timer input 1 (tim_ti1fp1)
- 00110: Filtered timer input 2 (tim_ti2fp2)
- 00111: External trigger input (tim_etrf)
- 01000: Internal trigger 4 (tim_itr4)
- 01001: Internal trigger 5 (tim_itr5)
- 01010: Internal trigger 6 (tim_itr6)
- 01011: Internal trigger 7 (tim_itr7)
- 01100: Internal trigger 8 (tim_itr8)
- 01101: Internal trigger 9 (tim_itr9)
- 01110: Internal trigger 10 (tim_itr10)
- 01111: Internal trigger 11 (tim_itr11)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)
- Others: Reserved

See Section 29.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation details.

**Note:** These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS: OCREF clear selection**

This bit is used to select the OCREF clear source

- 0: tim_ocref_clr_int is connected to the tim_ocref_clr input
- 1: tim_ocref_clr_int is connected to tim_etrf

**Note:** If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to '0'. Section 29.3: TIM2/TIM3/TIM4/TIM5 implementation.
Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIMx_SMCR for tim_etr_in and CCxP/CCxNP bits in TIMx_CCER register for tim_ti1fp1 and tim_ti2fp2).

0000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
### 29.5.4 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 2 to 5)

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 TERRF: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 IERRF: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.
0: No index error has been detected.
1: An index error has been detected
Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to ‘0’.
- 0: No direction change
- 1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to ‘0’.
- 0: No index event occurred.
- 1: An index event has occurred

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
- 0: No overcapture has been detected.
- 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input) when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
- 0: No trigger event occurred.
- 1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description
Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
- 0: No compare match / No input capture occurred
- 1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
- 0: No update occurred
- 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - At overflow or underflow and if UDIS=0 in the TIMx_CR1 register.
  - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
  - When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
- 0: No action
- 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description
29.5.7 TIMx capture/compare mode register 1 (TIMx_CCMR1) (x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:12 | IC2F[3:0]: Input capture 2 filter |
| Bits 11:10 | IC2PSC[1:0]: Input capture 2 prescaler |
Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER)*.

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: fsampling = ftim_ker_ck, N=2
0010: fsampling = ftim_ker_ck, N=4
0011: fSampling = ftim_ker_ck, N=8
0100: fSampling = fDTS/2, N=6
0101: fSampling = fDTS/2, N=8
0110: fSampling = fDTS/4, N=6
0111: fSampling = fDTS/4, N=8
1000: fSampling = fDTS/8, N=6
1001: fSampling = fDTS/8, N=8
1010: fSampling = fDTS/16, N=5
1011: fSampling = fDTS/16, N=6
1100: fSampling = fDTS/16, N=8
1101: fSampling = fDTS/32, N=5
1110: fSampling = fDTS/32, N=6
1111: fSampling = fDTS/32, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*
29.5.8 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 OC2CE: Output compare 2 clear enable

Bits 24, 14:12 OC2M[3:0]: Output compare 2 mode refer to OC1M description on bits 6:4

Bit 11 OC2PE: Output compare 2 preload enable

Bit 10 OC2FE: Output compare 2 fast enable

Bits 9:8 CC2S[1:0]: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_t12
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_t11
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7 OC1CE: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input
Bits 16, 6:4  **OC1M[3:0]:** Output compare 1 mode

These bits define the behavior of the output reference signal \( \text{tim\_oc1ref} \) from which \( \text{tim\_oc1} \) is derived. \( \text{tim\_oc1ref} \) is active high whereas \( \text{tim\_oc1} \) active level depends on CC1P bit.

- **0000:** Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

- **0001:** Set channel 1 to active level on match. \( \text{tim\_oc1ref} \) signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0010:** Set channel 1 to inactive level on match. \( \text{tim\_oc1ref} \) signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

- **0011:** Toggle - \( \text{tim\_oc1ref} \) toggles when TIMx_CNT=TIMx_CCR1.

- **0100:** Force inactive level - \( \text{tim\_oc1ref} \) is forced low.

- **0101:** Force active level - \( \text{tim\_oc1ref} \) is forced high.

- **0110:** PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (\( \text{tim\_oc1ref}=0 \)) as long as TIMx_CNT> TIMx_CCR1 else active (\( \text{tim\_oc1ref}=1 \)).

- **0111:** PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT> TIMx_CCR1 else inactive.

- **1000:** Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on \( \text{tim\_trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channel becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on \( \text{tim\_trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channel becomes active again at the next update.

- **1001:** Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on \( \text{tim\_trgi} \) signal). Then, a comparison is performed as in PWM mode 2 and the channel becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on \( \text{tim\_trgi} \) signal). Then, a comparison is performed as in PWM mode 1 and the channel becomes active again at the next update.

- **1010:** Reserved.

- **1011:** Reserved.

- **1100:** Combined PWM mode 1 - \( \text{tim\_oc1ref} \) has the same behavior as in PWM mode 1. \( \text{tim\_oc1refc} \) is the logical OR between \( \text{tim\_oc1ref} \) and \( \text{tim\_oc2ref} \).

- **1101:** Combined PWM mode 2 - \( \text{tim\_oc1ref} \) has the same behavior as in PWM mode 2. \( \text{tim\_oc1refc} \) is the logical AND between \( \text{tim\_oc1ref} \) and \( \text{tim\_oc2ref} \).

- **1110:** Asymmetric PWM mode 1 - \( \text{tim\_oc1ref} \) has the same behavior as in PWM mode 1. \( \text{tim\_oc1refc} \) outputs \( \text{tim\_oc1ref} \) when the counter is counting up, \( \text{tim\_oc2ref} \) when it is counting down.

- **1111:** Asymmetric PWM mode 2 - \( \text{tim\_oc1ref} \) has the same behavior as in PWM mode 2. \( \text{tim\_oc1refc} \) outputs \( \text{tim\_oc1ref} \) when the counter is counting up, \( \text{tim\_oc2ref} \) when it is counting down.

**Note:** In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.
**29.5.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 5)**

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Input capture mode

- **Bits 31:16**: Reserved, must be kept at reset value.
- **Bits 15:12**: IC4F[3:0]: Input capture 4 filter
- **Bits 11:10**: IC4PSC[1:0]: Input capture 4 prescaler
29.5.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

### Output compare mode

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
   Refer to **OC3M[3:0]**

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable
Bits 9:8  **CC4S[1:0]**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC4 channel is configured as output
- **01**: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- **10**: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- **11**: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).

Bit 7  **OC3CE**: Output compare 3 clear enable
Bits 16, 6:4 **OC3M[3:0]:** Output compare 3 mode

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs (this mode is used to generate a timing base).

0001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - tim_oc3ref toggles when TIMx_CNT=TIMx_CCR3.

0100: Force inactive level - tim_oc3ref is forced low.

0101: Force active level - tim_oc3ref is forced high.

0110: PWM mode 1 - In upcounting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In downcounting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else active (tim_oc3ref='1').

0111: PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In downcounting, channel 3 is active as long as TIMx_CNT>TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc is the logical OR between tim_oc3ref and tim_oc4ref.

1101: Combined PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc is the logical AND between tim_oc3ref and tim_oc4ref.

1110: Asymmetric PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
29.5.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5)

Address offset: 0x020

Reset value: 0x0000

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.
Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.
Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.
Refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.
Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.
Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable.
Refer to CC1E description

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity.
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity.
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable.
Refer to CC1E description

---

Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).
Bit 3 **CC1NP**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output**: CC1NP must be kept cleared in this case.

**CC1 channel configured as input**: This bit is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity. Refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of Ti1FP1 and Ti2FP1 for trigger or capture operations.

**CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to Ti1FP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode or encoder mode).

**CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to Ti1FP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is inverted (trigger operation in gated mode or encoder mode).

**CC1NP=1, CC1P=1**: non-inverted/both edges. The circuit is sensitive to both Ti1FP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode).

**CC1NP=1, CC1P=0**: this configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

### Table 286. Output control bit for standard tim_ocx channels

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>tim_ocx output state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Output disabled (not driven by the timer: Hi-Z)</td>
</tr>
<tr>

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The CCR1[15:0] bits hold the capture value. The CCR1[19:16] bits are reserved.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR1[19:0]. The CCR1[3:0] bits are reset.
29.5.18 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2, 5)

**If channel CC3 is configured as output:**
CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.

- **Non-dithering mode (DITHEN = 0)**
The register holds the compare value.

- **Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR3[31:4]. The CCR3[3:0] bitfield contains the dithered part.

**If channel CC3 is configured as input:**
CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
The register holds the capture value.

- **Dithering mode (DITHEN = 1)**
The register holds the capture in CCR3[31:0]. The CCR3[3:0] bits are reset.

### 29.5.23 TIMx capture/compare register 4 (TIMx_CCR4)(x = 3, 4)

**Address offset**: 0x040

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR4[19:0]**: Capture/compare 4 value

If channel CC4 is configured as output:
- CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc4 output.

  Non-dithering mode (DITHEN = 0)
  - The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.
  
  Dithering mode (DITHEN = 1)

If channel CC4 is configured as input:
- CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

  Non-dithering mode (DITHEN = 0)
  - The CCR4[15:0] bits hold the capture value. The CCR4[19:16] bits are reserved.
  
  Dithering mode (DITHEN = 1)
  - The register holds the capture in CCR4[19:0]. The CCR4[3:0] bits are reset.

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 PWPRSC[2:0]: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

\[ t_{PWG} = \left(2^{(PWPRSC[2:0])}\right) \times t_{\text{tim.ker_ck}} \]

Bits 23:16 PW[7:0]: Pulse width

This bitfield defines the pulse duration, as following:

\[ t_W = PW[7:0] \times t_{PWG} \]

Bits 15:8 Reserved, must be kept at reset value.
Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.
- 00: Index resets the counter when AB = 00
- 01: Index resets the counter when AB = 01
- 10: Index resets the counter when AB = 10
- 11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicate on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.
- x0: Index resets the counter when clock is 0
- x1: Index resets the counter when clock is 1

*Note: IPOS[1] bit is not significant*

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account
- 0: Index is always active
- 1: the first index only resets the counter

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:1 **IDIR[1:0]**: Index direction

This bit indicates in which direction the Index event resets the counter.
- 00: Index resets the counter whatever the direction
- 01: Index resets the counter when up-counting only
- 10: Index resets the counter when down-counting only
- 11: Reserved

*Note: The IDR[1:0] bitfield must be written when IE bit is reset (index disabled).*

Bit 0 **IE**: Index enable

This bit indicates if the Index event resets the counter.
- 0: Index disabled
- 1: Index enabled

</thead>
</table>

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
- ...
- 11010: 26 transfers

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.

- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:
  
  \[(\text{TIMx}_\text{CR1 address}) + \text{DBA} + (\text{DMA index})\]

  where DMA index = DBL

  In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

- If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**

- 00000: TIMx_CR1,
- 00001: TIMx_CR2,
- 00010: TIMx_SMCR,
- ...
29.5.30 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>DMAB[31:16]</th>

<tr>
<td>15</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DMAB[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:0 DMAB[31:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 29.5.31 TIMx register map

TIMx registers are mapped as described in the table below.

30 General purpose timers (TIM15/TIM16/TIM17)

30.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 30.4.26: Timer synchronization (TIM15 only).

30.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
30.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
### 30.4 TIM15/TIM16/TIM17 functional description

#### 30.4.1 Block diagram

**Figure 439. TIM15 block diagram**

1. Refer to Section 30.4.15: Using the break function for details.
1. Refer to Section 30.4.15: Using the break function for details.
2. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See Section 30.4.27: Using timer output as trigger for other timers (TIM16/TIM17 only) for details.

30.4.2 TIM15/TIM16/TIM17 pins and internal signals

Table 288 and Table 289 in this section summarize the TIM inputs and outputs.

30.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 441* and *Figure 442* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 441. Counter timing diagram with prescaler division change from 1 to 2

Counter register: F7 F8 F9 FA FB FC 00 01 02 03

Update event (UEV)

Write a new value in TIMx_PSC

Prescaler buffer: 0 3

Prescaler counter: 0 0 1 2 3 0 1 2 3
30.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Counter register:

- Counter overflow
- Update event (UEV)
- Update interrupt flag (UIF)

Auto-reload preload register:

- FF
- Write a new value in TIMx_ARR
Section 30.4.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 449). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
30.4.6 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer to enable another timer for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed...
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 450 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 450. Control circuit in normal mode, internal clock divided by 1**

![Control circuit diagram](image)

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 451. tim_ti2 external clock connection example**

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper `tim_t2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the `tim_t2` input by writing `CC2S = '01'` in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the TIMx_CCMR1 register (if no filter is needed, keep `IC2F=0000`).
4. Select rising edge polarity by writing `CC2P=0` in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing `SMS=111` in the TIMx_SMCR register.
6. Select `tim_t2` as the trigger input source by writing `TS=00110` in the TIMx_SMCR register.
7. Enable the counter by writing `CEN=1` in the TIMx_CR1 register.

*Note:* The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on `tim_t2`, the counter counts once and the TIF flag is set. The delay between the rising edge on `tim_t2` and the actual clock of the counter is due to the resynchronization circuit on `tim_t2` input.

**Figure 452. Control circuit in external clock mode 1**

---

### 30.4.7 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 453* to *Figure 456* give an overview of one Capture/Compare channel.

The input stage samples the corresponding `tim_tix` input to generate a filtered signal `tim_tixf`. Then, an edge detector with polarity selection generates a signal (`tim_tixfpy`) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (`ICxPS`).
The output stage generates an intermediate waveform which is then used for reference: `tim_occxref` (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 30.4.8 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding TIMx_ICx signal. When a capture occurs, the corresponding CCXI flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCXI flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

1. Select the proper tim_t1_in[15:1] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_t1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
30.4.9 **PWM input mode (only for TIM15)**

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1f1p1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1f2p (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_ti1f1p1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
30.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

30.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP...
bit in the TIMx_CCRER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxE = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 458.
30.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1363.
In the following example, we consider PWM mode 1. The reference PWM signal `tim_ocxref` is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then `tim_ocxref` is held at ‘1’. If the compare value is 0 then `tim_ocxref` is held at ‘0’. Figure 459 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

**Figure 459. Edge-aligned PWM waveforms (ARR=8)**

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 460 below presents the dithering principle applied to 4 consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as following (see Figure 461 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The ARR and CCR values will be updated automatically if the DITHEN bit is set / reset (for instance, if ARR= 0x05 with DITHEN=0, it will be updated to ARR = 0x50 with DITHEN = 1).

The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CCIF flags must be cleared
5. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:
The maximum TIMx_ARR and TIMxCCRx values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 462 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Note: The maximum TIMx_ARR and TIMxCCRx values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 462 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 462. PWM resolution vs frequency

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 463 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 296 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

30.4.13 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 464** represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
30.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output \text{tim\_ocx} or complementary \text{tim\_ocxn}) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals \text{tim\_ocx} and \text{tim\_ocxn} are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to Table 303: Output control bits for complementary \text{tim\_oc1} and \text{tim\_oc1n} channels with break feature (TIM16/TIM17) on page 1444 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

![Figure 465. Complementary output with symmetrical dead-time insertion.](image)

The DTAE bit in the TIMx_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on Figure 466.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must be not modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

*Note:* If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 30.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1448 for delay calculation.
Re-directing `tim_ocxref` to `tim_ocx` or `tim_ocxn`

In output mode (forced, output compare or PWM), `tim_ocxref` can be re-directed to the `tim_ocx` output or to `tim_ocxn` output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only `tim_ocxn` is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as `tim_ocxref` is high. For example, if CCxNP=0 then `tim_ocx=tim_ocxref`. On the other hand, when both `tim_ocx` and `tim_ocxn` are enabled (CCxE=CCxNE=1) `tim_ocx` becomes active when `tim_ocxref` is high whereas `tim_ocxn` is complemented and becomes active when `tim_ocxref` is low.

30.4.15 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register is used to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The `tim_ocx` and `tim_ocxn` outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 303: Output control bits for complementary `tim_ocx` and `tim_ocxn` channels with break feature (TIM16/TIM17) on page 1444 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
The break is generated by the tim_brk inputs which has:
- Programmable polarity (BKP bit in the TIMx_BDTR register)
- Programmable enable bit (BKE bit in the TIMx_BDTR register)
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (tim_brk) channel are:
- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 30.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)
  - coming from a system break request on the tim_sys_brk inputs (refer to Section 30.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk inputs, as per Figure 469 below.

**Figure 469. Break circuitry overview**

Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_oxx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

**Note:** The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_occx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 30.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17). The LOCK bits can be written only once after an MCU reset.

The Figure 470 shows an example of behavior of the outputs in response to a break.

30.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on Figure 471.

They are used to have:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKINP and BKP bits). Any break request coming either from system (for example CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (triggered by setting the BG bit) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:
- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 297)

Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).
The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

30.4.17 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int input can be selected among several inputs, as shown on Figure 472 below.
When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 473 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.
Figure 473. 6-step generation, COM example (OSSR=1)

Counter (CNT) (CCRx)

Example 1
- **tim_ocx**: CCxE = 1, CCxNE = 0, OCxM = 0010 (forced inactive)
- **tim_ocxref**: Write COM to 1
- **tim_ocxn**: Write OCxM to 0100

Example 2
- **tim_ocx**: CCxE = 1, CCxNE = 0, OCxM = 0100 (forced inactive)
- **tim_ocxref**: Write CCxNE to 1 and OCxM to 0101
- **tim_ocxn**: CxM = 0101

Example 3
- **tim_ocx**: CCxE = 1, CCxNE = 0, OCxM = 0010 (forced inactive)
- **tim_ocxref**: Write CCxNE to 0 and OCxM to 0100
- **tim_ocxn**: CCxE = 1, CCxNE = 1, OCxM = 0100
30.4.19 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- \( \text{CNT} < \text{CCRx} \leq \text{ARR} \) (in particular, \( 0 < \text{CCRx} \))

**Figure 474. Example of one pulse mode.**

For example one may want to generate a positive pulse on \( \text{tim_oc1} \) with a length of \( \text{tPULSE} \) and after a delay of \( \text{tDELAY} \) as soon as a positive edge is detected on the \( \text{tim_ti2} \) input pin.

Let’s use \( \text{tim_ti2fp2} \) as trigger 1:

1. Select the proper \( \text{tim_ti2\_in}[15:1] \) source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map \( \text{tim_ti2fp2} \) to \( \text{tim_ti2} \) by writing CC2S='01' in the TIMx_CCMR1 register.
3. \( \text{tim_ti2fp2} \) must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure \( \text{tim_ti2fp2} \) as trigger for the slave mode controller (tim_trgi) by writing TS='00110' in the TIMx_SMCR register.
5. \( \text{tim_ti2fp2} \) is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the
clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value $(\text{TIMx.ARR} - \text{TIMx.CCR1})$.
- Let's say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare
  match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload
  value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the
  TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing
  OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CCR1 register. In this
  case one has to write the compare value in the TIMx_CCR1 register, the auto-reload
  value in the TIMx_ARR register, generate an update by setting the UG bit and wait for
  external trigger event on tim_ti2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to
stop the counter at the next update event (when the counter rolls over from the auto-reload
value back to 0).

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the
counter. Then the comparison between the counter and the compare value makes the
output toggle. But several clock cycles are needed for these operations and it limits the
minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the
TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the
stimulus, without taking in account the comparison. Its new level is the same as if a compare
match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2
mode.

### 30.4.20 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a
pulse with a programmable length, but with the following differences with Non-retriggerable
one pulse mode described in Section 30.4.19:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger
mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for
Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0
(the ARR register sets the pulse length). If the timer is configured in Down-counting mode,
CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the
most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have
CMS[1:0] = 00 in TIMx_CR1.
30.4.21 **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMx_CNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

30.4.22 **Timer input XOR function (TIM15 only)**

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in *Figure 476*.

30.4.23 **External trigger synchronization (TIM15 only)**

The TIM timers are linked together internally for timer synchronization or chaining.
The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 477. Control circuit in reset mode**

![Control circuit in reset mode](MSv62361V1)
**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when `tim_ti1` input is low:

1. Configure the channel 1 to detect low levels on `tim_ti1`. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select `tim_ti1` as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as `tim_ti1` is low and stops as soon as `tim_ti1` becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on `tim_ti1` and the actual stop of the counter is due to the resynchronization circuit on `tim_ti1` input.

**Figure 478. Control circuit in gated mode**
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=’1’ and CC2NP=’0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

**Figure 479. Control circuit in trigger mode**

Slave mode selection preload for run-time update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

### 30.4.24 Slave mode – combined reset + trigger mode (TIM15 only)

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

### 30.4.25 Slave mode – combined reset + gated mode (TIM15 only)

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).
30.4.26  Timer synchronization (TIM15 only)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 29.4.23: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TIM_TRGO signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

30.4.27  Using timer output as trigger for other timers (TIM16/TIM17 only)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

30.4.28  ADC triggers (TIM15 only)

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the TIM_TRGO signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

30.4.29  DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
For example, the timer DMA burst feature can be used to update the contents of the CCRx registers \((x = 2, 3, 4)\) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   \(DBL = 3\) transfers, \(DBA = 0x E\).
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

### 30.4.30 TIM15/TIM16/TIM17 DMA requests

The TIM15/TIM16/TIM17 can generate a DMA requests, as shown in Table 298.

<table>
<thead>
<tr>
<th>DMA request signal</th>
<th>DMA acronym</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>

<td>Trigger</td>
<td>TDE</td>
</tr>
</tbody>
</table>

1. Available for TIM15 only.

### 30.4.31 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 with FPU core halted), the TIMx counter can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.
For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

For more details, refer to the debug section.

### 30.5 TIM15/TIM16/TIM17 low-power modes

Table 299. Effect of low-power modes on TIM15/TIM16/TIM17

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

### 30.6 TIM15/TIM16/TIM17 interrupts

The TIM15/TIM16/TIM17 can generate multiple interrupts, as shown in Table 300.

Table 300. Interrupt requests

<table>
<thead>
<tr>

1. Available for TIM15 only.
30.7 TIM15 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

30.7.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x00
Reset value: 0x0000

| Bit 15:13 Reserved, must be kept at reset value. |
| Bit 12 DITHEN: Dithering enable |
| 0: Dithering disabled |
| 1: Dithering enabled |
| Note: The DITHEN bit can only be modified when CEN bit is reset. |
| Bit 11 UIFREMAP: UIF status bit remapping |
| 0: No remapping. UIF status bit is not copied to TIM15_CNT register bit 31. |
| 1: Remapping enabled. UIF status bit is copied to TIM15_CNT register bit 31. |
| Bit 10 Reserved, must be kept at reset value. |
| Bits 9:8 CKD[1:0]: Clock division |
| This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix) |
| 00: tDTS = tim_ker_ck |
| 01: tDTS = 2*tim_ker_ck |
| 10: tDTS = 4*tim_ker_ck |
| 11: Reserved |
| Bit 7 ARPE: Auto-reload preload enable |
| 0: TIM15_ARR register is not buffered |
| 1: TIM15_ARR register is buffered |
| Bits 6:4 Reserved, must be kept at reset value. |
| Bit 3 OPM: One-pulse mode |
| 0: Counter is not stopped at update event |
| 1: Counter stops counting at the next update event (clearing the bit CEN) |
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt if enabled. These events can be:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
*Note: External clock and gated mode can work only if the CEN bit has been previously set by
software. However trigger mode can set the CEN bit automatically by hardware.*

30.7.2 **TIM15 control register 2 (TIM15_CR2)**

Address offset: 0x04
Reset value: 0x0000

<table>
<thead>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
0: tim_oc2=0 when MOE=0
1: tim_oc2=1 when MOE=0
*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in the TIM15_BKR register).*

Bit 9 **OIS1N**: Output Idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in TIM15_BKR register).*

Bit 8 **OIS1**: Output Idle state 1 (tim_oc1 output)
0: tim_oc1=0 after a dead-time when MOE=0
1: tim_oc1=1 after a dead-time when MOE=0
*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in TIM15_BKR register).*
Bit 7  **TI1S**: tim_t1 selection
0: The tim_t1_in[15:0] multiplexer output is connected to tim_t1 input
1: The tim_t1_in[15:0] and tim_t12_in[15:0] multiplexers output are connected to the tim_t1 input (XOR combination)

Bits 6:4  **MMS[2:0]**: Master mode selection
These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:
000: **Reset** - the UG bit from the TIM15_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM15_SMCR register).
010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo).
101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo).

Bit 3  **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2  **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1  Reserved, must be kept at reset value.

Bit 0  **CCPC**: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
### 30.7.3 TIM15 slave mode control register (TIM15_SMCR)

Address offset: 0x08
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>

</tbody>
</table>

Bits 31:25: Reserved, must be kept at reset value.

Bit 24 **SMSPE**: SMS preload enable
- This bit selects whether the SMS[3:0] bitfield is preloaded.
  - 0: SMS[3:0] bitfield is not preloaded
  - 1: SMS[3:0] preload is enabled

Bits 23:22: Reserved, must be kept at reset value.

Bits 19:17: Reserved, must be kept at reset value.

Bits 15:8: Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/slave mode
- 0: No action
- 1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]: Trigger selection**

This bit field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (tim_itr0)
- 00001: Internal Trigger 1 (tim_itr1)
- 00010: Internal Trigger 2 (tim_itr2)
- 00011: Internal Trigger 3 (tim_itr3)
- 00100: tim_ti1 Edge Detector (tim_ti1f_ed)
- 00101: Filtered Timer Input 1 (tim_ti1fp1)
- 00110: Filtered Timer Input 2 (tim_ti2fp2)
- 00111: Reserved
- 01000: Internal Trigger 4 (tim_itr4)
- 01001: Internal Trigger 5 (tim_itr5)
- 01010: Internal Trigger 6 (tim_itr6)
- 01011: Internal Trigger 7 (tim_itr7)
- 01100: Internal Trigger 8 (tim_itr8)
- 01101: Internal Trigger 9 (tim_itr9)
- 01110: Internal Trigger 10 (tim_itr10)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)

Others: Reserved

See [Section 30.4.2: TIM15/TIM16/TIM17 pins and internal signals](#) for more details on tim_itrx meaning for each timer.

**Note:** These bits must be changed only when they are not used (for example when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  **Reserved, must be kept at reset value.**

<td>CC1OF: Capture/Compare 1 overcapture flag</td>
</tr>
</tbody>
</table>

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected
1: The counter value has been captured in TIM15_CCR1 register while CC1F flag was already set

Bit 8 Reserved, must be kept at reset value.
Bit 7  **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input

Bit 6  **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred
1: Trigger interrupt pending

Bit 5  **COMIF**: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
0: No COM event occurred
1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag
refer to CC1IF description

Bit 1  **CC1IF**: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIM15_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIM15_EGR register, if URS=0 and UDIS=0 in the TIM15_CR1 register.
– When CNT is reinitialized by a trigger event (refer to Section 30.7.3: TIM15 slave mode control register (TIM15_SMCR)), if URS=0 and UDIS=0 in the TIM15_CR1 register.
30.7.6 TIM15 event generation register (TIM15_EGR)

Address offset: 0x14
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 BG: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 TG: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIM15_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 COMG: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 CC2G: Capture/Compare 2 generation
Refer to CC1G description

Bit 1 CC1G: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**
CC1IF flag is set. Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**
The current value of the counter is captured in TIM15_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 UG: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
30.7.7 TIM15 capture/compare mode register 1 (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

- **IC2F[3:0]**: Input capture 2 filter
- **IC2PSC[1:0]**: Input capture 2 prescaler
- **CC2S[1:0]**: Capture/Compare 2 selection
  - Bits 9:8 This bit-field defines the direction of the channel (input/output) as well as the used input.
    - 00: CC2 channel is configured as output
    - 01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
    - 10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
    - 11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).*
Bits 7:4 **IC1F[3:0]**: Input capture 1 filter
This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=ftim_ker_ck, N=2
- 0010: fSAMPLING=ftim_ker_ck, N=4
- 0011: fSAMPLING=ftim_ker_ck, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/32, N=5
- 1101: fSAMPLING=fDTS/32, N=6
- 1110: fSAMPLING=fDTS/32, N=8
- 1111: fSAMPLING=fDTS/32, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIM15_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- 10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- 11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).

### 30.7.8 TIM15 capture/compare mode register 1 [alternate]
**(TIM15_CCMR1)**

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12  **OC2M[3:0]**: Output compare 2 mode

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output.
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
10: C2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM15_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIM15_CCER).*

Bit 7  **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input.
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input.
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal `tim_oc1ref` from which `tim_oc1` and `tim_oc1n` are derived. `tim_oc1ref` is active high whereas `tim_oc1` and `tim_oc1n` active level depends on CC1P and CC1NP bits.

</tbody>
</table>

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output). In PWM mode, the OCRE1 level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIM15_CCR1 disabled. TIM15_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIM15_CCR1 enabled. Read/Write operations access the preload register. TIM15_CCR1 preload value is loaded in the active register at each update event.

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM15_SMCR register)

**Note**: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM15_CCER).

### 30.7.9 TIM15 capture.compare enable register (TIM15_CCER)

Address offset: 0x20

Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-8</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>7</td>
<td><strong>CC2NP</strong>: Capture/Compare 2 complementary output polarity</td>
</tr>
<tr>
<td></td>
<td>Refer to CC1NP description</td>
</tr>
<tr>
<td>6</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>5</td>
<td><strong>CC2P</strong>: Capture/Compare 2 output polarity</td>
</tr>
<tr>
<td></td>
<td>Refer to CC1P description</td>
</tr>
<tr>
<td>4</td>
<td><strong>CC2E</strong>: Capture/Compare 2 output enable</td>
</tr>
<tr>
<td></td>
<td>Refer to CC1E description</td>
</tr>
</tbody>
</table>
Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:
0: tim_oc1n active high
1: tim_oc1n active low

CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1. Refer to CC1P description.

**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register) and CC1S="00" (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

CC1 channel configured as output:
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of T1FP1 and T2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to T1xP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), T1xP1 is not inverted (trigger operation in gated mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is inverted (trigger operation in gated mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), T1xFP1 is not inverted (trigger operation in gated mode).

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM15_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 301 for details.
Table 301. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature (TIM15)

</tbody>
</table>

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and GPIO control and alternate function selection registers.

Bit 31 **UIFCPY**: UIF Copy  
This bit is a read-only copy of the UIF bit in the TIM15_ISR register.

Bits 30:16 **Reserved, must be kept at reset value.**

Bits 15:0 **CNT[15:0]**: Counter value  
- **Non-dithering mode (DITHEN = 0)**  
The register holds the counter value.
- **Dithering mode (DITHEN = 1)**  
The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

### 30.7.11 TIM15 prescaler (TIM15_PSC)

</table>

Bits 31:20 Reserved, must be kept at reset value.

**Bits 19:0 CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

- CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIM15_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIM15_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

- The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

- The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

- CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

- The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

- The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.
30.7.15  TIM15 capture/compare register 2 (TIM15_CCR2)

Address offset: 0x38
Reset value: 0x0000 0000

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  CCR2[19:0]: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM15_CCMR2 register
(bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIM15_CNT and signalled on tim_oc2 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the
dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 1 event (tim_ic2). The
TIMx_CCR2 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

MOE AOE BKP BKE OSSR OSSI LOCK[1:0] DTG[7:0]

Note:  As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSR, OSSR and DTG[7:0] bits may
be write-locked depending on the LOCK configuration, it may be necessary to configure all
of them during the first write access to the TIM15_BDTR register.
Bits 31:29  Reserved, must be kept at reset value.

Bit 28  **BKBID**: Break bidirectional
- 0: Break input tim\_brk in input mode
- 1: Break input tim\_brk in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15\_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  Reserved, must be kept at reset value.

Bit 26  **BKDSRM**: Break disarm
- 0: Break input tim\_brk is armed
- 1: Break input tim\_brk is disarmed

This bit is cleared by hardware when no break source is active.

The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample the tim\_brk input signal and the length of the digital filter applied to tim\_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, tim\_brk acts asynchronously
- 0001: f\_{SAMPLING}=f\_{tim\_ker\_ck}, N=2
- 0010: f\_{SAMPLING}=f\_{tim\_ker\_ck}, N=4
- 0011: f\_{SAMPLING}=f\_{tim\_ker\_ck}, N=8
- 0100: f\_{SAMPLING}=f\_{DTS}/2, N=6
- 0101: f\_{SAMPLING}=f\_{DTS}/2, N=8
- 0110: f\_{SAMPLING}=f\_{DTS}/4, N=6
- 0111: f\_{SAMPLING}=f\_{DTS}/4, N=8
- 1000: f\_{SAMPLING}=f\_{DTS}/8, N=6
- 1001: f\_{SAMPLING}=f\_{DTS}/8, N=8
- 1010: f\_{SAMPLING}=f\_{DTS}/16, N=5
- 1011: f\_{SAMPLING}=f\_{DTS}/16, N=6
- 1100: f\_{SAMPLING}=f\_{DTS}/16, N=8
- 1101: f\_{SAMPLING}=f\_{DTS}/32, N=5
- 1110: f\_{SAMPLING}=f\_{DTS}/32, N=6
- 1111: f\_{SAMPLING}=f\_{DTS}/32, N=8

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15\_BDTR register).
General purpose timers (TIM15/TIM16/TIM17)

Bit 15  **MOE**: Main output enable

- This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
- 0: tim_ocx and tim_ocxn outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: tim_ocx and tim_ocxn outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIM15_CCER register)

See tim_ocx/tim_ocxn enable description for more details (Section 30.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1416).

Bit 14  **AOE**: Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 13  **BKP**: Break polarity

- 0: Break input tim_brk is active low
- 1: Break input tim_brk is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable

- 0: Break inputs (tim_brk and tim_sys_brk clock failure event) disabled
- 1: Break inputs (tim_brk and tim_sys_brk clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11  **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_ocx/tim_ocxn enable description for more details (Section 30.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1416).

- 0: When inactive, tim_ocx/tim_ocxn outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
- 1: When inactive, tim_ocx/tim_ocxn outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 10  **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_ocx/tim_ocxn enable description for more details (Section 30.7.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1416).

- 0: When inactive, tim_ocx/tim_ocxn outputs are disabled (tim_ocx/tim_ocxn enable output signal=0)
- 1: When inactive, tim_ocx/tim_ocxn outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. tim_ocx/tim_ocxn enable output signal=1)

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM15_BDTR register).
### 30.7.17 TIM15 timer deadtime register 2 (TIM15_DTR2)

</tr>
</tbody>
</table>

**Bits 31:18** Reserved, must be kept at reset value.

**Bit 17** DTPE: Deadtime preload enable

- 0: Deadtime value is not preloaded
- 1: Deadtime value preload is enabled

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 16  **DTAE:** Deadtime asymmetric enable
0: Deadtime on rising and falling edges are identical, and defined with \( DTG[7:0] \) register
1: Deadtime on rising edge is defined with \( DTG[7:0] \) register and deadtime on falling edge is defined with \( DTGF[7:0] \) bits.

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **DTGF[7:0]:** Dead-time falling edge generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

\[ DTGF[7:5] = 0 \Rightarrow DTF = \frac{DTGF[7:0] \times t_{dlg}}{t_{dtg}} = \frac{DTGF[5:0]}{TDTS} \]
\[ DTGF[7:5] = 10 \Rightarrow DTF = [64 + DTGF[5:0]] \times t_{dlg} \times T_{dty} = 2 \times t_{dtg} \]
\[ DTGF[7:5] = 110 \Rightarrow DTF = [32 + DTGF[4:0]] \times t_{dlg} \times T_{dty} = 8 \times t_{dtg} \]
\[ DTGF[7:5] = 111 \Rightarrow DTF = [32 + DTGF[4:0]] \times t_{dlg} \times T_{dty} = 16 \times t_{dtg} \]

Example if \( TDTS = 125\, ns \) (8MHz), dead-time possible values are:
- 0 to 15875\, ns by 125\, ns steps,
- 16\, us to 31750\, ns by 250\, ns steps,
- 32\, us to 63\, us by 1\, us steps,
- 64\, us to 126\, us by 2\, us steps

*Note:* This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BDTR register).

Refer to Section 30.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation.

**Bits 31:14** Reserved, must be kept at reset value.

**Bit 13 BKCMP4P: tim_brk_cmp4 input polarity**

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: tim_brk_cmp4 input is active high
- 1: tim_brk_cmp4 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

**Bit 12 BKCMP3P: tim_brk_cmp3 input polarity**

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: tim_brk_cmp3 input is active high
- 1: tim_brk_cmp3 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

**Bit 11 BKCMP2P: tim_brk_cmp2 input polarity**

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: tim_brk_cmp2 input is active high
- 1: tim_brk_cmp2 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

**Bit 10 BKCMP1P: tim_brk_cmp1 input polarity**

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: tim_brk_cmp1 input is active high
- 1: tim_brk_cmp1 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 9 **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer's tim_brk input. mdf_brkx output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer's tim_brk input. COMP7 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer's tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).*
Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer’s tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.
- 0: tim_brk_cmp2 input disabled
- 1: tim_brk_cmp2 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer’s tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.
- 0: tim_brk_cmp1 input disabled
- 1: tim_brk_cmp1 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

Bit 0 **BKINE**: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer’s tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.
- 0: TIMx_BKIN input disabled
- 1: TIMx_BKIN input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).

### 30.7.20 TIM15 alternate function register 2 (TIM15_AF2)

**Address offset**: 0x064

**Reset value**: 0x0000 0000

**OCRSEL[2:0]**: ocref_clr source selection

These bits select the ocref_clr input source.
- 000: tim_ocref_clr0
- 001: tim_ocref_clr1
- 010: tim_ocref_clr2
- 011: tim_ocref_clr3
- 100: tim_ocref_clr4
- 101: tim_ocref_clr5
- 110: tim_ocref_clr6
- 111: tim_ocref_clr7

*Note*: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM15_BDTR register).
### 30.7.21 TIM15 DMA control register (TIM15_DCR)

**Address offset:** 0x3DC  
**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bits 15:0** Reserved, must be kept at reset value.

**Bits 12:8** **DBL[4:0]: DMA burst length**  
This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM15_DMAR address).  
00000: 1 transfer,  
00001: 2 transfers,  
00010: 3 transfers,  
...  
10001: 18 transfers.

**Bits 7:5** Reserved, must be kept at reset value.

**Bits 4:0** **DBA[4:0]: DMA base address**  
This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIM15_DMAR address). DBA is defined as an offset starting from the address of the TIM15_CR1 register.  
Example:  
00000: TIM15_CR1,  
00001: TIM15_CR2,  
00010: TIM15_SMCR,  
...

### 30.7.22 TIM15 DMA address for full transfer (TIM15_DMAR)

</tr>
</tbody>
</table>
Bits 31:0  **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIM15_CR1 address) + (DBA + DMA index) x 4

where TIM15_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM15_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM15_DCR).

### 30.7.23 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table below:

<table>
<thead>
<tr>
<th>Offset</th>

Table 302. TIM15 register map and reset values (continued)
30.8 **TIM16/TIM17 registers**

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

### 30.8.1 TIMx control register 1 (TIMx_CR1)(x = 16 to 17)

Address offset: 0x00

Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:13</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 12</td>
<td><strong>DITHEN</strong>: Dithering enable</td>
</tr>
<tr>
<td></td>
<td>0: Dithering disabled</td>
</tr>
<tr>
<td></td>
<td>1: Dithering enabled</td>
</tr>
<tr>
<td></td>
<td><em>Note</em>: The DITHEN bit can only be modified when CEN bit is reset.</td>
</tr>
<tr>
<td>Bit 11</td>
<td><strong>UIFREMAP</strong>: UIF status bit remapping</td>
</tr>
<tr>
<td></td>
<td>0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.</td>
</tr>
<tr>
<td></td>
<td>1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.</td>
</tr>
<tr>
<td>Bit 10</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bits 9:8</td>
<td><strong>CKD[1:0]</strong>: Clock division</td>
</tr>
<tr>
<td></td>
<td>This bit-field indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix),</td>
</tr>
<tr>
<td></td>
<td>00: tDTS = tim_ker_ck</td>
</tr>
<tr>
<td></td>
<td>01: tDTS = 2*tim_ker_ck</td>
</tr>
<tr>
<td></td>
<td>10: tDTS = 4*tim_ker_ck</td>
</tr>
<tr>
<td></td>
<td>11: Reserved</td>
</tr>
<tr>
<td>Bit 7</td>
<td><strong>ARPE</strong>: Auto-reload preload enable</td>
</tr>
<tr>
<td></td>
<td>0: TIMx_ARR register is not buffered</td>
</tr>
<tr>
<td></td>
<td>1: TIMx_ARR register is buffered</td>
</tr>
<tr>
<td>Bits 6:4</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 3</td>
<td><strong>OPM</strong>: One pulse mode</td>
</tr>
<tr>
<td></td>
<td>0: Counter is not stopped at update event</td>
</tr>
<tr>
<td></td>
<td>1: Counter stops counting at the next update event (clearing the bit CEN)</td>
</tr>
<tr>
<td>Bit 2</td>
<td><strong>URS</strong>: Update request source</td>
</tr>
<tr>
<td></td>
<td>This bit is set and cleared by software to select the UEV event sources.</td>
</tr>
<tr>
<td></td>
<td>0: Any of the following events generate an update interrupt or DMA request if enabled.</td>
</tr>
<tr>
<td></td>
<td>These events can be:</td>
</tr>
<tr>
<td></td>
<td>– Counter overflow/underflow</td>
</tr>
<tr>
<td></td>
<td>– Setting the UG bit</td>
</tr>
<tr>
<td></td>
<td>– Update generation through the slave mode controller</td>
</tr>
<tr>
<td></td>
<td>1: nly counter overflow/underflow generates an update interrupt or DMA request if enabled.</td>
</tr>
</tbody>
</table>
Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   – Counter overflow/underflow
   – Setting the UG bit
   – Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
   (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
   set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled
*Note*: External clock and gated mode can work only if the CEN bit has been previously set by
   software. However trigger mode can set the CEN bit automatically by hardware.

### 30.8.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04
Reset value: 0x0000

<table>

</tbody>
</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag
This flag is set by hardware as soon as the tim_brk input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMIF**: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
0: No COM event occurred
1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
30.8.5 TIMx event generation register (TIMx_EGR)(x = 16 to 17)

</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action.
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG**: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action.
1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**
CC1IF flag is set. Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
30.8.6 TIMx capture/compare mode register 1 (TIMx_CCMR1)  
x = 16 to 17

Address offset: 0x18  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:4  IC1F[3:0]: Input capture 1 filter  
This bit-field defines the frequency used to sample tim_t1 input and the length of the digital filter applied to tim_t1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fT1, N=2
- 0010: fSAMPLING=fT1, N=4
- 0011: fSAMPLING=fT1, N=8
- 0100: fSAMPLING=fDTS/2, N=
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bits 3:2  IC1PSC[1:0]: Input capture 1 prescaler  
This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input.
- 01: capture is done each time an edge is detected on the capture input.
- 10: capture is done once every 2 events
- 11: capture is done once every 4 events
30.8.7 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 16 to 17)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode:

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 OC1CE: Output Compare 1 clear enable
0: tim_oc1ref is not affected by the tim_ocref_clr input.
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr input.
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal Tim_oc1ref from which Tim_oc1 and Tim_oc1n are derived. Tim_oc1ref is active high whereas Tim_oc1 and Tim_oc1n active level depends on CC1P and CC1NP bits.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.
- **0001**: Set channel 1 to active level on match. Tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. Tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - Tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.
- **0100**: Force inactive level - Tim_oc1ref is forced low.
- **0101**: Force active level - Tim_oc1ref is forced high.
- **0110**: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.
- **0111**: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.
- Others: Reserved

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output Compare 1 preload enable

- **0**: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1**: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- **0**: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1**: An active edge on the trigger input acts like a compare match on CC1 output. Then, Tim_ocx is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output
- **01**: CC1 channel is configured as input, Tim_ic1 is mapped on Tim_ti1
- Others: Reserved

**Note:** CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).
30.8.8  TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

Address offset: 0x20
Reset value: 0x0000

</tr>
</tbody>
</table>

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:
0: tim_oc1n active high
1: tim_oc1n active low

CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1. Refer to the description of CC1P.

**Note**: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.
Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of Ti1FP1 and Ti2FP1 for trigger or capture operations.

- CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to Ti1FP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode).
- CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to Ti1FP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both Ti1FP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode).
- CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 303 for details.

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OIS1, OIS1N, CC1P and CC1NP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary tim\_oc1 and tim\_oc1n channels depends on the tim\_oc1 and tim\_oc1n channel state and GPIO control and alternate function selection registers.
30.8.9 TIMx counter (TIMx_CNT)(x = 16 to 17)

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 Arr[19:0]: Auto-reload value
- Arr is the value to be loaded in the actual auto-reload register.
- Refer to the Section 30.4.3: Time-base unit on page 1361 for more details about ARR update and behavior.
- The counter is blocked while the auto-reload value is null.
- Non-dithering mode (DITHEN = 0)
  - The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reset.
- Dithering mode (DITHEN = 1)

30.8.12 TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30
Reset value: 0x0000

<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 Rep[7:0]: Repetition counter reload value
- This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
- When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
- It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode:
  - the number of PWM periods in edge-aligned mode
  - the number of half PWM period in center-aligned mode
### 30.8.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit Position</th>
<th>Description</th>
<th>Access</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–20</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>19–0</td>
<td>CCR1[19:0]: Capture/Compare 1 value</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**If channel CC1 is configured as output:**
- CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

**Non-dithering mode (DITHEN = 0):**
- The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1):**
- The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
- CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1).

**Non-dithering mode (DITHEN = 0):**
- The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

**Dithering mode (DITHEN = 1):**
- The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

Note: As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:29  Reserved, must be kept at reset value.

Bit 28  BKBID: Break Bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  Reserved, must be kept at reset value.

Bit 26  BKDSRM: Break Disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed

This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, tim_brk acts asynchronously
- 0001: \( f_{SAMPLING} = f_{tim_ker_ck} \), \( N = 2 \)
- 0010: \( f_{SAMPLING} = f_{tim_ker_ck} \), \( N = 4 \)
- 0011: \( f_{SAMPLING} = f_{tim_ker_ck} \), \( N = 8 \)
- 0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
- 0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
- 0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
- 0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
- 1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
- 1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
- 1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
- 1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
- 1100: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
- 1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
- 1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)
- 1111: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the tim_brk input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: tim_oc1 and tim_oc1n outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: tim_oc1 and tim_oc1n outputs are enabled if their respective enable bits are set (CC1E, CC1NE in TIMx_CCER register)

See tim_oc1/tim_oc1n enable description for more details (Section 30.8.8: TIMx capture/compare enable register (TIMx_CCER)\((x = 16 \text{ to } 17)\) on page 1442).

Bit 14  **AOE**: Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the tim_brk input is not active)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 13  **BKP**: Break polarity

- 0: Break input tim_brk is active low
- 1: Break input tim_brk is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable

- 0: Break inputs (tim_brk and tim_sys_brk event) disabled
- 1: Break inputs (tim_brk and tim_sys_brk event) enabled

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See tim_oc1/tim_oc1n enable description for more details (Section 30.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1442).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
1: When inactive, tim_oc1/tim_oc1n outputs are enabled with their inactive level as soon as CC1E=1 or CC1NE=1 (the output is still controlled by the timer).

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See tim_oc1/tim_oc1n enable description for more details (Section 30.8.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1442).

0: When inactive, tim_oc1/tim_oc1n outputs are disabled (tim_oc1/tim_oc1n enable output signal=0)
1: When inactive, tim_oc1/tim_oc1n outputs are forced first with their idle level as soon as CC1E=1 or CC1NE=1. tim_oc1/tim_oc1n enable output signal=1)

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxn bits in TIMx_CR2 register and BKBD/BK/BK/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note:** The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

```
DTG[7:0]=0xx => DT=DTG[7:0]x tDTS with tDTS=TDTS
DTG[7:0]=10x => DT=(64+DTG[5:0])x tDTS with TdTS=2xTDTS
DTG[7:0]=110 => DT=(32+DTG[4:0])x tDTS with TdTS=8xTDTS
DTG[7:0]=111 => DT=(32+DTG[4:0])x tDTS with TdTS=16xTDTS
```

Example if TDTS=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

**Note:** This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
### 30.8.15 TIMx timer deadtime register 2 (TIMx_DTR2) (x = 16 to 17)

Bits 31:14 Reserved, must be kept at reset value.
Bit 13 Bkcmp4p: tim_brk_cmp4 input polarity
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input is active high
1: tim_brk_cmp4 input is active low
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 12 **BKCMPP3**: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input is active high
1: tim_brk_cmp3 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 11 **BKCMPP2**: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input is active high
1: tim_brk_cmp2 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMPP1**: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input is active high
1: tim_brk_cmp1 input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input is active high
1: TIMx_BKIN input is active low

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKCMPP8**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. mdf_brkx output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **BKCMPP7**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 6 **BKCMPP6**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 5 **BKCMP5E**: tim_brk_cmp5 enable
This bit enables the tim_brk_cmp5 for the timer’s tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp5 input disabled
1: tim_brk_cmp5 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable
This bit enables the tim_brk_cmp4 for the timer’s tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp4 input disabled
1: tim_brk_cmp4 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable
This bit enables the tim_brk_cmp3 for the timer’s tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp3 input disabled
1: tim_brk_cmp3 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable
This bit enables the tim_brk_cmp2 for the timer’s tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp2 input disabled
1: tim_brk_cmp2 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable
This bit enables the tim_brk_cmp1 for the timer’s tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp1 input disabled
1: tim_brk_cmp1 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **BKINE**: TIMx_BKIN input enable
This bit enables the TIMx_BKIN alternate function input for the timer’s tim_brk input. TIMx_BKIN input is 'ORed' with the other tim_brk sources.
0: TIMx_BKIN input disabled
1: TIMx_BKIN input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**DBL[4:0]: DMA burst length**

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

**DBA[4:0]: DMA base address**

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example:**

- 00000: TIMx_CR1,
- 00001: TIMx_CR2,
- 00010: TIMx_SMCR,
- ...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

30.8.21  **TIM16/TIM17 DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)**

1456/2138  
RM0440 Rev 8
Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 30.8.22 TIM16/TIM17 register map

TIM16/TIM17 registers are mapped as 16-bit addressable registers as described in the table below:

**Table 304. TIM16/TIM17 register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | TIMx_CR1      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | TIMx_CR2      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

31 Basic timers (TIM6/TIM7)

31.1 TIM6/TIM7 introduction

The basic timers TIM6/TIM7 consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation.

The basic timer can also be used for triggering the digital-to-analog converter. This is done with the trigger output of the timer.

The timers are completely independent, and do not share any resources.

31.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow
31.3 TIM6/TIM7 functional description

</tr>
</tbody>
</table>
31.3.3 TIM6/TIM7 clocks

The timer bus interface is clocked by the tim_pclk APB clock.

The counter clock tim_ker_ck is connected to the tim_pclk input.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

*Figure 481* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

![Figure 481. Control circuit in normal mode, internal clock divided by 1](MSv62317v2)

31.3.4 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.
The counter is clocked by the prescaler output `tim_cnt_ck`, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal `tim_cnt_en` is set 1 clock cycle after CEN bit set.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 482 and Figure 483* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

**Figure 482. Counter timing diagram with prescaler division change from 1 to 2**
31.3.5 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):
- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This affects the way the TIMx_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger (typically for a DAC).

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.

The Figure 490 below presents the dithering principle applied to 4 consecutive counting periods.
When the dithering mode is enabled, the register coding is changed as following (see Figure 491 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

**Note:** The ARR values are updated automatically if the DITHEN bit is set / reset (for instance, if ARR= 0x05 with DITHEN=0, it is updated to ARR = 0x50 with DITHEN = 1). The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CEN bit can be set (eventually with ARPE = 1).

**Figure 491. Data format and register coding in dithering mode**
The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Note: The maximum TIMx.ARR value is limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 492 below, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

**Figure 492. F\text{Cnt} resolution vs frequency**

The period changes are spread over 16 consecutive periods, as described in the Figure 493 below.

**Figure 493. PWM dithering pattern**
The auto-reload and compare values increments are spread following specific patterns described in the Table 306 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

31.3.6 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.
31.3.7 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the TIM_trgo signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

31.3.8 TIM6/TIM7 DMA requests

The TIM6/TIM7 can generate a single DMA request, as shown in Table 307.

<table>
<thead>
<tr>
<th>DMA request signal</th>
<th>DMA acronym</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>
<td>TIM_UP</td>
<td>Update</td>
<td>UDE</td>
</tr>
</tbody>
</table>

31.3.9 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 with FPU core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

31.3.10 TIM6/TIM7 low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

31.3.11 TIM6/TIM7 interrupts

The TIM6/TIM7 can generate a single interrupt, as shown in Table 309.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
<th>Exit from Sleep mode</th>
<th>Exit from Stop and Standby mode</th>

<td>No</td>
</tr>
</tbody>
</table>
31.4 TIM6/TIM7 registers

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

31.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Address offset: 0x00
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10:8</th>
<th>Bit 7</th>
<th>Bit 6:4</th>
<th>Bit 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>DITHEN</td>
<td>UIFREMAP</td>
<td>Reserved</td>
<td>ARPE</td>
<td>Reserved</td>
<td>OPM</td>
</tr>
<tr>
<td>RW</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 DITHEN: Dithering enable
   0: Dithering disabled
   1: Dithering enabled

   Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 UIFREMAP: UIF status bit remapping
   0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
   1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 ARPE: Auto-reload preload enable
   0: TIMx_ARR register is not buffered.
   1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 OPM: One-pulse mode
   0: Counter is not stopped at update event
   1: Counter stops counting at the next update event (clearing the CEN bit).
Bit 2 **URS**: Update request source
   
   This bit is set and cleared by software to select the UEV event sources.
   
   0: Any of the following events generates an update interrupt or DMA request if enabled.
   These events can be:
   
   – Counter overflow/underflow
   – Setting the UG bit
   – Update generation through the slave mode controller
   
   1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
   
   This bit is set and cleared by software to enable/disable UEV event generation.
   
   0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   
   – Counter overflow/underflow
   – Setting the UG bit
   – Update generation through the slave mode controller
   
   Buffered registers are then loaded with their preload values.
   
   1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
   
   0: Counter disabled
   1: Counter enabled
   
   CEN is cleared automatically in one-pulse mode, when an update event occurs.
31.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7)

Address offset: 0x04
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]:** Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000: Reset** - the UG bit from the TIMx_EGR register is used as a trigger output (tim_trgo).
- **001: Enable** - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo).
- **010: Update** - The update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

**Note:** The clock of the slave timer or the peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0 Reserved, must be kept at reset value.

31.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

Address offset: 0x0C
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE:** Update DMA request enable

- 0: Update DMA request disabled.
- 1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE:** Update interrupt enable

- 0: Update interrupt disabled.
- 1: Update interrupt enabled.
### 31.4.4 TIMx status register (TIMx_SR)(x = 6 to 7)

**Address offset:** 0x10  
**Reset value:** 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>
<th>Bit 9</th>

<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>UIF (rc_w0)</strong></td>
</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

**Bit 0 ** **UIF:** Update interrupt flag

- This bit is set by hardware on an update event. It is cleared by software.
- 0: No update occurred.
- 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - On counter overflow if UDIS = 0 in the TIMx_CR1 register.
  - When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 31.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)

**Address offset:** 0x14  
**Reset value:** 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>

<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>Reserved</strong></td>
<td><strong>UG (w)</strong></td>
</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

**Bit 0 ** **UG:** Update generation

- This bit can be set by software, it is automatically cleared by hardware.
- 0: No action.
- 1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 31.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)

**Address offset:** 0x24  
**Reset value:** 0x0000 0000

</tbody>
</table>
31.4.7 TIMx prescaler (TIMx_PSC)(x = 6 to 7)

Address offset: 0x28
Reset value: 0x0000

<table>
<thead>
<tr>
<th>PSC[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value
The counter clock frequency \( f_{\text{tim\_cnt\_ck}} \) is equal to \( f_{\text{tim\_psc\_ck}} / (\text{PSC}[15:0] + 1) \).
PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register.

31.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)

Address offset: 0x2C
Reset value: 0x0000 FFFF

<table>
<thead>
<tr>
<th>ARR[19:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ARR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 ARR[19:0]: Auto-reload value
ARR is the value to be loaded into the actual auto-reload register.
Refer to Section 31.3.4: Time-base unit on page 1462 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.
31.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

### Table 310. TIMx register map and reset values

| Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name |
|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|--------|---------------|
| 0x00   | TIMx_CR1      | 0x04   | TIMx_CR2      | 0x08   | Reserved      | 0x0C   | TIMx_DIER     | 0x10   | TIMx_SR       | 0x14   | TIMx_EGR      | 0x18   | Reserved      | 0x24   | TIMx_CNT      | 0x28   | TIMx_PSC      | 0x2C   | TIMx_ARR      |
|        | Reset value   |        | Reset value   |        | Reserved      |        | Reset value   |        | Reset value   |        | Reset value   |        | Reserved      |        | Reset value   |        | Reset value   |
|        | 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 |        | 0            |        | 0            |        | 0            |        | 0            |        | 0            |        | 0            |        | 0            |        | 0            |
|        | 0x08 Reserved |        | 0x0C Reserved |        | 0x10 Reserved |        | 0x14 Reserved |        | 0x18-0x20 Reserved |        | 0x24 Reserved |        | 0x28 Reserved |        | 0x2C Reserved |

Refer to *Section 2.2 on page 81* for the register boundary addresses.
32 Low-power timer (LPTIM)

32.1 Introduction
The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

32.2 LPTIM main features
- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no embedded oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
32.3 LPTIM implementation

Table 311 describes LPTIM implementation on STM32G4 series devices.

<table>
<thead>
<tr>

</tbody>
</table>
32.4.3 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external

clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will use an external clock source or an internal one. When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal should also be provided (first configuration). In this case, the internal clock signal frequency should be at least four times higher than the external clock signal frequency.

### 32.4.4 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.

The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

**Note:** The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. Figure 495 shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.
32.4.5 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

32.4.6 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 13 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals '00', The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 13 trigger inputs is used to start the counter.
The external triggers are considered asynchronous signals for the LPTIM. So after a trigger
detection, a two-counter-clock period latency is needed before the timer starts running due
to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless
timeout function is enabled).

**Note:** The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these
bits when the timer is disabled will be discarded by hardware.

**Note:** When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock
cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits)
and the effective start of the counter.

### 32.4.7 Operating mode

The LPTIM features two operating modes:

- **The Continuous mode:** the timer is free running, the timer is started from a trigger event
  and never stops until the timer is disabled

- **One-shot mode:** the timer is started from a trigger event and stops when reaching the
  ARR value.

#### One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts
and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the
SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will
start the counter for a new one-shot counting cycle as shown in **Figure 496**.

**Figure 496. LPTIM output waveform, single counting mode configuration**

**Set-once mode activated:**

It should be noted that when the WAVE bit-field in the LPTIM_CFGR register is set, the Set-
onece mode is activated. In this case, the counter is only started once following the first
trigger, and any subsequent trigger event is discarded as shown in **Figure 497**.
In case of software start (TRIGEN[1:0] = '00'), the SNGSTRT setting will start the counter for one-shot counting.

**Continuous mode**

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in *Figure 498*.

In case of software start (TRIGEN[1:0] = '00'), setting CNTSTRT will start the counter for continuous counting.

**Figure 498. LPTIM output waveform, Continuous counting mode configuration**

SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT will switch the LPTIM to the One-shot mode. The counter (if active) will stop as soon as it reaches ARR.

If the One-shot mode was previously selected, setting CNTSTRT will switch the LPTIM to the Continuous mode. The counter (if active) will restart as soon as it reaches ARR.
32.4.8 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

32.4.9 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CMP (compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM_ARR and the LPTIM_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset.
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CMP register value.

The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to ‘0’ forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 499 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.
### 32.4.10 Register update

The LPTIM_ARR register and LPTIM_CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR and the LPTIM_CMP registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR and the LPTIM_CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR and the LPTIM_CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register and the LPTIM_CMP register.

After a write to the LPTIM_ARR register or the LPTIM_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.
32.4.11 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- **CKSEL = 0**: the LPTIM is clocked by an internal clock source
  - **COUNTMODE = 0**: The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - **COUNTMODE = 1**: The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM.

Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).

- **CKSEL = 1**: the LPTIM is clocked by an external clock source
  - **COUNTMODE** value is don’t care.

In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

32.4.12 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.

The LPTIM_CFGR and LPTIM_IER registers must be modified only when the LPTIM is disabled.
32.4.13 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bit-field to '1', the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic will elapse before the reset is taken into account. This will make the LPTIM counter count few extra pulses between the time when the reset is triggered and it becomes effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing '1' to the COUNTRST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to '1', any read access to the LPTIM_CNT register will reset its content to zero. Asynchronous reset should be triggered within a timeframe in which no LPTIM core clock is provided. For example, when LPTIM Input1 is used as external clock source, the asynchronous reset should be applied only when there is enough insurance that no toggle will occur on the LPTIM Input1.

It should be noted that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

---

**Warning:** There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So developer should make sure that these two mechanisms are used exclusively.

---

32.4.14 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.

Direction change is signaled by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.
To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Rising</td>
<td>Falling</td>
<td>Rising</td>
</tr>
<tr>
<td>Rising Edge</td>
<td>High</td>
<td>Down</td>
<td>No count</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>Up</td>
<td>No count</td>
</tr>
<tr>
<td>Falling Edge</td>
<td>High</td>
<td>No count</td>
<td>Up</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>No count</td>
<td>Down</td>
</tr>
<tr>
<td>Both Edges</td>
<td>High</td>
<td>Down</td>
<td>Up</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>Up</td>
<td>Down</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).
32.4.15 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

32.5 LPTIM low-power modes

Table 317. Effect of low-power modes on the LPTIM

32.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

Note: If any bit in the LPTIM_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

<table>

Bits 31:7 Reserved, must be kept at reset value.

- **Bit 6 DOWN**: Counter direction change up to down  
  In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.  
  Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 32.3: LPTIM implementation.*

- **Bit 5 UP**: Counter direction change down to up  
  In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.  
  Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 32.3: LPTIM implementation.*

- **Bit 4 ARROK**: Autoreload register update OK  
  ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

- **Bit 3 CMPOK**: Compare register update OK  
  CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_CMP register has been successfully completed. CMPOK flag can be cleared by writing 1 to the CMPOKCF bit in the LPTIM_ICR register.

- **Bit 2 EXTTRIG**: External trigger edge event  
  EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

- **Bit 1 ARRM**: Autoreload match  
  ARRM is set by hardware to inform application that LPTIM_CNT register's value reached the LPTIM_ARR register's value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

- **Bit 0 CMPM**: Compare match  
  The CMPM bit is set by hardware to inform application that LPTIM_CNT register value reached the LPTIM_CMP register's value. CMPM flag can be cleared by writing 1 to the CMPMCF bit in the LPTIM_ICR register.

Bits 31:7 Reserved, must be kept at reset value.

- Bit 6 DOWNCF: Direction change to down clear flag
  - Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 32.3: LPTIM implementation.

- Bit 5 UPCF: Direction change to UP clear flag
  - Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.
  - Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 32.3: LPTIM implementation.

- Bit 4 ARROKCF: Autoreload register update OK clear flag
  - Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

- Bit 3 CMPOKCF: Compare register update OK clear flag
  - Writing 1 to this bit clears the CMPOK flag in the LPTIM_ISR register

- Bit 2 EXTTRIGCF: External trigger valid edge clear flag
  - Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

- Bit 1 ARRMCF: Autoreload match clear flag
  - Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

- Bit 0 CMPMCF: Compare match clear flag
  - Writing 1 to this bit clears the CMPM flag in the LPTIM_ISR register

Bits 31:30  Reserved, must be kept at reset value.
Bits 28:25  Reserved, must be kept at reset value.

Bit 24  **ENC**: Encoder mode enable
   - The ENC bit controls the Encoder mode
   - 0: Encoder mode disabled
   - 1: Encoder mode enabled
   **Note**: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 32.3: LPTIM implementation.

Bit 23  **COUNTMODE**: counter mode enabled
   - The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
   - 0: the counter is incremented following each internal clock pulse
   - 1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22  **PRELOAD**: Registers update mode
   - The PRELOAD bit controls the LPTIM_ARR and the LPTIM_CMP registers update modality
   - 0: Registers are updated after each APB bus write access
   - 1: Registers are updated at the end of the current LPTIM period

Bit 21  **WAVPOL**: Waveform shape polarity
   - The WAVPOL bit controls the output polarity
   - 0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CMP registers
   - 1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CMP registers

Bit 20  **WAVE**: Waveform shape
   - The WAVE bit controls the output shape
   - 0: Deactivate Set-once mode
   - 1: Activate the Set-once mode

Bit 19  **TIMOUT**: Timeout enable
   - The TIMOUT bit controls the Timeout feature
   - 0: A trigger event arriving when the timer is already started will be ignored
   - 1: A trigger event arriving when the timer is already started will reset and restart the counter

Bits 18:17  **TRIGEN[1:0]**: Trigger enable and polarity
   - The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
   - 00: software trigger (counting start is initiated by software)
   - 01: rising edge is the active edge
   - 10: falling edge is the active edge
   - 11: both edges are active edges

Bit 16  Reserved, must be kept at reset value.
The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 13 available sources:

- 0000: lptim_ext_trig0
- 0001: lptim_ext_trig1
- 0010: lptim_ext_trig2
- 0011: lptim_ext_trig3
- 0100: lptim_ext_trig4
- 0101: lptim_ext_trig5
- 0110: lptim_ext_trig6
- 0111: lptim_ext_trig7
- 1000: lptim_ext_trig8
- 1001: lptim_ext_trig9
- 1010: lptim_ext_trig10
- 1011: lptim_ext_trig11
- 1100: lptim_ext_trig12

Others: Reserved

See Section 32.4.2: LPTIM input and trigger mapping for details.

Bit 12 Reserved, must be kept at reset value.

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

- 000: /1
- 001: /2
- 010: /4
- 011: /8
- 100: /16
- 101: /32
- 110: /64
- 111: /128

Bit 8 Reserved, must be kept at reset value.

The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature.

- 00: any trigger active level change is considered as a valid trigger
- 01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
- 10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
- 11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.
Bits 4:3  **CKFLT[1:0]:** Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

<table>
<thead>
<tr>
<th>CKFLT value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>any external clock signal level change is considered as a valid transition</td>

</tr>
<tr>
<td>10</td>
<td>external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.</td>
</tr>
<tr>
<td>11</td>
<td>external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.</td>
</tr>
</tbody>
</table>

Bits 2:1  **CKPOL[1:0]:** Clock polarity

If LPTIM is clocked by an external clock source:

If the LPTIM is configured in Encoder mode (ENC bit is set), the encoder sub-mode 1 is active.

- 00: the rising edge is the active edge used for counting.
- 01: the falling edge is the active edge used for counting.
- 10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.
- 11: not allowed

Refer to [Section 32.4.14: Encoder mode](#) for more details about Encoder mode sub-modes.

Bit 0  **CKSEL:** Clock selector

The CKSEL bit selects which clock source the LPTIM will use:

- 0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)
- 1: LPTIM is clocked by an external clock source through the LPTIM external Input1

**Caution:** The LPTIM_CFG register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’).

### 32.7.5  **LPTIM control register (LPTIM_CR)**

**Note:**

- RST: Reset
- COUN: Counter
- CNT: Counter
- SNG: Single
- STRT: Start
- ENA: Enable
- rw: Read and Write
- rs: Read and Set
- rw: Read and Write
- rw: Read and Write
- rw: Read and Write
Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **RSTARE**: Reset after read enable

This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register will asynchronously reset LPTIM_CNT register content.

This bit can be set only when the LPTIM is enabled.

Bit 3 **COUNTRST**: Counter reset

This bit is set by software and cleared by hardware. When set to ‘1’ this bit will trigger a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).

This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

**Caution**: COUNTRST must never be set to ‘1’ by software before it is already cleared to ‘0’ by hardware. Software should consequently check that COUNTRST bit is already cleared to ‘0’ before attempting to set it to ‘1’.

Bit 2 **CNTSTRT**: Timer start in Continuous mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in Continuous mode.

If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.

If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM_ARR and LPTIM_CNT registers and the LPTIM counter keeps counting in Continuous mode.

This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1 **SNGSTRT**: LPTIM start in Single mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in single pulse mode.

If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.

If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM_ARR and LPTIM_CNT registers.

This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0 **ENABLE**: LPTIM enable

The ENABLE bit is set and cleared by software.

0: LPTIM is disabled
1: LPTIM is enabled
32.7.6 LPTIM compare register (LPTIM_CMP)

Address offset: 0x014
Reset value: 0x0000 0000

Caution: The LPTIM_CMP register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

32.7.7 LPTIM autoreload register (LPTIM_ARR)

Address offset: 0x018
Reset value: 0x0000 0001

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).
## 32.7.8 LPTIM counter register (LPTIM_CNT)

Address offset: 0x01C  
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **Cnt[15:0]:** Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

It should be noted that for a reliable LPTIM_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

Refer to Section 2.2 on page 81 for the register boundary addresses.
Infrared interface (IRTIM)

An infrared interface (IRTIM) for remote control is available on the device. It can be used with an infrared LED to perform remote control functions.

It uses internal connections with TIM16, and TIM17 as shown in Figure 501.

To generate the infrared remote control signals, the IR interface must be enabled and TIM16 channel 1 (TIM16_OC1) and TIM17 channel 1 (TIM17_OC1) must be properly configured to generate correct waveforms.

The infrared receiver can be implemented easily through a basic input capture mode.

Figure 501. IRTIM internal hardware connections with TIM16 and TIM17

All standard IR pulse modulation modes can be obtained by programming the two timer output compare channels.

TIM17 is used to generate the high frequency carrier signal, while TIM16 generates the modulation envelope.

The infrared function is output on the IR_OUT pin. The activation of this function is done through the GPIOx_AFRx register by enabling the related alternate function bit.

The high sink LED driver capability (only available on the PB9 and PA13 pins) can be activated through the I2C_PB9_FMP bit in the SYSCFG_CFGR1 register and used to sink the high current needed to directly control an infrared LED.
34 AES hardware accelerator (AES)

34.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197.

The peripheral supports CTR, GCM, GMAC, CCM, ECB, and CBC chaining modes for key sizes of 128 or 256 bits.

AES is an AMBA AHB slave peripheral accessible through 32-bit single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels required).

34.2 AES main features

- Compliance with NIST “Advanced encryption standard (AES), FIPS publication 197” from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated round key scheduler to compute the last round key for ECB/CBC decryption
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit register for storing the cryptographic key (eight 32-bit registers)
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message

34.3 AES implementation

The devices have one AES peripheral.
34.4 AES functional description

34.4.1 AES block diagram

Figure 502 shows the block diagram of AES.

Figure 502. AES block diagram

34.4.3 AES cryptographic core

Overview

The AES cryptographic core consists of the following components:

- AES core algorithm (AEA)
- multiplier over a binary Galois field (GF2mul)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR, feedback/counter, mask)
The AES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the AES requires zero or one 128-bit initialization vector IV.

The AES features the following modes of operation:

- **Mode 1:**
  Plaintext encryption using a key stored in the AES_KEYRx registers

- **Mode 2:**
  ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the AES_KEYRx registers. Now the AES peripheral is ready to switch to Mode 3 for executing data decryption.

- **Mode 3:**
  Ciphertext decryption using a key stored in the AES_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.

- **Mode 4:**
  ECB or CBC ciphertext single decryption using the key stored in the AES_KEYRx registers (the initial key is derived automatically).

**Note:** Mode 2 and mode 4 are only used when performing ECB and CBC decryption. When Mode 4 is selected only one decryption can be done, therefore usage of Mode 2 and Mode 3 is recommended instead.

The operating mode is selected by programming the MODE[1:0] bitfield of the AES_CR register. It may be done only when the AES peripheral is disabled.

**Typical data processing**

Typical usage of the AES is described in Section 34.4.4: AES procedure to perform a cipher operation on page 1512.

**Note:** The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IVI bitfield.

**Chaining modes**

The following chaining modes are supported by AES, selected through the CHMOD[2:0] bitfield of the AES_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)
- Counter (CTR)
- Galois counter mode (GCM)
- Galois message authentication code (GMAC)
- Counter with CBC-MAC (CCM)

**Note:** The chaining mode may be changed only when AES is disabled (bit EN of the AES_CR register cleared).

Principle of each AES chaining mode is provided in the following subsections. Detailed information is in dedicated sections, starting from Section 34.4.8: AES basic chaining modes (ECB, CBC).
Electronic codebook (ECB) mode

Figure 503. ECB encryption and decryption principle

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

Note: For decryption, a special key scheduling is required before processing the first block.
Cipher block chaining (CBC) mode

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

*Note:* For decryption, a special key scheduling is required before processing the first block.
Counter (CTR) mode

Figure 505. CTR encryption and decryption principle

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

Note: Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the key stream, or counter blocks.
Galois/counter mode (GCM)

In Galois/counter mode (GCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

Galois message authentication code (GMAC) principle

Galois message authentication code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload).

**Counter with CBC-MAC (CCM) principle**

In Counter with cipher block chaining-message authentication code (CCM) mode, the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM, the CCM chaining mode can be applied on a message composed only by plaintext authenticated data (that is, only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its use is not recommended by NIST.

**34.4.4 AES procedure to perform a cipher operation**

**Introduction**

A typical cipher operation is explained below. Detailed information is provided in sections starting from *Section 34.4.8: AES basic chaining modes (ECB, CBC)*.
Initialization of AES

To initialize AES, first disable it by clearing the EN bit of the AES_CR register. Then perform the following steps in any order:

- Configure the AES mode, by programming the MODE[1:0] bitfield of the AES_CR register.
  - For encryption, select Mode 1 (MODE[1:0] = 00).
  - For decryption, select Mode 3 (MODE[1:0] = 10), unless ECB or CBC chaining modes are used. In this latter case, perform an initial key derivation of the encryption key, as described in Section 34.4.5: AES decryption round key preparation.

- Select the chaining mode, by programming the CHMOD[2:0] bitfield of the AES_CR register.

- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the AES_CR register.

- When it is required (for example in CBC or CTR chaining modes), write the initialization vector into the AES_IVRx registers.

- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the AES_CR register.

- Write a symmetric key into the AES_KEYRx registers (4 or 8 registers depending on the key size).

Data append

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits.

For ECB or CBC mode, refer to Section 34.4.6: AES ciphertext stealing and data padding. The last block management in these cases is more complex than in the sequence described in this section.

Data append through polling

This method uses flag polling to control the data append through the following sequence:

1. Enable the AES peripheral by setting the EN bit of the AES_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_SR, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCFC bit of the AES_CR register.
   d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag.
3. As it is the last block, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.

NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.
Data append using interrupt

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES by setting the CCFIE bit of the AES_CR register.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine, upon interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCFC bit of the AES_CR register.
   c) If the data block just processed is the second-last block of a message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag. Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations. NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.

Data append using DMA

With this method, all the transfers and processing are managed by DMA and AES. To use the method, proceed as follows:

1. Prepare the last four-word data block (if the data to process does not fill it completely), by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in Section 34.4.16: AES DMA interface. Configure the DMA controller so as to generate an interrupt on transfer completion. In case of GCM payload encryption or CCM payload decryption, DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Data append through polling must be used instead for this last block, because NPBLB bits must be setup before processing the block, for AES to compute a correct tag.
3. Enable the AES peripheral by setting the EN bit of the AES_CR register
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

Note: The CCF flag has no use with this method, because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase. NPBLB bits are not used in header phase of GCM, GMAC, and CCM chaining modes.
34.4.5 AES decryption round key preparation

Internal key schedule is used to generate AES round keys. In AES encryption, the round 0 key is the one stored in the key registers. AES decryption must start using the last round key. As the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key. This key scheduling is only required for AES decryption in ECB and CBC modes.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR. The CHMOD[2:0] bitfield is not significant in this case because this key derivation mode is independent of the chaining algorithm selected.
3. Set key length to 128 or 256 bits, via KEYSIZE bit of AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key, as shown in Figure 509. Writes to the AES_IVRx registers have no effect.
5. Enable the AES peripheral, by setting the EN bit of the AES_CR register.
6. Wait until the CCF flag is set in the AES_SR register.
7. Clear the CCF flag. Derived key is available in AES core, ready to use for decryption. Application can also read the AES_KEYRx register to obtain the derived key if needed, as shown in Figure 509 (the processed key is loaded automatically into the AES_KEYRx registers).

Note: The AES is disabled by hardware when the derivation key is available.

To restart a derivation key computation, repeat steps 4, 5, 6, and 7.

Figure 509. Encryption key derivation for ECB/CBC decryption (Mode 2)

If the software stores the initial key prepared for decryption, it is enough to do the key schedule operation only once for all the data to be decrypted with a given cipher key.

Note: The operation of the key preparation lasts 59 or 82 clock cycles, depending on the key size (128- or 256-bit).
34.4.6 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the AES peripheral does not support such techniques, the application must complete the last block of input data using data from the second last block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when AES is used in other modes than ECB or CBC, an incomplete input data block (that is, block with input data shorter than 128 bits) must be padded with zeros prior to encryption (that is, extra bits must be appended to the trailing end of the data string). After decryption, the extra bits must be discarded. As AES does not implement automatic data padding operation to the last block, the application must follow the recommendation given in Section 34.4.4: AES procedure to perform a cipher operation on page 1512 to manage messages the size of which is not a multiple of 128 bits.

Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the AES_CR register (see Section 34.4.13: AES data registers and data swapping for details).

34.4.7 AES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as AES is enabled again to receive the next data block. Figure 510 gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 510. Example of suspend mode management
A detailed description of suspend/resume operations is in the sections dedicated to each AES mode.

### 34.4.8 AES basic chaining modes (ECB, CBC)

#### Overview

This section gives a brief explanation of the four basic operation modes provided by the AES core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.

*Figure 511* illustrates the electronic codebook (ECB) encryption.

*Figure 511. ECB encryption*

In ECB encrypt mode, the 128-bit plaintext input data block $P_x$ in the AES_DINR register first goes through bit/byte/half-word swapping. The swap result $I_x$ is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result $O_x$ goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit ciphertext output data block $C_x$. The ECB encryption continues in this way until the last complete plaintext block is encrypted.

*Figure 512* illustrates the electronic codebook (ECB) decryption.

*Figure 512. ECB decryption*

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.
In ECB decrypt mode, the 128-bit ciphertext input data block $C_1$ in the AES_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result $I_1$ is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit plaintext output data block $P_1$. The ECB decryption continues in this way until the last complete ciphertext block is decrypted.

*Figure 513* illustrates the cipher block chaining (CBC) encryption.

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping ($P_1'$), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the $I_1$ input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block $O_1$, after swapping operation, is used as ciphertext $C_1$. The $O_1$ data is then XOR-ed with the second-block plaintext data $P_2'$ to produce the $I_2$ input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in *Section 34.4.6: AES ciphertext stealing and data padding*. 

*Figure 514* illustrates the cipher block chaining (CBC) decryption.
In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IV field (that must be identical to that used during encryption) to produce the first plaintext block P1.

The second ciphertext block is processed in the same way as the first block, except that the I1 data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted.

If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in Section 34.4.6: AES ciphertext stealing and data padding.

For more information on data swapping, refer to Section 34.4.13: AES data registers and data swapping.

**ECB/CBC encryption sequence**

The sequence of events to perform an ECB/CBC encryption (more detail in Section 34.4.4):

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select the Mode 1 by setting to 00 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield.
3. Select 128- or 256-bit key length through the KEYSIZE bit of the AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key. Fill the AES_IVRx registers with the initialization vector data if CBC mode has been selected.
5. Enable the AES peripheral by setting the EN bit of the AES_CR register.
6. Write the AES_DINR register four times to input the plaintext (MSB first), as shown in Figure 515.
7. Wait until the CCF flag is set in the AES_SR register.
8. Read the AES_DOUTR register four times to get the ciphertext (MSB first) as shown in Figure 515. Then clear the CCF flag by setting the CCFC bit of the AES_CR register.
9. Repeat steps 6-7-8 to process all the blocks with the same encryption key.

**Figure 515. ECB/CBC encryption (Mode 1)**
**ECB/CBC decryption sequence**

The sequence of events to perform an AES ECB/CBC decryption is as follows (More detail in *Section 34.4.4*).

1. Follow the steps described in *Section 34.4.5: AES decryption round key preparation*, in order to prepare the decryption key in AES core.
2. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. KEYSIZE bitfield must be kept as-is.
3. Write the AES_IVRx registers with the initialization vector (required in CBC mode only).
4. Enable AES by setting the EN bit of the AES_CR register.
5. Write the AES_DINR register four times to input the cipher text (MSB first), as shown in *Figure 516*.
6. Wait until the CCF flag is set in the AES_SR register.
7. Read the AES_DOUTR register four times to get the plain text (MSB first), as shown in *Figure 516*. Then clear the CCF flag by setting the CCFC bit of the AES_CR register.
8. Repeat steps 5-6-7 to process all the blocks encrypted with the same key.

**Suspend/resume operations in ECB/CBC modes**

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register.
2. If DMA is not used, read four times the AES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.
3. If DMA is not used, poll the CCF flag of the AES_SR register until it becomes 1 (computation completed).
4. Clear the CCF flag by setting the CCFC bit of the AES_CR register.
5. Save initialization vector registers (only required in CBC mode as AES_IVRx registers are altered during the data processing).
6. Disable the AES peripheral by clearing the bit EN of the AES_CR register.
7. Save the AES_CR register and clear the key registers if they are not needed, to process the higher priority message.
8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).

Note: In point 7, the derived key information stored in AES_KEYRx registers can optionally be saved in memory if the interrupted process is a decryption. Otherwise those registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
3. Restore AES_CR register (with correct KEYSIZE) then restore AES_KEYRx registers.
   In case of decryption, derived key information can be written in AES_KEYRx register instead of the original key value.
4. Prepare the decryption key as described in Section 34.4.5: AES decryption round key preparation (only required for ECB or CBC decryption). This step is not necessary if derived key information is loaded in AES_KEYRx registers.
5. Restore AES_IVRx registers using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral by setting the EN bit of the AES_CR register.
7. If DMA is used, enable AES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.

Alternative single ECB/CBC decryption using Mode 4

The sequence of events to perform a single round of ECB/CBC decryption using Mode 4 is:
1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select the Mode 4 by setting to 11 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 0x0 or 0x1, respectively.
3. Select key length of 128 or 256 bits via KEYSIZE bitfield of the AES_CR register.
4. Write the AES_KEYRx registers with the encryption key. Write the AES_IVRx registers if the CBC mode is selected.
5. Enable the AES peripheral by setting the EN bit of the AES_CR register.
6. Write the AES_DINR register four times to input the cipher text (MSB first).
7. Wait until the CCF flag is set in the AES_SR register.
8. Read the AES_DOUTR register four times to get the plain text (MSB first). Then clear the CCF flag by setting the CCFC bit of the AES_CR register.

Note: When mode 4 is selected mode 3 cannot be used.

In mode 4, the AES_KEYRx registers contain the encryption key during all phases of the processing. No derivation key is stored in these registers. It is stored internally in AES.
### 34.4.9 AES counter (CTR) mode

**Overview**

The counter mode (CTR) uses AES as a key-stream generator. The generated keys are then XOR-ed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*. A typical message construction in CTR mode is given in Figure 517.

![Figure 517. Message construction in CTR mode](MSv42156V1)

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

**CTR encryption and decryption**

*Figure 518* and *Figure 519* describe the CTR encryption and decryption process, respectively, as implemented in the AES peripheral. The CTR mode is selected by writing 010 to the CHMOD[2:0] bitfield of AES_CR register.
In CTR mode, the cryptographic core output (also called keystream) Ox is XOR-ed with relevant input block (Px' for encryption, Cx' for decryption), to produce the correct output block (Cx' for encryption, Px' for decryption). Initialization vectors in AES must be initialized as shown in Table 321.

### Table 321. CTR mode initialization vector definition

</tr>
</tbody>
</table>

Unlike in CBC mode that uses the AES_IVRx registers only once when processing the first data block, in CTR mode AES_IVRx registers are used for processing each data block, and the AES peripheral increments the counter bits of the initialization vector (leaving the nonce bits unchanged).
CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that is then XOR-ed with the plaintext (CTR encryption) or ciphertext (CTR decryption) input. In CTR mode, the MODE[1:0] bitfield setting 01 (key derivation) is forbidden and all the other settings default to encryption mode.

The sequence of events to perform an encryption or a decryption in CTR chaining mode:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CTR chaining mode by setting to 010 the CHMOD[2:0] bitfield of the AES_CR register. Set MODE[1:0] bitfield to any value other than 01.
3. Initialize the AES_KEYRx registers, and load the AES_IVRx registers as described in Table 321.
4. Set the EN bit of the AES_CR register, to start encrypting the current counter (EN is automatically reset when the calculation finishes).
5. If it is the last block, pad the data with zeros to have a complete block, if needed.
6. Append data in AES, and read the result. The three possible scenarios are described in Section 34.4.4: AES procedure to perform a cipher operation.
7. Repeat the previous step till the second-last block is processed. For the last block, apply the two previous steps and discard the bits that are not part of the payload (if the size of the significant data in the last input block is less than 16 bytes).

**Suspend/resume operations in CTR mode**

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message that was interrupted. Detailed CBC suspend/resume sequence is described in Section 34.4.8: AES basic chaining modes (ECB, CBC).

*Note:* Like for CBC mode, the AES_IVRx registers must be reloaded during the resume operation.

### 34.4.10 AES Galois/counter mode (GCM)

**Overview**

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 520.
The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. Note that the GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 128-bit blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 322.

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P. When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

GCM processing

Figure 521 describes the GCM implementation in the AES peripheral. The GCM is selected by writing 011 to the CHMOD[2:0] bitfield of the AES_CR register.

Figure 521. GCM authenticated encryption

The mechanism for the confidentiality of the plaintext in GCM mode is similar to that in the Counter mode, with a particular increment function (denoted 32-bit increment) that generates the sequence of input counter blocks.

AES_IVRx registers keeping the counter block of data are used for processing each data block. The AES peripheral automatically increments the Counter[31:0] bitfield. The first counter block (CB1) is derived from the initial counter block ICB by the application software (see Table 323).

Table 323. Initialization of AES_IVRx registers in GCM mode

<td></td>
</tr>
</tbody>
</table>

Note: In this mode, the settings 01 and 11 of the MODE[1:0] bitfield are forbidden.
The authentication mechanism in GCM mode is based on a hash function called GF2mul that performs multiplication by a fixed parameter, called hash subkey (H), within a binary Galois field.

A GCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES prepares the GCM hash subkey (H).
- **Header phase**: AES processes the additional authenticated data (AAD), with hash computation only.
- **Payload phase**: AES processes the plaintext (P) with hash computation, counter block encryption and data XOR-ing. It operates in a similar way for ciphertext (C).
- **Final phase**: AES generates the authenticated tag (T) using the last block of the message.

**GCM init phase**
During this first step, the GCM hash subkey (H) is calculated and saved internally, to be used for processing all the blocks. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select GCM chaining mode, by setting to 011 the CHMOD[2:0] bitfield of the AES_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES_CR register.
4. Set the MODE[1:0] bitfield of the AES_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES_KEYRx registers with a key, and initialize AES_IVRx registers with the information as defined in Table 323.
6. Start the calculation of the hash key, by setting to 1 the EN bit of the AES_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag of the AES_SR register, by setting the CCFC bit of the AES_CR register.

**GCM header phase**
This phase coming after the GCM Init phase must be completed before the payload phase. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in Section 34.4.4: AES procedure to perform a cipher operation. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

*Note: The header phase can be skipped if there is no AAD, that is, Len(A) = 0.*
GCM payload phase

This phase, identical for encryption and decryption, is executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:

1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 34.4.4: AES procedure to perform a cipher operation on page 1512, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, discard the bits that are not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, Len(C) = 0 (see GMAC mode).

GCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Compose the data of the block, by concatenating the AAD bit length and the payload bit length, as shown in Table 322. Write the block into the AES_DINR register.
3. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1.
4. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
5. Clear the CCF flag of the AES_SR register, by setting the CCFC bit of the AES_CR register.
6. Disable the AES peripheral, by clearing the bit EN of the AES_CR register. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data is written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.
Suspend/resume operations in GCM mode

To suspend the processing of a message, proceed as follows:
1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.
3. Clear the CCF flag of the AES_SR register, by setting the CCFC bit of the AES_CR register.
4. Save the AES_SUSPxR registers in the memory, where x is from 0 to 7.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.
7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.
8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:
1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.
2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPxR registers, where x is from 0 to 7.
4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.
6. Enable the AES peripheral by setting the EN bit of the AES_CR register.
If DMA is used, enable AES DMA requests by setting the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

34.4.11 AES Galois message authentication code (GMAC)

Overview

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
A typical message construction for GMAC is given in Figure 522.

**Figure 522. Message construction in GMAC mode**

The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

**AES GMAC processing**

*Figure 523* describes the GMAC mode implementation in the AES peripheral. This mode is selected by writing 011 to the CHMOD[2:0] bitfield of the AES_CR register.

**Figure 523. GMAC authentication mode**

The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.
Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.

34.4.12 AES counter with CBC-MAC (CCM)

Overview

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES in counter mode. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction for CCM is given in Figure 524.

Figure 524. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q**: a bit string representation of the octet length of P (Len(P))
  - **Nonce (N)**: a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags**: most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values \( t \) (MAC length expressed in bytes) and \( Q \) (plaintext length such that Len(P) < \( 2^Q \) bytes). The counter blocks range associated to \( Q \) is equal to \( 2^{8Q-4} \), that is, if the maximum value of \( Q \) is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B)** associated to the Associated Data (A).

This part of the message is only authenticated, not encrypted. This section has a
known length Len(A) that can be a non-multiple of 16 bytes (see Figure 524). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:

- If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
- If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as $0xff || 0xfe || [a]_{32}$, that is, on six bytes.
- If $2^{32} < a < 2^{64}$, then it is encoded as $0xff || 0xff || [a]_{64}$, that is, on ten bytes.

• **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see Figure 524).

• **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

*Note:* *CCM chaining mode can also be used with associated data only (that is, no payload).*

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

- N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)
- A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)
- P: 20212223 (Len(P) = 32 bits or 4 bytes)
- T: 6084341B (Len(T) = 32 bits or $t = 4$)
- B0: 4F101112 13141516 00000000 00000004
- B1: 00080001 02030405 06070000 00000000
- B2: 20212223 00000000 00000000 00000000
- CTR0: 0710111213 141516 00000000 00000000
- CTR1: 0710111213 141516 00000000 00000001

Generation of formatted input data blocks Bx (especially B0 and B1) must be managed by the application.
CCM processing

*Figure 525* describes the CCM implementation within the AES peripheral (encryption example). This mode is selected by writing 100 into the CHMOD[2:0] bitfield of the AES_CR register.

*Figure 525. CCM mode authenticated encryption*

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted plaintext data to generate a MAC, with a known length. Counter mode encryption that requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting ciphertext C is the output of the generation-encryption process on plaintext P.

AES_IVRx registers are used for processing each data block, AES automatically incrementing the CTR counter with a bit length defined by the first block B0. *Table 324* shows how the application must load the B0 data.

*Note:* The AES peripheral in CCM mode supports counters up to 64 bits, as specified by NIST.

**Table 324. Initialization of AES_IVRx registers in CCM mode**

<table>
<thead>
<tr>
<th>AES_IVR3[31:0]</th>
<th>AES_IVR2[31:0]</th>
<th>AES_IVR1[31:0]</th>
<th>AES_IVR0[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>B0[127:96]</td>
<td>B0[95:64]</td>
<td>B0[63:32]</td>
<td>B0[31:0]</td>
</tr>
</tbody>
</table>
A CCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES processes the first block and prepares the first counter block.
- **Header phase**: AES processes associated data (A), with tag computation only.
- **Payload phase**: IP processes plaintext (P), with tag computation, counter block encryption, and data XOR-ing. It works in a similar way for ciphertext (C).
- **Final phase**: AES generates the message authentication code (MAC).

**CCM Init phase**

In this phase, the first block B0 of the CCM message is written into the AES_IVRx register. The AES_DOUTR register does not contain any output data. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CCM chaining mode, by setting to 100 the CHMOD[2:0] bitfield of the AES_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES_CR register.
4. Set the MODE[1:0] bitfield of the AES_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES_KEYRx registers with a key, and initialize AES_IVRx registers with B0 data as described in Table 324.
6. Start the calculation of the counter, by setting to 1 the EN bit of the AES_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag in the AES_SR register, by setting to 1 the CCFC bit of the AES_CR register.

**CCM header phase**

This phase coming after the GCM Init phase must be completed before the payload phase. During this phase, the AES_DOUTR register does not contain any output data. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in Section 34.4.4: AES procedure to perform a cipher operation. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

**Note:** The header phase can be skipped if there is no associated data, that is, Len(A) = 0.

The first block of the associated data (B1) must be formatted by software, with the associated data length.
CCM payload phase (encryption or decryption)

This phase, identical for encryption and decryption, is executed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:

1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last data block to encrypt and the plaintext size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 34.4.4: AES procedure to perform a cipher operation on page 1512, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), apply the two previous steps. For the last block, discard the data that is not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, \( \text{Len(P)} = 0 \) or \( \text{Len(C)} = \text{Len(T)} \).
Remove \( \text{LSB}_{\text{Len(T)}}(\text{C}) \) encrypted tag information when decrypting ciphertext \( \text{C} \).

CCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Wait until the end-of-computation flag CCF of the AES_SR register is set.
3. Read four times the AES_DOUTR register: the output corresponds to the CCM authentication tag.
4. Clear the CCF flag of the AES_SR register by setting the CCFC bit of the AES_CR register.
5. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.
6. For authenticated decryption, compare the generated encrypted tag with the encrypted tag padded in the ciphertext.

Note: In this final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.
Application must mask the authentication tag output with tag length to obtain a valid tag.

Suspend/resume operations in CCM mode

To suspend the processing of a message in header or payload phase, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the
AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. Clear the CCF flag of the AES_SR register, by setting to 1 the CCFC bit of the AES_CR register.

4. Save the AES_SUSPxR registers (where x is from 0 to 7) in the memory.

5. Save the AES_IVRx registers as, during the data processing, they changed from their initial values.

6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.

7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.

2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.

3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPxR registers (where x is from 0 to 7).

4. Write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers.

5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.

6. Enable the AES peripheral by setting the EN bit of the AES_CR register.

7. If DMA is used, enable AES DMA requests by setting to 1 the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

34.4.13 AES data registers and data swapping

Data input and output

A 128-bit data block is entered into the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the AES peripheral with four successive 32-bit word reads from the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for AES_DINR register or from AES_DOUTR register is organized in big endian order, that is:

- the most significant byte of a word to write into AES_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
- the most significant byte of a word read from AES_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into AES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See Section 34.4.16: AES DMA interface.
Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, Figure 526 shows the construction of AES processing core input buffer data P127 to P0, from the input data entered through the AES_DINR register, or the construction of the output data available through the AES_DOUTR register, from the AES processing core output buffer data P127 to P0.

Figure 526. 128-bit block construction with respect to data swap

</tbody>
</table>

Legend:
- AES input/output data block in memory
- AES core input/output buffer data
- Zero padding (example)
- Data swap
- MSB: most significant bit (127) of memory data block / AEC core buffer
- LSB: least significant bit (0) of memory data block / AEC core buffer
- Order of write to AES_DINR / read from AES_DOUTR: input/output data bit 'x'
The data in AES key registers (AES_KEYRx) and initialization registers (AES_IVRx) are not sensitive to the swap mode selection.

### Data padding

*Figure 526* also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11

### 34.4.14 AES key registers

The AES_KEYRx registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address.

The key is spread over eight registers as shown in *Table 325*.

*Table 325. Key endianness in AES_KEYRx registers (128- or 256-bit key length)*

<table>
<thead>
<tr>
<th>AES_KEYR7 [31:0]</th>
<th>AES_KEYR6 [31:0]</th>
<th>AES_KEYR5 [31:0]</th>
<th>AES_KEYR4 [31:0]</th>
<th>AES_KEYR3 [31:0]</th>
<th>AES_KEYR2 [31:0]</th>
<th>AES_KEYR1 [31:0]</th>
<th>AES_KEYR0 [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key for encryption or decryption may be written into these registers when the AES peripheral is disabled, by clearing the EN bit of the AES_CR register.

The key registers are not affected by the data swapping controlled by DATATYPE[1:0] bitfield of the AES_CR register.

### 34.4.15 AES initialization vector registers

The four AES_IVRx registers keep the initialization vector input bitfield IVI[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (AES_IVR0) to highest address (AES_IVR3).

The signification of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the AES_IVRx registers when the AES peripheral is enabled have no effect to the register contents. For modifying the contents of the AES_IVRx registers, the EN bit of the AES_CR register must first be cleared.

Reading the AES_IVRx registers returns the latest counter value (useful for managing suspend mode).

The AES_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the AES_CR register.
34.4.16 AES DMA interface

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the AES_CR register.

Data input using DMA

Setting the DMAINEN bit of the AES_CR register enables DMA writing into AES. The AES peripheral then initiates a DMA request during the input phase each time it requires to write a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 527.

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required. For example, in case of AES GCM encryption or AES CCM decryption, a DMA transfer must not include the last block. For details, refer to Section 34.4.4: AES procedure to perform a cipher operation.

```
Figure 527. DMA transfer of a 128-bit data block during input phase
```

Data output using DMA

Setting the DMAOUTEN bit of the AES_CR register enables DMA reading from AES. The AES peripheral then initiates a DMA request during the Output phase each time it requires to read a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 528.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.
DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register AES_CR. As in Mode 2 (key derivation) the AES_KEYRx registers must be written by software, enabling the DMA transfer through the DMAINEN and DMAOUTEN bits of the AES_CR register have no effect in that mode.

DMA single requests are generated by AES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, AES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between AES and memory is managed by DMA, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to data transferring managed by software. See Section 34.4.4: AES procedure to perform a cipher operation, subsection Data append, for details.

34.4.17 AES error management

AES configuration can be changed at any moment by clearing the EN bit of the AES_CR register.

Read error flag (RDERR)

Unexpected read attempt of the AES_DOUTR register sets the RDERR flag of the AES_SR register, and returns zero.

RDERR is triggered during the computation phase or during the input phase.

Note: AES is not disabled upon a RDERR error detection and continues processing.

An interrupt is generated if the ERRIE bit of the AES_CR register is set. For more details, refer to Section 34.5: AES interrupts.

The RDERR flag is cleared by setting the ERRIE bit of the AES_CR register.

Write error flag (WDERR)

Unexpected write attempt of the AES_DINR register sets the WRERR flag of the AES_SR register, and has no effect on the AES_DINR register. The WRERR is triggered during the computation phase or during the output phase.
**Note:** AES is not disabled after a WRERR error detection and continues processing.

An interrupt is generated if the ERRIE bit of the AES_CR register is set. For more details, refer to [Section 34.5: AES interrupts](#).

The WRERR flag is cleared by setting the ERRC bit of the AES_CR register.

### 34.5 AES interrupts

Individual maskable interrupt sources generated by the AES peripheral signal the following events:

- computation completed
- read error
- write error

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Arm® Cortex® interrupt controller. Each can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the AES_CR register, and cleared by setting the corresponding bit of the AES_CR register.

The status of each can be read from the AES_SR register. *Table 326* gives a summary of the interrupt sources, their event flags and enable bits.

1. Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle).

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block  
The bitfield sets the number of padding bytes in last block of payload:  
0000: All bytes are valid (no padding)  
0001: Padding for one least-significant byte of last block  
...  
1111: Padding for 15 least-significant bytes of last block  

Bit 19 Reserved, must be kept at reset value.
Bit 18 **KEYSIZE**: Key size selection
   This bitfield defines the length of the key used in the AES cryptographic core, in bits:
   0: 128  
   1: 256
   Attempts to write the bit are ignored when the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **GCMPH[1:0]**: GCM or CCM phase selection
   This bitfield selects the phase of GCM, GMAC or CCM algorithm:
   00: Init phase  
   01: Header phase  
   10: Payload phase  
   11: Final phase
   The bitfield has no effect if other than GCM, GMAC or CCM algorithms are selected (through the ALGOMODE bitfield).

Bit 12 **DMAOUTEN**: DMA output enable
   This bit enables/disables data transferring with DMA, in the output phase:
   0: Disable  
   1: Enable
   When the bit is set, DMA requests are automatically generated by AES during the output data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation). Use of DMA with Mode 4 (single decryption) is not recommended.

Bit 11 **DMAINEN**: DMA input enable
   This bit enables/disables data transferring with DMA, in the input phase:
   0: Disable  
   1: Enable
   When the bit is set, DMA requests are automatically generated by AES during the input data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation). Use of DMA with Mode 4 (single decryption) is not recommended.

Bit 10 **ERRIE**: Error interrupt enable
   This bit enables or disables (masks) the AES interrupt generation when RDERR and/or WRERR is set:
   0: Disable (mask)  
   1: Enable

Bit 9 **CCFIE**: CCF interrupt enable
   This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set:
   0: Disable (mask)  
   1: Enable

Bit 8 **ERRC**: Error flag clear
   Upon written to 1, this bit clears the RDERR and WRERR error flags in the AES_SR register:
   0: No effect  
   1: Clear RDERR and WRERR flags
   Reading the flag always returns zero.
Bit 7 \textbf{CCFC}: Computation complete flag clear
   Upon written to 1, this bit clears the computation complete flag (CCF) in the AES_SR register:
   0: No effect
   1: Clear CCF
   Reading the flag always returns zero.

Bits 16, 6:5 \textbf{CHMOD[2:0]}: Chaining mode selection
   This bitfield selects the AES chaining mode:
   000: Electronic codebook (ECB)
   001: Cipher-block chaining (CBC)
   010: Counter mode (CTR)
   011: Galois counter mode (GCM) and Galois message authentication code (GMAC)
   100: Counter with CBC-MAC (CCM)
   others: Reserved
   Attempts to write the bitfield are ignored when the EN bit of the AES_CR register is set before the
   write access and it is not cleared by that write access.

Bits 4:3 \textbf{MODE[1:0]}: AES operating mode
   This bitfield selects the AES operating mode:
   00: Mode 1: encryption
   01: Mode 2: key derivation (or key preparation for ECB/CBC decryption)
   10: Mode 3: decryption
   11: Mode 4: key derivation then single decryption
   Attempts to write the bitfield are ignored when the EN bit of the AES_CR register is set before the
   write access and it is not cleared by that write access. Any attempt to selecting Mode 4 while either
   ECB or CBC chaining mode is not selected, defaults to effective selection of Mode 3. It is not
   possible to select a Mode 3 following a Mode 4.

Bits 2:1 \textbf{DATATYPE[1:0]}: Data type selection
   This bitfield defines the format of data written in the AES_DINR register or read from the
   AES_DOUTR register, through selecting the mode of data swapping:
   00: None
   01: Half-word (16-bit)
   10: Byte (8-bit)
   11: Bit
   For more details, refer to \textit{Section 34.4.13: AES data registers and data swapping.}
   Attempts to write the bitfield are ignored when the EN bit of the AES_CR register is set before the
   write access and it is not cleared by that write access.

Bit 0 \textbf{EN}: AES enable
   This bit enables/disables the AES peripheral:
   0: Disable
   1: Enable
   At any moment, clearing then setting the bit re-initializes the AES peripheral.
   This bit is automatically cleared by hardware upon the completion of the key preparation (Mode 2)
   and upon the completion of GCM/GMAC/CCM initial phase.
34.7.2 AES status register (AES_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy
This flag indicates whether AES is idle or busy during GCM payload encryption phase:
0: Idle
1: Busy
When the flag indicates "idle", the current GCM encryption processing may be suspended to process a higher-priority message. In other chaining modes, or in GCM phases other than payload encryption, the flag must be ignored for the suspend process.

Bit 2 **WRERR**: Write error
This flag indicates the detection of an unexpected write operation to the AES_DINR register (during computation or data output phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the ERRC bit of the AES_CR register.
Upon the flag setting, an interrupt is generated if enabled through the ERRIE bit of the AES_CR register.
The flag setting has no impact on the AES operation. Unexpected write is ignored.

Bit 1 **RDERR**: Read error flag
This flag indicates the detection of an unexpected read operation from the AES_DOUTR register (during computation or data input phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the ERRC bit of the AES_CR register.
Upon the flag setting, an interrupt is generated if enabled through the ERRIE bit of the AES_CR register.
The flag setting has no impact on the AES operation. Unexpected read returns zero.

Bit 0 **CCF**: Computation completed flag
This flag indicates whether the computation is completed:
0: Not completed
1: Completed
The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCFC bit of the AES_CR register.
Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the AES_CR register.
The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA_EN is 1.
34.7.3  AES data input register (AES_DINR)

Address offset: 0x08
Reset value: 0x0000 0000
Only 32-bit access type is supported.

</tbody>
</table>

Bits 31:0  **DIN[31:0]**: Input data word

A four-fold sequential write to this bitfield during the input phase results in writing a complete 128-bit block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.

The data signification of the input data block depends on the AES operating mode:
- **Mode 1** (encryption): plaintext
- **Mode 2** (key derivation): the bitfield is not used (AES_KEYRx registers used for input)
- **Mode 3** (decryption) and **Mode 4** (key derivation then single decryption): ciphertext

The data swap operation is described in Section 34.4.13: AES data registers and data swapping on page 1536.

34.7.16 AES key register 7 (AES_KEYR7)

Address offset: 0x3C
Reset value: 0x0000 0000

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]
Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield.

**Note:** The key registers from 4 to 7 are used only when the key length of 256 bits is selected. They have no effect when the key length of 128 bits is selected (only key registers 0 to 3 are used in that case).

34.7.17 AES suspend registers (AES_SUSPxR)

Address offset: 0x040 + 0x4 \* x, (x = 0 to 7)
Reset value: 0x0000 0000

These registers contain the complete internal register states of the AES processor when the AES processing of the current task is suspended to process a higher-priority task.
Upon suspend, the software reads and saves the AES_SUSPxR register contents (where x is from 0 to 7) into memory, before using the AES processor for the higher-priority task.
Upon completion, the software restores the saved contents back into the corresponding suspend registers, before resuming the original task.

**Note:** These registers are used only when GCM, GMAC, or CCM chaining mode is selected.
These registers can be read only when AES is enabled. Reading these registers while AES is disabled returns 0x0000 0000.

Refer to Section 2.2 on page 81 for the register boundary addresses.
35 Real-time clock (RTC)

35.1 Introduction

The RTC provides an automatic wakeup to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

The RTC is functional in \( V_{BAT} \) mode.

35.2 RTC main features

The RTC supports the following features (see Figure 529: RTC block diagram):

- Calendar with subsecond, seconds, minutes, hours (12 or 24 format), week day, date, month, year, in BCD (binary-coded decimal) format.
- Automatic correction for 28, 29 (leap year), 30, and 31 days of the month.
- Two programmable alarms.
- On-the-fly correction from 1 to 32767 RTC clock pulses. This can be used to synchronize it with a master clock.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Digital calibration circuit with 0.95 ppm resolution, to compensate for quartz crystal inaccuracy.
- Timestamp feature which can be used to save the calendar content. This function can be triggered by an event on the timestamp pin, or by a tamper event, or by a switch to \( V_{BAT} \) mode.
- 17-bit auto-reload wakeup timer (WUT) for periodic events with programmable resolution and period.

The RTC is supplied through a switch that takes power either from the \( V_{DD} \) supply when present or from the \( V_{BAT} \) pin.

The RTC clock sources can be:

- A 32.768 kHz external crystal (LSE)
- An external resonator or oscillator (LSE)
- The internal low power RC oscillator (LSI, with typical frequency of 32 kHz)
- The high-speed external clock (HSE), divided by a prescaler in the RCC.

The RTC is functional in \( V_{BAT} \) mode and in all low-power modes when it is clocked by the LSE. When clocked by the LSI, the RTC is not functional in \( V_{BAT} \) mode, but is functional in all low-power modes except Shutdown mode.

All RTC events (Alarm, WakeUp Timer, Timestamp) can generate an interrupt and wakeup the device from the low-power modes.
35.3 **RTC functional description**

35.3.1 **RTC block diagram**

- RTC_OUT1 and RTC_OUT2 which selects one of the following two outputs:
  - CALIB: 512 Hz or 1 Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
  - TAMPALRM: This output is the OR between TAMP and ALARM outputs.

ALARM is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the alarm A, alarm B or wakeup outputs. TAMP is enabled by setting the TAMPOE bit in the RTC_CR register which selects the tamper event outputs.

The RTC kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some functions are not available in some low-power modes or $V_{BAT}$ when the selected clock is not LSE. Refer to Section 35.4: RTC low-power modes for more details.
The triggers outputs can be used as triggers for other peripherals.

### 35.3.3 GPIOs controlled by the RTC and TAMP

The GPIOs included in the Battery Backup Domain ($V_{BAT}$) are directly controlled by the peripherals providing functions on these I/Os, whatever the GPIO configuration.

Both RTC and TAMP peripherals provide functions on these I/Os (refer to Section 36: Tamper and backup registers (TAMP)).

UART.OUT1, UART.TS and TAMP.IN1 are mapped on the same pin (PC13). The RTC and TAMP functions mapped on PC13 are available in all low-power modes and in $V_{BAT}$ mode.

The output mechanism follows the priority order shown in Table 333.

Table 333. PC13 configuration(1) (continued)
In addition, it is possible to output RTC_OUT2 on PB2 pin thanks to OUT2EN bit. This output is not available in \( V_{\text{BAT}} \) mode. The different functions are mapped on RTC_OUT1 or on RTC_OUT2 depending on OSEL, COE and OUT2EN configuration, as show in Table 334.

For PB2, the GPIO should be configured as an alternate function.

### 35.3.4 Clock and prescalers

The RTC clocks must respect this ratio: \( \text{frequency}(PCLK) \geq 2 \times \text{frequency}(RTCCLK) \).

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to Section 7: Reset and clock control (RCC).
A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 529: RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$ is given by the following formula:

$$f_{ck\_apre} = \frac{f_{RTC\_CLK}}{PREDIV\_A + 1}$$

The $ck\_apre$ clock is used to clock the binary RTC_SSR subseconds downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

$f_{ck\_spre}$ is given by the following formula:

$$f_{ck\_spre} = \frac{f_{RTC\_CLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

The $ck\_spre$ clock can be used either to update the calendar or as timebase for the 16-bit wakeup auto-reload timer. To obtain short timeout periods, the 16-bit wakeup auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 35.3.7: Periodic auto-wakeup for details).

### 35.3.5 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ICSR register is set (see Section 35.6.10: RTC shift control register (RTC_SHIFTR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 4 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the
BYPHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPHAD = 0 mode, the frequency of the APB clock (f_{APB}) must be at least 7 times the frequency of the RTC clock (f_{RTCCLK}).

The shadow registers are reset by system reset.

### 35.3.6 Programmable alarms

The RTC unit provides programmable alarm: alarm A and alarm B. The description below is given for alarm A, but can be translated in the same way for alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register.

The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASR register.

The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the TAMPALRM output. TAMPALRM output polarity can be configured through bit POL the RTC_CR register.

### 35.3.7 Periodic auto-wakeup

The periodic wakeup flag is generated by a 16-bit programmable auto-reload down-counter. The wakeup timer range can be extended to 17 bits.

The wakeup function is enabled through the WUTE bit in the RTC_CR register.

The wakeup timer clock input ck_wut can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.
  When RTCCLK is LSE (32.768 kHz), this allows to configure the wakeup interrupt period from 122 µs to 32 s, with a resolution down to 61 µs.
- ck_spre (usually 1 Hz internal clock)
  When ck_spre frequency is 1 Hz, this allows to achieve a wakeup time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1 s to 18 hours when WUCKSEL[2:1] = 10
  - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case $2^{16}$ is added to the 16-bit counter current value. When the initialization sequence is complete (see *Programming the wakeup timer on page 1563*), the timer starts counting down. When the wakeup function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in
the RTC_SR register, and the wakeup counter is automatically reloaded with its
reload value (RTC_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wakeup interrupt is enabled by setting the WUTIE bit in the RTC_CR
register, it can exit the device from low-power modes.

The periodic wakeup flag can be routed to the TAMPALRM output provided it has been
enabled through bits OSEL[1:0] of RTC_CR register. TAMPALRM output polarity can be
configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on
the wakeup timer.

35.3.8 RTC initialization and configuration

RTC register access

The RTC registers are 32-bit registers. The APB interface introduces two wait states in RTC
register accesses except on read accesses to calendar shadow registers when
BYPSHAD = 0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by the
DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit
must be set in order to enable RTC registers write access.

After Backup domain reset, some of the RTC registers are write-protected.

Writing to the protected RTC registers is enabled by writing a key into the Write Protection
register, RTC_WPR.

The following steps are required to unlock the write protection on the protected RTC
registers.
1. Write 0xCA into the RTC_WPR register.
2. Write 0x53 into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the
prescaler configuration, the following sequence is required:
1. Set INIT bit to 1 in the RTC_ICSR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.

2. Poll INITF bit of in the RTC_ICSR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).

3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.

4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.

5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

**Note:** After a system reset, the application can read the INITS flag in the RTC_ICSR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ICSR register.

**Daylight saving time**

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

**Programming the alarm**

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for alarm A but can be translated in the same way for alarm B.

1. Clear ALRAE in RTC_CR to disable alarm A.
2. Program the alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).
3. Set ALRAE in the RTC_CR register to enable alarm A again.

**Note:** Each change of the RTC CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

**Programming the wakeup timer**

The following sequence is required to configure or change the wakeup timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wakeup timer.
2. Poll WUTWF until it is set in RTC_ICSR to make sure the access to wakeup auto-reload counter and to WUCKSEL[2:0] bits is allowed. This step must be skipped in calendar initialization mode. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wakeup auto-reload value WUT[15:0], and the wakeup clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again.
The wakeup timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clock cycles after WUTE is cleared, due to clock synchronization.

### 35.3.9 Reading the calendar

#### When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB1 clock frequency (fPCLK) must be equal to or greater than seven times the RTC clock frequency (fRTCCLK). This ensures a secure behavior of the synchronization mechanism.

If the APB1 clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB1 clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ICSR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCLK cycles. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK periods: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wakeup and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 1562): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to Section 35.3.11: RTC synchronization): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

#### When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (Stop or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.
Note: While BYPSHAD = 1, instructions which read the calendar registers require one extra APB cycle to complete.

35.3.10 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ICSR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the wakeup timer register (RTC_WUTR), and the alarm A and alarm B registers (RTC_ALRMASSR/RTC_ALRMAR and RTC_ALRMBSSR/RTC_ALRMBR).

In addition, when clocked by LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to RCC for details about RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

35.3.11 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

RTC_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of $1 / (PREDIV_S + 1)$ seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value ($PREDIV_S[14:0]$). The maximum resolution allowed (30.52 µs with a 32768 Hz clock) is obtained with $PREDIV_S$ set to 0x7FFF.

However, increasing $PREDIV_S$ means that $PREDIV_A$ must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of $1 / (PREDIV_S + 1)$ seconds. The shift operation consists of adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this will delay the clock. If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

Caution: Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.
Caution: This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON = 1.

35.3.12 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the asynchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:
- PREDIV_A = 0x007F
- PREDIV_S = 0x00FF

Note: RTC_REFIN clock detection is not available in Standby mode.

35.3.13 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about \(2^{20}\) RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, cal_cnt[19:0], clocked by RTCCLK.
The smooth calibration register (RTC_CALR) specifies the number of RTCCLK clock cycles to be masked during the calibration cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked.
- Setting CALM[2] to 1 causes four additional cycles to be masked.
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

Note: CALM[8:0] (RTC_CALR) specifies the number of RTCCLK pulses to be masked during the calibration cycle. Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the calibration cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1] = 1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2] = 1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8] = 1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to 1 effectively inserts an extra RTCCLK pulse every 211 RTCCLK cycles, which means that 512 clocks are added during every calibration cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the calibration cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (FCAL) given the input frequency (FRTCCLK) is as follows:

\[ FCAL = F_{RTCCLK} \times \left[ 1 + \frac{(CALP \times 512 - CALM)}{(2^{20} + CALM - CALP \times 512)} \right] \]

**Calibration when PREDIV_A < 3**

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV_A less than 3, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every calibration cycle. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each calibration cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

\[ FCAL = F_{RTCCLK} \times \left[ 1 + \frac{(256 - CALM)}{(2^{20} + CALM - 256)} \right] \]

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.
Verifying the RTC calibration

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16-second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC_CALR register can be set to 1 to force an 8-second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8 s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

Re-calibration on-the-fly

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ICSR/INITF = 0, by using the follow process:

1. Poll the RTC_ICSR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

35.3.14 Timestamp function

Timestamp is enabled by setting the TSE or ITSE bits of RTC_CR register to 1.

When TSE is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a timestamp event is detected on the RTC_TS pin.

When TAMPTS is set:

The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a tamper event is detected on the TAM_DP pin.x

When ITSE is set:
The calendar is saved in the timestamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal timestamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a timestamp event occurs, due to internal or external event, the timestamp flag bit (TSF) in RTC_SR register is set. In case the event is internal, the ITSF flag is also set in RTC_SR register.

By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a timestamp event occurs.

If a new timestamp event is detected while the timestamp flag (TSF) is already set, the timestamp overflow flag (TSOVF) flag is set and the timestamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

**Note:** TSF is set 2 ck_apre cycles after the timestamp event occurs due to synchronization process.

There is no delay in the setting of TSOVF. This means that if two timestamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

**Caution:** If a timestamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a timestamp event occurring at the same moment, the application must not write 0 into TSF bit unless it has already read it to 1.

Optionally, a tamper event can cause a timestamp to be recorded. See the description of the TAMPTS control bit in the RTC control register (RTC_CR).

### 35.3.15 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the CALIB frequency is fRTCCLK/64. This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the CALIB frequency is fRTCCLK/(256 * (PREDIV_A+1)). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = Ox7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz.

**Note:** When the CALIB output is selected, the RTC_OUT1 pin is automatically configured but the RTC_OUT2 pin must be set as alternate function.

When COSEL is cleared, the CALIB output is the output of the 6th stage of the asynchronous prescaler.

When COSEL is set, the CALIB output is the output of the 8th stage of the synchronous prescaler.

### 35.3.16 Tamper and alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output TAMPALRM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_SR register.
When the TAMPOE control bit is set in the RTC_CR, all external and internal tamper flags are ORed and routed to the TAMPALRM output. If OSEL = 00 the TAMPALRM output reflects only the tampers flags. If OSEL ≠ 00, the signal on TAMPALRM provides both tamper flags and alarm A, B, or wakeup flag.

The polarity of the TAMPALRM output is determined by the POL control bit in RTC_CR so that the opposite of the selected flags bit is output when POL is set to 1.

**TAMPALRM output**

The TAMPALRM pin can be configured in output open drain or output push-pull using the control bit TAMPALRM_TYPE in the RTC_CR register. It is possible to apply the internal pull-up in output mode thanks to TAMPALRM_PU in the RTC_CR.

*Note:* Once the TAMPALRM output is enabled, it has priority over CALIB on RTC_OUT1.

When TAMPALRM output is selected, the RTC_OUT1 pin is automatically configured but the RTC_OUT2 pin must be set as alternate function. In case the TAMPALRM is configured open-drain in the RTC, the RTC_OUT1 GPIO must be configured as input.

### 35.4 RTC low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect RTC interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC interrupts cause the device to exit the Standby mode.</td>
</tr>
<tr>
<td>Shutdown</td>
<td>The RTC remains active when the RTC clock source is LSE. RTC interrupts cause the device to exit the Shutdown mode.</td>
</tr>
</tbody>
</table>

The table below summarizes the RTC pins and functions capability in all modes.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. The event flags are in the RTC_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the RTC_MISR register.
3. Wakeup from Stop and Standby modes is possible only when the RTC clock source is LSE or LSI.
4. Wakeup from Shutdown modes is possible only when the RTC clock source is LSE.

35.6 RTC registers

Refer to Section 1.2 on page 73 of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

35.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 1562 and Reading the calendar on page 1564.

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset value: 0x0000 0000 (when BYPSHAD = 0, not affected when BYPSHAD = 1)

```
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |

35.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 1562 and Reading the calendar on page 1564.

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x04
Backup domain reset value: 0x0000 2101
System reset value: 0x0000 2101 (when BYPSHAD = 0, not affected when BYPSHAD = 1)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 SS[15:0]: Sub second value

SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:

Second fraction = (PREDIV_S - SS) / (PREDIV_S + 1)

Note: SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.

35.6.4 RTC initialization control and status register (RTC_ICSR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x0C
Backup domain reset value: 0x0000 0007
System reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx 000x xxxx (not affected, except INIT, INITF, and RSF bits which are cleared to 0)

</table>

Bits 17:16 Reserved, read only
Bits 31:17  Reserved, must be kept at reset value.

Bit 16 **RECALPF**: Recalibration pending Flag
The RECALPF status flag is automatically set to 1 when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to 0. Refer to Re-calibration on-the-fly.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7 **INIT**: Initialization mode
- 0: Free running mode
- 1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and prescaler register (RTC_PRER). Counters are stopped and start counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.
- 0: Calendar registers update is not allowed
- 1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag
This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF = 1), or when in bypass shadow register mode (BYPSHAD = 1). This bit can also be cleared by software.
 It is cleared either by software or by hardware in initialization mode.
- 0: Calendar shadow registers not yet synchronized
- 1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag
This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).
- 0: Calendar has not been initialized
- 1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending
This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.
- 0: No shift operation is pending
- 1: A shift operation is pending
35.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 1562.

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 PREDIV_A[6:0]: Asynchronous prescaler factor
This is the asynchronous division factor:
\[
\text{ck_apre frequency} = \frac{\text{RTCCLK frequency}}{(\text{PREDIV}_A+1)}
\]

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 PREDIV_S[14:0]: Synchronous prescaler factor
This is the synchronous division factor:
\[
\text{ck_spres frequency} = \frac{\text{ck_apre frequency}}{(\text{PREDIV}_S+1)}
\]
35.6.6 RTC wakeup timer register (RTC_WUTR)

This register can be written only when WUTWF is set to 1 in RTC_ICSR. This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x14
Backup domain reset value: 0x0000 FFFF
System reset: not affected

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | WUT[15:0]: Wakeup auto-reload value bits |

- When the wakeup timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.
- When WUCKSEL[2] = 1, the wakeup timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.
- The first assertion of WUTF occurs between WUT and (WUT + 1) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.

35.6.7 RTC control register (RTC_CR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x18
Backup domain reset value: 0x0000 0000
System reset: not affected

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | WUCKSEL[2:0]: Select the period of the wakeup timer. |

- The first assertion of WUTF occurs between WUT and (WUT + 1) ck_wut cycles after WUTE is set.
- Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.
Bit 31  **OUT2EN**: RTC_OUT2 output enable  
Setting this bit allows to remap the RTC outputs on RTC_OUT2 as follows:  
**OUT2EN = 0**: RTC output 2 disable  
If OSEL ≠ 00 or TAMPOE = 1: TAMPALRM is output on RTC_OUT1  
If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT1  
**OUT2EN = 1**: RTC output 2 enable  
If (OSEL ≠ 00 or TAMPOE = 1) and COE = 0: TAMPALRM is output on RTC_OUT2  
If OSEL = 00 and TAMPOE = 0 and COE = 1: CALIB is output on RTC_OUT2  
If (OSEL≠ 00 or TAMPOE = 1) and COE = 1: CALIB is output on RTC_OUT2 and TAMPALRM is output on RTC_OUT1.

Bit 30  **TAMPALRM_TYPE**: TAMPALRM output type  
0: TAMPALRM is push-pull output  
1: TAMPALRM is open-drain output

Bit 29  **TAMPALRM_PU**: TAMPALRM pull-up enable  
0: No pull-up is applied on TAMPALRM output  
1: A pull-up is applied on TAMPALRM output

Bits 28:27 Reserved, must be kept at reset value.

Bit 26  **TAMPOE**: Tamper detection output enable on TAMPALRM  
0: The tamper flag is not routed on TAMPALRM  
1: The tamper flag is routed on TAMPALRM, combined with the signal provided by OSEL and with the polarity provided by POL.

Bit 25  **TAMPTS**: Activate timestamp on tamper detection event  
0: Tamper detection event does not cause a RTC timestamp to be saved  
1: Save RTC timestamp on tamper detection event  
TAMPTS is valid even if TSE = 0 in the RTC_CR register. Timestamp flag is set after the tamper flags, therefore if TAMPTS and TSIE are set, it is recommended to disable the tamper interrupts in order to avoid servicing 2 interrupts.

Bit 24  **ITSE**: timestamp on internal event enable  
0: internal event timestamp disabled  
1: internal event timestamp enabled

Bit 23  **COE**: Calibration output enable  
This bit enables the CALIB output  
0: Calibration output disabled  
1: Calibration output enabled

Bits 22:21  **OSEL[1:0]**: Output selection  
These bits are used to select the flag to be routed to TAMPALRM output.  
00: Output disabled  
01: Alarm A output enabled  
10: Alarm B output enabled  
11: Wakeup output enabled

Bit 20  **POL**: Output polarity  
This bit is used to configure the polarity of TAMPALRM output.  
0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).  
1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]), or when a TAMPxF/ITAMPxF is asserted (if TAMPOE = 1).
Bit 19 **COSEL**: Calibration output selection
When COE = 1, this bit selects which signal is output on CALIB.
0: Calibration output is 512 Hz
1: Calibration output is 1 Hz
These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A = 127 and PREDIV_S = 255). Refer to Section 35.3.15: Calibration clock output.

Bit 18 **BKP**: Backup
This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 **SUB1H**: Subtract 1 hour (winter time change)
When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change.

Bit 16 **ADD1H**: Add 1 hour (summer time change)
When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0.
0: No effect
1: Adds 1 hour to the current time. This can be used for summer time change.

Bit 15 **TSIE**: Timestamp interrupt enable
0: Timestamp interrupt disable
1: Timestamp interrupt enable

Bit 14 **WUTIE**: Wakeup timer interrupt enable
0: Wakeup timer interrupt disabled
1: Wakeup timer interrupt enabled

Note: When the wakeup timer is disabled, wait for WUTF = 1 before enabling it again.

Bit 13 **ALRBIE**: Alarm B interrupt enable
0: Alarm B interrupt disable
1: Alarm B interrupt enable

Bit 12 **ALRAIE**: Alarm A interrupt enable
0: Alarm A interrupt disabled
1: Alarm A interrupt enabled

Bit 11 **TSE**: Timestamp enable
0: timestamp disable
1: timestamp enable

Bit 10 **WUTE**: Wakeup timer enable
0: Wakeup timer disabled
1: Wakeup timer enabled

Bit 9 **ALRBE**: Alarm B enable
0: Alarm B disabled
1: Alarm B enabled

Bit 8 **ALRAE**: Alarm A enable
0: Alarm A disabled
1: Alarm A enabled

Bit 7 Reserved, must be kept at reset value.
Bit 6 **FMT**: Hour format
0: 24 hour/day format
1: AM/PM hour format

Bit 5 **BYPShad**: Bypass the shadow registers
0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.
1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.

*Note: If the frequency of the APB1 clock is less than seven times the frequency of RTCCLK, BYPShad must be set to 1.*

Bit 4 **REFCKON**: RTC_REFIN reference clock detection enable (50 or 60 Hz)
0: RTC_REFIN detection disabled
1: RTC_REFIN detection enabled

*Note: PREDIV_S must be 0x00FF.*

Bit 3 **TSEdge**: Timestamp event active edge
0: RTC_TS input rising edge generates a timestamp event
1: RTC_TS input falling edge generates a timestamp event

TSE must be reset when TSEedge is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSel[2:0]**: ck_wut wakeup clock selection
000: RTC/16 clock is selected
001: RTC/8 clock is selected
010: RTC/4 clock is selected
011: RTC/2 clock is selected
10x: ck_spRE (usually 1 Hz) clock is selected
11x: ck_spRE (usually 1 Hz) clock is selected and 2^16 is added to the WUT counter value

*Note: Bits 6 and 4 of this register can be written in initialization mode only (RTC_ICSR/INITF = 1). WUT = wakeup unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSel[2:1 = 11].

Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ICSR WUTWF bit = 1.

It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.

ADD1H and SUB1H changes are effective in the next second.

### 35.6.8 RTC write protection register (RTC_WPR)

Address offset: 0x24

Reset value: 0x0000 0000
35.6.9 RTC calibration register (RTC_CALR)

This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x28
Backup domain reset value: 0x0000 0000
System reset: not affected

<table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 CALP: Increase frequency of RTC by 488.5 ppm
0: No RTCCCLK pulses are added.
1: One RTCCCLK pulse is effectively inserted every $2^{11}$ pulses (frequency increased by 488.5 ppm).
This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCCLK pulses added during a 32-second window is calculated as follows: $(512 \times \text{CALP}) - \text{CALM}$.
Refer to Section 35.3.13: RTC smooth digital calibration.

Bit 14 CALW8: Use an 8-second calibration cycle period
When CALW8 is set to 1, the 8-second calibration cycle period is selected.

Note: CALM[1:0] are stuck at 00 when CALW8 = 1. Refer to Section 35.3.13: RTC smooth digital calibration.
Bit 13 CALW16: Use a 16-second calibration cycle period
When CALW16 is set to 1, the 16-second calibration cycle period is selected. This bit must not be set to 1 if CALW8 = 1.

Note: CALM[0] is stuck at 0 when CALW16 = 1. Refer to Section 35.3.13: RTC smooth digital calibration.

Bits 12:9 Reserved, must be kept at reset value.

Bits 8:0 CALM[8:0]: Calibration minus
The frequency of the calendar is reduced by masking CALM out of $2^{20}$ RTCCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See Section 35.3.13: RTC smooth digital calibration on page 1566.

35.6.10 RTC shift control register (RTC_SHIFTR)
This register is write protected. The write access procedure is described in RTC register write protection on page 1562.

Address offset: 0x2C
Backup domain reset value: 0x0000 0000
System reset: not affected

Bit 31 ADD1S: Add one second
0: No effect
1: Add one second to the clock/calendar
This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).
This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 SUBFS[14:0]: Subtract a fraction of a second
These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF = 1, in RTC_ICSR).
The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

$$\text{Delay (seconds)} = \text{SUBFS} / (\text{PREDIV}_S + 1)$$

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

$$\text{Advance (seconds)} = (1 - (\text{SUBFS} / (\text{PREDIV}_S + 1)))$$

Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF = 1 to be sure that the shadow registers have been updated with the shifted time.
### 35.6.11 RTC timestamp time register (RTC_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC_SR. It is cleared when TSF bit is reset.

**Address offset:** 0x30

**Backup domain reset value:** 0x0000 0000

**System reset:** not affected

35.6.17  RTC alarm B sub second register (RTC_ALRMBSSR)

This register can be written only when ALRBE is reset in RTC_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in Section : RTC register write protection.

Address offset: 0x4C
Backup domain reset value: 0x0000 0000
System reset: not affected

<table>

</table>

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  MASKSS[3:0]: Mask the most-significant bits starting at this bit
0x0: No comparison on sub seconds for alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).
0x1: SS[14:1] are don’t care in alarm B comparison. Only SS[0] is compared.
0x2: SS[14:2] are don’t care in alarm B comparison. Only SS[1:0] are compared.
0x3: SS[14:3] are don’t care in alarm B comparison. Only SS[2:0] are compared.
... 0xC: SS[14:12] are don’t care in alarm B comparison. SS[11:0] are compared.
0xD: SS[14:13] are don’t care in alarm B comparison. SS[12:0] are compared.
0xE: SS[14] is don’t care in alarm B comparison. SS[13:0] are compared.
0xF: All 15 SS bits are compared and must match to activate alarm.
The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15  Reserved, must be kept at reset value.

Bits 14:0  SS[14:0]: Sub seconds value
This value is compared with the contents of the synchronous prescaler counter to determine if alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.

35.6.18  RTC status register (RTC_SR)

Address offset: 0x50
Backup domain reset value: 0x0000 0000
System reset: not affected
Note: The bits of this register are cleared few APB clock cycles after setting their corresponding clear bit in the RTC_SCR register. After clearing the flag, read it until it is read at 0 before leaving the interrupt routine.

35.6.19 RTC masked interrupt status register (RTC_MISR)

Address offset: 0x54
Backup domain reset value: 0x0000 0000
System reset: not affected
Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **ITSMF**: Internal timestamp masked flag
This flag is set by hardware when a timestamp on the internal event occurs and
timestamp interrupt is raised.

Bit 4 **TSOVMF**: Timestamp overflow masked flag
This flag is set by hardware when a timestamp interrupt occurs while TSMF is already set.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise,
an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit
is cleared.

Bit 3 **TSMF**: Timestamp masked flag
This flag is set by hardware when a timestamp interrupt occurs.
If ITSF flag is set, TSF must be cleared together with ITSF.

Bit 2 **WUTMF**: Wakeup timer masked flag
This flag is set by hardware when the wakeup timer interrupt occurs.
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1
again.

Bit 1 **ALRBMF**: Alarm B masked flag
This flag is set by hardware when the alarm B interrupt occurs.

Bit 0 **ALRAMF**: Alarm A masked flag
This flag is set by hardware when the alarm A interrupt occurs.

**Note:** The bits of this register are cleared few APB clock cycles after setting their corresponding
clear bit in the RTC_SCR register. After clearing the flag, read it until it is read at 0 before
leaving the interrupt routine.

### 35.6.20 RTC status clear register (RTC_SCR)

Address offset: 0x5C

Backup domain reset value: 0x0000 0000

System reset: not affected

</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CITSF**: Clear internal timestamp flag
Writing 1 in this bit clears the ITSF bit in the RTC_SR register.

Bit 4 **CTSOVF**: Clear timestamp overflow flag
Writing 1 in this bit clears the TSOVF bit in the RTC_SR register.
It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise,
an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit
is cleared.
Bit 3  **CTSF**: Clear timestamp flag
       Writing 1 in this bit clears the TSOVF bit in the RTC_SR register.
       If ITSF flag is set, TSF must be cleared together with ITSF by setting CRSF and CITSF.

Bit 2  **CWUTF**: Clear wakeup timer flag
       Writing 1 in this bit clears the WUTF bit in the RTC_SR register.

Bit 1  **CALRBF**: Clear alarm B flag
       Writing 1 in this bit clears the ALRBF bit in the RTC_SR register.

Bit 0  **CALRAF**: Clear alarm A flag
       Writing 1 in this bit clears the ALRAF bit in the RTC_SR register.

Refer to Section 2.2 on page 81 for the register boundary addresses.
36 Tamper and backup registers (TAMP)

36.1 Introduction

32 (category 3 and category 4 devices) or 16 (category 2 devices) 32-bit backup registers are retained in all low-power modes and also in V_{BAT} mode. They can be used to store sensitive data as their content is protected by an tamper detection circuit. 3 tamper pins and 4 internal tampers are available for anti-tamper detection. The external tamper pins can be configured for edge detection, or level detection with or without filtering.

36.2 TAMP main features

- 32 (category 3 and category 4 devices) or 16 (category 2 devices) backup registers:
  - the backup registers (TAMP_BKPxR) are implemented in the RTC domain that remains powered-on by V_{BAT} when the V_{DD} power is switched off.
- 3 external tamper detection events.
  - External passive tampers with configurable filter and internal pull-up.
- 4 internal tamper events.
- Any tamper detection can generate a RTC timestamp event.
- Any tamper detection can erase the backup registers.
36.3 TAMP functional description

36.3.1 TAMP block diagram

Figure 530. TAMP block diagram

1. The number of external and internal tampers depends on products.

<td>Tamper detection trigger</td>
</tr>
</tbody>
</table>

The TAMP kernel clock is usually the LSE at 32.768 kHz although it is possible to select other clock sources in the RCC (refer to RCC for more details). Some detections modes are not available in some low-power modes or V_{BAT} when the selected clock is not LSE (refer to Section 36.4: TAMP low-power modes for more details).

</table>

36.3.3 TAMP register write protection

After system reset, the TAMP registers (including backup registers) are protected against parasitic write access by the DBP bit in the power control peripheral (refer to the PWR power control section). DBP bit must be set in order to enable TAMP registers write access.
36.3.4 Tamper detection

The tamper detection can be configured for the following purposes:
- erase the backup registers (default configuration)
- generate an interrupt, capable to wakeup from Stop and Standby mode
- generate a hardware trigger for the low-power timers

TAMP backup registers

The backup registers (TAMP_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs except if the TAMPxNOER bit is set, or if the TAMPxMSK is set in the TAMP_CR2 register.

Note: The backup registers are also erased when the readout protection of the flash is changed from level 1 to level 0.

Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the TAMP_CR register.

Each TAMP_INx tamper detection input is associated with a flag TAMPxF in the TAMP_SR register.

When TAMPxMSK is cleared:
- The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:
  - 3 ck_apre cycles when TAMPFLT differs from 0x0 (level detection with filtering)
  - 3 ck_apre cycles when TAMPTS = 1 (timestamp on tamper event)
  - No latency when TAMPFLT = 0x0 (edge detection) and TAMPTS = 0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

When TAMPxMSK is set:
- A new tamper occurring on the same pin cannot be detected during the latency described above and 2.5 ck_rtc additional cycles.

By setting the TAMPxE bit in the TAMP_IER register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPxE is not allowed when the corresponding TAMPxMSK is set.

Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMSK bit in cleared in TAMP_CR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMSK bit is set, the TAMPxF flag is masked, and kept cleared in TAMP_SR register. This configuration allows to trig automatically the low-power timers in Stop mode, without requiring the system wakeup to perform the TAMPxF clearing. In this case, the backup registers are not cleared.
This feature is available only when the tamper is configured in the Level detection with filtering on tamper inputs (passive mode) mode (TAMPFLT ≠ 00 and active mode is not selected).

**Timestamp on tamper event**

With TAMPTS set to 1 in the RTC_CR, any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit is set in RTC_SR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set in the TAMP_SR at the same time that TSF or TSOVF is set in the RTC_SR.

**Edge detection on tamper inputs (passive mode)**

If the TAMPFLT bits are 00, the TAMP_INx pins generate tamper detection events when either a rising edge/high level or a falling edge/low level is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMP_INx inputs are deactivated when edge detection is selected.

**Caution:** When using the edge detection, it is recommended to check by software the tamper pin level just after enabling the tamper detection (by reading the GPIO registers), and before writing sensitive values in the backup registers, to ensure that an active edge did not occur before enabling the tamper event detection.

When TAMPFLT = 00 and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the TAMP_INx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (TAMP_BKPxR). This prevents the application from writing to the backup registers while the TAMP_INx input value still indicates a tamper detection. This is equivalent to a level detection on the TAMP_INx input.

**Note:** Tamper detection is still active when VDD power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPx is mapped should be externally tied to the correct level.

**Level detection with filtering on tamper inputs (passive mode)**

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The TAMP_INx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the TAMP_INx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

**Note:** Refer to the datasheet for the electrical characteristics of the pull-up resistors.
36.4 TAMP low-power modes

Table 342. Effect of low-power modes on TAMP

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. TAMP interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on all features, except for level detection with filtering mode which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>No effect on all features, except for level detection with filtering mode which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.</td>
</tr>
<tr>
<td>Shutdown</td>
<td>No effect on all features, except for level detection with filtering mode which remain active only when the clock source is LSE. Tamper events cause the device to exit the Shutdown mode.</td>
</tr>
</tbody>
</table>

36.5 TAMP interrupts

The interrupt channel is set in the interrupt status register. The interrupt output is also activated.

Table 343. Interrupt requests

</tbody>
</table>

1. The event flags are in the TAMP_SR register.
2. The interrupt masked flags (resulting from event flags AND enable control bits) are in the TAMP_MISR register.
3. The number of tampers and internal tampers events depend on products.
4. In case of level detection with filtering passive tamper mode, wakeup from Stop and Standby modes is possible only when the TAMPER clock source is LSE or LSI.
5. In case of level detection with filtering passive tamper mode, wakeup from Shutdown modes is possible only when the TAMPER clock source is LSE.

36.6 TAMP registers

Refer to Section 1.2 on page 73 of the reference manual for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by words (32-bit).

Bits 31:27 Reserved, must be kept at reset value.

- **Bit 26 TAMP3TRG**: Active level for tamper 3 input (active mode disabled)
  0: If TAMPFLT ≠ 00 Tamper 3 input staying low triggers a tamper detection event.
  1: If TAMPFLT = 00 Tamper 3 input staying high triggers a tamper detection event.

- **Bit 25 TAMP2TRG**: Active level for tamper 2 input (active mode disabled)
  0: If TAMPFLT ≠ 00 Tamper 2 input staying low triggers a tamper detection event.
  1: If TAMPFLT = 00 Tamper 2 input staying high triggers a tamper detection event.

- **Bit 24 TAMP1TRG**: Active level for tamper 1 input (active mode disabled)
  0: If TAMPFLT ≠ 00 Tamper 1 input staying low triggers a tamper detection event.
  1: If TAMPFLT = 00 Tamper 1 input staying high triggers a tamper detection event.
Bit 23 Reserved, must be kept at reset value.

Bits 22:19 Reserved, must be kept at reset value.

Bit 18 **TAMP3MSK**: Tamper 3 mask

0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.
1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers are not erased.

*The tamper 3 interrupt must not be enabled when TAMP3MSK is set.*

Bit 17 **TAMP2MSK**: Tamper 2 mask

0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.
1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers are not erased.

*The tamper 2 interrupt must not be enabled when TAMP2MSK is set.*

Bit 16 **TAMP1MSK**: Tamper 1 mask

0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.
1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers are not erased.

*The tamper 1 interrupt must not be enabled when TAMP1MSK is set.*

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **TAMP3NOER**: Tamper 3 no erase

0: Tamper 3 event erases the backup registers.
1: Tamper 3 event does not erase the backup registers.

Bit 1 **TAMP2NOER**: Tamper 2 no erase

0: Tamper 2 event erases the backup registers.
1: Tamper 2 event does not erase the backup registers.

Bit 0 **TAMP1NOER**: Tamper 1 no erase

0: Tamper 1 event erases the backup registers.
1: Tamper 1 event does not erase the backup registers.

Bits 31:0  **BKP[31:0]**

The application can write or read data to and from these registers.
They are powered-on by VBAT when VDD is switched off, so that they are not reset by System reset, and their contents remain valid when the device operates in low-power mode.
In the default configuration this register is reset on a tamper detection event. It is forced to reset value as long as there is at least one internal or external tamper flag being set. This register is also reset when the readout protection (RDP) is disabled.

37 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART).

37.1 USART introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and half-duplex single-wire communications, as well as LIN (local interconnection network), smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.
37.2 **USART main features**

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data
  
  Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous master/slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Interrupt sources with flags
- Multiprocessor communications: wake-up from mute mode by idle line detection or address mark detection
- Wake-up from Stop mode
37.3 **USART extended features**

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
  - Supports the \( T = 0 \) and \( T = 1 \) asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for smartcard operation
- Support for Modbus communication
  - Timeout feature
  - CR/LF character recognition

37.4 **USART implementation**

The table(s) below describe(s) USART implementation. It(they) also include(s) LPUART for comparison.

37.5 USART functional description

37.5.1 USART block diagram

The simplified block diagram given in Figure 531 shows two fully-independent clock domains:

- The **usart_pclk** clock domain
  
  The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.

- The **usart_ker_ck** kernel clock domain.
  
  The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.

  When the dual clock domain feature is disabled, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**: **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external CK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.
37.5.2 USART signals

USART bidirectional communications

USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX** (Receive Data Input)
  RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.

- **TX** (Transmit Data Output)
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In single-wire and smartcard modes, this I/O is used to transmit and receive data.

RS232 hardware flow control mode

The following pins are required in RS232 hardware flow control mode:

- **CTS** (Clear To Send)
  When driven high, this signal blocks the data transmission at the end of the current transfer.

- **RTS** (Request To Send)
  When it is low, this signal indicates that the USART is ready to receive data.

RS485 hardware flow control mode

The following pin is required in RS485 hardware control mode:

- **DE** (Driver Enable)
  This signal activates the transmission mode of the external transceiver.

*Note:* DE and RTS share the same pin.

Synchronous master/slave mode and smartcard mode

The following pin is required in synchronous master/slave mode and smartcard mode:

- **CK**
  This pin acts as Clock output in synchronous master and smartcard modes. It acts as Clock input is synchronous slave mode.
  In synchronous master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable.
  In smartcard mode, CK output provides the clock to the smartcard.

- **NSS**
  This pin acts as slave Select input in synchronous slave mode.

Refer to Table 346 and Table 347 for the list of USART input/output pins and internal signals.

2. UART_DE and UART_RTS share the same pin.
3. USART_NSS and USART_CTS share the same pin.

### 37.5.3 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see Figure 532):

- 7-bit character length: M[1:0] = ‘10’
- 8-bit character length: M[1:0] = ‘00’
- 9-bit character length: M[1:0] = ‘01’

Note: In 7-bit data length mode, the smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An *Idle character* is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).
A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.

**LBCL bit controls last data clock pulse**
37.5.4 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:

- The RXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields. This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.
  RXFTCFG data have been received: one data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101’, the RXFT flag is set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data is not set the overrun flag.

- The TXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields. This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

37.5.5 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.
Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.

**Note:** The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost. An idle frame is sent when the TE bit is enabled.

**Configurable stop bits**

The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13, 12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 stop bits:** This is supported by normal USART, single-wire and modem modes.
- **1.5 stop bits:** To be used in smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission features 10 low bits (when M[1:0] = ‘00’) or 11 low bits (when M[1:0] = ‘01’) or 9 low bits (when M[1:0] = ‘10’) followed by 2 stop bits (see Figure 533). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 533. Configurable stop bits**
Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in Section 37.5.19: Continuous communication using USART and DMA.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the USART_TDR register, wait until TC = 1.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.
Single byte communication

- When FIFO mode is disabled
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
  - the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data.
  This flag generates an interrupt if the TXEIE bit is set.

  When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.

  When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.

  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFIE bit is set.

  Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.

  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

  After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the device to enter the low-power mode (see Figure 534: TC/TXE behavior when transmitting).
Figure 534. TC/TXE behavior when transmitting

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see Figure 532).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

37.5.6 USART receiver

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0 X 0X 0.
Figure 535. Start bit detection when oversampling by 16 or 8

<table>
<thead>
<tr>
<th>RX state</th>
<th>Idle</th>
<th>Start bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RX line</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ideal sample clock</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Conditions to validate the start bit</td>
<td>1 1 0 X X X 0 0 0 X X X X</td>
<td></td>
</tr>
</tbody>
</table>

Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE = 1, or RXFNE flag set and interrupt generated if RXFNEIE = 1 if FIFO mode enabled) if the 3 sampled bits are at '0' (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at '0' and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at '0').

The start bit is validated but the NE noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at '0' (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)

or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at '0'.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).
Character reception

During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure

To receive a character, follow the sequence below:
1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to ‘1’.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 37.5.19: Continuous communication using USART and DMA.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:
- When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
- The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
- In multibuffer communication mode:
  – When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  – When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
- In single buffer mode:
  – When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to ‘1’ in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  – When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to ‘1’ in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be
generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  An overrun error occurs if a character is received and RXNE has not been reset.
  Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte reception.
  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available by reading the USART_RDR register.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE or the EIE bit is set.

- **FIFO mode enabled**
  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full.
  Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.
  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - The ORE bit is set.
  - The first entry in the RXFIFO is not lost. It is available by reading the USART_RDR register.
  - The shift register is overwritten. After that point, any data received during overrun is lost.
  - An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USART_ICR register.

*Note:* The ORE bit, when set, indicates that at least 1 data has been lost.

When the FIFO mode is disabled, there are two possibilities

- if RXNE = 1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE = 0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.
Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see Section Reset and clock control (RCC)). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:
- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is uart_ker_ck.

When the dual clock domain and the wake-up from low-power mode features are supported, the uart_ker_ck clock source can be configurable in the RCC (see Section Reset and clock control (RCC)). Otherwise the uart_ker_ck clock is the same as uart_pclk.

The uart_ker_ck clock can be divided by a programmable factor, defined in the USART_PRESC register.

Some uart_ker_ck sources enable the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to enable USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise. This enables obtaining the best a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register either to 16 or 8 times the baud rate clock (see Figure 537 and Figure 538).

Depending on your application:
- select oversampling by 8 (OVER8 = 1) to achieve higher speed (up to usart_ker_ck_pres/8). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 37.5.8: Tolerance of the USART receiver to clock deviation on page 1627)
- select oversampling by 16 (OVER8 = 0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum
Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. Two options are available:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.
- A single sample in the center of the received bit

Depending on your application:
- select the three sample majority vote method (ONEBIT = 0) when operating in a noisy environment and reject the data when a noise is detected (refer to Figure 348) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT = 1) when the line is noise-free to increase the receiver tolerance to clock deviations (see Section 37.5.8: Tolerance of the USART receiver to clock deviation on page 1627). In this case the NE bit is never set.

When noise is detected in a frame:
- The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NE bit is reset by setting NECF bit in USART_ICR register.

Note: Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to ‘0’ by hardware.

Figure 537. Data sampling when oversampling by 16
Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled);
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing ‘1’ to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in normal mode and 0.5 or 1.5 in smartcard mode.

- **0.5 stop bit (reception in smartcard mode):** no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (smartcard mode):**
  
  When transmitting in smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE = 1 in USART_CR1) and the stop bit is checked to test if the smartcard has detected a parity error.

  In the event of a parity error, the smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to Section 37.5.16: USART receiver timeout on page 1641 for more details).

- **2 stop bits:**
  
  Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. The framing error flag is set if a framing error is detected during the first stop bit. The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.

### 37.5.7 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

**Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = ‘0’ or ‘1’)**

In case of oversampling by 16, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ckpres}}{\text{USARTDIV}}
\]

In case of oversampling by 8, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{2 \times \text{usart_ker_ckpres}}{\text{USARTDIV}}
\]

**Equation 2: baud rate in smartcard, LIN and IrDA modes (OVER8 = 0)**

The baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ckpres}}{\text{USARTDIV}}
\]
USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When $\text{OVER8} = 0$, $\text{BRR} = \text{USARTDIV}$.
- When $\text{OVER8} = 1$
  - $\text{BRR}[2:0] = \text{USARTDIV}[3:0]$ shifted 1 bit to the right.
  - $\text{BRR}[3]$ must be kept cleared.
  - $\text{BRR}[15:4] = \text{USARTDIV}[15:4]$

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value should not be changed during communication.

*In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.*

### How to derive USARTDIV from USART_BRR register values

#### Example 1

To obtain 9600 baud with $\text{usart_ker_ck_pres} = 8 \text{ MHz}$:

- In case of oversampling by 16:
  
  USARTDIV = $\frac{8 \times 000 \times 000}{9600}$
  
  $\text{BRR} = \text{USARTDIV} = 0d833 = 0x0341$

- In case of oversampling by 8:
  
  USARTDIV = $2 \times \frac{8 \times 000 \times 000}{9600}$
  
  USARTDIV = 1666,66 (0d1667 = 0x683)
  
  $\text{BRR}[3:0] = 0x3 >> 1 = 0x1$
  
  $\text{BRR} = 0x681$

#### Example 2

To obtain 921.6 Kbaud with $\text{usart_ker_ck_pres} = 48 \text{ MHz}$:

- In case of oversampling by 16:
  
  USARTDIV = $\frac{48 \times 000 \times 000}{921 \times 600}$
  
  USARTDIV = 52 (0d52 = 0x34)
  
  $\text{BRR}[3:0] = \text{USARTDIV}[3:0] >> 1 = 0x1$
  
  $\text{BRR} = 0x681$

- In case of oversampling by 8:
  
  USARTDIV = $2 \times \frac{48 \times 000 \times 000}{921 \times 600}$
  
  USARTDIV = 104 (0d104 = 0x68)
  
  BRR[3:0] = USARTDIV[3:0] >> 1 = 0x8 >> 1 = 0x4
  
  $\text{BRR} = 0x64$

### 37.5.8 Tolerance of the USART receiver to clock deviation

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.
The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
\text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{USART receiver tolerance}
\]

where

\[
\text{DWU} = \frac{t_{\text{WUUSART}}}{\text{M[1:0]} \times \text{Tbit}}
\]

- when \( \text{M[1:0]} = 01 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{11 \times \text{Tbit}}
  \]
- when \( \text{M[1:0]} = 00 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{10 \times \text{Tbit}}
  \]
- when \( \text{M[1:0]} = 10 \):
  \[
  \text{DWU} = \frac{t_{\text{WUUSART}}}{9 \times \text{Tbit}}
  \]

\( t_{\text{WUUSART}} \) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 349, Table 350, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.

**Table 349. Tolerance of the USART receiver when BRR [3:0] = 0000**

<table>
<thead>
<tr>
<th>M bits</th>

</table>

Note: The data specified in Table 349 and Table 350 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M = 01 or 9-bit times when M = 10).

37.5.9 USART auto baud rate detection

The USART can detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism enables the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.

- When oversampling by 16, the baud rate ranges from \( \frac{\text{usart_ker_ck_pres}}{65535} \) and \( \frac{\text{usart_ker_ck_pres}}{16} \).
- When oversampling by 8, the baud rate ranges from \( \frac{\text{usart_ker_ck_pres}}{65535} \) and \( \frac{\text{usart_ker_ck_pres}}{8} \).

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.
These modes are the following:

- **Mode 0**: Any character starting with a bit at ‘1’.
  In this case the USART measures the duration of the start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern.
  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit0 to bit6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame.
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a ‘0’).

When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection should be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

**Note:** The BRR value might be corrupted if the USART is disabled (UE = 0) during an auto baud rate operation.
37.5.10 USART multiprocessor communication

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in mute mode by means of the muting function. To use the mute mode feature, the MME bit must be set in the USART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart_ker_ck cycles), otherwise mute mode might remain active.

When the mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

Idle line detection (WAKE = 0)

The USART enters mute mode when the MMRQ bit is written to ‘1’ and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of mute mode behavior using Idle line detection is given in Figure 539.
If the MMRQ is set while the IDLE character has already elapsed, mute mode is not entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE = 1)

In this mode, bytes are recognized as addresses if their MSB is a ‘1’, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters mute mode. When FIFO management is enabled, the software should ensure that there is at least one empty location in the RXFIFO before entering mute mode.

The USART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in mute mode

An example of mute mode behavior using address mark detection is given in Figure 540.
37.5.11 **USART Modbus communication**

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

**Modbus/RTU**

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

**Modbus/ASCII**

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE = 1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.
37.5.12 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 351.

### Table 351. USART frame formats

</tr>
</tbody>
</table>

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data = 00110101 and 4 bits are set, the parity bit is equal to 0 if even parity is selected (PS bit in USART_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data = 00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in USART_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

#### Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS = 0) or an odd number of “1s” if odd parity is selected (PS=1).
37.5.13 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Refer to Section 37.4: USART implementation on page 1610.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:
- STOP[1:0] and CLKEN in the USART_CR2 register,
- SCEN, HDSEL and IREN in the USART_CR3 register.

LIN transmission

The procedure described in Section 37.5.4 has to be applied for LIN master transmission. It must be the same as for normal USART transmission with the following differences:
- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 ‘0’ bits as a break character. Then two bits of value ‘1’ are sent to enable the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE = 1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL = 1 in USART_CR2) consecutive bits are detected as ‘0’, and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit = 1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1’ is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN = 0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN = 1), as soon as a framing error occurs (i.e. stop bit detected at ‘0’, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1’, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 541: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 1636.

Examples of break frames are given on Figure 542: Break detection in LIN mode vs. Framing error detection on page 1637.

37.5.14 USART synchronous mode

Master mode

The synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to ‘1’. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 543, Figure 544 and Figure 545).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous master mode, the USART transmitter operates exactly like in asynchronous mode. However, since CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In synchronous master mode, the USART receiver operates in a different way compared to asynchronous mode. If RE is set to 1, the data are sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).
Note: In master mode, the CK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE = 1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

Figure 543. USART example of synchronous master transmission

Figure 544. USART data clock timing diagram in synchronous master mode (M bits = 00)

*LBCL bit controls last data pulse
Slave mode

The synchronous slave mode is selected by programming the SLVEN bit in the USART_CR2 register to ‘1’. In synchronous slave mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in slave mode. The CK pin is the input of the USART in slave mode.

**Note:** When the peripheral is used in SPI slave mode, the frequency of peripheral clock source (usart_ker_ck_pres) must be greater than 3 times the CK input frequency.

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock polarity and the phase of the external clock, respectively (see Figure 546).

An underrun error flag is available in slave transmission mode. This flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value to USART_TDR.

The slave supports the hardware and software NSS management.
Slave select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- Software NSS management (DIS_NSS = 1)
  - The SPI slave is always selected and NSS input pin is ignored.
  - The external NSS pin remains free for other application uses.
- Hardware NSS management (DIS_NSS = 0)
  - The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

**Note:** The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE = 0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master.

The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave transmits zeros.

**SPI slave underrun error**

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.
In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error enables sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

**Note:** An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first CK transmission edge. To avoid this underrun error, the USART_TDR should be written 3 usart_ker_ck cycles before the first CK edge.

### 37.5.15 USART single-wire half-duplex communication

Single-wire half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to ‘1’:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

### 37.5.16 USART receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if STOP = ‘00’ or STOP = ‘11’
- from the end of the second stop bit if STOP = ‘10’.
- from the beginning of the stop bit if STOP = ‘01’.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout is generated if RTOIE bit in USART_CR1 register is set.
37.5.17  USART smartcard mode

This section is relevant only when smartcard mode is supported. Refer to Section 37.4: USART implementation on page 1610.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the smartcard.

The smartcard interface is designed to support asynchronous smartcard protocol as defined in the ISO 7816-3 standard. Both \( T = 0 \) (character mode) and \( T = 1 \) (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: \( M = 1 \) and \( PCE = 1 \) in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: \( STOP = '11' \) in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In \( T = 0 \) (character) mode, the parity error is indicated at the end of each character during the guard time period.

*Figure 547* shows examples of what can be seen on the data line with and without parity error.

*Figure 547. ISO 7816-3 asynchronous protocol*

When connected to a smartcard, the TX output of the USART drives a bidirectional line that is also driven by the smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.
The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T = 1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled)/receive DMA request is not activated. According to the protocol specification, the smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bitfield, the USART stops transmitting the NACK and signals the error as a parity error.

- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn’t repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.

- The deassertion of TC flag is unaffected by smartcard mode.

- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

*Note:* Break characters are not significant in smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

*Figure 548* shows how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.
The USART can provide a clock to the smartcard through the CK output. In smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the USART_GTPR register. CK frequency can be programmed from usart_ker_ck_pres/2 to usart_ker_ck_pres/62, where usart_ker_ck_pres is the peripheral input clock divided by a programmed prescaler.

### Block mode (T = 1)

In T = 1 (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the USART_CR3 register.

When requesting a read from the smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt is generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

**Note:** The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time -11 value), in order to enable the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baud time units. If the smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals it to the software through the RTOF flag and interrupt (when RTOIE bit is set).

**Note:** As in the smartcard protocol definition, the BWT/CWT values should be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT -11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value.
With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN = LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN = LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN = LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN = LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character Wait Time overflow).

**Note:** The error checking code (LRC/CRC) must be computed/verified by software.

**Direct and inverse convention**

The smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST = 0, DATAINV = 0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST = 1, DATAINV = 1.

**Note:** When logical data values are inverted (0 = H, 1 = L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to ‘3F’.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to ‘3B’.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, assuming that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH results in a USART received character of 03 and an odd parity.
Therefore, two methods are available for TS pattern recognition:

**Method 1**
The USART is programmed in standard smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART.

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**
The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

- (H) LHHL LLL LLH = 0x103: inverse convention to be chosen
- (H) LHHL HHH LLH = 0x13B: direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

**37.5.18 USART IrDA SIR ENDEC block**

This section is relevant only when IrDA mode is supported. Refer to *Section 37.4: USART implementation on page 1610.*

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see *Figure 549*).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 kbaud for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not
encoded. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.

- A ‘0’ is transmitted as a high pulse and a ‘1’ is transmitted as a ‘0’. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see Figure 550).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than two periods are accepted as a pulse. The IrDA encoder/decoder doesn’t work when PSC = 0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the stop bits in the USART_CR2 register must be configured to ‘1 stop bit’.

**IrDA low-power mode**

- **Transmitter**
  In low-power mode, the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC < 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.
- **Receiver**
  Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART_GTPR).

**Note:** A pulse of width less than two and greater than one PSC period(s) may or may not be rejected. The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).

Figure 550. IrDA data modulation (3/16) - normal mode
37.5.19 Continuous communication using USART and DMA

The USART is capable of performing continuous communications using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

**Note:** Refer to Section 37.4: USART implementation on page 1610 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 37.5.6. To perform continuous communications when the FIFO is disabled, clear the TXE/RXNE flags in the USART_ISR register.

**Transmission using DMA**

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or before the system enters a low-power mode when the peripheral clock is disabled. Software must wait until TC = 1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

</table>

Note: When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).

Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data are loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.
**Figure 552. Reception using DMA**

</tbody>
</table>

Software configures the DMA to receive 3 data blocks and enables the USART.

**Note:** When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

**Error flagging and interrupt generation in multibuffer communication**

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

### 37.5.20 RS232 hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The **Figure 553** shows how to connect 2 devices in this mode:
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits to '1' in the USART_CR3 register.

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE = 1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. Figure 554 shows an example of communication with RTS flow control enabled.

![Figure 554. RS232 RTS flow control](image)

**Note:** When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE = 0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. Figure 555 shows an example of communication with CTS flow control enabled.
RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This enables the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the USART_CR1 control register. The deassertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

Note: For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.
37.5.21 USART low-power management

The USART has advanced low-power mode functions, that enables transferring properly data even when the usart_pclk clock is disabled.

The USART is able to wake up the MCU from low-power mode when the UESM bit is set.

When the usart_pclk is gated, the USART provides a wake-up interrupt (usart_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- If FIFO mode is disabled
  usart_pclk clock has to be activated to empty the USART data register.
  In this case, the usart_wkup interrupt source is RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled
  usart_pclk clock has to be activated to:
  - to fill the TXFIFO
  - or to empty the RXFIFO
  In this case, the usart_wkup interrupt source can be:
  - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
  - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
  - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.

This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.

To avoid overrun/underrun errors and transmit/receive data in low-power mode, the usart_wkup interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time required to receive a single byte across the line.

Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many USART transfers as possible during low-power mode with the benefit of optimizing consumption.

Alternatively, a specific usart_wkup interrupt can be selected through the WUS bitfields.

When the wake-up event is detected, the WUF flag is set by hardware and a usart_wkup interrupt is generated if the WUFIE bit is set.
Note: Before entering low-power mode, make sure that no USART transfers are ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to make sure the USART is enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled when exiting from low-power mode.

When the FIFO is enabled, waking up from low-power mode on address match is only possible when mute mode is enabled.

Using mute mode with low-power mode

If the USART is put into mute mode before entering low-power mode:

- Wake-up from mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from mute mode on address match is used, then the low-power mode wake-up source must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in mute mode upon address match and wake up from low-power mode.

Note: When FIFO management is enabled, mute mode can be used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about mute and low-power mode are valid only when FIFO management is disabled).

Wake-up from low-power mode when USART kernel clock (usart_ker_ck) is OFF in low-power mode

If during low-power mode, the usart_ker_ck clock is switched OFF when a falling edge on the USART receive line is detected, the USART interface requests the usart_ker_ck clock to be switched ON thanks to the usart_ker_ck_req signal. usart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, usart_ker_ck is switched OFF again, the MCU is not woken up and remains in low-power mode, and the kernel clock request is released.

The example below shows the case of a wake-up event programmed to “address match detection” and FIFO management disabled.
Figure 556 shows the USART behavior when the wake-up event is verified.

**Figure 556. Wake-up event verified (wake-up event = address match, FIFO disabled)**

![Diagram showing USART behavior when wake-up event is verified](image1)

Figure 557 shows the USART behavior when the wake-up event is not verified.

**Figure 557. Wake-up event not verified (wake-up event = address match, FIFO disabled)**

![Diagram showing USART behavior when wake-up event is not verified](image2)

**Note:** The figures above are valid when address match or any received frame is used as wake-up event. If the wake-up event is the start bit detection, the USART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum USART baud rate that enables to correctly wake up the device from low-power mode

The maximum baud rate that enables to correctly wake up the device from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the USART receiver tolerance (see Section 37.5.8: Tolerance of the USART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = '01', ONEBIT = 0 and BRR [3:0] = 0000. In these conditions, according to Table 349: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance equals 3.41%.

Let us take the example of OVER8 = 0, M bits = '01', ONEBIT = 0 and BRR [3:0] = 0000. In these conditions, according to Table 349: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance equals 3.41%.

\[
D_{WU\text{max}} = \frac{t_{WU\text{USART}}}{11 \times T_{\text{bit Min}}}
\]

\[
T_{\text{bit Min}} = \frac{t_{WU\text{USART}}}{11 \times D_{WU\text{max}}}
\]

where \( t_{WU\text{USART}} \) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the \( \text{usart}_\text{ker}_\text{ck} \) inaccuracy.

For example, if HSI16 is used as \( \text{usart}_\text{ker}_\text{ck} \), and the HSI16 inaccuracy is of 1%, then we obtain:

\[
t_{WU\text{USART}} = 3 \, \mu s
\]

\[
D_{WU\text{max}} = 3.41% - 1% = 2.41%
\]

\[
T_{\text{bit Min}} = 3 \, \mu s / (11 \times 2.41%) = 11.32 \, \mu s.
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \( 1/11.32 \, \mu s = 88.36 \, \text{Kbaud} \).

### 37.6 USART in low-power modes

Table 352. Effect of low-power modes on the USART

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. USART interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^1)</td>
<td>The content of the USART registers is kept. The USART is able to wake up the microcontroller from Stop mode when the USART is clocked by an oscillator available in Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The USART peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 37.4: USART implementation to know if the wake-up from Stop mode is supported for a given peripheral instance. If an instance is not functional in a given Stop mode, it must be disabled before entering this Stop mode.
# 37.7 USART interrupts

Refer to Table 353 for a detailed description of all USART interrupt requests.

## Table 353. USART interrupt requests

</tbody>
</table>

1. The USART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 37.4: USART implementation for the list of supported Stop modes.
2. RXFF flag is asserted if the USART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in USART_RDR. In Stop mode, USART_RDR is not clocked. As a result, this register is not written and once n data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. When OVRDIS = 0.

37.8 USART registers

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

37.8.1 USART control register 1 (USART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

FIFO mode enabled

Bit 31 RXFFIE: RXFIFO full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when RXFF = 1 in the USART_ISR register

Bit 30 TXFEIE: TXFIFO empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when TXFE = 1 in the USART_ISR register

Bit 29 FIFOEN: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.

This bitfield can only be written when the USART is disabled (UE = 0).

Note: FIFO mode can be used on standard UART communication, in SPI master/slave mode and in smartcard modes only. It must not be enabled in IrDA and LIN modes.
Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.

- M[1:0] = '00': 1 start bit, 8 Data bits, n Stop bit
- M[1:0] = '01': 1 start bit, 9 Data bits, n Stop bit
- M[1:0] = '10': 1 start bit, 7 Data bits, n Stop bit

This bit can only be written when the USART is disabled (UE = 0).

**Note:** In 7-bits data length mode, the smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bit 27  **EOBIE**: End-of-block interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register

**Note:** If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 26  **RTOIE**: Receiver timeout interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.

**Note:** If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 37.4: USART implementation on page 1610.

Bits 25:21  **DEAT[4:0]**: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

This bitfield can only be written when the USART is disabled (UE = 0).

**Note:** If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bits 20:16  **DEDT[4:0]**: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the USART is disabled (UE = 0).

**Note:** If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 15  **OVER8**: Oversampling mode
0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE = 0).

**Note:** In LIN, IrDA and smartcard modes, this bit must be kept cleared.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.
Bit 13 **MME**: Mute mode enable
This bit enables the USART mute mode function. When set, the USART can switch between active and mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between mute mode and active mode.

Bit 12 **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the USART is disabled (UE = 0).

Bit 11 **WAKE**: Receiver wake-up method
This bit determines the USART wake-up method from mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE = 1 in the USART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not-full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXFNF = 1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC = 1 in the USART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE = 1 or RXFNE = 1 in the USART_ISR register
Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE = 1 in the USART_ISR register

Bit 3 **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

*Note:* During transmission, a low pulse on the TE bit (‘0’ followed by ‘1’) sends a preamble (idle line) after the current word, except in smartcard mode. In order to generate an idle character, the TE must not be immediately written to ‘1’. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in low-power mode
When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode
1: USART able to wake up the MCU from low-power mode

*Note:* It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.

If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 0 **UE**: USART enable
When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note:* To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

In smartcard mode, (SCEN = 1), the CK is always available when CLKEN = 1, regardless of the UE bit value.
37.8.2 **USART control register 1 [alternate] (USART_CR1)**

Address offset: 0x00  
Reset value: 0x0000 0000  
The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).  

**FIFO mode disabled**

**Bits 31:30** Reserved, must be kept at reset value.  
**Bit 29** **FIFOEN**: FIFO mode enable  
This bit is set and cleared by software.  
0: FIFO mode is disabled.  
1: FIFO mode is enabled.  
This bitfield can only be written when the USART is disabled (UE = 0).  
**Note**: FIFO mode can be used on standard UART communication, in SPI master/slave mode and in smartcard modes only. It must not be enabled in IrDA and LIN modes.  

**Bit 28** **M1**: Word length  
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.  
M[1:0] = '00': 1 start bit, 8 Data bits, n Stop bit  
M[1:0] = '01': 1 start bit, 9 Data bits, n Stop bit  
M[1:0] = '10': 1 start bit, 7 Data bits, n Stop bit  
This bit can only be written when the USART is disabled (UE = 0).  
**Note**: In 7-bits data length mode, the smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.  

**Bit 27** **EOBIE**: End of Block interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register  
**Note**: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.  

**Bit 26** **RTOIE**: Receiver timeout interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.  
**Note**: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 37.4: USART implementation on page 1610.
Bits 25:21 **DEAT[4:0]**: Driver enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bits 20:16 **DEDT[4:0]**: Driver enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 15 **OVER8**: Oversampling mode

0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE = 0).

*Note: In LIN, IrDA and smartcard modes, this bit must be kept cleared.*

Bit 14 **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME**: Mute mode enable

This bit enables the USART mute mode function. When set, the USART can switch between active and mute mode, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently
1: Receiver can switch between mute mode and active mode.

Bit 12 **M0**: Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).

This bit can only be written when the USART is disabled (UE = 0).

Bit 11 **WAKE**: Receiver wake-up method

This bit determines the USART wake-up method from mute mode. It is set or cleared by software.

0: Idle line
1: Address mark

This bitfield can only be written when the USART is disabled (UE = 0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the USART is disabled (UE = 0).
Bit 9  **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 8  **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE = 1 in the USART_ISR register

Bit 7  **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXE =1 in the USART_ISR register

Bit 6  **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC = 1 in the USART_ISR register

Bit 5  **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE =1 or RXNE = 1 in the USART_ISR register

Bit 4  **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE = 1 in the USART_ISR register

Bit 3  **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

Note: *During transmission, a low pulse on the TE bit ('0' followed by '1') sends a preamble (idle line) after the current word, except in smartcard mode. In order to generate an idle character, the TE must not be immediately written to '1'. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.*

*In smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.*
Bit 2  **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1  **UESM**: USART enable in low-power mode
When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

*Note*: It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 0  **UE**: USART enable
When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note*: To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

*In smartcard mode, (SCEN = 1), the CK pin is always available when CLKEN = 1, regardless of the UE bit value.*

### 37.8.3 USART control register 2 (USART_CR2)

Address offset: 0x04
Reset value: 0x0000 0000

Bits 31:24 **ADD[7:0]:** Address of the USART node

These bits give the address of the USART node in mute mode or a character code to be recognized in low-power or Run mode:

- In mute mode: they are used in multiprocessor communication to wake up from mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM7 bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.
- In Run mode with mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

**Bit 23 RTOEN: Receiver timeout enable**

This bit is set and cleared by software.

0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bits 22:21 **ABRMOD[1:0]:** Auto baud rate mode

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 and Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection.

This bitfield can only be written when ABREN = 0 or the USART is disabled (UE = 0).

*Note: If DATAINV = 1 and/or MSBFIRST = 1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)*

*If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

**Bit 20 ABREN: Auto baud rate enable**

This bit is set and cleared by software.

0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

**Bit 19 MSBFIRST: Most significant bit first**

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the USART is disabled (UE = 0).
Bit 18  **DATAINV**: Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1 = H, 0 = L)
1: Logical data from the data register are send/received in negative/inverse logic. (1 = L, 0 = H).
The parity bit is also inverted.
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 17  **TXINV**: TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD =1/Idle, Gnd = 0/Mark)
1: TX pin signal values are inverted (VDD =0/Mark, Gnd = 1/Idle).
This enables the use of an external inverter on the TX line.
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 16  **RXINV**: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD =1/Idle, Gnd = 0/Mark)
1: RX pin signal values are inverted (VDD =0/Mark, Gnd = 1/Idle).
This enables the use of an external inverter on the RX line.
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 15  **SWAP**: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 14  **LINEN**: LIN mode enable
This bit is set and cleared by software.
0: LIN mode disabled
1: LIN mode enabled
The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.
This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bits 13:12  **STOP[1:0]**: Stop bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: 0.5 stop bit.
10: 2 stop bits
11: 1.5 stop bits
This bitfield can only be written when the USART is disabled (UE = 0).
Bit 11 **CLKEN**: Clock enable
This bit enables the user to enable the CK pin.
0: CK pin disabled
1: CK pin enabled
This bit can only be written when the USART is disabled (UE = 0).

*Note*: If neither synchronous mode nor smartcard mode is supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

In smartcard mode, in order to provide correctly the CK clock to the smartcard, the steps below must be respected:

- UE = 0
- SCEN = 1
- GTPR configuration
- CLKEN = 1
- UE = 1

Bit 10 **CPOL**: Clock polarity
This bit enables the user to select the polarity of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on CK pin outside transmission window
1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE = 0).

*Note*: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 9 **CPHA**: Clock phase
This bit is used to select the phase of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 537 and Figure 538)

0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE = 0).

*Note*: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 8 **LBCL**: Last bit clock pulse
This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin
1: The clock pulse of the last data bit is output to the CK pin

*Caution*: The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bit in the USART_CR1 register.

This bit can only be written when the USART is disabled (UE = 0).

*Note*: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable
Break interrupt mask (break detection using break delimiter).
0: Interrupt is inhibited
1: An interrupt is generated whenever LBDF = 1 in the USART_ISR register

*Note*: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.
Bit 5 **LBDL**: LIN break detection length

This bit is for selection between 11 bit or 10 bit break detection.

- 0: 10-bit break detection
- 1: 11-bit break detection

This bit can only be written when the USART is disabled (UE = 0).

**Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 4 **ADDM7**: 7-bit address detection/4-bit address detection

This bit is for selection between 4-bit address detection or 7-bit address detection.

- 0: 4-bit address detection
- 1: 7-bit address detection (in 8-bit data mode)

This bit can only be written when the USART is disabled (UE = 0)

**Note**: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

Bit 3 **DIS_NSS**: NSS pin enable

When the DIS_NSS bit is set, the NSS pin input is ignored.

- 0: SPI slave selection depends on NSS input pin.
- 1: SPI slave is always selected and NSS input pin is ignored.

**Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **SLVEN**: Synchronous slave mode enable

When the SLVEN bit is set, the synchronous slave mode is enabled.

- 0: Slave mode disabled.
- 1: Slave mode enabled.

**Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

**Note**: The CPOL, CPHA and LBCL bits should not be written while the transmitter is enabled.

</table>
Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth
- 001: TXFIFO reaches 1/4 of its depth
- 010: TXFIFO reaches 1/2 of its depth
- 011: TXFIFO reaches 3/4 of its depth
- 100: TXFIFO reaches 7/8 of its depth
- 101: TXFIFO becomes empty
  Remaining combinations: Reserved

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth
- 001: Receive FIFO reaches 1/4 of its depth
- 010: Receive FIFO reaches 1/2 of its depth
- 011: Receive FIFO reaches 3/4 of its depth
- 100: Receive FIFO reaches 7/8 of its depth
- 101: Receive FIFO becomes full
  Remaining combinations: Reserved

Bit 24 **TCBGTIE**: Transmission complete before guard time, interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TCBGT=1 in the USART_ISR register

*Note: If the USART does not support the smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wake-up from low-power mode interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever WUF = 1 in the USART_ISR register

*Note: WUFIE must be set before entering in low-power mode.*

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*
Bits 21:20 **WUS[1:0]:** Wake-up from low-power mode interrupt flag selection

This bitfield specifies the event which activates the WUF (wake-up from low-power mode flag).
- 00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
- 01: Reserved.
- 10: WUF active on start bit detection
- 11: WUF active on RXNE/RXFNE.

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bits 19:17 **SCARCNT[2:0]:** Smartcard auto-retry count

This bitfield specifies the number of retries for transmission and reception in smartcard mode.

In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).

In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).

This bitfield must be programmed only when the USART is disabled (UE = 0).

When the USART is enabled (UE = 1), this bitfield may only be written to 0x0, in order to stop retransmission.

- 0x0: retransmission disabled - No automatic retransmission in transmit mode.
- 0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note: If smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 16 **Reserved, must be kept at reset value.**

Bit 15 **DEP:** Driver enable polarity selection

- 0: DE signal is active high.
- 1: DE signal is active low.

This bit can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 14 **DEM:** Driver enable mode

This bit enables the user to activate the external transceiver control, through the DE signal.

- 0: DE function is disabled.
- 1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Section 37.4: USART implementation on page 1610.*

Bit 13 **DDRE:** DMA Disable on reception error

- 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred (used for smartcard mode).
- 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE/RXFNE is case FIFO mode is enabled) before clearing the error flag.

This bit can only be written when the USART is disabled (UE=0).

*Note: The reception errors are: parity error, framing error or noise error.*
Bit 12 **OVRDIS**: Overrun disable

This bit is used to disable the receive overrun detection.

0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.

1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO is bypassed and data is written directly in USART_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.

This bit can only be written when the USART is disabled (UE = 0).

*Note: This control bit enables checking the communication flow w/o reading the data*

Bit 11 **ONEBIT**: One sample bit method enable

This bit enables the user to select the sample method. When the one sample bit method is selected the noise detection flag (NE) is disabled.

0: Three sample bit method

1: One sample bit method

This bit can only be written when the USART is disabled (UE = 0).

Bit 10 **CTSE**: CTS interrupt enable

0: Interrupt is inhibited

1: An interrupt is generated whenever CTSIF = 1 in the USART_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 9 **CTSE**: CTS enable

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).

If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.

This bit can only be written when the USART is disabled (UE = 0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 8 **RTSE**: RTS enable

0: RTS hardware flow control disabled

1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.

This bit can only be written when the USART is disabled (UE = 0).

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 7 **DMAT**: DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission

0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception
Bit 5  **SCEN**: Smartcard mode enable
   This bit is used for enabling smartcard mode.
   0: Smartcard mode disabled
   1: Smartcard mode enabled
   This bitfield can only be written when the USART is disabled (UE = 0).
   **Note**: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 4  **NACK**: Smartcard NACK enable
   0: NACK transmission in case of parity error is disabled
   1: NACK transmission during parity error is enabled
   This bitfield can only be written when the USART is disabled (UE = 0).
   **Note**: If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 3  **HDSEL**: Half-duplex selection
   Selection of single-wire half-duplex mode
   0: Half duplex mode is not selected
   1: Half duplex mode is selected
   This bit can only be written when the USART is disabled (UE = 0).

Bit 2  **IRLP**: IrDA low-power
   This bit is used for selecting between normal and low-power IrDA modes
   0: Normal mode
   1: Low-power mode
   This bit can only be written when the USART is disabled (UE = 0).
   **Note**: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 1  **IREN**: IrDA mode enable
   This bit is set and cleared by software.
   0: IrDA disabled
   1: IrDA enabled
   This bit can only be written when the USART is disabled (UE = 0).
   **Note**: If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 0  **EIE**: Error interrupt enable
   Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error noise flag or SPI slave underrun error (FE = 1 or ORE = 1 or NE = 1 or UDR = 1 in the USART_ISR register).
   0: Interrupt inhibited
   1: interrupt generated when FE = 1 or ORE = 1 or NE = 1 or UDR = 1 (in SPI slave mode) in the USART_ISR register.
37.8.5 USART baud rate register (USART_BRR)

This register can only be written when the USART is disabled (UE = 0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>BRR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRR[15:0]:** USART baud rate

**BRR[15:4]**

**BRR[3:0]**

When OVER8 = 0, BRR[3:0] = USARTDIV[3:0].
When OVER8 = 1:
BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.
BRR[3] must be kept cleared.

37.8.6 USART guard time and prescaler register (USART_GTPR)

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>GT[7:0]</th>
<th>PSC[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
<td></td>
</tr>
</tbody>
</table>

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

This register can only be written when the USART is disabled (UE = 0). It may be automatically updated by hardware in auto baud rate detection mode.
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **GT[7:0]:** Guard time value
This bitfield is used to program the Guard time value in terms of number of baud clock periods.
This is used in smartcard mode. The Transmission Complete flag is set after this guard time value.
This bitfield can only be written when the USART is disabled (UE = 0).

*Note:* If smartcard mode is not supported, this bit is reserved and must be kept at reset value.
Refer to Section 37.4: USART implementation on page 1610.

Bits 7:0  **PSC[7:0]:** Prescaler value

**In IrDA low-power and normal IrDA mode:**
PSC[7:0] = IrDA normal and low-power baud rate
PSC[7:0] is used to program the prescaler for dividing the USART source clock to achieve the low-power frequency: the source clock is divided by the value given in the register (8 significant bits):

**In smartcard mode:**
PSC[4:0] = Prescaler value
PSC[4:0] is used to program the prescaler for dividing the USART source clock to provide the smartcard clock. The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

00000: Reserved - do not program this value
00001: Divides the source clock by 1 (IrDA mode) / by 2 (smartcard mode)
00010: Divides the source clock by 2 (IrDA mode) / by 4 (smartcard mode)
00011: Divides the source clock by 3 (IrDA mode) / by 6 (smartcard mode)
...
11111: Divides the source clock by 31 (IrDA mode) / by 62 (smartcard mode)
0010 0000: Divides the source clock by 32 (IrDA mode)
...
1111 1111: Divides the source clock by 255 (IrDA mode)

This bitfield can only be written when the USART is disabled (UE = 0).
*Note:* Bits [7:5] must be kept cleared if smartcard mode is used.
This bitfield is reserved and forced by hardware to '0' when the smartcard and IrDA modes are not supported. Refer to Section 37.4: USART implementation on page 1610.

### 37.8.7  USART receiver timeout register (USART_RTOR)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:24 **BLEN[7:0]:** Block length

This bitfield gives the Block length in smartcard T = 1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:
- BLEN = 0: 0 information characters + LEC
- BLEN = 1: 0 information characters + CRC
- BLEN = 255: 254 information characters + CRC (total 256 characters))

In smartcard mode, the Block length counter is reset when TXE = 0 (TXFE = 0 in case FIFO mode is enabled).

This bitfield can be used also in other modes. In this case, the Block length counter is reset when RE = 0 (receiver disabled) and/or when the EOFBF bit is written to 1.

*Note:* This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.

Bits 23:0 **RTO[23:0]:** Receiver timeout value

This bitfield gives the Receiver timeout value in terms of number of bits during which there is no activity on the RX line.

In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In smartcard mode, this value is used to implement the CWT and BWT. See smartcard chapter for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.

*Note:* This value must only be programmed once per received character.

*Note:* RTOR can be written on-the-fly. If the new value is lower than or equal to the counter, the RTOF flag is set.

This register is reserved and forced by hardware to “0x00000000” when the Receiver timeout feature is not supported. Refer to Section 37.4: USART implementation on page 1610.

### 37.8.8 USART request register (USART_RQR)

Address offset: 0x18

Reset value: 0x0000 0000
Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **TXFRQ**: Transmit data flush request

When FIFO mode is disabled, writing ‘1’ to this bit sets the TXE flag. This enables to discard the transmit data. This bit must be used only in smartcard mode, when data have not been sent due to errors (NACK) and the FE flag is active in the USART_ISR register. If the USART does not support smartcard mode, this bit is reserved and must be kept at reset value.

When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the TXFE flag (Transmit FIFO empty, bit 23 in the USART_ISR register). Flushing the Transmit FIFO is supported in both UART and smartcard modes.

*Note*: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3  **RXFRQ**: Receive data flush request

Writing 1 to this bit empties the entire receive FIFO i.e. clears the bit RXFNE. This enables to discard the received data without reading them, and avoid an overrun condition.

Bit 2  **MMRQ**: Mute mode request

Writing 1 to this bit puts the USART in mute mode and resets the RWU flag.

Bit 1  **SBKRQ**: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note*: When the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0  **ABRRQ**: Auto baud rate request

Writing 1 to this bit resets the ABRF and ABRE flags in the USART_ISR and requests an automatic baud rate measurement on the next received data frame.

*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

### 37.8.9 USART interrupt and status register (USART_ISR)

**Address offset**: 0x1C

**Reset value**: 0x000 0000C

X = 2 if FIFO/smartcard mode is enabled

X = 0 if FIFO is enabled and smartcard mode is disabled

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

#### FIFO mode enabled

1678/2138  RM0440 Rev 8
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag
This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG of USART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the USART_CR3 register.
0: TXFIFO does not reach the programmed threshold.
1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag
This bit is set by hardware when the threshold programmed in RXFTCFG in USART_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the USART_CR3 register.
0: Receive FIFO does not reach the programmed threshold.
1: Receive FIFO reached the programmed threshold.

Note: When the RXFTCFG threshold is configured to ‘101’, RXFT flag is set if 16 data are available i.e. 15 data in the RXFIFO and 1 data in the USART_RDR. Consequently, the 17th received data does not cause an overrun error. The overrun error occurs after receiving the 18th data.

Bit 25  **TCBGT**: Transmission complete before guard time flag
This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.
It is set by hardware in smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE = 1 in the USART_CR3 register.
This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

Note: If the USART does not support the smartcard mode, this bit is reserved and kept at reset value. If the USART supports the smartcard mode and the smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 37.4: USART implementation on page 1610.

Bit 24  **RXFF**: RXFIFO full
This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the USART_RDR register.
An interrupt is generated if the RXFFIE bit = 1 in the USART_CR1 register.
0: RXFIFO not full.
1: RXFIFO Full.

Bit 23  **TXFE**: TXFIFO empty
This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.
An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the USART_CR1 register.
0: TXFIFO not empty.
1: TXFIFO empty.
Bit 22 **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note*: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 21 **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the USART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 **WUF**: Wake-up from low-power mode flag
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.
An interrupt is generated if WUFIE = 1 in the USART_CR3 register.

*Note*: When UESM is cleared, WUF flag is also cleared.

*If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 19 **RWU**: Receiver wake-up from mute mode
This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.

0: Receiver in active mode
1: Receiver in mute mode

*Note*: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.

0: Break character transmitted
1: Break character requested by setting SBKRQ bit in USART_RQR register

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
An interrupt is generated if CMIE = 1 in the USART_CR1 register.

0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: USART is idle (no reception)
1: Reception on going
Bit 15  **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXFNE is also set, generating an interrupt if RXFNEIE = 1) or when the auto baud rate operation was completed without success (ABRE = 1) (ABRE, RXFNE and FE are also set in this case). It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14  **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).

It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13  **UDR**: SPI slave underrun error flag
In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.

0: No underrun error
1: underrun error

*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 12  **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T = 1 smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4. An interrupt is generated if the EOBIE = 1 in the USART_CR1 register.

It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.

0: End of Block not reached
1: End of Block (number of characters) reached

*Note: If smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 11  **RTOF**: Receiver timeout
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE = 1 in the USART_CR2 register.

In smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached
1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.

The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.

If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*
Bit 10 **CTS**: CTS flag
   This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
   0: CTS line set
   1: CTS line reset
   *Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSF**: CTS interrupt flag
   This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
   An interrupt is generated if CTSIE = 1 in the USART_CR3 register.
   0: No change occurred on the CTS status line
   1: A change occurred on the CTS status line
   *Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 **LBDF**: LIN break detection flag
   This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
   An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
   0: LIN Break not detected
   1: LIN break detected
   *Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value.*
   Refer to Section 37.4: USART implementation on page 1610.

Bit 7 **TXFNF**: TXFIFO not full
   TXFNF is set by hardware when TXFIFO is not full meaning that data can be written in the USART_TDR. Every write operation to the USART_TDR places the data in the TXFIFO.
   This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the USART_TDR.
   An interrupt is generated if the TXFNFIE bit = 1 in the USART_CR1 register.
   0: Transmit FIFO is full
   1: Transmit FIFO is not full
   *Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).
   This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete
   This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register.
   It is set by hardware when the transmission of a frame containing data is complete and when TXFE is set.
   An interrupt is generated if TCIE = 1 in the USART_CR1 register.
   TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.
   0: Transmission is not complete
   1: Transmission is complete
   *Note: If TE bit is reset and no transmission is on going, the TC bit is immediately set.*
Bit 5 **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, meaning that data can be read from the USART_RDR register. Every read operation from the USART_RDR frees a location in the RXFIFO.

RXFNE is cleared when the RXFIFO is empty. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXFNEIE = 1 in the USART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.

0: No Idle line is detected
1: Idle line is detected

**Note:** The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).

If mute mode is enabled (MME = 1), IDLE is set if the USART is not mute (RWU = 0), whatever the mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.

Bit 3 **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.

An interrupt is generated if RXFNEIE = 1 in the USART_CR1 register, or EIE = 1 in the USART_CR3 register.

0: No overrun error
1: Overrun error is detected

**Note:** When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
**37.8.10 USART interrupt and status register [alternate] (USART_ISR)**

Address offset: 0x1C

Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

### FIFO mode disabled

Note: This error is associated with the character in the USART_RDR.
Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **TCBGT**: Transmission complete before guard time flag
This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.
It is set by hardware in smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE = 1 in the USART_CR3 register.
This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

**Note:** If the USART does not support the smartcard mode, this bit is reserved and kept at reset value. If the USART supports the smartcard mode and the smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 37.4: USART implementation on page 1610.

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
It can be used to verify that the USART is ready for reception before entering low-power mode.

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 21 **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the USART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 **WUF**: Wake-up from low-power mode flag
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register. An interrupt is generated if WUFIE = 1 in the USART_CR3 register.

**Note:** When UESM is cleared, WUF flag is also cleared.
If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bit 19 **RWU**: Receiver wake-up from mute mode
This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
0: Receiver in active mode
1: Receiver in mute mode

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.
Bit 18 **SBKF**: Send break flag
   This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
   0: Break character transmitted
   1: Break character requested by setting SBKRQ bit in USART_RQR register

Bit 17 **CMF**: Character match flag
   This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
   An interrupt is generated if CMIE = 1 in the USART_CR1 register.
   0: No Character match detected
   1: Character Match detected

Bit 16 **BUSY**: Busy flag
   This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
   0: USART is idle (no reception)
   1: Reception on going

Bit 15 **ABRF**: Auto baud rate flag
   This bit is set by hardware when the automatic baud rate has been set (RXNE is also set, generating an interrupt if RXNIE = 1) or when the auto baud rate operation was completed without success (ABRE = 1) (ABRE, RXNE and FE are also set in this case)
   It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.
   Note: *If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14 **ABRE**: Auto baud rate error
   This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)
   It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.
   Note: *If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13 **UDR**: SPI slave underrun error flag
   In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.
   0: No underrun error
   1: underrun error
   Note: *If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*

Bit 12 **EOBF**: End of block flag
   This bit is set by hardware when a complete block has been received (for example T = 1 smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.
   An interrupt is generated if the EOBIE = 1 in the USART_CR1 register.
   It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.
   0: End of Block not reached
   1: End of Block (number of characters) reached
   Note: *If smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation on page 1610.*
Bit 11  **RTOF**: Receiver timeout
   This bit is set by hardware when the timeout value, programmed in the RTOR register has 
lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in 
the USART_ICR register.
   
   An interrupt is generated if RTOIE = 1 in the USART_CR2 register.
   
   In smartcard mode, the timeout corresponds to the CWT or BWT timings.
   
   0: Timeout value not reached
   1: Timeout value reached without any data reception

   **Note:** If a time equal to the value programmed in RTOR register separates 2 characters, 
   RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, 
   depending on the oversampling method), RTOF flag is set.

   The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has 
   already elapsed when RE is set, then RTOF is set.

   If the USART does not support the Receiver timeout feature, this bit is reserved and 
   kept at reset value.

Bit 10  **CTS**: CTS flag
   This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
   
   0: CTS line set
   1: CTS line reset

   **Note:** If the hardware flow control feature is not supported, this bit is reserved and kept at 
   reset value.

Bit 9  **CTSIF**: CTS interrupt flag
   This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by 
software, by writing 1 to the CTSCF bit in the USART_ICR register.

   An interrupt is generated if CTSIE = 1 in the USART_CR3 register.
   
   0: No change occurred on the CTS status line
   1: A change occurred on the CTS status line

   **Note:** If the hardware flow control feature is not supported, this bit is reserved and kept at 
   reset value.

Bit 8  **LBDF**: LIN break detection flag
   This bit is set by hardware when the LIN break is detected. It is cleared by software, by 
writing 1 to the LBDCF in the USART_ICR.

   An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
   
   0: LIN Break not detected
   1: LIN break detected

   **Note:** If the USART does not support LIN mode, this bit is reserved and kept at reset value. 
   Refer to Section 37.4: USART implementation on page 1610.

Bit 7  **TXE**: Transmit data register empty
   TXE is set by hardware when the content of the USART_TDR register has been transferred 
to the shift register. It is cleared by writing to the USART_TDR register. The TXE flag can 
also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the 
data (only in smartcard T = 0 mode, in case of transmission failure).

   An interrupt is generated if the TXEIE bit = 1 in the USART_CR1 register.
   
   0: Data register full
   1: Data register not full
Bit 6  TC: Transmission complete

This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register.
It is set by hardware when the transmission of a frame containing data is complete and when TXE is set.
An interrupt is generated if TCIE = 1 in the USART_CR1 register.
TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete
1: Transmission is complete

*Note:* If TE bit is reset and no transmission is on going, the TC bit is set immediately.

Bit 5  RXNE: Read data register not empty

RXNE bit is set by hardware when the content of the USART_RDR shift register has been transferred to the USART_RDR register. It is cleared by reading from the USART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.
An interrupt is generated if RXNEIE = 1 in the USART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4  IDLE: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.
0: No Idle line is detected
1: Idle line is detected

*Note:* The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).

*If mute mode is enabled (MME = 1), IDLE is set if the USART is not mute (RWU = 0), whatever the mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.*

Bit 3  ORE: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXNE = 1. It is cleared by a software, writing 1 to the OREC, in the USART_ICR register.
An interrupt is generated if RXNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the USART_CR3 register.
0: No overrun error
1: Overrun error is detected

*Note:* When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

*This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.*
Bit 2 **NE**: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NECF bit in the USART_ICR register.

- 0: No noise is detected
- 1: Noise is detected

**Note:** This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 37.5.8: Tolerance of the USART receiver to clock deviation on page 1627).

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FE CF bit in the USART_ICR register.

When transmitting data in smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART_CR3 register.

- 0: No Framing error is detected
- 1: Framing error or break character is detected

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.

An interrupt is generated if PEIE = 1 in the USART_CR1 register.

- 0: No parity error
- 1: Parity error

### 37.8.11 USART interrupt flag clear register (USART_ICR)

**Address offset:** 0x20

**Reset value:** 0x0000 0000

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WUCF**: Wake-up from low-power mode clear flag

Writing 1 to this bit clears the WUF flag in the USART_ISR register.

**Note:** If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the USART_ISR register.
Bits 16:14  Reserved, must be kept at reset value.

Bit 13  **UDRCF**: SPI slave underrun clear flag
  Writing 1 to this bit clears the UDRF flag in the USART_ISR register.
  \*Note: If the UART does not support SPI slave mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: UART implementation on page 1610\*

Bit 12  **EOBCF**: End of block clear flag
  Writing 1 to this bit clears the EOBF flag in the USART_ISR register.
  \*Note: If the UART does not support smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 37.4: UART implementation on page 1610.\*

Bit 11  **RTOCF**: Receiver timeout clear flag
  Writing 1 to this bit clears the RTOF flag in the USART_ISR register.
  \*Note: If the UART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: UART implementation on page 1610.\*

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CTSCF**: CTS clear flag
  Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.
  \*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: UART implementation on page 1610.\*

Bit 8  **LBDCF**: LIN break detection clear flag
  Writing 1 to this bit clears the LBDF flag in the USART_ISR register.
  \*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 37.4: UART implementation on page 1610.\*

Bit 7  **TCBGTCF**: Transmission complete before Guard time clear flag
  Writing 1 to this bit clears the TCBGT flag in the USART_ISR register.

Bit 6  **TCCF**: Transmission complete clear flag
  Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5  **TXFECF**: TXFIFO empty clear flag
  Writing 1 to this bit clears the TXFE flag in the USART_ISR register.

Bit 4  **IDLECF**: Idle line detected clear flag
  Writing 1 to this bit clears the IDLE flag in the USART_ISR register.

Bit 3  **ORECF**: Overrun error clear flag
  Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2  **NECF**: Noise detected clear flag
  Writing 1 to this bit clears the NE flag in the USART_ISR register.

Bit 1  **FECF**: Framing error clear flag
  Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0  **PECF**: Parity error clear flag
  Writing 1 to this bit clears the PE flag in the USART_ISR register.
37.8.12 USART receive data register (USART_RDR)

Address offset: 0x24
Reset value: 0x0000 0000

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]**: Receive data value
Contains the received data character.
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 531).
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

37.8.13 USART transmit data register (USART_TDR)

Address offset: 0x28
Reset value: 0x0000 0000

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]**: Transmit data value
Contains the data character to be transmitted.
The USART_TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 531).
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

Note: This register must be written only when TXE/TXFN=1.
37.8.14 USART prescaler register (USART_PRESC)

This register can only be written when the USART is disabled (UE = 0).

Address offset: 0x2C

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRESCALER[3:0]:** Clock prescaler

The USART input clock can be divided by a prescaler factor:

0000: input clock not divided
0001: input clock divided by 2
0010: input clock divided by 4
0011: input clock divided by 6
0100: input clock divided by 8
0101: input clock divided by 10
0110: input clock divided by 12
0111: input clock divided by 16
1000: input clock divided by 32
1001: input clock divided by 64
1010: input clock divided by 128
1011: input clock divided by 256

Remaining combinations: Reserved

**Note:** When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is 1011 i.e. input clock divided by 256.

If the prescaler is not supported, this bitfield is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation on page 1610.

38 Low-power universal asynchronous receiver transmitter (LPUART)

This section describes the low-power universal asynchronous receiver transmitter (LPUART).

38.1 LPUART introduction

The LPUART is an UART which enables bidirectional UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to enable UART communications up to 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the device is in low-power mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports half-duplex single-wire communications and modem operations (CTS/RTS).

It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.
38.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- From 300 baud to 9600 baud using a 32.768 kHz clock source.
- Higher baud rates can be achieved by using a higher frequency clock source
- Two internal FIFOs to transmit and receive data
  Each FIFO can be enabled/disabled by software and come with status flags for FIFOs states.
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK.
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - Busy and end of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Interrupt sources with flags
- Multiprocessor communications: wake-up from mute mode by idle line detection or address mark detection
38.3 LPUART implementation

The table(s) below describe(s) LPUART implementation. It(they) also include(s) USARTs for comparison.

38.4 LPUART functional description

38.4.1 LPUART block diagram

The simplified block diagram given in Figure 558 shows two fully independent clock domains:

- The lpuart_pclk clock domain
  The lpuart_pclk clock signal feeds the peripheral bus interface. It must be active when accesses to the LPUART registers are required.

- The lpuart_ker_ck kernel clock domain
  The lpuart_ker_ck is the LPUART clock source. It is independent of the lpuart_pclk and delivered by the RCC. So, the LPUART registers can be written/read even when the lpuart_ker_ck is stopped.

When the dual clock domain feature is disabled, the lpuart_ker_ck is the same as the lpuart_pclk clock.

There is no constraint between lpuart_pclk and lpuart_ker_ck: lpuart_ker_ck can be faster or slower than lpuart_pclk, with no more limitation than the ability for the software to manage the communication fast enough.
38.4.2 LPUART signals

LPUART bidirectional communications requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX** (Receive Data Input)
  - RX is the serial data input.
- **TX** (Transmit Data Output)
  - When the transmitter is disabled, the output pin returns to its I/O port configuration.
  - When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire mode, this I/O is used to transmit and receive the data.

**RS232 hardware flow control mode**

The following pins are required in RS232 hardware flow control mode:

- **CTS** (Clear To Send)
  - When driven high, this signal blocks the data transmission at the end of the current transfer.
- **RTS** (Request to send)
  - When it is low, this signal indicates that the USART is ready to receive data.

**RS485 hardware flow control mode**

The following pin is required in RS485 hardware control mode:

- **DE** (Driver Enable)
  - This signal activates the transmission mode of the external transceiver.

*Note: DE and RTS share the same pin.*

Refer to Table 356 and Table 357 for the list of USART input/output pins and internal signals.

38.4.3 LPUART character description

The word length can be set to 7 or 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see Figure 532).

- 7-bit character length: M[1:0] = ‘10’
- 8-bit character length: M[1:0] = ‘00’
- 9-bit character length: M[1:0] = ‘01’

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An **Idle character** is interpreted as an entire frame of “1”s. (The number of “1”’s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clocks are generated when the enable bit is set for the transmitter and receiver, respectively.

The details of each block is given below.

38.4.4 **LPUART FIFOs and thresholds**

The LPUART can operate in FIFO mode.

The LPUART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN bit (bit 29) in LPUART_CR1 register.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store...
the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

**Note:** The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the LPUART_ISR register.

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in LPUART_CR3 control register.

In this case:

- The RXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  
  This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.

  RXFTCFG data have been received: one data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to '101', the RXFT flag is set when a number of data corresponding to the FIFO size has been received: FIFO size - 1 data in the RXFIFO and 1 data in the LPUART_RDR. As a result, the next received data does not set the overrun flag.

- The TXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.
  
  This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

### 38.4.5 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

**Character transmission**

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 558).

When FIFO mode is enabled, the data written to the LPUART_TDR register are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be 1 or 2.

**Note:**

- The TE bit must be set before writing the data to be transmitted to the LPUART_TDR.
- The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters is frozen. The current data being transmitted are lost.
- An idle frame is sent after the TE bit is enabled.
Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in LPUART_CR2 (bits 13,12).

- **1 stop bit**: This is the default value of number of stop bits.
- **2 Stop bits**: This is supported by normal LPUART, single-wire and modem modes.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = ‘00’) or 11 low bits (when M[1:0] = ‘01’) or 9 low bits (when M[1:0] = ‘10’) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 560. Configurable stop bits**

Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to ‘1’.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in Section 38.4.12: Continuous communication using DMA and LPUART.
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this operation for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO. Write operations to the LPUART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the LPUART_TDR register, wait until TC = 1. This indicates that the transmission of the last frame is complete.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty. This check is required to avoid corrupting the last transmission when the LPUART is disabled or enters Halt mode.

Single byte communication

- When FIFO mode disabled:
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware to indicate that:
  - the data have been moved from the LPUART_TDR register to the shift register and data transmission has started;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data.
  The TXE flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the LPUART_TDR register stores the data in the TDR register, which is copied to the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO Not Full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.
  Alternatively, interrupts can be generated and data can be written to the TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.
  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.
  After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC = 1 before disabling the LPUART or causing the device to enter the low-power mode (see Figure 561: TC/TXE behavior when transmitting).
When FIFO management is enabled, the TXFNF flag is used for data transmission.

**Break characters**

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 559).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

**Idle characters**

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

**38.4.6 LPUART receiver**

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART_CR1 register.

**Start bit detection**

In the LPUART, the start bit is detected when a falling edge occurs on the Rx line, followed by a sample taken in the middle of the start bit to confirm that it is still ‘0’. If the start sample is at ‘1’, then the noise error flag (NE) is set, then the start bit is discarded and the receiver waits for a new start bit. Else, the receiver continues to sample all incoming bits normally.
Character reception

During an LPUART reception, data are shifted in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in LPUART.CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART_BRR.
3. Program the number of stop bits in LPUART.CR2.
4. Enable the LPUART by writing the UE bit in LPUART.CR1 register to ‘1’.
5. Select DMA enable (DMAR) in LPUART.CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 38.4.12: Continuous communication using DMA and LPUART.
6. Set the RE bit LPUART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. Reading the LPUART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO, together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO is not empty i.e. there is a data in the RXFIFO to be read.
- In single buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read operation from the LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set.
Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the LPUART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs when a character is received when RXNE has not been reset.
  
  Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received.
  
  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available when a read to LPUART_RDR is performed.;
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE bit or EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full.
  
  Data can not be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.
  
  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - the ORE bit is set;
  - the first entry in the RXFIFO is not lost. It is available when a read to LPUART_RDR is performed.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXFNEIE bit or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.

*Note: The ORE bit, when set, indicates that at least 1 data has been lost.*

*When the FIFO mode is disabled, there are two possibilities*

- if RXNE = 1, then the last valid data is stored in the receive register (RDR) and can be read,

- if RXNE = 0, then the last valid data has already been read and there is nothing left to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.
Selecting the clock source

The choice of the clock source is done through the Clock Control system (see Section Reset and clock controller (RCC)). The clock source must be selected through the UE bit, before enabling the LPUART.

The clock source must be selected according to two criteria:
- Possible use of the LPUART in low-power mode
- Communication speed.

The clock source frequency is \( \text{lpuart}_\text{ker}_\text{ck} \).

When the dual clock domain and the wake-up from low-power mode features are supported, the \( \text{lpuart}_\text{ker}_\text{ck} \) clock source can be configured in the RCC (see Section Reset and clock controller (RCC)). Otherwise, the \( \text{lpuart}_\text{ker}_\text{ck} \) is the same as \( \text{lpuart}_\text{pclk} \).

The \( \text{lpuart}_\text{ker}_\text{ck} \) can be divided by a programmable factor in the LPUART_PRESC register.

Some \( \text{lpuart}_\text{ker}_\text{ck} \) sources enable the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART_RDR register or by DMA.

For the other clock sources, the system must be active to enable LPUART communications. The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Only a single sample is taken of each of the incoming bits.

**Note:** There is no noise detection for data.

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the LPUART_RDR register.
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of
multibuffer communication, an interrupt is issued if the EIE bit is set in the LPUART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART_ICR register.

### Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of LPUART_CR2: it can be either 1 or 2 in normal mode.

- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **2 stop bits**: sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

### 38.4.7 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the LPUART_BRR register.

\[
\text{Tx/Rx baud} = \frac{256 \times \text{lpuartckpres}}{\text{LPUARTDIV}}
\]

LPUARTDIV is defined in the LPUART_BRR register.

**Note:**

- The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value should not be changed during communication.
- It is forbidden to write values lower than 0x300 in the LPUART_BRR register.
- \( f_{CK} \) must range from 3 x baud rate to 4096 x baud rate.

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock. For example, if the LPUART clock source frequency is 100 MHz, the maximum baud rate that can be reached is about 33 Mbaud.

| Table 358. Error calculation for programmed baud rates at lpuart_ker_ck_pres = 32.768 kHz |
|-----------------------------------------------|-----------------------------------------------|-------------------------------|-----------------------------------------------|
| Baud rate | Desired | Actual | Value programmed in the baud rate register | \% Error = (Calculated - Desired) B. rate / Desired B. rate |
| S.No | Desired | Actual | 0x6D3A | 0x369D | 0x1B4E | 0xDA7 | 0x6D3 | 0x369 |
| 1 | 300 bauds | 300 baud | 0x6D3A | 0 | 0.07 |
| 2 | 600 baud | 600 baud | 0x369D | 0 | 0 |
| 3 | 1200 baud | 1200.087 baud | 0x1B4E | 0.007 |
| 4 | 2400 baud | 2400.17 baud | 0xDA7 | 0.007 |
| 5 | 4800 baud | 4801.72 baud | 0x6D3 | 0.035 |
| 6 | 9600 baud | 9608.94 baud | 0x369 | 0.093 |
38.4.8 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
\text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{LPUART receiver tolerance}
\]

where

- DWU is the error due to sampling point deviation when the wake-up from low-power mode is used.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 360:

- Number of Stop bits defined through STOP[1:0] bits in the LPUART_CR2 register
- LPUART_BRR register value.

Note: The data specified in Table 360 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = '00' (11-bit times when M = '01' or 9-bit times when M = '10').

38.4.9 LPUART multiprocessor communication

It is possible to perform LPUART multiprocessor communications (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, with its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, with their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices can be placed in mute mode by means of the muting function. To use the mute mode feature, the MME bit must be set in the LPUART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two lpuart_ker_ck cycles), otherwise mute mode might remain active.

When the mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in LPUART_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.
Idle line detection (WAKE = 0)

The LPUART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The LPUART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of mute mode behavior using Idle line detection is given in Figure 563.

Figure 563. Mute mode using Idle line detection

Note: If the MMRQ is set while the IDLE character has already elapsed, the mute mode is not entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE = 1)

In this mode, bytes are recognized as addresses if their MSB is a ‘1’ otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters mute mode.

The LPUART also enters mute mode when the MMRQ bit is written to ‘1’. The RWU bit is also automatically set in this case.

The LPUART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data, this data may be received before effectively entering in mute mode.
An example of mute mode behavior using address mark detection is given in Figure 564.

**Figure 564. Mute mode using address mark detection**

### 38.4.10 LPUART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in Table 361.

#### Table 361: LPUART frame formats

<table>
<thead>
<tr>

<tr>
<td>10</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

2. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data equal 00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data equal 00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).
Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission

If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS = 0) or an odd number of “1s” if odd parity is selected (PS = 1)).

38.4.11 LPUART single-wire half-duplex communication

Single-wire half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register. In this mode, the following bits must be kept cleared:
- LINEN and CLKEN bits in the LPUART_CR2 register,
- SCEN and IREN bits in the LPUART_CR3 register.

The LPUART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to ‘1’:
- The TX and RX lines are internally connected.
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

Note: In LPUART communications, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.

38.4.12 Continuous communication using DMA and LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 37.4: USART implementation on page 1610 to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT as explained in Section 37.5.6. To perform continuous communication. When FIFO is disabled, you can clear the TXE/ RXNE flags in the LPUART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the LPUART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):
1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.

2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.

3. Configure the total number of bytes to be transferred to the DMA control register.

4. Configure the channel priority in the DMA register

5. Configure DMA interrupt generation after half/full transfer as required by the application.

6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.

7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering low-power mode. Software must wait until TC = 1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

**Figure 565. Transmission using DMA**

**Note:** When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).
Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data are loaded from the LPUART_RDR register to a SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller (DMA) section) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 566. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt.
enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

### 38.4.13 RS232 hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The [Figure 553](#) shows how to connect 2 devices in this mode:

**Figure 553. Hardware flow control between 2 LPUARTs**

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE = 1), then RTS is deasserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. [Figure 568](#) shows an example of communication with RTS flow control enabled.

**Figure 568. RS232 RTS flow control**

*Note:* When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.
RS232 CTS flow control

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE = 0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. Figure 569 shows an example of communication with CTS flow control enabled.

![Figure 569. RS232 CTS flow control](Figure569)

**Note:** For correct behavior, CTS must be deasserted at least 3 LPUART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This enables activating the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the LPUART_CR1 control register. The deassertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.
The LPUART DEAT and DEDT are expressed in LPUART clock source \( f_{CK} \) cycles:

- The Driver enable assertion time equals
  - \( (1 + (DEAT \times P)) \times f_{CK} \), if \( P \neq 0 \)
  - \( (1 + DEAT) \times f_{CK} \), if \( P = 0 \)
- The Driver enable deassertion time equals
  - \( (1 + (DEDT \times P)) \times f_{CK} \), if \( P \neq 0 \)
  - \( (1 + DEDT) \times f_{CK} \), if \( P = 0 \)

where \( P = BRR[20:11] \)

### 38.4.14 LPUART low-power management

The LPUART has advanced low-power mode functions that enable it to transfer properly data even when the lpuart_pclk clock is disabled.

The LPUART is able to wake up the MCU from low-power mode when the UESM bit is set. When the lpuart_pclk is gated, the LPUART provides a wake-up interrupt (lpuart_wkup) if a specific action requiring the activation of the lpuart_pclk clock is needed:

- If FIFO mode is disabled
  - lpuart_pclk clock has to be activated to empty the LPUART data register.
    - In this case, the lpuart_wkup interrupt source is the RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled
  - lpuart_pclk clock has to be activated
    - to fill the TXFIFO
    - or to empty the RXFIFO
    - In this case, the lpuart_wkup interrupt source can be:
      - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
      - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
      - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.

This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.

To avoid overrun/underrun errors and transmit/receive data in low-power mode, the lpuart_wkup interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time to receive a single byte across the line.

Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many LPUART transfers as possible during low-power mode with the benefit of optimizing consumption.
Alternatively, a specific lpuart_wkup interrupt may be selected through the WUS bitfields.

When the wake-up event is detected, the WUF flag is set by hardware and lpuart_wkup interrupt is generated if the WUFIE bit is set.

**Note:** Before entering low-power mode, make sure that no LPUART transfer is ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or in an active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the LPUART is actually enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled upon exit from low-power mode.

When FIFO is enabled, the wake-up from low-power mode on address match is only possible when mute mode is enabled.

**Using mute mode with low-power mode**

If the LPUART is put into mute mode before entering low-power mode:

- Wake-up from mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from mute mode on address match is used, then the low-power mode wake-up source from must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in mute mode upon address match and wake up from low-power mode.

**Note:** When FIFO management is enabled, mute mode is used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about mute and low-power mode are valid only when FIFO management is disabled).

**Wake-up from low-power mode when LPUART kernel clock lpuart_ker_ck is OFF in low-power mode**

If during low-power mode, the lpuart_ker_ck clock is switched OFF, when a falling edge on the LPUART receive line is detected, the LPUART interface requests the lpuart_ker_ck clock to be switched ON thanks to the lpuart_ker_ck_req signal. The lpuart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, the lpuart_ker_ck is switched OFF again, the MCU is not waken up and stays in low-power mode and the kernel clock request is released.

The example below shows the case of wake-up event programmed to “address match detection” and FIFO management disabled.

*Figure 570* shows the behavior when the wake-up event is verified.
Figure 570. Wake-up event verified (wake-up event = address match, FIFO disabled)

Address match event WUF = '1'
LPUART sends a wakeup event to the MCU

Data reception goes on

Figure 571 shows the behavior when the wake-up event is not verified.

Figure 571. Wake-up event not verified (wake-up event = address match, FIFO disabled)

Address does not match

Note: The above figures are valid when address match or any received frame is used as wake-up event. In the case the wake-up event is the start bit detection, the LPUART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum LPUART baud rate that enables to correctly wake up the MCU from low-power mode

The maximum baud rate that enables to correctly wake up the MCU from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the LPUART receiver tolerance (see Section 38.4.8: Tolerance of the LPUART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = ‘01’, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 360: Tolerance of the LPUART receiver, the LPUART receiver tolerance equals 3.41%.

\[
D_{WU\text{max}} = t_{WULPUART} \times (11 \times T_{\text{bit Min}})
\]

\[
T_{\text{bit Min}} = t_{WULPUART} / (11 \times D_{WU\text{max}})
\]

where \( t_{WULPUART} \) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the \( \text{lpuart\_ker\_ck} \) inaccuracy.

For example, if HSI16 is used as \( \text{lpuart\_ker\_ck} \), and the HSI16 inaccuracy is of 1%, then we obtain:

\[
t_{WULPUART} = 3 \, \mu s \text{ (values provided only as examples; for correct values, refer to the device datasheet)}.
\]

\[
D_{WU\text{max}} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{\text{bit min}} = 3 \, \mu s / (11 \times 2.41\%) = 11.32 \, \mu s.
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \( 1/11.32 \, \mu s = 88.36 \, \text{kbaud} \).

38.5 LPUART in low-power modes

Table 362. Effect of low-power modes on the LPUART

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPUART interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The content of the LPUART registers is kept. The LPUART is able to wake up the microcontroller from Stop mode when the LPUART is clocked by an oscillator available in Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The LPUART peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

\(^{(1)}\) Refer to Section 38.3: LPUART implementation to know if the wake-up from Stop mode is supported for a given peripheral instance. If an instance is not functional in a given Stop mode, it must be disabled before entering this Stop mode.
## 38.6 LPUART interrupts

Refer to *Table 363* for a detailed description of all LPUART interrupt requests.

</table>
1. The LPUART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 38.3: LPUART implementation for the list of supported Stop modes.

2. RXFF flag is asserted if the LPUART receives \( n+1 \) data (\( n \) being the RXFIFO size): \( n \) data in the RXFIFO and 1 data in LPUART_RDR. In Stop mode, LPUART_RDR is not clocked. As a result, this register is not written and once \( n \) data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. When OVRDIS = 0.

### 38.7 LPUART registers

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

#### 38.7.1 LPUART control register 1 (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

**Bit 31 RXFFIE:** RXFIFO full interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated when RXFF = 1 in the LPUART_ISR register

**Bit 30 TXFEIE:** TXFIFO empty interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An LPUART interrupt is generated when TXFE = 1 in the LPUART_ISR register

**Bit 29 FIFOEN:** FIFO mode enable

This bit is set and cleared by software.

0: FIFO mode is disabled.

1: FIFO mode is enabled.
Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.

- M[1:0] = ’00’: 1 Start bit, 8 Data bits, n Stop bit
- M[1:0] = ’01’: 1 Start bit, 9 Data bits, n Stop bit
- M[1:0] = ’10’: 1 Start bit, 7 Data bits, n Stop bit

This bit can only be written when the LPUART is disabled (UE = 0).

*Note: In 7-bit data length mode, the smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.*

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 37.5.20: RS232 hardware flow control and RS485 Driver Enable.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bits 20:16  **DEDT[4:0]**: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer Section 38.4.13: RS232 hardware flow control and RS485 Driver Enable.

If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit activates the mute mode function of the LPUART. When set, the LPUART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.

- 0: Receiver in active mode permanently
- 1: Receiver can switch between mute mode and active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).

This bit can only be written when the LPUART is disabled (UE = 0).

Bit 11  **WAKE**: Receiver wake-up method
This bit determines the LPUART wake-up method from mute mode. It is set or cleared by software.

- 0: Idle line
- 1: Address mark

This bitfield can only be written when the LPUART is disabled (UE = 0).
Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

0: Even parity
1: Odd parity

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE = 1 in the LPUART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not full interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE/TXFNF = 1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC = 1 in the LPUART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE = 1 or RXNE/RXFNE = 1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE = 1 in the LPUART_ISR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled
1: Transmitter is enabled

**Note**: During transmission, a low pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.

When TE is set there is a 1 bit-time delay before the transmission starts.
Bit 2 **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: LPUART enable in Stop mode
When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode.
When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI16 or LSE in the RCC.
This bit is set and cleared by software.
0: LPUART not able to wake up the MCU from low-power mode.
1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI16 or LSE (see RCC chapter)

**Note**: It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.

Bit 0 **UE**: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
0: LPUART prescaler and outputs disabled, low-power mode
1: LPUART enabled

**Note**: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

### 38.7.2 LPUART control register 1 [alternate] (LPUART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

**FIFO mode disabled**

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **FIFOEN**: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.

Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
- \[M[1:0] = '00': 1\] Start bit, 8 Data bits, n Stop bit
- \[M[1:0] = '01': 1\] Start bit, 9 Data bits, n Stop bit
- \[M[1:0] = '10': 1\] Start bit, 7 Data bits, n Stop bit
This bit can only be written when the LPUART is disabled (UE = 0).

*Note: In 7-bit data length mode, the smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.*

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to Section 37.5.20: RS232 hardware flow control and RS485 Driver Enable.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bits 20:16  **DEDT[4:0]**: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to Section 38.4.13: RS232 hardware flow control and RS485 Driver Enable.
If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit activates the mute mode function of the LPUART. When set, the LPUART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between mute mode and active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the LPUART is disabled (UE = 0).
Bit 11 **WAKE**: Receiver wake-up method
This bit determines the LPUART wake-up method from mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE = 1 in the LPUART_ISR register

Bit 7 **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE/TXFNF = 1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC = 1 in the LPUART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE = 1 or RXNE/RXFNE = 1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE = 1 in the LPUART_ISR register
Bit 3 TE: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

Note: During transmission, a low pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.
When TE is set there is a 1 bit-time delay before the transmission starts.

Bit 2 RE: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 UESM: LPUART enable in Stop mode
When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode. When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI16 or LSE in the RCC. This bit is set and cleared by software.
0: LPUART not able to wake up the MCU from low-power mode.
1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI16 or LSE (see RCC chapter)

Note: It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.

Bit 0 UE: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
0: LPUART prescaler and outputs disabled, low-power mode
1: LPUART enabled

Note: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

Bits 31:24 ADD[7:0]: Address of the LPUART node

These bits give the address of the LPUART node in mute mode or a character code to be recognized in low-power or Run mode:

- In mute mode: they are used in multiprocessor communication to wake up from mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM[7] bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.
- In Run mode with mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 MSBFIRST: Most significant bit first

This bit is set and cleared by software.

0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 18 DATAINV: Binary data inversion

This bit is set and cleared by software.

0: Logical data from the data register are send/received in positive/direct logic. (1 = H, 0 = L)
1: Logical data from the data register are send/received in negative/inverse logic. (1 = L, 0 = H).

The parity bit is also inverted.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 17 TXINV: TX pin active level inversion

This bit is set and cleared by software.

0: TX pin signal works using the standard logic levels (VDD = 1/idle, Gnd = 0/mark)
1: TX pin signal values are inverted (VDD = 0/mark, Gnd = 1/idle).

This enables the use of an external inverter on the TX line.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 16 RXINV: RX pin active level inversion

This bit is set and cleared by software.

0: RX pin signal works using the standard logic levels (VDD = 1/idle, Gnd = 0/mark)
1: RX pin signal values are inverted (VDD = 0/mark, Gnd = 1/idle).

This enables the use of an external inverter on the RX line.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15 SWAP: Swap TX/RX pins

This bit is set and cleared by software.

0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.

This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 14 Reserved, must be kept at reset value.
38.7.4 LPUART control register 3 (LPUART_CR3)

Address offset: 0x08

Reset value: 0x0000 0000

Bit 13:12 **STOP[1:0]**: STOP bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: Reserved.
10: 2 stop bits
11: Reserved
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **ADDM7**: 7-bit address detection/4-bit address detection
This bit is for selection between 4-bit address detection or 7-bit address detection.
0: 4-bit address detection
1: 7-bit address detection (in 8-bit data mode)
This bit can only be written when the LPUART is disabled (UE = 0)

*Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.*

Bits 3:0 Reserved, must be kept at reset value.
Bits 31:29  **TXFTCFG[2:0]:** TX FIFO threshold configuration
110: TX FIFO reaches 1/2 of its depth.
101: TX FIFO reaches 3/4 of its depth.
011: TX FIFO reaches 7/8 of its depth.
100: TX FIFO becomes empty.
Remaining combinations: Reserved.

Bit 28  **RXFTIE:** RX FIFO threshold interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated when RX FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25  **RXFTCFG[2:0]:** Receive FIFO threshold configuration
011: Receive FIFO reaches 3/4 of its depth.
110: Receive FIFO reaches 1/2 of its depth.
100: Receive FIFO reaches 7/8 of its depth.
101: Receive FIFO becomes full.
Remaining combinations: Reserved.

Bit 24  Reserved, must be kept at reset value.

Bit 23  **TXFTIE:** TX FIFO threshold interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated when TX FIFO reaches the threshold programmed in TXFTCFG.

Bit 22  **WUFIE:** Wake-up from low-power mode interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever WUF = 1 in the LPUART_ISR register

**Note:** If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation.

Bits 21:20  **WUS[1:0]:** Wake-up from low-power mode interrupt flag selection
This bitfield specifies the event which activates the WUF (wake-up from low-power mode flag).
00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
01: Reserved.
10: WUF active on Start bit detection
11: WUF active on RXNE.

This bitfield can only be written when the LPUART is disabled (UE = 0).

**Note:** If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 37.4: USART implementation.

Bits 19:16  Reserved, must be kept at reset value.
Bit 15 **DEP**: Driver enable polarity selection
- 0: DE signal is active high.
- 1: DE signal is active low.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 14 **DEM**: Driver enable mode
This bit enables the user to activate the external transceiver control, through the DE signal.
- 0: DE function is disabled.
- 1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 13 **DDRE**: DMA disable on reception error
- 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred.
- 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.
This bit can only be written when the LPUART is disabled (UE = 0).
*Note*: The reception errors are: parity error, framing error or noise error.

Bit 12 **OVRDIS**: Overrun disable
This bit is used to disable the receive overrun detection.
- 0: Overrun Error Flag, ORE is set when received data is not read before receiving new data.
- 1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.
This bit can only be written when the LPUART is disabled (UE = 0).
*Note*: This control bit enables checking the communication flow w/o reading the data.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **CTSIE**: CTS interrupt enable
- 0: Interrupt is inhibited
- 1: An interrupt is generated whenever CTSIF = 1 in the LPUART_ISR register

Bit 9 **CTSE**: CTS enable
- 0: CTS hardware flow control disabled
- 1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).
If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
This bit can only be written when the LPUART is disabled (UE = 0)

Bit 8 **RTSE**: RTS enable
- 0: RTS hardware flow control disabled
- 1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted.
The RTS output is deasserted (pulled to 0) when data can be received.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 7 **DMAT**: DMA enable transmitter
- This bit is set/reset by software
- 1: DMA mode is enabled for transmission
- 0: DMA mode is disabled for transmission
38.7.5 LPUART baud rate register (LPUART_BRR)

This register can only be written when the LPUART is disabled (UE = 0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **BRR[19:0]:** LPUART baud rate

**Note:** It is forbidden to write values lower than 0x300 in the LPUART_BRR register. Provided that LPUART_BRR must be ≥ 0x300 and LPUART_BRR is 20 bits, a care should be taken when generating high baud rates using high fck values. fck must be in the range [3 x baud rate..4096 x baud rate].
38.7.6 LPUART request register (LPUART_RQR)

Address offset: 0x18
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 TXFRQ: Transmit data flush request
This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register).

Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3 RXFRQ: Receive data flush request
Writing 1 to this bit clears the RXNE flag. This enables discarding the received data without reading it, and avoid an overrun condition.

Bit 2 MMRQ: Mute mode request
Writing 1 to this bit puts the LPUART in mute mode and resets the RWU flag.

Bit 1 SBKRQ: Send break request
Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

Note: If the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0 Reserved, must be kept at reset value.

38.7.7 LPUART interrupt and status register (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0080 00C0

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

FIFO mode enabled
Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **TXFT**: TXFIFO threshold flag

This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG in LPUART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the LPUART_CR3 register.

0: TXFIFO does not reach the programmed threshold.
1: TXFIFO reached the programmed threshold.

Bit 26 **RXFT**: RXFIFO threshold flag

This bit is set by hardware when the RXFIFO reaches the threshold programmed in RXFTCFG in LPUART_CR3 register i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the LPUART_CR3 register.

0: Receive FIFO does not reach the programmed threshold.
1: Receive FIFO reached the programmed threshold.

Bit 25 Reserved, must be kept at reset value.

Bit 24 **RXFF**: RXFIFO full

This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the LPUART_RDR register. An interrupt is generated if the RXFFIE bit = 1 in the LPUART_CR1 register.

0: RXFIFO is not full
1: RXFIFO is full

Bit 23 **TXFE**: TXFIFO empty

This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register.

An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the LPUART_CR1 register.

0: TXFIFO is not empty
1: TXFIFO is empty

Bit 22 **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART.

It can be used to verify that the LPUART is ready for reception before entering low-power mode.

*N*ote: *If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.

It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the LPUART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 **WUF**: Wake-up from low-power mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register.

An interrupt is generated if WUFIE = 1 in the LPUART_CR3 register.

*N*ote: *When UESM is cleared, WUF flag is also cleared.*

*If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*
Bit 19  **RWU**: Receiver wake-up from mute mode
This bit indicates if the LPUART is in mute mode. It is cleared/set by hardware when a wake-
up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is
selected by the WAKE bit in the LPUART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the
MMRQ bit in the LPUART_RQR register.
0: Receiver in Active mode
1: Receiver in mute mode
*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and
kept at reset value.*

Bit 18  **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing
1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during
the stop bit of break transmission.
0: Break character transmitted
1: Break character requested by setting SBKRQ bit in LPUART_RQR register

Bit 17  **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is
cleared by software, writing 1 to the CMCF in the LPUART_ICR register.
An interrupt is generated if CMIE = 1 in the LPUART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16  **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX
line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: LPUART is idle (no reception)
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10  **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at
reset value.*

Bit 9  **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by
software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE = 1 in the LPUART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at
reset value.*

Bit 8  Reserved, must be kept at reset value.
Bit 7 **TXFNF**: TXFIFO not full

TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the LPUART_TDR.

The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).

An interrupt is generated if the TXFNFIE bit = 1 in the LPUART_CR1 register.

0: Data register is full/Transmit FIFO is full.

1: Data register/Transmit FIFO is not full.

*Note*: This bit is used during single buffer transmission.

Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXFF is set. An interrupt is generated if TCIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.

An interrupt is generated if TCIE = 1 in the LPUART_CR1 register.

0: Transmission is not complete

1: Transmission is complete

*Note*: If TE bit is reset and no transmission is on going, the TC bit is set immediately.

Bit 5 **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.

The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXFNEIE = 1 in the LPUART_CR1 register.

0: Data is not received

1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

0: No Idle line is detected

1: Idle line is detected

*Note*: The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).

If mute mode is enabled (MME = 1), IDLE is set if the LPUART is not mute (RWU = 0), whatever the mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.
Bit 3 **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXFNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.

0: No overrun error
1: Overrun error is detected

*Note*: When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.

Bit 2 **NE**: Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NECF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note*: This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

This error is associated with the character in the LPUART_RDR.

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note*: This error is associated with the character in the LPUART_RDR.

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

*Note*: This error is associated with the character in the LPUART_RDR.
38.7.8 LPUART interrupt and status register [alternate] (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

FIFO mode disabled

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 REACK: Receive enable acknowledge flag
This bit is set/reset by hardware when the Receive Enable value is taken into account by the LPUART.
It can be used to verify that the LPUART is ready for reception before entering low-power mode.

Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 21 TEACK: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.
It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the LPUART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 WUF: Wake-up from low-power mode flag
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register.
An interrupt is generated if WUFIE = 1 in the LPUART_CR3 register.

Note: When UESM is cleared, WUF flag is also cleared.

If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 19 RWU: Receiver wake-up from mute mode
This bit indicates if the LPUART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
0: Receiver in active mode
1: Receiver in mute mode

Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.
Bit 18 **SBKF**: Send break flag

This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.

0: Break character transmitted
1: Break character requested by setting SBKRQ bit in LPUART_RQR register

Bit 17 **CMF**: Character match flag

This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.

An interrupt is generated if CMIE = 1 in the LPUART_CR1 register.

0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag

This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: LPUART is idle (no reception)
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.

0: CTS line set
1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSIF**: CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.

An interrupt is generated if CTSIE = 1 in the LPUART_CR3 register.

0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXE**: Transmit data register empty/TXFIFO not full

TXE is set by hardware when the content of the LPUART_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART_TDR register.

An interrupt is generated if the TXEIE bit = 1 in the LPUART_CR1 register.

0: Data register full
1: Data register not full

*Note: This bit is used during single buffer transmission.*
Bit 6  **TC**: Transmission complete
This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.
An interrupt is generated if TCIE = 1 in the LPUART_CR1 register.
0: Transmission is not complete
1: Transmission is complete
*Note: If TE bit is reset and no transmission is on going, the TC bit is immediately set.*

Bit 5  **RXNE**: Read data register not empty
RXNE bit is set by hardware when the content of the LPUART_RDR shift register has been transferred to the LPUART_RDR register. It is cleared by reading from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.
An interrupt is generated if RXNEIE = 1 in the LPUART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.
0: No Idle line is detected
1: Idle line is detected
*Note: The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs). If mute mode is enabled (MME = 1), IDLE is set if the LPUART is not mute (RWU = 0), whatever the mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.*

Bit 3  **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXNE = 1. It is cleared by a software, writing 1 to the OREC, in the LPUART_ICR register.
An interrupt is generated if RXNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.
0: No overrun error
1: Overrun error is detected
*Note: When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set. This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.*
Bit 2 NE: Start bit noise detection flag
This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NECF bit in the LPUART_ICR register.
0: No noise is detected
1: Noise is detected

Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

Bit 1 FE: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.
When transmitting data in smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if EIE = 1 in the LPUART_CR3 register.
0: No Framing error is detected
1: Framing error or break character is detected

Bit 0 PE: Parity error
This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.
An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.
0: No parity error
1: Parity error

38.7.9 LPUART interrupt flag clear register (LPUART_ICR)
Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 WUCF: Wake-up from low-power mode clear flag
Writing 1 to this bit clears the WUF flag in the LPUART_ISR register.

Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 37.4: USART implementation.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 CMCF: Character match clear flag
Writing 1 to this bit clears the CMF flag in the LPUART_ISR register.

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 CTSCF: CTS clear flag
Writing 1 to this bit clears the CTSIF flag in the LPUART_ISR register.
38.7.10  LPUART receive data register (LPUART_RDR)

Address offset: 0x24
Reset value: 0x0000 0000

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  RDR[8:0]: Receive data value
Contains the received data character.
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 558).
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

38.7.11  LPUART transmit data register (LPUART_TDR)

Address offset: 0x28
Reset value: 0x0000 0000

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  TDR[8:0]: Transmit data value
Contains the transmitted data character.
38.7.12 LPUART prescaler register (LPUART_PRESC)

This register can only be written when the LPUART is disabled (UE = 0).

Address offset: 0x2C

</table>

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PRESCALER[3:0]:** Clock prescaler

The LPUART input clock can be divided by a prescaler:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved.

*Note: When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is 1011 i.e. input clock divided by 256. If the prescaler is not supported, this bitfield is reserved and must be kept at reset value. Refer to Section 38.3: LPUART implementation on page 1697.*

Serial peripheral interface / integrated interchip sound (SPI/I2S)

39.1 Introduction

The SPI/I²S interface can be used to communicate with external devices using the SPI protocol or the I²S audio protocol. SPI or I²S mode is selectable by software. SPI Motorola mode is selected by default after a device reset.

The serial peripheral interface (SPI) protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

The integrated interchip sound (I²S) protocol is also a synchronous serial communication interface. It can operate in slave or master mode with half-duplex communication. It can address four different audio standards including the Philips I²S standard, the MSB- and LSB-justified standards and the PCM standard.

39.2 SPI main features

- Master or slave operation
- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- 4 to 16-bit data size selection
- Multimaster mode capability
- 8 master mode baud rate prescalers up to \( f_{PCLK}/2 \)
- Slave mode frequency up to \( f_{PCLK}/2 \)
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI Motorola support
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun flags with interrupt capability
- CRC Error flag
- Two 32-bit embedded Rx and Tx FIFOs with DMA capability
- Enhanced TI and NSS pulse modes support
39.3 I2S main features

- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler to reach accurate audio sample frequencies (from 8 kHz to 192 kHz)
- Data format may be 16-bit, 24-bit, or 32-bit
- Packet frame is fixed to 16-bit (16-bit data frame) or 32-bit (16-bit, 24-bit, 32-bit data frame) by audio channel
- Programmable clock polarity (steady state)
- Underrun flag in slave transmission mode, overrun flag in reception mode (master and slave) and Frame Error Flag in reception and transmitter mode (slave only)
- 16-bit register for transmission and reception with one data register for both channel sides
- Supported I2S protocols:
  - I2S Philips standard
  - MSB-justified standard (left-justified)
  - LSB-justified standard (right-justified)
  - PCM standard (with short and long frame synchronization on 16-bit channel frame or 16-bit data frame extended to 32-bit channel frame)
- Data direction is always MSB first
- DMA capability for transmission and reception (16-bit wide)
- Master clock can be output to drive an external audio component. The ratio is fixed at 256 \times f_s for all I2S modes, and to 128 \times f_s for all PCM modes (where f_s is the audio sampling frequency).

39.4 SPI/I2S implementation

39.5 SPI functional description

39.5.1 General description

The SPI allows synchronous, serial communication between the MCU and external devices. Application software can manage the communication by polling the status flag or using dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram

Figure 572. SPI block diagram

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO**: Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI**: Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK**: Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **NSS**: Slave select pin. Depending on the SPI and NSS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame or
  - detect a conflict between multiple masters

See Section 39.5.5: Slave select (NSS) pin management for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires - one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management.
39.5.2 Communications between one master and one slave

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software NSS management) or 3 or 4 wires (with hardware NSS management). Communication is always initiated by the master.

Full-duplex communication

By default, the SPI is configured for full-duplex communication. In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During SPI communication, data is shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

\[\text{Figure 573. Full-duplex single master/ single slave application}\]

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 39.5.5: Slave select (NSS) pin management.

Half-duplex communication

The SPI can communicate in half-duplex mode by setting the BIDIMODE bit in the SPIx_CR1 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data is synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the BDIOE bit in their SPIx_CR1 registers. In this configuration, the master’s MISO pin and the slave’s MOSI pin are free for other application uses and act as GPIOs.
1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 39.5.5: Slave select (NSS) pin management.

2. In this configuration, the master’s MISO pin and the slave’s MOSI pin can be used as GPIOs.

3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communication data). Both nodes then fight while providing opposite output levels on the common line temporary till next node changes its direction settings correspondingly, too. It is suggested to insert a serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

**Simplex communications**

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the RXONLY bit in the SPIx_CR1 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO and MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode (RXONLY=0):** The configuration settings are the same as for full-duplex. The application has to ignore the information captured on the unused input pin. This pin can be used as a standard GPIO.
- **Receive-only mode (RXONLY=1):** The application can disable the SPI output function by setting the RXONLY bit. In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see 39.5.5: Slave select (NSS) pin management). Received data events appear depending on the data buffer configuration. In the master configuration, the MOSI output is disabled and the pin can be used as a GPIO. The clock signal is generated continuously as long as the SPI is enabled. The only way to stop the clock is to clear the RXONLY bit or the SPE bit and wait until the incoming pattern from the MISO pin is finished and fills the data buffer structure, depending on its configuration.
1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 39.5.5: Slave select (NSS) pin management.

2. An accidental input information is captured at the input of transmitter Rx shift register. All the events associated with the transmitter receive flow must be ignored in standard transmit only mode (e.g. OVR flag).

3. In this configuration, both the MISO pins can be used as GPIOs.

Note: Any simplex communication can be alternatively replaced by a variant of the half-duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled while BDIO bit is not changed).

### 39.5.3 Standard multislave communication

In a configuration with two or more independent slaves, the master uses GPIO pins to manage the chip select lines for each slave (see Figure 576). The master must select one of the slaves individually by pulling low the GPIO connected to the slave NSS input. When this is done, a standard master and dedicated slave communication is established.
39.5.4 Multimaster communication

Unless SPI bus is not designed for a multimaster capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, NSS pin is used configured at hardware input mode.

The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.
If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

Figure 577. Multimaster application

1. The NSS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as the passive node is configured as a slave.

39.5.5 Slave select (NSS) pin management

In slave mode, the NSS works as a standard “chip select” input and lets the slave communicate with the master. In master mode, NSS can be used either as output or input. As an input it can prevent multimaster bus collision, and as an output it can drive a slave select signal of a single slave.

Hardware or software slave select management can be set using the SSM bit in the SPIx_CR1 register:

- **Software NSS management (SSM = 1)**: in this configuration, slave select information is driven internally by the SSI bit value in register SPIx_CR1. The external NSS pin is free for other application uses.

- **Hardware NSS management (SSM = 0)**: in this case, there are two possible configurations. The configuration used depends on the NSS output configuration (SSOE bit in register SPIx_CR1).
  - **NSS output enable (SSM=0, SSOE = 1)**: this configuration is only used when the MCU is set as master. The NSS pin is managed by the hardware. The NSS signal is driven low as soon as the SPI is enabled in master mode (SPE=1), and is kept low until the SPI is disabled (SPE =0). A pulse can be generated between continuous communications if NSS pulse mode is activated (NSSP=1). The SPI cannot work in multimaster configuration with this NSS setting.
  - **NSS output disable (SSM=0, SSOE = 0)**: if the microcontroller is acting as the master on the bus, this configuration allows multimaster capability. If the NSS pin is pulled low in this mode, the SPI enters master mode fault state and the device is automatically reconfigured in slave mode. In slave mode, the NSS pin works as a standard “chip select” input and the slave is selected while NSS line is at low level.
39.5.6 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slaves devices must follow the same communication format.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPIx_CR1 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.
Figure 579, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPIx_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

Figure 579. Data clock timing diagram

![Data clock timing diagram]

1. The order of data bits depends on LSBFIRST bit setting.

Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit. The data frame size is chosen by using the DS bits. It can be set from 4-bit up to 16-bit length and the setting applies for both transmission and reception. Whatever the selected data frame size, read access to the FIFO must be aligned with the FRXTH level. When the SPIx_DR register is accessed, data frames are always right-aligned into either a byte (if the data fits into a byte) or a half-word (see Figure 580). During communication, only bits within the data frame are clocked and transferred.

Note: The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 8-bit data frame size.

39.5.7 Configuration of SPI

The configuration procedure is almost the same for master and slave. For specific mode setups, follow the dedicated sections. When a standard communication is to be initialized, perform these steps:

1. Write proper GPIO registers: Configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI_CR1 register:
   a) Configure the serial clock baud rate using the BR[2:0] bits (Note: 4).
   b) Configure the CPOL and CPHA bits combination to define one of the four relationships between the data transfer and the serial clock (CPHA must be cleared in NSSP mode). (Note: 2 - except the case when CRC is enabled at TI mode).
   c) Select simplex or half-duplex mode by configuring RXONLY or BIDIMODE and BIDIOE (RXONLY and BIDIMODE cannot be set at the same time).
   d) Configure the LSBFIRST bit to define the frame format (Note: 2).
   e) Configure the CRCL and CRCEN bits if CRC is needed (while SCK clock signal is at idle state).
   f) Configure SSM and SSI (Notes: 2 & 3).
   g) Configure the MSTR bit (in multimaster NSS configuration, avoid conflict state on NSS if master is configured to prevent MODF error).
3. Write to SPI_CR2 register:
   a) Configure the DS[3:0] bits to select the data length for the transfer.
   b) Configure SSOE (Notes: 1 & 2 & 3).
   c) Set the FRF bit if the TI protocol is required (keep NSSP bit cleared in TI mode).
   d) Set the NSSP bit if the NSS pulse mode between two data units is required (keep CHPA and TI bits cleared in NSSP mode).
   e) Configure the FRXTH bit. The RXFIFO threshold must be aligned to the read access size for the SPIx_DR register.
   f) Initialize LDMA_TX and LDMA_RX bits if DMA is used in packed mode.
4. Write to SPI_CRCPR register: Configure the CRC polynomial if needed.
5. Write proper DMA registers: Configure DMA streams dedicated for SPI Tx and Rx in DMA registers if the DMA streams are used.
Note:  
(1) Step is not required in slave mode.  
(2) Step is not required in TI mode.  
(3) Step is not required in NSSP mode.  
(4) The step is not required in slave mode except slave working at TI mode.

39.5.8 Procedure for enabling SPI

It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave must already contain data to be sent before starting communication with the master (either on the first edge of the communication clock, or before the end of the ongoing communication if the clock signal is continuous). The SCK signal must be settled at an idle state level corresponding to the selected polarity before the SPI slave is enabled.

The master at full-duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled and TXFIFO is not empty, or with the next write to TXFIFO.

In any master receive only mode (RXONLY = 1 or BIDIMODE = 1 & BIDIOE = 0), master starts to communicate and the clock starts running immediately after SPI is enabled.

For handling DMA, follow the dedicated section.

39.5.9 Data transmission and reception procedures

RXFIFO and TXFIFO

All SPI data transactions pass through the 32-bit embedded FIFOs. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short. Each direction has its own FIFO called TXFIFO and RXFIFO. These FIFOs are used in all SPI modes except for receiver-only mode (slave or master) with CRC calculation enabled (see Section 39.5.14: CRC calculation).

The handling of FIFOs depends on the data exchange mode (duplex, simplex), data frame format (number of bits in the frame), access size performed on the FIFO data registers (8-bit or 16-bit), and whether or not data packing is used when accessing the FIFOs (see Section 39.5.13: TI mode).

A read access to the SPIx_DR register returns the oldest value stored in RXFIFO that has not been read yet. A write access to the SPIx_DR stores the written data in the TXFIFO at the end of a send queue. The read access must be always aligned with the RXFIFO threshold configured by the FRXTH bit in SPIx_CR2 register. FTLVL[1:0] and FRLVL[1:0] bits indicate the current occupancy level of both FIFOs.  

A read access to the SPIx_DR register must be managed by the RXNE event. This event is triggered when data is stored in RXFIFO and the threshold (defined by FRXTH bit) is reached. When RXNE is cleared, RXFIFO is considered to be empty. In a similar way, write access of a data frame to be transmitted is managed by the TXE event. This event is triggered when the TXFIFO level is less than or equal to half of its capacity. Otherwise TXE is cleared and the TXFIFO is considered as full. In this way, RXFIFO can store up to four data frames, whereas TXFIFO can only store up to three when the data frame format is not greater than 8 bits. This difference prevents possible corruption of 3x 8-bit data frames already stored in the TXFIFO when software tries to write more data in 16-bit mode into TXFIFO. Both TXE and RXNE events can be polled or handled by interrupts. See Figure 582 through Figure 585.
Another way to manage the data exchange is to use DMA (see Communication using DMA (direct memory addressing)).

If the next data is received when the RXFIFO is full, an overrun event occurs (see description of OVR flag at Section 39.5.10: SPI status flags). An overrun event can be polled or handled by an interrupt.

The BSY bit being set indicates ongoing transaction of a current data frame. When the clock signal runs continuously, the BSY flag stays set between data frames at master but becomes low for a minimum duration of one SPI clock at slave between each data frame transfer.

Sequence handling

A few data frames can be passed at single sequence to complete a message. When transmission is enabled, a sequence begins and continues while any data is present in the TXFIFO of the master. The clock signal is provided continuously by the master until TXFIFO becomes empty, then it stops waiting for additional data.

In receive-only modes, half-duplex (BIDIMODE=1, BIDIOE=0) or simplex (BIDIMODE=0, RXONLY=1) the master starts the sequence immediately when both SPI is enabled and receive-only mode is activated. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled by the master. The master receives data frames continuously up to this moment.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays. Be aware there is no underflow error signal for master or slave in SPI mode, and data from the slave is always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are shorter and bus rate is high.

Each sequence must be encased by the NSS pulse in parallel with the multislave system to select just one of the slaves for communication. In a single slave system it is not necessary to control the slave with NSS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. NSS can be managed by both software and hardware (see Section 39.5.5: Slave select (NSS) pin management).

When the BSY bit is set it signifies an ongoing data frame transaction. When the dedicated frame transaction is finished, the RXNE flag is raised. The last bit is just sampled and the complete data frame is stored in the RXFIFO.

Procedure for disabling the SPI

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph. It is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Ongoing transactions can be corrupted in this case. In some modes the disable procedure is the only way to stop continuous communication running.

Master in full-duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. Special care must be taken in packing mode when an odd number of data frames are transacted to prevent some dummy byte exchange (refer to Data packing section). Before the SPI is disabled in these modes, the user must follow standard disable procedure. When
the SPI is disabled at the master transmitter while a frame transaction is ongoing or next data frame is stored in TXFIFO, the SPI behavior is not guaranteed.

When the master is in any receive only mode, the only way to stop the continuous clock is to disable the peripheral by SPE=0. This must occur in specific time window within last data frame transaction just between the sampling time of its first bit and before its last bit transfer starts (in order to receive a complete number of expected data frames and to prevent any additional “dummy” data reading after the last valid data frame). Specific procedure must be followed when disabling SPI in this mode.

Data received but not read remains stored in RXFIFO when the SPI is disabled, and must be processed the next time the SPI is enabled, before starting a new sequence. To prevent having unread data, ensure that RXFIFO is empty when disabling the SPI, by using the correct disabling procedure, or by initializing all the SPI registers with a software reset via the control of a specific register dedicated to peripheral reset (see the SPIiRST bits in the RCC_APBiRSTR registers).

Standard disable procedure is based on pulling BSY status together with FTLVL[1:0] to check if a transmission session is fully completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When NSS signal is managed by software and master has to provide proper end of NSS pulse for slave, or
- When transactions’ streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

The correct disable procedure is (except when receive only mode is used):
1. Wait until FTLVL[1:0] = 00 (no more data to transmit).
2. Wait until BSY=0 (the last data frame is processed).
3. Disable the SPI (SPE=0).
4. Read data until FRLVL[1:0] = 00 (read all the received data).

The correct disable procedure for certain receive only modes is:
1. Interrupt the receive flow by disabling SPI (SPE=0) in the specific time window while the last data frame is ongoing.
2. Wait until BSY=0 (the last data frame is processed).
3. Read data until FRLVL[1:0] = 00 (read all the received data).

Note: If packing mode is used and an odd number of data frames with a format less than or equal to 8 bits (fitting into one byte) has to be received, FRXTH must be set when FRLVL[1:0] = 01, in order to generate the RXNE event to read the last odd data frame and to keep good FIFO pointer alignment.

Data packing

When the data frame size fits into one byte (less than or equal to 8 bits), data packing is used automatically when any read or write 16-bit access is performed on the SPIx_DR register. The double data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other half stored in the MSB. Figure 581 provides an example of data packing mode sequence handling. Two data frames are sent after the single 16-bit access the SPIx_DR register of the transmitter. This sequence can generate just one RXNE event in the receiver if the RXFIFO threshold is set to 16 bits (FRXTH=0). The receiver then has to access both data frames by a single 16-bit read of SPIx_DR as a response to this single RXNE event. The
Rx_FIFO threshold setting and the following read access must be always kept aligned at the receiver side, as data can be lost if it is not in line.

A specific problem appears if an odd number of such “fit into one byte” data frames must be handled. On the transmitter side, writing the last data frame of any odd sequence with an 8-bit access to SPIx_DR is enough. The receiver has to change the Rx_FIFO threshold level for the last data frame received in the odd sequence of frames in order to generate the RXNE event.

Figure 581. Packing data in FIFO for transmission and reception

1. In this example: Data size DS[3:0] is 4-bit configured, CPOL=0, CPHA=1 and LSBFIRST =0. The Data storage is always right aligned while the valid bits are performed on the bus only, the content of LSB byte goes first on the bus, the unused bits are not taken into account on the transmitter side and padded by zeros at the receiver side.

Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXDMAEN or RXDMAEN enable bit in the SPIx_CR2 register is set. Separate requests must be issued to the Tx and Rx buffers.

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPIx_DR register.
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPIx_DR register.

See Figure 582 through Figure 585.

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received is not read. When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until FTLVL[1:0]=00 and then until BSY=0.
When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:
1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CR2 register, if DMA Rx is used.
2. Enable DMA streams for Tx and Rx in DMA registers, if the streams are used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CR2 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:
1. Disable DMA streams for Tx and Rx in the DMA registers, if the streams are used.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CR2 register, if DMA Tx and/or DMA Rx are used.

**Packing with DMA**

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPIx_CR2 register) packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel. If the DMA channel PSIZE value is equal to 16-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPIx_DR register.

If data packing mode is used and the number of data to transfer is not a multiple of two, the LDMA_TX/LDMA_RX bits must be set. The SPI then considers only one data for the transmission or reception to serve the last DMA transfer (for more details refer to [Data packing on page 1762](#)).
Communication diagrams

Some typical timing schemes are explained in this section. These schemes are valid no matter if the SPI events are handled by polling, interrupts or DMA. For simplicity, the LSBFIRST=0, CPOL=0 and CPHA=1 setting is used as a common assumption here. No complete configuration of DMA streams is provided.

The following numbered notes are common for Figure 582 on page 1766 through Figure 585 on page 1769:

1. The slave starts to control MISO line as NSS is active and SPI is enabled, and is disconnected from the line when one of them is released. Sufficient time must be provided for the slave to prepare data dedicated to the master in advance before its transaction starts.

   At the master, the SPI peripheral takes control at MOSI and SCK signals (occasionally at NSS signal as well) only if SPI is enabled. If SPI is disabled the SPI peripheral is disconnected from GPIO logic, so the levels at these lines depends on GPIO setting exclusively.

2. At the master, BSY stays active between frames if the communication (clock signal) is continuous. At the slave, BSY signal always goes down for at least one clock cycle between data frames.

3. The TXE signal is cleared only if TXFIFO is full.

4. The DMA arbitration process starts just after the TXDMAEN bit is set. The TXE interrupt is generated just after the TXEIE is set. As the TXE signal is at an active level, data transfers to TxFIFO start, until TxFIFO becomes full or the DMA transfer completes.

5. If all the data to be sent can fit into TxFIFO, the DMA Tx TCIF flag can be raised even before communication on the SPI bus starts. This flag always rises before the SPI transaction is completed.

6. The CRC value for a package is calculated continuously frame by frame in the SPIx_TXCRCR and SPIx_RXCRCR registers. The CRC information is processed after the entire data package has completed, either automatically by DMA (Tx channel must be set to the number of data frames to be processed) or by SW (the user must handle CRCNEXT bit during the last data frame processing).

   While the CRC value calculated in SPIx_TXCRCR is simply sent out by transmitter, received CRC information is loaded into RxFIFO and then compared with the SPIx_RXCRCR register content (CRC error flag can be raised here if any difference). This is why the user must take care to flush this information from the FIFO, either by software reading out all the stored content of RxFIFO, or by DMA when the proper number of data frames is preset for Rx channel (number of data frames + number of CRC frames) (see the settings at the example assumption).

7. In data packed mode, TxE and RxNE events are paired and each read/write access to the FIFO is 16 bits wide until the number of data frames are even. If the TxFIFO is ¾ full FTLVL status stays at FIFO full level. That is why the last odd data frame cannot be stored before the TxFIFO becomes ½ full. This frame is stored into TxFIFO with an 8-bit access either by software or automatically by DMA when LDMA_TX control is set.

8. To receive the last odd data frame in packed mode, the Rx threshold must be changed to 8-bit when the last data frame is processed, either by software setting FRXTH=1 or automatically by a DMA internal signal when LDMA_RX is set.
Assumptions for master full-duplex communication example:

- Data size > 8 bit

If DMA is used:
- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams on page 1765 for details about common assumptions and notes.
Figure 583. Slave full-duplex communication

Assumptions for slave full-duplex communication example:
- Data size > 8 bit
- If DMA is used:
  - Number of Tx frames transacted by DMA is set to 3
  - Number of Rx frames transacted by DMA is set to 3

See also Communication diagrams on page 1765 for details about common assumptions and notes.
Figure 584. Master full-duplex communication with CRC

Assumptions for master full-duplex communication with CRC example:
- Data size = 16 bit
- CRC enabled

If DMA is used:
- Number of Tx frames transacted by DMA is set to 2
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams on page 1765 for details about common assumptions and notes.
Assumptions for master full-duplex communication in packed mode example:

- Data size = 5 bit
- Read/write FIFO is performed mostly by 16-bit access
- FRXTH=0

If DMA is used:
- Number of Tx frames to be transacted by DMA is set to 3
- Number of Rx frames to be transacted by DMA is set to 3
- PSIZE for both Tx and Rx DMA channel is set to 16-bit
- LDMA_TX=1 and LDMA_RX=1

See also: Communication diagrams on page 1765 for details about common assumptions and notes.
39.5.10 SPI status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

**Tx buffer empty flag (TXE)**

The TXE flag is set when transmission TXFIFO has enough space to store data to send. TXE flag is linked to the TXFIFO level. The flag goes high and stays high until the TXFIFO level is lower or equal to 1/2 of the FIFO depth. An interrupt can be generated if the TXEIE bit in the SPIx_CR2 register is set. The bit is cleared automatically when the TXFIFO level becomes greater than 1/2.

**Rx buffer not empty (RXNE)**

The RXNE flag is set depending on the FRXTH bit value in the SPIx_CR2 register:

- If FRXTH is set, RXNE goes high and stays high until the RXFIFO level is greater or equal to 1/4 (8-bit).
- If FRXTH is cleared, RXNE goes high and stays high until the RXFIFO level is greater than or equal to 1/2 (16-bit).

An interrupt can be generated if the RXNEIE bit in the SPIx_CR2 register is set.

The RXNE is cleared by hardware automatically when the above conditions are no longer true.

**Busy flag (BSY)**

The BSY flag is set and cleared by hardware (writing to this flag has no effect).

When BSY is set, it indicates that a data transfer is in progress on the SPI (the SPI bus is busy).

The BSY flag can be used in certain modes to detect the end of a transfer so that the software can disable the SPI or its peripheral clock before entering a low-power mode which does not provide a clock for the peripheral. This avoids corrupting the last transfer.

The BSY flag is also useful for preventing write collisions in a multimaster system.

The BSY flag is cleared under any one of the following conditions:

- When the SPI is correctly disabled
- When a fault is detected in Master mode (MODF bit set to 1)
- In Master mode, when it finishes a data transmission and no new data is ready to be sent
- In Slave mode, when the BSY flag is set to '0' for at least one SPI clock cycle between each data transfer.

*Note:* When the next transmission can be handled immediately by the master (e.g. if the master is in Receive-only mode or its Transmit FIFO is not empty), communication is continuous and the BSY flag remains set to '1' between transfers on the master side. Although this is not the case with a slave, it is recommended to use always the TXE and RXNE flags (instead of the BSY flags) to handle data transmission or reception operations.
39.5.11  SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the ERRIE bit.

**Overrun flag (OVR)**

An overrun condition occurs when data is received by a master or slave and the RXFIFO has not enough space to store this received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RXFIFO) or when space for data storage is limited e.g. the RXFIFO is not available when CRC is enabled in receive only mode so in this case the reception buffer is limited into a single data frame buffer (see Section 39.5.14: CRC calculation).

When an overrun condition occurs, the newly received value does not overwrite the previous one in the RXFIFO. The newly received value is discarded and all data transmitted subsequently is lost. Clearing the OVR bit is done by a read access to the SPI_DR register followed by a read access to the SPI_SR register.

**Mode fault (MODF)**

Mode fault occurs when the master device has its internal NSS signal (NSS pin in NSS hardware mode, or SSI bit in NSS software mode) pulled low. This automatically sets the MODF bit. Master mode fault affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:
1. Make a read or write access to the SPIx_SR register while the MODF bit is set.
2. Then write to the SPIx_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence. As a security, hardware does not allow the SPE and MSTR bits to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multimaster conflict.

**CRC error (CRCERR)**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPIx_CR1 register is set. The CRCERR flag in the SPIx_SR register is set if the value received in the shift register does not match the receiver SPIx_RXCRCR value. The flag is cleared by the software.

**TI mode frame format error (FRE)**

A TI mode frame format error is detected when an NSS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPIx_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of two data bytes.
The FRE flag is cleared when SPIx_SR register is read. If the ERRIE bit is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no longer guaranteed and communications should be reinitiated by the master when the slave SPI is enabled again.

### 39.5.12 NSS pulse mode

This mode is activated by the NSSP bit in the SPIx_CR2 register and it takes effect only if the SPI interface is configured as Motorola SPI master (FRF=0) with capture on the first edge (SPIx_CR1 CPHA = 0, CPOL setting is ignored). When activated, an NSS pulse is generated between two consecutive data frame transfers when NSS stays at high level for the duration of one clock period at least. This mode allows the slave to latch data. NSSP pulse mode is designed for applications with a single master-slave pair. 

*Figure 586* illustrates NSS pin management when NSSP pulse mode is enabled.

*Figure 586. NSSP pulse generation in Motorola SPI master mode*

![NSS pulse generation in Motorola SPI master mode](image)

**Note:** Similar behavior is encountered when CPOL = 0. In this case the sampling edge is the *rising* edge of SCK, and NSS assertion and deassertion refer to this sampling edge.

### 39.5.13 TI mode

**TI protocol in master mode**

The SPI interface is compatible with the TI protocol. The FRF bit of the SPIx_CR2 register can be used to configure the SPI to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPIx_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPIx_CR1 and SPIx_CR2 registers (SSM, SSI, SSOE) impossible in this case.

In slave mode, the SPI baud rate prescaler is used to control the moment when the MISO pin state changes to HiZ when the current transaction finishes (see *Figure 587*). Any baud rate can be used, making it possible to determine this moment with optimal flexibility. However, the baud rate is generally set to the external master clock baud rate. The delay for the MISO signal to become HiZ ($t_{release}$) depends on internal resynchronization and on the
baud rate value set in through the BR[2:0] bits in the SPIx_CR1 register. It is given by the formula:

\[ \frac{t_{\text{baud rate}}}{2} + 4 \times t_{\text{pclk}} < t_{\text{release}} < \frac{t_{\text{baud rate}}}{2} + 6 \times t_{\text{pclk}} \]

If the slave detects a misplaced NSS pulse during a data frame transaction the TIFRE flag is set.

If the data size is equal to 4-bits or 5-bits, the master in full-duplex mode or transmit-only mode uses a protocol with one more dummy data bit added after LSB. TI NSS pulse is generated above this dummy bit clock cycle instead of the LSB in each period.

This feature is not available for Motorola SPI communications (FRF bit set to 0).

*Figure 587: TI mode transfer* shows the SPI communication waveforms when TI mode is selected.

**Figure 587. TI mode transfer**

---

### 39.5.14 CRC calculation

Two separate CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers CRC8 or CRC16 calculation independently of the frame data length, which can be fixed to 8-bit or 16-bit. For all the other data frame lengths, no CRC is available.

**CRC principle**

CRC calculation is enabled by setting the CRCEN bit in the SPIx_CR1 register before the SPI is enabled (SPE = 1). The CRC value is calculated using an odd programmable polynomial on each bit. The calculation is processed on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx_CR1 register. The calculated CRC value is checked automatically at the end of the data block as well as for transfer managed by CPU or by the DMA. When a mismatch is detected between the CRC calculated internally on the received data and the CRC sent by the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC calculation depends on the SPI configuration and the chosen transfer management.
Note: The polynomial value should only be odd. No even values are supported.

**CRC transfer managed by CPU**

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx_DR register. Then CRCNEXT bit has to be set in the SPIx_CR1 register to indicate that the CRC frame transaction follows after the transaction of the currently processed data frame. The CRCNEXT bit must be set before the end of the last data frame transaction. CRC calculation is frozen during CRC transaction.

The received CRC is stored in the RXFIFO like a data byte or word. That is why in CRC mode only, the reception buffer has to be considered as a single 16-bit buffer used to receive only one data frame at a time.

A CRC-format transaction usually takes one more data frame to communicate at the end of data sequence. However, when setting an 8-bit data frame checked by 16-bit CRC, two more frames are necessary to send the complete CRC.

When the last CRC data is received, an automatic check is performed comparing the received value and the value in the SPIx_RXCRC register. Software has to check the CRCERR flag in the SPIx_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing '0' to it.

After the CRC reception, the CRC value is stored in the RXFIFO and must be read in the SPIx_DR register in order to clear the RXNE flag.

**CRC transfer managed by DMA**

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication is automatic (with the exception of reading CRC data in receive only mode). The CRCNEXT bit does not have to be handled by the software. The counter for the SPI transmission DMA channel has to be set to the number of data frames to transmit excluding the CRC frame. On the receiver side, the received CRC value is handled automatically by DMA at the end of the transaction but user must take care to flush out received CRC information from RXFIFO as it is always loaded into it. In full-duplex mode, the counter of the reception DMA channel can be set to the number of data frames to receive including the CRC, which means, for example, in the specific case of an 8-bit data frame checked by 16-bit CRC:

\[
\text{DMA_RX} = \text{Numb_of_data} + 2
\]

In receive only mode, the DMA reception channel counter should contain only the amount of data transferred, excluding the CRC calculation. Then based on the complete transfer from DMA, all the CRC values must be read back by software from FIFO as it works as a single buffer in this mode.

At the end of the data and CRC transfers, the CRCERR flag in the SPIx_SR register is set if corruption occurred during the transfer.

If packing mode is used, the LDMA_RX bit needs managing if the number of data is odd.

**Resetting the SPIx_TXCRC and SPIx_RXCRC values**

The SPIx_TXCRC and SPIx_RXCRC values are cleared automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode (not available in receive-only mode) in order to transfer data without any interruption, (several data blocks covered by intermediate CRC checking phases).
If the SPI is disabled during a communication the following sequence must be followed:
1. Disable the SPI
2. Clear the CRCEN bit
3. Enable the CRCEN bit
4. Enable the SPI

**Note:** When the SPI interface is configured as a slave, the NSS internal signal needs to be kept low during transaction of the CRC phase once the CRCNEXT signal is released. That is why the CRC calculation cannot be used at NSS Pulse mode when NSS hardware mode should be applied at slave normally.

At TI mode, despite the fact that clock phase and clock polarity setting is fixed and independent on SPIx_CR1 register, the corresponding setting CPOL=0 CPHA=1 has to be kept at the SPIx_CR1 register anyway if CRC is applied. In addition, the CRC calculation has to be reset between sessions by SPI disable sequence with re-enable the CRCEN bit described above at both master and slave side, else CRC calculation can be corrupted at this specific mode.

### 39.6 SPI interrupts

During SPI communication an interrupt can be generated by the following events:

- Transmit TXFIFO ready to be loaded
- Data received in Receive RXFIFO
- Master mode fault
- Overrun error
- TI frame format error
- CRC protocol error

Interrupts can be enabled and disabled separately.

39.7 I2S functional description

39.7.1 I2S general description

The block diagram of the I2S is shown in Figure 588.

The SPI can function as an audio I2S interface when the I2S capability is enabled (by setting the I2SMOD bit in the SPIx_I2SCFGR register). This interface mainly uses the same pins, flags and interrupts as the SPI.
The I2S shares three common pins with the SPI:

- **SD**: Serial Data (mapped on the MOSI pin) to transmit or receive the two time-multiplexed data channels (in half-duplex mode only).
- **WS**: Word Select (mapped on the NSS pin) is the data control signal output in master mode and input in slave mode.
- **CK**: Serial Clock (mapped on the SCK pin) is the serial clock output in master mode and serial clock input in slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- **MCK**: Master Clock (mapped separately) is used, when the I2S is configured in master mode (and when the MCKOE bit in the SPIx_I2SPR register is set), to output this additional clock generated at a preconfigured frequency rate equal to \(256 \times f_S\) for all I2S modes, and to \(128 \times f_S\) for all PCM modes, where \(f_S\) is the audio sampling frequency.

The I2S uses its own clock generator to produce the communication clock when it is set in master mode. This clock generator is also the source of the master clock output. Two additional registers are available in I2S mode. One is linked to the clock generator configuration SPIx_I2SPR and the other one is a generic I2S configuration register SPIx_I2SCFGR (audio standard, slave/master mode, data format, packet frame, clock polarity, etc.).

The SPIx_CR1 register and all CRC registers are not used in the I2S mode. Likewise, the SSOE bit in the SPIx_CR2 register and the MODF and CRCERR bits in the SPIx_SR are not used.

The I2S uses the same SPI register for data transfer (SPIx_DR) in 16-bit wide mode.

### 39.7.2 Supported audio protocols

The three-line bus has to handle only audio data generally time-multiplexed on two channels: the right channel and the left channel. However there is only one 16-bit register for transmission or reception. So, it is up to the software to write into the data register the appropriate value corresponding to each channel side, or to read the data from the data register and to identify the corresponding channel by checking the CHSIDE bit in the SPIx_SR register. Channel left is always sent first followed by the channel right (CHSIDE has no meaning for the PCM protocol).

Four data and packet frames are available. Data may be sent with a format of:

- 16-bit data packed in a 16-bit frame
- 16-bit data packed in a 32-bit frame
- 24-bit data packed in a 32-bit frame
- 32-bit data packed in a 32-bit frame

When using 16-bit data extended on 32-bit packet, the first 16 bits (MSB) are the significant bits, the 16-bit LSB is forced to 0 without any need for software action or DMA request (only one read/write operation).

The 24-bit and 32-bit data frames need two CPU read or write operations to/from the SPIx_DR register or two DMA operations if the DMA is preferred for the application. For 24-bit data frame specifically, the 8 non-significant bits are extended to 32 bits with 0-bits (by hardware).
For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I²S interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPIx_I2SCFGR register.

**I²S Philips standard**

For this standard, the WS signal is used to indicate which channel is being transmitted. It is activated one CK clock cycle before the first bit (MSB) is available.

Data are latched on the falling edge of CK (for the transmitter) and are read on the rising edge (for the receiver). The WS signal is also latched on the falling edge of CK.

This mode needs two write or read operations to/from the SPIx_DR register.

- In transmission mode:
  - If 0x8EAA33 has to be sent (24-bit):
In reception mode:
If data 0x8EAA33 is received:

**Figure 592. Receiving 0x8EAA33**

First read to Data register

| 0x8EAA |

Second read to Data register

| 0x33XX |

Only the 8 MSB are sent to compare the 24 bits. 8 LSBs have no meaning and can be anything.

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

If the data to transmit or the received data are 0x76A3 (0x76A30000 extended to 32-bit), the operation shown in **Figure 594** is required.

**Figure 594. Example of 16-bit data frame extended to 32-bit channel frame**

Only one access to SPIx_DR

| 0x76A3 |
For transmission, each time an MSB is written to SPIx_DR, the TXE flag is set and its interrupt, if allowed, is generated to load the SPIx_DR register with the new value to send. This takes place even if 0x0000 have not yet been sent because it is done by hardware.

For reception, the RXNE flag is set and its interrupt, if allowed, is generated when the first 16 MSB half-word is received.

In this way, more time is provided between two write or read operations, which prevents underrun or overrun conditions (depending on the direction of the data transfer).

**MSB justified standard**

For this standard, the WS signal is generated at the same time as the first data bit, which is the MSBit.

**Figure 595. MSB Justified 16-bit or 32-bit full-accuracy length**

Data are latched on the falling edge of CK (for transmitter) and are read on the rising edge (for the receiver).

**Figure 596. MSB justified 24-bit frame length**
**LSB justified standard**

This standard is similar to the MSB justified standard (no difference for the 16-bit and 32-bit full-accuracy frame formats).

The sampling of the input and output signals is the same as for the I²S Philips standard.

---

**Figure 597. MSB justified 16-bit extended to 32-bit packet frame**

**Figure 598. LSB justified 16-bit or 32-bit full-accuracy**

**Figure 599. LSB justified 24-bit frame length**

- In transmission mode:
  - If data 0x3478AE have to be transmitted, two write operations to the SPIx_DR register are required by software or by DMA. The operations are shown below.
• In reception mode:
  If data $0x3478AE$ are received, two successive read operations from the SPIx_DR register are required on each RXNE event.

**Figure 601. Operations required to receive $0x3478AE$**

First read from Data register conditioned by RXNE=1

$0xXX34$

Only the 8 LSB of the half-word are significant. A field of 0x00 is forced instead of the 8 MSBs.

Second read from Data register conditioned by RXNE=1

$0x78AE$

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format. In this case it corresponds to the half-word MSB.

If the data to transmit or the received data are $0x76A3$ ($0x0000 76A3$ extended to 32-bit), the operation shown in Figure 603 is required.
In transmission mode, when a TXE event occurs, the application has to write the data to be transmitted (in this case 0x76A3). The 0x000 field is transmitted first (extension on 32-bit). The TXE flag is set again as soon as the effective data (0x76A3) is sent on SD.

In reception mode, RXNE is asserted as soon as the significant half-word is received (and not the 0x0000 field).

In this way, more time is provided between two write or read operations to prevent underrun or overrun conditions.

**PCM standard**

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPIx_I2SCFGR register.

In PCM mode, the output signals (WS, SD) are sampled on the rising edge of CK signal. The input signals (WS, SD) are captured on the falling edge of CK.

Note that CK and WS are configured as output in MASTER mode.

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode.

For short frame synchronization, the WS synchronization signal is only one cycle long.
Note: For both modes (master and slave) and for both synchronizations (short and long), the number of bits between two consecutive pieces of data (and so two synchronization signals) needs to be specified (DATLEN and CHLEN bits in the SPIx_I2SCFGR register) even in slave mode.

39.7.3 Start-up description

The Figure 606 shows how the serial interface is handled in MASTER mode, when the SPI/I2S is enabled (via I2SE bit). It shows as well the effect of CKPOL on the generated signals.
In slave mode, the way the frame synchronization is detected, depends on the value of ASTRTEN bit.

If ASTRTEN = 0, when the audio interface is enabled (I2SE = 1), then the hardware waits for the appropriate transition on the incoming WS signal, using the CK signal.
The appropriate transition is a falling edge on WS signal when I²S Philips Standard is used, or a rising edge for other standards. The falling edge is detected by sampling first WS to 1 and then to 0, and vice-versa for the rising edge detection.

If ASTRTEN = 1, the user has to enable the audio interface before the WS becomes active. This means that the I2SE bit must be set to 1 when WS = 1 for I²S Philips standard, or when WS = 0 for other standards.

39.7.4 Clock generator

The I²S bit rate determines the data flow on the I²S data line and the I²S clock signal frequency.

I²S bit rate = number of bits per channel × number of channels × sampling audio frequency

For a 16-bit audio, left and right channel, the I²S bit rate is calculated as follows:

I²S bit rate = 16 × 2 × f_S

It is: I²S bit rate = 32 x 2 x f_S if the packet length is 32-bit wide.

**Figure 607. Audio sampling frequency definition**

When the master mode is configured, a specific action needs to be taken to properly program the linear divider in order to communicate with the desired audio frequency.

**Figure 608. I²S clock generator architecture**

1. Where x can be 2 or 3.
Figure 608 presents the communication clock architecture. The I2SxCLK clock is provided by the reset and clock controller (RCC) of the product. The I2SxCLK clock can be asynchronous with respect to the SPI/I2S APB clock.

Warning: In addition, it is mandatory to keep the I2SxCLK frequency higher or equal to the APB clock used by the SPI/I2S block. If this condition is not respected the SPI/I2S does not work properly.

The audio sampling frequency may be 192 kHz, 96 kHz, 48 kHz, 44.1 kHz, 32 kHz, 22.05 kHz, 16 kHz, 11.025 kHz or 8 kHz (or any other value within this range).

In order to reach the desired frequency, the linear divider needs to be programmed according to the formulas below:

For I²S modes:

When the master clock is generated (MCKOE in the SPIx_I2SPR register is set):

\[
F_s = \frac{F_{I2SxCLK}}{256 \times ((2 \times I2SDIV) + ODD)}
\]

When the master clock is disabled (MCKOE bit cleared):

\[
F_s = \frac{F_{I2SxCLK}}{32 \times (\text{CHLEN} + 1) \times ((2 \times I2SDIV) + ODD)}
\]

CHLEN = 0 when the channel frame is 16-bit wide and,
CHLEN = 1 when the channel frame is 32-bit wide.

For PCM modes:

When the master clock is generated (MCKOE in the SPIx_I2SPR register is set):

\[
F_s = \frac{F_{I2SxCLK}}{128 \times ((2 \times I2SDIV) + ODD)}
\]

When the master clock is disabled (MCKOE bit cleared):

\[
F_s = \frac{F_{I2SxCLK}}{16 \times (\text{CHLEN} + 1) \times ((2 \times I2SDIV) + ODD)}
\]

CHLEN = 0 when the channel frame is 16-bit wide and,
CHLEN = 1 when the channel frame is 32-bit wide.

Where \(F_s\) is the audio sampling frequency, and \(F_{I2SxCLK}\) is the frequency of the kernel clock provided to the SPI/I2S block.
Note: \textit{I2SDIV must be strictly higher than 1.}

The following table provides example precision values for different clock configurations.

Note: \textit{Other configurations are possible that allow optimum clock precision.}

</table>
39.7.5 **\(^2\)S master mode**

The \(^2\)S can be configured in master mode. This means that the serial clock is generated on the CK pin as well as the Word Select signal WS. Master clock (MCK) may be output or not, controlled by the MCKOE bit in the SPIx_I2SPR register.

**Procedure**

1. Select the I2SDIV[7:0] bits in the SPIx_I2SPR register to define the serial clock baud rate to reach the proper audio sample frequency. The ODD bit in the SPIx_I2SPR register also has to be defined.
2. Select the CKPOL bit to define the steady level for the communication clock. Set the MCKOE bit in the SPIx_I2SPR register if the master clock MCK needs to be provided to the external DAC/ADC audio component (the I2SDIV and ODD values should be computed depending on the state of the MCK output, for more details refer to Section 39.7.4: Clock generator).
3. Set the I2SMOD bit in the SPIx_I2SCFGR register to activate the \(^2\)S functions and choose the \(^2\)S standard through the I2SSTD[1:0] and PCMSYNC bits, the data length through the DATLEN[1:0] bits and the number of bits per channel by configuring the CHLEN bit. Select also the \(^2\)S master mode and direction (Transmitter or Receiver) through the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.
4. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.
5. The I2SE bit in SPIx_I2SCFGR register must be set.

WS and CK are configured in output mode. MCK is also an output, if the MCKOE bit in SPIx_I2SPR is set.

**Transmission sequence**

The transmission sequence begins when a half-word is written into the Tx buffer.

Let’s assume the first data written into the Tx buffer corresponds to the left channel data. When data are transferred from the Tx buffer to the shift register, TXE is set and data corresponding to the right channel have to be written into the Tx buffer. The CHSIDE flag indicates which channel is to be transmitted. It has a meaning when the TXE flag is set because the CHSIDE flag is updated when TXE goes high.

A full frame has to be considered as a left channel data transmission followed by a right channel data transmission. It is not possible to have a partial frame where only the left channel is sent.

The data half-word is parallel loaded into the 16-bit shift register during the first bit transmission, and then shifted out, serially, to the MOSI/SD pin, MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

For more details about the write operations depending on the \(^2\)S standard mode selected, refer to Section 39.7.2: Supported audio protocols.

To ensure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission.
To switch off the I2S, by clearing I2SE, it is mandatory to wait for TXE = 1 and BSY = 0.

**Reception sequence**

The operating mode is the same as for transmission mode except for the point 3 (refer to the procedure described in Section 39.7.5: I²S master mode), where the configuration should set the master reception mode through the I2SCFG[1:0] bits.

Whatever the data or channel length, the audio data are received by 16-bit packets. This means that each time the Rx buffer is full, the RXNE flag is set and an interrupt is generated if the RXNEIE bit is set in SPIx_CR2 register. Depending on the data and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the Rx buffer.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

CHSIDE is updated after each reception. It is sensitive to the WS signal generated by the I2S cell.

For more details about the read operations depending on the I²S standard mode selected, refer to Section 39.7.2: Supported audio protocols.

If data are received while the previously received data have not been read yet, an overrun is generated and the OVR flag is set. If the ERRIE bit is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I2S, specific actions are required to ensure that the I2S completes the transfer cycle properly without initiating a new data transfer. The sequence depends on the configuration of the data and channel lengths, and on the audio protocol mode selected. In the case of:

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) using the LSB justified mode (I2SSTD = 10)
  a) Wait for the second to last RXNE = 1 (n – 1)
  b) Then wait 17 I2S clock cycles (using a software loop)
  c) Disable the I2S (I2SE = 0)

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) in MSB justified, I²S or PCM modes (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)
  a) Wait for the last RXNE
  b) Then wait 1 I2S clock cycle (using a software loop)
  c) Disable the I2S (I2SE = 0)

- For all other combinations of DATLEN and CHLEN, whatever the audio mode selected through the I2SSTD bits, carry out the following sequence to switch off the I2S:
  a) Wait for the second to last RXNE = 1 (n – 1)
  b) Then wait one I2S clock cycle (using a software loop)
  c) Disable the I2S (I2SE = 0)

*Note:* The BSY flag is kept low during transfers.

### 39.7.6 I²S slave mode

For the slave configuration, the I2S can be configured in transmission or reception mode. The operating mode is following mainly the same rules as described for the I²S master
configuration. In slave mode, there is no clock to be generated by the I2S interface. The clock and WS signals are input from the external master connected to the I2S interface. There is then no need, for the user, to configure the clock.

The configuration steps to follow are listed below:

1. Set the I2SMOD bit in the SPIx_I2SCFGR register to select I²S mode and choose the I²S standard through the I2SSTD[1:0] bits, the data length through the DATLEN[1:0] bits and the number of bits per channel for the frame configuring the CHLEN bit. Select also the mode (transmission or reception) for the slave through the I2SCFG[1:0] bits in SPIx_I2SCFGR register.

2. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.

3. The I2SE bit in SPIx_I2SCFGR register must be set.

Transmission sequence

The transmission sequence begins when the external master device sends the clock and when the NSS_WS signal requests the transfer of data. The slave has to be enabled before the external master starts the communication. The I2S data register has to be loaded before the master initiates the communication.

For the I2S, MSB justified and LSB justified modes, the first data item to be written into the data register corresponds to the data for the left channel. When the communication starts, the data are transferred from the Tx buffer to the shift register. The TXE flag is then set in order to request the right channel data to be written into the I2S data register.

The CHSIDE flag indicates which channel is to be transmitted. Compared to the master transmission mode, in slave mode, CHSIDE is sensitive to the WS signal coming from the external master. This means that the slave needs to be ready to transmit the first data before the clock is generated by the master. WS assertion corresponds to left channel transmitted first.

Note: The I2SE has to be written at least two PCLK cycles before the first clock of the master comes on the CK line.

The data half-word is parallel-loaded into the 16-bit shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI/SD pin MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

Note that the TXE flag should be checked to be at 1 before attempting to write the Tx buffer.

For more details about the write operations depending on the I²S standard mode selected, refer to Section 39.7.2: Supported audio protocols.

To secure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission. An underrun flag is set and an interrupt may be generated if the data are not written into the SPIx_DR register before the first clock edge of the next data communication. This indicates to the software that the transferred data are wrong. If the ERRIE bit is set into the SPIx_CR2 register, an interrupt is generated when the UDR flag in the SPIx_SR register goes high. In this case, it is mandatory to switch off the I2S and to restart a data transfer starting from the left channel.

To switch off the I2S, by clearing the I2SE bit, it is mandatory to wait for TXE = 1 and BSY = 0.
Reception sequence

The operating mode is the same as for the transmission mode except for the point 1 (refer to the procedure described in Section 39.7.6: I²S slave mode), where the configuration should set the master reception mode using the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.

Whatever the data length or the channel length, the audio data are received by 16-bit packets. This means that each time the RX buffer is full, the RXNE flag in the SPIx_SR register is set and an interrupt is generated if the RXNEIE bit is set in the SPIx_CR2 register. Depending on the data length and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the RX buffer.

The CHSIDE flag is updated each time data are received to be read from the SPIx_DR register. It is sensitive to the external WS line managed by the external master component.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

For more details about the read operations depending the I²S standard mode selected, refer to Section 39.7.2: Supported audio protocols.

If data are received while the preceding received data have not yet been read, an overrun is generated and the OVR flag is set. If the bit ERRIE is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I²S in reception mode, I2SE has to be cleared immediately after receiving the last RXNE = 1.

Note: The external master components should have the capability of sending/receiving data in 16-bit or 32-bit packets via an audio channel.

39.7.7 I²S status flags

Three status flags are provided for the application to fully monitor the state of the I²S bus.

Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect). It indicates the state of the communication layer of the I²S.

When BSY is set, it indicates that the I²S is busy communicating. There is one exception in master receive mode (I2SCFG = 11) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software needs to disable the I²S. This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is set when a transfer starts, except when the I²S is in master receiver mode.

The BSY flag is cleared:

- When a transfer completes (except in master transmit mode, in which the communication is supposed to be continuous)
- When the I²S is disabled

When communication is continuous:

- In master transmit mode, the BSY flag is kept high during all the transfers
- In slave mode, the BSY flag goes low for one I²S clock cycle between each transfer

Note: Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.
**Tx buffer empty flag (TXE)**

When set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can then be loaded into it. The TXE flag is reset when the Tx buffer already contains data to be transmitted. It is also reset when the I2S is disabled (I2SE bit is reset).

**RX buffer not empty (RXNE)**

When set, this flag indicates that there are valid received data in the RX Buffer. It is reset when SPIx_DR register is read.

**Channel Side flag (CHSIDE)**

In transmission mode, this flag is refreshed when TXE goes high. It indicates the channel side to which the data to transfer on SD has to belong. In case of an underrun error event in slave transmission mode, this flag is not reliable and I2S needs to be switched off and switched on before resuming the communication.

In reception mode, this flag is refreshed when data are received into SPIx_DR. It indicates from which channel side data have been received. Note that in case of error (like OVR) this flag becomes meaningless and the I2S should be reset by disabling and then enabling it (with configuration if it needs changing).

This flag has no meaning in the PCM standard (for both Short and Long frame modes).

When the OVR or UDR flag in the SPIx_SR is set and the ERRIE bit in SPIx_CR2 is also set, an interrupt is generated. This interrupt can be cleared by reading the SPIx_SR status register (once the interrupt source has been cleared).

### 39.7.8 I2S error flags

There are three error flags for the I2S cell.

**Underrun flag (UDR)**

In slave transmission mode this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into SPIx_DR. It is available when the I2SMOD bit in the SPIx_I2SCFGR register is set. An interrupt may be generated if the ERRIE bit in the SPIx_CR2 register is set. The UDR bit is cleared by a read operation on the SPIx_SR register.

**Overrun flag (OVR)**

This flag is set when data are received and the previous data have not yet been read from the SPIx_DR register. As a result, the incoming data are lost. An interrupt may be generated if the ERRIE bit is set in the SPIx_CR2 register.

In this case, the receive buffer contents are not updated with the newly received data from the transmitter device. A read operation to the SPIx_DR register returns the previous correctly received data. All other subsequently transmitted half-words are lost.

Clearing the OVR bit is done by a read operation on the SPIx_DR register followed by a read access to the SPIx_SR register.

**Frame error flag (FRE)**

This flag can be set by hardware only if the I2S is configured in Slave mode. It is set if the external master is changing the WS line while the slave is not expecting this change. If the
synchronization is lost, the following steps are required to recover from this state and resynchronize the external master device with the I2S slave device:

1. Disable the I2S.
2. Enable it again when the correct level is detected on the WS line (WS line is high in I2S mode or low for MSB- or LSB-justified or PCM modes.

Desynchronization between master and slave devices may be due to noisy environment on the CK communication clock or on the WS frame synchronization line. An error interrupt can be generated if the ERRIE bit is set. The desynchronization flag (FRE) is cleared by software when the status register is read.

### 39.7.9 DMA features

In I2S mode, the DMA works in exactly the same way as it does in SPI mode. There is no difference except that the CRC feature is not available in I2S mode since there is no data transfer protection system.

### 39.8 I2S interrupts

*Table 368* provides the list of I2S interrupts.

<table>
<thead>
<tr>

</tbody>
</table>
Bit 10 **RXONLY:** Receive only mode enabled.

This bit enables simplex communication using a single unidirectional line to receive data exclusively. Keep BIDIMODE bit clear when receive only mode is active. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.

0: Full-duplex (Transmit and receive)
1: Output disabled (Receive-only mode)

*Note:* This bit is not used in I²S mode.

Bit 9 **SSM:** Software slave management

When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.

0: Software slave management disabled
1: Software slave management enabled

*Note:* This bit is not used in I²S mode and SPI TI mode.

Bit 8 **SSI:** Internal slave select

This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the I/O value of the NSS pin is ignored.

*Note:* This bit is not used in I²S mode and SPI TI mode.

Bit 7 **LSBFIRST:** Frame format

0: data is transmitted / received with the MSB first
1: data is transmitted / received with the LSB first

*Note:* 1. This bit should not be changed when communication is ongoing.
   2. This bit is not used in I²S mode and SPI TI mode.

Bit 6 **SPE:** SPI enable

0: Peripheral disabled
1: Peripheral enabled

*Note:* When disabling the SPI, follow the procedure described in Procedure for disabling the SPI on page 1761.

This bit is not used in I²S mode.

Bits 5:3 **BR[2:0]:** Baud rate control

000: \( f_{PCLK}/2 \)
001: \( f_{PCLK}/4 \)
010: \( f_{PCLK}/8 \)
011: \( f_{PCLK}/16 \)
100: \( f_{PCLK}/32 \)
101: \( f_{PCLK}/64 \)
110: \( f_{PCLK}/128 \)
111: \( f_{PCLK}/256 \)

*Note:* These bits should not be changed when communication is ongoing.
These bits are not used in I²S mode.

Bit 2 **MSTR:** Master selection

0: Slave configuration
1: Master configuration

*Note:* This bit should not be changed when communication is ongoing.
This bit is not used in I²S mode.
Bit 1  **CPOL**: Clock polarity
0: CK to 0 when idle
1: CK to 1 when idle

*Note: This bit should not be changed when communication is ongoing.*

This bit is not used in I²S mode and SPI TI mode except the case when CRC is applied at TI mode.

Bit 0  **CPHA**: Clock phase
0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge

*Note: This bit should not be changed when communication is ongoing.*

This bit is not used in I²S mode and SPI TI mode except the case when CRC is applied at TI mode.

### 39.9.2 SPI control register 2 (SPIx_CR2)

</tr>
</tbody>
</table>

**Bit 15**  **LDMA__TX**: Last DMA transfer for transmission

This bit is used in data packing mode, to define if the total number of data to transmit by DMA is odd or even. It has significance only if the TXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length <= 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register).

0: Number of data to transfer is even
1: Number of data to transfer is odd

*Note: Refer to Procedure for disabling the SPI on page 1761 if the CRCEN bit is set.*

This bit is not used in I²S mode.

**Bit 13**  **LDMA__RX**: Last DMA transfer for reception

This bit is used in data packing mode, to define if the total number of data to receive by DMA is odd or even. It has significance only if the RXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length <= 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register).

0: Number of data to transfer is even
1: Number of data to transfer is odd

*Note: Refer to Procedure for disabling the SPI on page 1761 if the CRCEN bit is set.*

This bit is not used in I²S mode.

**Bit 12**  **FRXTH**: FIFO reception threshold

This bit is used to set the threshold of the RXFIFO that triggers an RXNE event

0: RXNE event is generated if the FIFO level is greater than or equal to 1/2 (16-bit)
1: RXNE event is generated if the FIFO level is greater than or equal to 1/4 (8-bit)

*Note: This bit is not used in I²S mode.*
Bits 11:8 DS[3:0]: Data size

These bits configure the data length for SPI transfers.

0000: Not used
0001: Not used
0010: Not used
0011: 4-bit
0100: 5-bit
0101: 6-bit
0110: 7-bit
0111: 8-bit
1000: 9-bit
1001: 10-bit
1010: 11-bit
1011: 12-bit
1100: 13-bit
1101: 14-bit
1110: 15-bit
1111: 16-bit

If software attempts to write one of the “Not used” values, they are forced to the value “0111” (8-bit)

Note: These bits are not used in I²S mode.

Bit 7 TXEIE: Tx buffer empty interrupt enable

0: TXE interrupt masked
1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 RXNEIE: RX buffer not empty interrupt enable

0: RXNE interrupt masked
1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 ERRIE: Error interrupt enable

This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode, FRE at TI mode and UDR, OVR, and FRE in I²S mode).

0: Error interrupt is masked
1: Error interrupt is enabled

Bit 4 FRF: Frame format

0: SPI Motorola mode
1 SPI TI mode

Note: This bit must be written only when the SPI is disabled (SPE=0).
This bit is not used in I²S mode.

Bit 3 NSSP: NSS pulse management

This bit is used in master mode only. It allows the SPI to generate an NSS pulse between two consecutive data when doing continuous transfers. In the case of a single data transfer, it forces the NSS pin high level after the transfer.

It has no meaning if CPHA = ‘1’, or FRF = ‘1’.

0: No NSS pulse
1: NSS pulse generated

Note: 1. This bit must be written only when the SPI is disabled (SPE=0).
2. This bit is not used in I²S mode and SPI TI mode.
Bit 2  **SSOE**: SS output enable
- 0: SS output is disabled in master mode and the SPI interface can work in multimaster configuration
- 1: SS output is enabled in master mode and when the SPI interface is enabled. The SPI interface cannot work in a multimaster environment.

*Note*: This bit is not used in I²S mode and SPI TI mode.

Bit 1  **TXDMAEN**: Tx buffer DMA enable
- When this bit is set, a DMA request is generated whenever the TXE flag is set.
- 0: Tx buffer DMA disabled
- 1: Tx buffer DMA enabled

Bit 0  **RXDMAEN**: Rx buffer DMA enable
- When this bit is set, a DMA request is generated whenever the RXNE flag is set.
- 0: Rx buffer DMA disabled
- 1: Rx buffer DMA enabled

### 39.9.3 SPI status register (SPIx_SR)

**Address offset**: 0x08

- Bits 15:13  Reserved, must be kept at reset value.

- Bits 12:11  **FTLVL[1:0]**: FIFO transmission level
  - These bits are set and cleared by hardware.
  - 00: FIFO empty
  - 01: 1/4 FIFO
  - 10: 1/2 FIFO
  - 11: FIFO full (considered as FULL when the FIFO threshold is greater than 1/2)

*Note*: This bit is not used in I²S mode.

- Bits 10:9  **FRLVL[1:0]**: FIFO reception level
  - These bits are set and cleared by hardware.
  - 00: FIFO empty
  - 01: 1/4 FIFO
  - 10: 1/2 FIFO
  - 11: FIFO full

*Note*: These bits are not used in I²S mode and in SPI receive-only mode while CRC calculation is enabled.

- Bit 8  **FRE**: Frame format error
  - This flag is used for SPI in TI slave mode and I²S slave mode. Refer to Section 39.5.11: SPI error flags and Section 39.7.8: I²S error flags.
  - This flag is set by hardware and reset when SPIx_SR is read by software.
  - 0: No frame format error
  - 1: A frame format error occurred
Bit 7  **BSY:** Busy flag
0: SPI (or I2S) not busy
1: SPI (or I2S) is busy in communication or Tx buffer is not empty
This flag is set and cleared by hardware.

*Note:* The **BSY** flag must be used with caution: refer to Section 39.5.10: SPI status flags and Procedure for disabling the SPI on page 1761.

Bit 6  **OVR:** Overrun flag
0: No overrun occurred
1: Overrun occurred
This flag is set by hardware and reset by a software sequence. Refer to I2S error flags on page 1793 for the software sequence.

Bit 5  **MODF:** Mode fault
0: No mode fault occurred
1: Mode fault occurred
This flag is set by hardware and reset by a software sequence. Refer to Section: Mode fault (MODF) on page 1771 for the software sequence.

*Note:* This bit is not used in I2S mode.

Bit 4  **CRCERR:** CRC error flag
0: CRC value received matches the SPIx_RXCRCR value
1: CRC value received does not match the SPIx_RXCRCR value

*Note:* This flag is set by hardware and cleared by software writing 0.
This bit is not used in I2S mode.

Bit 3  **UDR:** Underrun flag
0: No underrun occurred
1: Underrun occurred
This flag is set by hardware and reset by a software sequence. Refer to I2S error flags on page 1793 for the software sequence.

*Note:* This bit is not used in SPI mode.

Bit 2  **CHSIDE:** Channel side
0: Channel Left has to be transmitted or has been received
1: Channel Right has to be transmitted or has been received

*Note:* This bit is not used in SPI mode. It has no significance in PCM mode.

Bit 1  **TXE:** Transmit buffer empty
0: Tx buffer not empty
1: Tx buffer empty

Bit 0  **RXNE:** Receive buffer not empty
0: Rx buffer empty
1: Rx buffer not empty
39.9.4 SPI data register (SPIx_DR)

Bits 15:0 **DR[15:0]**: Data register

Data received or to be transmitted

The data register serves as an interface between the Rx and Tx FIFOs. When the data register is read, Rx_FIFO is accessed while the write to data register accesses Tx_FIFO (See Section 39.5.9: Data transmission and reception procedures).

Note: Data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read. The Rx threshold setting must always correspond with the read access currently used.

</table>
Bits 15:0 **RXCRC[15:0]:** Rx CRC register

When CRC calculation is enabled, the RXCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPIx_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note:* A read to this register when the BSY Flag is set could return an incorrect value. These bits are not used in I2S mode.

### 39.9.7 SPI Tx CRC register (SPIx_TXCRCR)

Address offset: 0x18

Bits 15:0 **TXCRC[15:0]:** Tx CRC register

When CRC calculation is enabled, the TXCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPIx_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note:* A read to this register when the BSY flag is set could return an incorrect value. These bits are not used in I2S mode.

### 39.9.8 SPIx_I2S configuration register (SPIx_I2SCFGR)

Address offset: 0x1C

Reset value: 0x0000

```

</tr>
</tbody>
</table>
```

Bits 15:13 Reserved, must be kept at reset value.
Bit 12  **ASTRTEN**: Asynchronous start enable.
       0: The Asynchronous start is disabled.
       When the I2S is enabled in slave mode, the hardware starts the transfer when the I2S clock is
       received and an appropriate transition is detected on the WS signal.
       1: The Asynchronous start is enabled.
       When the I2S is enabled in slave mode, the hardware starts the transfer when the I2S clock is
       received and the appropriate level is detected on the WS signal.

       **Note**: The appropriate **transition** is a falling edge on WS signal when I²S Philips Standard is used,
       or a rising edge for other standards.
       The appropriate **level** is a low level on WS signal when I²S Philips Standard is used, or a high
       level for other standards.

       Please refer to **Section 39.7.3: Start-up description** for additional information.

Bit 11  **I2SMOD**: I2S mode selection
       0: SPI mode is selected
       1: I2S mode is selected

       **Note**: This bit should be configured when the SPI is disabled.

Bit 10  **I2SE**: I2S enable
       0: I2S peripheral is disabled
       1: I2S peripheral is enabled

       **Note**: This bit is not used in SPI mode.

Bits 9:8  **I2SCFG[1:0]**: I2S configuration mode
       00: Slave - transmit
       01: Slave - receive
       10: Master - transmit
       11: Master - receive

       **Note**: These bits should be configured when the I2S is disabled.
       They are not used in SPI mode.

Bit 7  **PCMSYNC**: PCM frame synchronization
       0: Short frame synchronization
       1: Long frame synchronization

       **Note**: This bit has a meaning only if I2SSTD = 11 (PCM standard is used).
       It is not used in SPI mode.

Bit 6  Reserved, must be kept at reset value.

Bits 5:4  **I2SSTD[1:0]**: I2S standard selection
       00: I²S Philips standard
       01: MSB justified standard (left justified)
       10: LSB justified standard (right justified)
       11: PCM standard

       For more details on I²S standards, refer to **Section 39.7.2 on page 1777**

       **Note**: For correct operation, these bits should be configured when the I2S is disabled.
       They are not used in SPI mode.
Bit 3 **CKPOL**: Inactive state clock polarity
- 0: I2S clock inactive state is low level
- 1: I2S clock inactive state is high level

*Note:* For correct operation, this bit should be configured when the I2S is disabled. It is not used in SPI mode. The bit CKPOL does not affect the CK edge sensitivity used to receive or transmit the SD and WS signals.

Bits 2:1 **DATLEN[1:0]**: Data length to be transferred
- 00: 16-bit data length
- 01: 24-bit data length
- 10: 32-bit data length
- 11: Not allowed

*Note:* For correct operation, these bits should be configured when the I2S is disabled. They are not used in SPI mode.

Bit 0 **CHLEN**: Channel length (number of bits per audio channel)
- 0: 16-bit wide
- 1: 32-bit wide

The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to 32-bit by hardware whatever the value filled in.

*Note:* For correct operation, this bit should be configured when the I2S is disabled. It is not used in SPI mode.

### 39.9.9 SPIx_I2S prescaler register (SPIx_I2SPR)

Address offset: 0x20
Reset value: 0x0002

</tbody>
</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **MCKOE**: Master clock output enable
- 0: Master clock output is disabled
- 1: Master clock output is enabled

*Note:* This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode. It is not used in SPI mode.

Bit 8 **ODD**: Odd factor for the prescaler
- 0: Real divider value is = I2SDIV * 2
- 1: Real divider value is = (I2SDIV * 2) + 1

Refer to Section 39.7.3 on page 1784.

*Note:* This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode. It is not used in SPI mode.
Bits 7:0  **I2SDIV[7:0]: I2S linear prescaler**

I2SDIV [7:0] = 0 or I2SDIV [7:0] = 1 are forbidden values.

Refer to Section 39.7.3 on page 1784.

**Note:** These bits should be configured when the I2S is disabled. They are used only when the I2S is in master mode.

They are not used in SPI mode.

Refer to Section 2.2 on page 81 for the register boundary addresses.
40 Serial audio interface (SAI)

40.1 Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC’97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

40.2 SAI main features

- Two independent audio subblocks, which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB- or MSB-justified, PCM/DSP, TDM, AC’97
- PDM interface, supporting up to 4 microphone pairs
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC’97 mode in reception.
- Interrupt sources when enabled:
  - Errors,
  - FIFO requests.
• 2-channel DMA interface.

40.3 SAI implementation

40.4 SAI functional description

40.4.1 SAI block diagram

Figure 609 shows the SAI block diagram while Table 371 and Table 372 list SAI internal and external signals.
The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD_x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set up the desired protocols (audio frame waveform generator).

The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC’97 protocol, it is an SAI output even if the SAI (link controller) is set up to consume the SCK clock (and so to be in Slave mode).

---

1. These signals might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.
40.4.2 SAI pins and internal signals

1. These signals might not be available in all SAI instances. Refer to Section 40.3: SAI implementation for details.

40.4.3 Main SAI modes

Each audio subblock of the SAI can be configured to be master or slave via the MODE bits in the SAI_xCR1 register of the selected audio block.

**Master mode**

In master mode, the SAI delivers the timing signals to the external connected device:
- The bit clock and the frame synchronization are output on pin SCK_x and FS_x, respectively.
- If needed, the SAI can also generate a master clock on the MCLK_x pin.

Both SCK_x, FS_x and MCLK_x are configured as outputs.
Slave mode

The SAI expects to receive timing signals from an external device.

- If the SAI subblock is configured in asynchronous mode, then the SCK_x and FS_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with the second audio subblock, the corresponding SCK_x and FS_x pins are left free to be used as general purpose I/Os.

In slave mode, the MCLK_x pin is not used and can be assigned to another function.

It is recommended to enable the slave device before enabling the master.

Configuring and enabling SAI modes

Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI_xCR1 register of the corresponding audio block. As a result, the SAI_SD_x pin is respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case, they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI is enabled by the SAIEN bit in the SAI_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock, data, and synchronization lines in slave mode.

In master Tx mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However, FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave Tx mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:

1. Write into the SAI_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

40.4.4 SAI synchronization mode

SAI subclock A and B can be synchronized.

Internal synchronization

An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK_x, FS_x, and MCLK_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS_x and SCK_x ad MCLK_x I/O pins are relevant (if the audio block is considered as master).
Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set to 00 in SAI_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01 in the SAI_xCR1 register).

**Note:** Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.

### 40.4.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI_xCR1 register. The data sizes may be 8, 10, 16, 20, 24, or 32 bits. During the transfer, either the MSB or the LSB of the data is sent first, depending on the configuration of the LSBFIRST bit in the SAI_xCR1 register.

### 40.4.6 Frame synchronization

The FS signal acts as the frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable to target the different audio protocols with their own specificities concerning this frame synchronization behavior. This reconfigurability is done using the SAI_xFRCR register. Figure 610 illustrates this flexibility.

![Figure 610. Audio frame](image-url)

In AC'97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI_xCR1 register), the frame synchronization shape is forced to match the AC'97 protocol. The SAI_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

**Frame length**

- **Master mode**
  
  The audio frame length can be configured to up to 256-bit clock cycles, by configuring the FRL[7:0] field in the SAI_xFRCR register.

  If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit are extended to 0 or the SD line is released to high-Z.
depending on the state of bit TRIS in the SAI_xCR2 register (refer to FS signal role). In 
reception mode, the remaining bit is ignored.
If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure 
that an audio frame contains an integer number of MCLK pulses per bit clock cycle.
If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to 
Section 40.4.8: SAI clock generator* 

• Slave mode 
The audio frame length is mainly used to specify to the slave the number of bit clock 
cycles per audio frame sent by the external master. It is used mainly to detect from the 
master any anticipated or late occurrence of the frame synchronization signal during an 
going audio frame. In this case, an error is generated. For more details, refer to 
Section 40.4.14: Error flags.
In slave mode, there are no constraints on the FRL[7:0] configuration in the 
SAI_xFRCR register.
The number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame is 8.

Frame synchronization polarity
The FSPOL bit in the SAI_xFRCR register sets the active polarity of the FS pin from which a 
frame is started. The start of the frame is edge sensitive.
In slave mode, the audio block waits for a valid frame to start transmitting or receiving. The 
start of the frame is synchronized to this signal. It is effective only if the start of the frame is 
not detected during an ongoing communication and assimilated to an anticipated start of 
frame (refer to Section 40.4.14: Error flags).
In master mode, the frame synchronization is sent continuously each time an audio frame is 
complete until the SAIEN bit in the SAI_xCR1 register is cleared. If no data are present in 
the FIFO at the end of the previous audio frame, an underrun condition is managed as 
described in Section 40.4.14: Error flags), but the audio communication flow is not 
interrupted.

Frame synchronization active level length
The FSALL[6:0] bits of the SAI_xFRCR register enable the configuration of the length of the 
active level of the frame synchronization signal. The length can be set from 1- to 128-bit 
clock cycles.
As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified 
modes, or one-bit wide for PCM/DSP or TDM.

Frame synchronization offset
Depending on the audio protocol targeted in the application, the frame synchronization 
signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is 
the case in I2S standard protocol and in MSB-justified protocol, respectively). The FSOFF 
bit in the SAI_xFRCR register enables the possibility to choose between two configurations.
FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI_xFRCR register selects which meaning it has:

- 0: start of frame, like, for instance, the PCM/DSP, TDM, AC’97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S or the MSB- or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI_xCR2 register. Otherwise, if TRIS = 1, the SD line is released to high-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.

Figure 611. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)

1. The frame length must be even.

If the FSDEF bit in SAI_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI_xSLOTx multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI_xSLOTx is less than the frame size (bit FRL[7:0] in the SAI_xFRCR register), then:
If TRIS = 0 in the SAI_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmitter,

If TRIS = 1, the line is released to high-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.

**Figure 612. FS role is start of frame (FSDEF = 0)**

The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O is released and left free for other purposes.

### 40.4.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to NBSLOT[3:0] + 1.

The maximum number of slots per audio frame is fixed at 16.

For AC’97 protocol or SPDIF (when bit PRTCFLG[1:0] = 10 or PRTCRL[1:0] = 01), the number of slots is automatically set to target the protocol specification, and the value of NBSLOT[3:0] is ignored.

Each slot can be defined as a valid slot, or not, by setting SLOTEN[15:0] bits of the SAI_xSLOTR register.

When an invalid slot is transferred, the SD data line is either forced to 0 or released to high-Z depending on the TRIS bit configuration (refer to Output data line management on an inactive slot) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in Figure 613. The size of the slots is selected by configuring the SLOTSZ[1:0] bits in the SAI_xSLOTR register. The size is applied identically for each slot in an audio frame.
It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

It is mandatory to respect the following conditions to avoid bad SAI behavior:

\[
\text{FBOFF} \leq (\text{SLOTSZ} - \text{DS}),
\]
\[
\text{DS} \leq \text{SLOTSZ},
\]
\[
\text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL} \text{ (frame length)},
\]

The number of slots must be even when bit FSDEF in the SAI_xFRCR register is set.

In AC'97 and SPDIF protocol (bit PRTC[1:0] = 10 or PRTC[1:0] = 01), the slot size is automatically set as defined in Section 40.4.11: AC'97 link controller.
40.4.8 SAI clock generator

Each audio block has its own clock generator. The clock generator builds the master clock (MCLK_x) and bit clock (SCK_x) signals from the sai_x_ker_ck. The sai_x_ker_ck clock is delivered by the clock controller of the product (RCC).

Generation of the master clock (MCLK_x)

The clock generator provides the master clock (MCLK_x) when the audio block is defined as Master or Slave. The master clock is generated as soon as the MCKEN bit is set to 1 even if the SAIEN bit for the corresponding block is set to 0. This feature can be useful if the MCLK_x clock is used as system clock for an external audio device, since it enables the generation of the MCLK_x before activating the audio stream.

To generate a master clock on MCLK_x output before transferring the audio samples, the user application has to follow the sequence below:
1. Check that SAIEN = 0.
2. Program the MCKDIV[5:0] divider to the required value.
3. Set the MCKEN bit to 1.
4. Later, the application can configure other parts of the SAI, and sets the SAIEN bit to 1 to start the transfer of audio samples.

To avoid disturbances on the clock generated on MCLK_x output, the following operations are not recommended:
- Changing MCKDIV when MCKEN = 1
- Setting MCKEN to 0 if the SAIEN = 1

The SAI makes sure that there are no spurs on MCLK_x output when the MCLK_x is switched ON and OFF via the MCKEN bit (with SAIEN = 0).

Table 373 shows MCLK_x activation conditions.

<table>
<thead>

</tr>
<tr>
<td>X</td>
<td>0</td>
<td>1</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Note: MCLK_x can also be generated in AC’97 mode, when MCLKEN is set to 1.
Generation of the bit clock (SCK\_x)

The clock generator provides the bit clock (SCK\_x) when the audio block is defined as Master. The frame synchronization (FS\_x) is also derived from the signals provided by the clock generator.

In Slave mode, the value of NODIV and OSR fields are ignored, and the SCK\_x clock is not generated.

The bit clock strobing edge of SCK\_x can be configured through the CKSTR fields, which is functional both in master and slave mode.

Figure 615 illustrates the architecture of the audio block clock generator.

![Figure 615. Audio block clock generator overview](image)

The NODIV bit must be used to force the ratio between the master clock (MCLK\_x) and the frame synchronization (FS\_x) frequency to 256 or 512.

- If NODIV is set to 0, the frequency ratio between the frame synchronization and the master clock is fixed to 512 or 256, according to OSR value, but the frame length must be a power of 2. More details are given below.
- If NODIV is set to 1, the application can adjust the frequency of the bit clock (SCK\_x) via MCKDIV. In addition, there is no restriction on the frame length value as long as the frame length is bigger or equal to 8 (that is, FRL[7:0] \geq 6). The frame synchronization frequency depends on MCKDIV and frame length (FRL[7:0]). In that case, the frequency of the MCLK\_x is equal to the SCK\_x.

The NODIV, MCKEN, SAIEN, OVR, CKSTR, and MCKDIV[5:0] bits belong to the SAI\_xCR1 register, while FRL[7:0] belongs to SAI\_xFRCR.
Clock generator programming when NODIV = 0

In that case, the MCLK_x frequency is:

- \( F_{MCLK_x} = 256 \times F_{FS_x} \) if OSR = 0
- \( F_{MCLK_x} = 512 \times F_{FS_x} \) if OSR = 1

When MCKDIV is different from 0, the MCLK_x frequency is given by the formula below:

\[
F_{MCLK_x} = \frac{F_{sai_x\_ker\_ck}}{MCKDIV}
\]

The frame synchronization frequency is given by:

\[
F_{FS_x} = \frac{F_{sai_x\_ker\_ck}}{MCKDIV \times (OSR + 1) \times 256}
\]

The bit clock frequency (SCK_x) is given by the following formula:

\[
F_{SCK_x} = \frac{F_{sai_x\_ker\_ck} \times (FRL + 1)}{MCKDIV \times (OSR + 1) \times 256}
\]

Note: When NODIV is equal to 0, \((FRL+1)\) must be a power of two. In addition, \((FRL+1)\) must range between 8 and 256. \((FRL+1)\) represents the number of bit clock in the audio frame.

When the MCKDIV division ratio is odd, the MCLK duty cycle is not 50%. The bit clock signal (SCK_x) can also have a duty cycle different from 50% if MCKDIV is odd, if OSR is equal to 0, and if \((FRL+1) = 2^8\).

It is recommended, to program MCKDIV to an even value or to large values (higher than 10).

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.

Clock generator programming when NODIV = 1

When MCKDIV is different from 0, the frequency of the bit clock (SCK_x) is given in the formula below:

\[
F_{SCK_x} = F_{MCLK_x} = \frac{F_{sai_x\_ker\_ck}}{MCKDIV}
\]

The frequency of the frame synchronization (FS_x) is given by the following formula:

\[
F_{FS_x} = \frac{F_{sai_x\_ker\_ck}}{(FRL + 1) \times MCKDIV}
\]

Note: When NODIV is set to 1, \((FRL+1)\) can take any values from 8 to 256.

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.

1. \( N \) is an integer value between 3 and 8.

40.4.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending on if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. Thus, there is only one FIFO request linked to the FREQ bit in the SAI_xSR register.

An interrupt is generated if the FREQIE bit is enabled in the SAI_xIM register. This depends on:

- The FIFO threshold setting (FLVL bits in SAI_xCR2).
- Communication direction (transmitter or receiver). Refer to Interrupt generation in transmitter mode and Interrupt generation in reception mode.

Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit set by hardware to 1 in the SAI_xSR register) if no data are available in the SAI_xDR register (FLVL[2:0] bits in SAI_xSR are less than 0b001). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when the FIFO is no longer empty (FLVL[2:0] bits in SAI_xSR are different from 0b000), that is, one or more data are stored in the FIFO.
- When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 0b001), an interrupt is generated (FREQ bit set by hardware to 1 in the SAI_xSR register) if less than a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b010). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b010).
• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit set by hardware to 1 in the SAI_xSR register) if less than half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b011). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when at least half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b011).

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO three quarter (FTH[2:0] set to 0b011), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if less than three quarters of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b100). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when at least three quarters of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b100).

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if the FIFO is not full (FLVL[2:0] bits in SAI_xSR are less than 0b101). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR are equal to 0b101).

**Interrupt generation in reception mode**

The interrupt generation depends on the FIFO configuration in reception mode:

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if at least one data is available in the SAI_xDR register (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b001). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI_xSR are equal to 0b000), that is, no data are stored in FIFO.

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 0b001), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b010). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR are less than 0b010).

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b011). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR are less than 0b011).

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 0b011), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR are higher than or equal to 0b100). This interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI_xSR is less than 0b100).

• When the FIFO threshold bits in the SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in the SAI_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI_xSR are equal to 0b101). This
interrupt (FREQ bit in the SAI_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI_xSR are less than 0b101).

Like interrupt generation, the SAI can use the DMA if the DMAEN bit in the SAI_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interrupt generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI_xDR register.

Data must be right-aligned when written in the SAI_xDR register.

Data received are right-aligned in the SAI_xDR register.

The FIFO pointers can be reinitialized when the SAI is disabled by configuring the FFLUSH bit in the SAI_xCR2 register. If FFLUSH is set when the SAI is enabled, the data present in the FIFO are lost automatically.

40.4.10 PDM interface

The PDM (Pulse Density Modulation) interface is provided in order to support digital microphones. Up to 4 digital microphone pairs can be connected in parallel. Depending on product implementation, less microphones can be supported (refer to Section 40.3: SAI implementation).

Figure 616 shows a typical connection of a digital microphone pair via a PDM interface. Both microphones share the same bitstream clock and data line. Thanks to a configuration pin (LR), a microphone can provide valid data on SAI_CK[m] rising edge while the other provides valid data on SAI_CK[m] falling edge (m being the number of clock lines).

Figure 616. PDM typical connection and timing

1. \( n \) refers to the number of data lines and \( p \) to the number of microphone pairs.

The PDM function is intended to be used in conjunction with SAI_A subblock configured in TDM master mode. It cannot be used with SAI_B subblock. The PDM interface uses the timing signals provided by the TDM interface of SAI_A and adapts them to generate a bitstream clock (SAI_CK[m]).
The data processing sequence into the PDM is the following:

1. The PDM interface builds the bitstream clock from the bit clock received from the TDM interface of SAI_A.
2. The bitstream data received from the microphones (SAI_D[n]) are de-interleaved and go through a 7-bit delay line to fine-tune the delay of each microphone with the accuracy of the bitstream clock.
3. The shift registers translate each serial bitstream into bytes.
4. The last operation consists in shifting-out the resulting bytes to SAI_A via the serial data line of the TDM interface.

*Figure 617* below shows the block diagram of the PDM interface, with a detailed view of a de-interleaver.

Note: The PDM interface does not embed the decimation filter required to build-up the PCM audio samples from the bitstream. It is up to the application software to perform this operation.

The PDM interface can be enabled through the PDMEN bit in the SAI_PDMCR register. However, the PDM interface must be enabled prior to enabling the SAI_A block.
To reduce the memory footprint, the user can select the number of microphones the application needs. This can be done through the MICNR[1:0] bits. It is possible to choose between 2, 4, 6, or 8 microphones. For example, if the application is using 3 microphones, the user has to select 4.

**Enabling the PDM interface**

To enable the PDM interface, follow the sequence below:
1. Configure SAI_A in TDM master mode (see Table 375).
2. Configure the PDM interface as follows:
   a) Define the number of digital microphones via MICNR.
   b) Enable the bitstream clock needed in the application by setting the corresponding bits on CKEN to 1.
3. Enable the PDM interface, via the PDMEN bit.
4. Enable the SAI_A.

*Note:* Once the PDM interface and SAI_A are enabled, the first two TDMA frames received on SAI_ADR are invalid and must be dropped.

**Startup sequence**

*Figure 618* shows the startup sequence: Once the PDM interface is enabled, it waits for the frame synchronization event prior to starting the acquisition of the microphone samples. After 8 SAI_CK clock periods, a data byte coming from each microphone is available, and transferred to the SAI, via the TDM interface.
SAI_ADR data format

The arrangement of the data coming from the microphone into the SAI_ADR register depends on the following parameters:

- The number of microphones.
- The slot width selected.
- The LSBFIRST bit.

The slot width defines the number of significant bits into each word available into the SAI_ADR.

When a slot width of 32 bits is selected, each data available into the SAI_ADR contains 32 useful bits. This reduces the number of words stored into the memory. However, the counterpart is that the software has to perform some operations to de-interleave the data of each microphone.

On the other hand, when the slot width is set to 8 bits, each data available into the SAI_ADR contains 8 useful bits. This increases the number of words stored in the memory. However, it offers the advantage of avoiding extra processing since each word contains information from one microphone.

SAI_ADR data format example

- **32-bit slot width** (DS = 0b111 and SLOTSZ = 0). Refer to Figure 619.
  
  For an 8 microphone configuration, two consecutive words read from the SAI_ADR register contain a data byte from each microphone.

  For a 4 microphones configuration, each word read from the SAI_ADR register contains a data byte from each microphone.

  **Figure 619. SAI_ADR format in TDM, 32-bit slot width**

- **16-bit slot width** (DS = 0b100 and SLOTSZ = 0). Refer to Figure 620.
  
  For an 8-microphone configuration, four consecutive words read from the SAI_ADR register contain a data byte from each microphone. Note that the 16-bit data of SAI_ADR are right-aligned.

  For a 4- or 2-microphone configuration, the SAI behavior is similar to the 8-microphone configuration. Up to 2 words of 16 bits are required to acquire a byte from 4 microphones and a single word for 2 microphones.
Using an 8-bit slot width (DS = 0b010 and SLOTSZ = 0). Refer to Figure 621.

For an 8-microphone configuration, 8 consecutive words read from the SAI_ADR register contain a byte of data from each microphone. Note that the 8-bit data of SAI_ADR are right-aligned.

For a 4- or 2-microphone configuration, the SAI behavior is similar to the 8-microphone configuration. Up to 4 words of 8 bits are required to acquire a byte from 4 microphones and 2 words from 2 microphones.
TDM configuration for PDM interface

SAI_A TDM interface is internally connected to the PDM interface to get the microphone samples. The user application must configure the PDM interface as shown in Table 375 to ensure a good connection with the PDM interface.

Adjusting the bitstream clock rate

To program the SAI TDM interface properly, the user application must take into account the settings given in Table 375, and follow the sequence below:

1. Adjust the bit clock frequency \(F_{SCK_A}\) according to the required frequency for the PDM bitstream clock, using the following formula:

\[
F_{SCK_A} = F_{PDM_CK} \times (MICNBR + 1) \times 2
\]

MICNBR can be 0, 1, 2 or 3 (0 = 2 microphones; see Section 40.6.17)

2. Set the frame length (FRL) using the following formula

\[
FRL = (16 \times (MICNBR + 1)) - 1
\]

3. Configure the slot size (DS) to a multiple of (FRL+1).

Adjusting the delay lines

When the PDM interface is enabled, the application can adjust on-the-fly the delay cells of each microphone input via the SAI_PDMDLY register.

The new delay values become effective after two TDM frames.
40.4.11 AC’97 link controller

The SAI is able to work as an AC’97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set the PRTCFG[1:0] bits in the SAI_xCR1 register to 10. When AC’97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- The NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed at 13 slots. The first one is 16 bits wide and all the others are 20 bits wide (data slots).
- The FBOFF[4:0] bits in the SAI_xSLOTR register are ignored.
- The SAI_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC’97 controller link drives the FS signal whatever the master or slave configuration.

Figure 622 shows an AC’97 audio frame structure.

![Figure 622. AC’97 audio frame](image)

Note: In the AC’97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC’97 protocol standard.

One SAI can be used to target an AC’97 point-to-point communication.

In receiver mode, the SAI acting as an AC’97 link controller requires no FIFO request and so no data storage in the FIFO when the codec-ready bit in slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI_xIM register, flag CNRDY is set in the SAI_xSR register and an interrupt is generated. This flag is dedicated to the AC’97 protocol.
Clock generator programming in AC’97 mode

In AC’97 mode, the frame length is fixed at 256 bits, and its frequency must be set to 48 kHz. The formulas given in Section 40.4.8: SAI clock generator must be used with FRL = 255, to generate the proper frame rate (F_Fs_x).

40.4.12 SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958.

To select SPDIF mode, set the PRTCFG[1:0] bits to 01 in the SAI_xCR1 register.

For SPDIF protocol:
- Only the SD data line is enabled.
- The FS, SCK, and MCLK I/Os pins are left free.
- The MODE[1] bit is forced to 0 to select the master mode to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in the DS[2:0] bits in the SAI_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock must be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI_xFRCR and SAI_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in Figure 623.

![Figure 623. SPDIF format](image)

An SPDIF block contains 192 frames. Each frame is composed of two 32-bit subframes, generally one for the left channel and one for the right channel. Each subframe is composed of a SOPD pattern (4-bit) to specify if the subframe is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see Table 377). The next 28 bits of channel information are composed of 24 data bits + 4 status bits.
The data stored in SAI_xDR has to be filled as follows:

- SAI_xDR[26:24] contain the channel status, user, and validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, the data must be mapped on SAI_xDR[23:4].
If the data size is 16 bits, the data must be mapped on SAI_xDR[23:8].
SAI_xDR[23] always represents the MSB.

**Table 377. SOPD pattern**

<table>

<td>11100010</td>
<td>00011101</td>
</tr>
</tbody>
</table>

**Figure 624. SAI_xDR register ordering**

Note: The transfer is always performed with LSB first.

The SAI first sends the adequate preamble for each subframe in a block. The SAI_xDR is then sent on the SD line (Manchester coded). The SAI ends the subframe by transferring the parity bit calculated as described in Table 378.

**Table 378. Parity bit calculation**

<table>

<td>1</td>
</tr>
</tbody>
</table>

The underrun is the only error flag available in the SAI_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence must be
executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:
1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in the SAI_xCR1 register.
3. Clear the COVRUNDR flag in the SAI_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI_xCR2.
   The software needs to point to the address of the future data corresponding to the start of a new block (data for preamble B). If the DMA is used, the DMA source base address pointer must be updated accordingly.
5. Enable the DMA stream (DMA peripheral) again if the DMA is used to manage data transfers according to the new source base address.
6. Enable the SAI again by configuring the SAIEN bit in the SAI_xCR1 register.

**Clock generator programming in SPDIF generator mode**

For the SPDIF generator, the SAI provides a bit clock twice as fast as the symbol-rate. The table below shows examples of symbol rates with respect to the audio sampling rate.

<table>
<thead>
<tr>
<th>Audio sampling frequencies (F_S)</th>
<th>Symbol-rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.1 kHz</td>
<td>2.8224 MHz</td>
</tr>
<tr>
<td>48 kHz</td>
<td>3.072 MHz</td>
</tr>
<tr>
<td>96 kHz</td>
<td>6.144 MHz</td>
</tr>
<tr>
<td>192 kHz</td>
<td>12.288 MHz</td>
</tr>
</tbody>
</table>

More generally, the relationship between the audio sampling frequency (F_S) and the bit clock rate (F_{SCK,x}) is given by the formula:

\[ F_S = \frac{F_{SCK,x}}{128} \]

The bit clock rate is obtained as follows:

\[ F_{SCK,x} = \frac{F_{sai,x \_ ker \_ ck}}{MCKDIV} \]

*Note:* The above formulas are valid only if NODIV is set to 1 in the SAI_ACR1 register.
40.4.13  **Specific features**

The SAI interface embeds specific features that can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI_xCR2 register.

**Mute mode**

The mute mode can be used when the audio subblock is a transmitter or a receiver.

**Audio subblock in transmission mode**

In transmitter mode, the mute mode can be selected at any time. The mute mode is active for entire audio frames. The MUTE bit in the SAI_xCR2 register enables the mute mode when it is configured during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame is still a mute frame.

If the number of slots set through the NBSLOT[3:0] bits in the SAI_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via the MUTEVAL bit in the SAI_xCR2 register.

If the number of slots set in the NBSLOT[3:0] bits in the SAI_xSLOTR register is greater than 2, the MUTEVAL bit in the SAI_xCR2 register is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

**Audio subblock in reception mode**

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI_xSR register is set and an interrupt can be generated if the MUTEDETIE bit is set in SAI_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in the MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

*Note: The mute mode is not available for SPDIF audio blocks.*

**Mono/stereo mode**

In transmitter mode, the mono mode can be addressed without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI_xSLOTR). In this case, the access time to and from the FIFO is reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode:

1. Set the MONO bit to 1 in the SAI_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI_xSLOTR.
In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2, like in transmitter mode. When it is set, only slot 0 data are stored in the FIFO. The data belonging to slot 1 are discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

**Companding mode**

Telecommunication applications can require processing the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI_xCR2 register (used only when free protocol mode is selected), the application software can choose to process or not the data before sending it on the SD serial output line (compression) or to expand the data after the reception on the SD serial input line (expansion), as illustrated in *Figure 625*. The two companding modes supported are the µ-Law and the A-Law logs, which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the µ-Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI_xCR2 register).

Both µ-Law and A-Law companding standard can be computed based on 1’s complement or 2’s complement representation, depending on the CPL bit setting in the SAI_xCR2 register.

In µ-Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8 bits wide. For this reason, the DS[2:0] bits in the SAI_xCR1 register are forced to 010 when the SAI audio block is enabled (the SAIEN bit = 1 in the SAI_xCR1 register) and when one of these two companding modes is selected through the COMP[1:0] bits.

If no companding processing is required, the COMP[1:0] bits must be kept clear.
Expansion and compression mode are automatically selected through SAI_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

**Output data line management on an inactive slot**

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via the TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in high-Z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which may result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting the bit SLOTSZ[1:0] = 10 in the SAI_xSLOTR register. The SD output pin is then tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tri-stated when the padding to 0 is done to complete the audio frame.

*Figure 626* illustrates these behaviors.
When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI_xFRCR register), the tristate mode is managed according to Figure 627 (where the bit TRIS in the SAI_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).
If the TRIS bit in the SAI_xCR2 register is cleared, all the high impedance states on the SD output line in Figure 626 and Figure 627 are replaced by a drive with a value of 0.

40.4.14 Error flags

The SAI implements the following error flags:
- FIFO overrun/underrun.
- Anticipated frame synchronization detection.
- Late frame synchronization detection.
- Codec not ready (AC’97 exclusively).
- Wrong clock configuration in master mode.

FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI_xSR register.

Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the OVRUDR flag in the SAI_xSR register is set, and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from a new audio frame) from the slot number that was stored internally when the overrun condition was detected. This avoids data slot dealignment in the destination memory (refer to Figure 628).

The OVRUDR flag is cleared when the COVRUDR bit is set in the SAI_xCLRFR register.
Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and the MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to Figure 629). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. To clear this flag, set the COVRUDR bit in the SAI_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.
Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, and the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI_xSR register.

This detection has no effect on the current audio frame, which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI_xIM register. To clear the AFSDET flag, the CAFSDET bit must be set in the SAI_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting the SAIEN bit in the SAI_xCR1 register. To make sure that the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via the FFLUS bit in the SAI_xCR2 register.
3. Enable the SAI peripheral again (SAIEN bit set to 1).
4. The SAI block waits for the assertion on FS to restart the synchronization with master.

Note: The AFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.

Late frame synchronization detection

The LFSDET flag in the SAI_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity, and the frame-offset configuration are known in register SAI_xFRCR.

If the external master does not send the FS signal at the expected time, thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if the LFSDETIE bit is set in the SAI_xIM register.

The LFSDET flag is cleared when the CLFSDET bit is set in the SAI_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in Anticipated frame synchronization detection (AFSDET)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which must not be the case in most applications. In this case, the LFSDET flag is set.

Note: The LFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.
Codec not ready (CNRDY AC’97)

The CNRDY flag in the SAI_xSR register is relevant only if the SAI audio block is configured to operate in AC’97 mode (PRTCFG[1:0] = 10 in the SAI_xCR1 register). If the CNRDYIE bit is set in the SAI_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the codec is not ready to communicate during the reception of the TAG 0 (slot 0) of the AC’97 audio frame. In this case, no data are automatically stored into the FIFO since the codec is not ready, until the TAG 0 indicates that the codec is ready. All the active slots defined in the SAI_xSLOTR register are captured when the codec is ready.

To clear the CNRDY flag, the CCNRDY bit must be set in the SAI_xCLRFR register.

Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and the NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

The MODE, NODIV, and SAIEN bits belong to the SAI_xCR1 register and FRL to the SAI_xFRCR register.

If the WCKCFGIE bit is set, an interrupt is generated when the WCKCFG flag is set in the SAI_xSR register. To clear this flag, set the CWCKCFG bit in the SAI_xCLRFR register.

When the WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of the SAIEN bit.

40.4.15 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing the SAIEN bit in the SAI_xCR1 register. All the already started frames are automatically completed before the SAI stops working. The SAIEN bit remains high until the SAI is completely switched off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one that is the master must be disabled first.

40.4.16 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting the basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set the DMAEN bit in the SAI_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to Section 40.4.9: Internal FIFOs). The DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI_xDR register.
- If the audio block operates as a receiver, the DMA request is related to read operations from the SAI_xDR register.

Follow the sequence below to configure the SAI interface in DMA mode:
1. Configure the SAI and FIFO threshold levels to specify when the DMA request is launched.
2. Configure the SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

### 40.5 SAI interrupts

The SAI supports 7 interrupt sources, as shown in Table 380.

#### Table 380. SAI interrupt sources

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt source</th>
<th>Interrupt group</th>
<th>Audio block mode</th>
<th>Interrupt enable</th>
<th>Interrupt clear</th>
</tr>
</thead>
</table>
| FREQ              | FREQ             | FREQ           | Master or slave Receiver or transmitter | FREQIE in SAI_xIM register | Depends on:  
   - FIFO threshold setting (FLVL bits in SAI_xCR2)  
   - Communication direction (transmitter or receiver)  
   For more details refer to Section 40.4.9: Internal FIFOs |
| OVRUDR            | ERROR            | Master or slave Receiver or transmitter | OVRUDRIE in SAI_xIM register | COVRUDR = 1 in SAI_xCLRFR register |
| AFSDET            | ERROR            | Slave (not used in AC’97 mode and SPDIF mode) | AFSDETIE in SAI_xIM register | CAFSDET = 1 in SAI_xCLRFR register |
| LFSDET            | ERROR            | Slave (not used in AC’97 mode and SPDIF mode) | LFSDETIE in SAI_xIM register | CLFSDET = 1 in SAI_xCLRFR register |
| CNRDY             | ERROR            | Slave (only in AC’97 mode) | CNRDYIE in SAI_xIM register | CCNRDY = 1 in SAI_xCLRFR register |
| MUTEDET           | MUTE             | Master or slave Receiver mode only | MUTEDETIE in SAI_xIM register | CMUTEDET = 1 in SAI_xCLRFR register |
| WCKCFG            | ERROR            | Master with NODIV = 0 in SAI_xCR1 register | WCKCFGIE in SAI_xIM register | CWCKCFG = 1 in SAI_xCLRFR register |

Follow the sequence below to enable an interrupt:
1. Disable SAI interrupt.
2. Configure SAI.
3. Configure SAI interrupt source.
4. Enable SAI.
40.6 SAI registers

The peripheral registers have to be accessed by words (32 bits).

40.6.1 SAI configuration register 1 (SAI_ACR1)

Address offset: 0x0004
Reset value: 0x0000 0040

| Bit 31:28 | Reserved, must be kept at reset value. |
| Bit 27  | **MCKEN**: Master clock generation enable |
| 0: The master clock is not generated |
| 1: The master clock is generated independently of SAIEN bit |
| Bit 26  | **OSR**: Oversampling ratio for master clock |
| This bit is meaningful only when NODIV bit is set to 0. |
| 0: Master clock frequency = FFS x 256 |
| 1: Master clock frequency = FFS x 512 |
| Bits 25:20 | **MCKDIV[5:0]**: Master clock divider |
| These bits are set and cleared by software. |
| 000000: Divides by 1 the kernel clock input (sai_x_ker_ck). |
| Otherwise, The master clock frequency is calculated according to the formula given in Section 40.4.8: SAI clock generator. |
| These bits have no meaning when the audio block is slave. |
| They have to be configured when the audio block is disabled. |
| Bit 19  | **NODIV**: No divider |
| This bit is set and cleared by software. |
| 0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512 |
| 1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0] |
| Bit 18  | Reserved, must be kept at reset value. |
| Bit 17  | **DMAEN**: DMA enable |
| This bit is set and cleared by software. |
| 0: DMA disabled |
| 1: DMA enabled |
| Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode. |
Bit 16 **SAIEN**: Audio block enable

This bit is set by software.

To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.

This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.

0: SAI audio block disabled

1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive

This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.

When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to [Section: Mono/stereo mode](#) for more details.

0: Stereo mode

1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.

01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode.

10: Reserved.

11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.

1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first

1: Data are transferred with LSB first
Bits 7:5 DS[2:0]: Data size
These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are
selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the
companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is
fixed to 8 bits by the algorithm.
These bits must be configured when the audio block is disabled.
000: Reserved
001: Reserved
010: 8 bits
011: 10 bits
100: 16 bits
101: 20 bits
110: 24 bits
111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 PRTCFG[1:0]: Protocol configuration
These bits are set and cleared by software. These bits have to be configured when the audio block is
disabled.
00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to
address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting
most of the configuration register bits as well as frame configuration register.
01: SPDIF protocol
10: AC’97 protocol
11: Reserved

Bits 1:0 MODE[1:0]: SAIx audio block mode
These bits are set and cleared by software. They must be configured when SAIx audio block is
disabled.
00: Master transmitter
01: Master receiver
10: Slave transmitter
11: Slave receiver

Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced
(MODE[1:0] = 00).

40.6.2 SAI configuration register 2 (SAI_ACR2)

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:14 **COMP[1:0]**: Companding mode.

These bits are set and cleared by software. The µ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.

The data expansion or data compression are determined by the state of bit MODE[0].

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to Section : Companding mode for more details.

- 00: No companding algorithm
- 01: Reserved.
- 10: µ-Law algorithm
- 11: A-Law algorithm

**Note:** Companding mode is applicable only when Free protocol mode is selected.

Bit 13 **CPL**: Complement bit.

This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

- 0: 1’s complement representation.
- 1: 2’s complement representation.

**Note:** This bit has effect only when the companding mode is µ-Law algorithm or A-Law algorithm.

Bits 12:7 **MUTECNT[5:0]**: Mute counter.

These bits are set and cleared by software. They are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.

Refer to Section : Mute mode for more details.

Bit 6 **MUTEVAL**: Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.

This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.

If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.

If the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.

Refer to Section : Mute mode for more details.

- 0: Bit value 0 is sent during the mute mode.
- 1: Last values are sent during the mute mode.

**Note:** This bit is meaningless and must not be used for SPDIF audio blocks.

Bit 5 **MUTE**: Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.

Refer to Section : Mute mode for more details.

- 0: No mute mode.
- 1: Mute mode enabled.

**Note:** This bit is meaningless and must not be used for SPDIF audio blocks.
Bit 4 TRIS: Tristate management on data line.
   This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.
   Refer to Section: Output data line management on an inactive slot for more details.
   0: SD output line is still driven by the SAI when a slot is inactive.
   1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 FFLUSH: FIFO flush.
   This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
   0: No FIFO flush.
   1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled

Bits 2:0 FTH[2:0]: FIFO threshold.
   This bit is set and cleared by software.
   000: FIFO empty
   001: ¼ FIFO
   010: ½ FIFO
   011: ¾ FIFO
   100: FIFO full
   101: Reserved
   110: Reserved
   111: Reserved

40.6.3 SAI frame configuration register (SAI_AFRCR)

Address offset: 0x000C
Reset value: 0x0000 0007

Note: This register has no meaning in AC’97 and SPDIF audio protocol.

</table>

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 FSOFF: Frame synchronization offset.
   This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
   0: FS is asserted on the first bit of the slot 0.
   1: FS is asserted one bit before the first bit of the slot 0.
Bit 17  **FSPOL**: Frame synchronization polarity.
This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration.
This bit must be configured when the audio block is disabled.
0: FS is active low (falling edge)
1: FS is active high (rising edge)

Bit 16  **FSDEF**: Frame synchronization definition.
This bit is set and cleared by software.
0: FS signal is a start frame signal
1: FS signal is a start of frame signal + channel side identification
When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots are dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).
This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **FSALL[6:0]**: Frame synchronization active level length.
These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
They must be configured when the audio block is disabled.

Bits 7:0  **FRL[7:0]**: Frame length.
These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration. They must be configured when the audio block is disabled.

### 40.6.4  **SAI slot register (SAI_ASLOTR)**

Address offset: 0x0010
Reset value: 0x0000 0000

*Note:*  This register has no meaning in AC’97 and SPDIF audio protocol.
**40.6.5 SAI interrupt mask register (SAI_AIM)**

Address offset: 0x0014

Reset value: 0x0000 0000
Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **LFSDETIE**: Late frame synchronization detection interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
       This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 5  **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.
       This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 4  **CNRDYIE**: Codec not ready interrupt enable (AC’97).
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the
       Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR
       register is set and an interrupt is generated.
       This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio
       block is operates as a receiver.

Bit 3  **FREQIE**: FIFO request interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
       Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be
       configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.

Bit 2  **WCKCFGIE**: Wrong clock configuration interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and
       NODIV = 0.
       It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.

       Note:  *This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1  **MUTEDETIE**: Mute detection interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
       This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0  **OVRUDRIE**: Overrun/underrun interrupt enable.
       This bit is set and cleared by software.
       0: Interrupt is disabled
       1: Interrupt is enabled
       When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.

Bits 31:19 Reserved, must be kept at reset value.

**Bits 18:16 FLVL[2:0]: FIFO level threshold.**

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

- 000: FIFO empty (transmitter and receiver modes)
- 001: FIFO \( \leq \frac{1}{4} \) but not empty (transmitter mode), FIFO \( < \frac{1}{4} \) but not empty (receiver mode)
- 010: \( \frac{1}{4} < \text{FIFO} \leq \frac{1}{2} \) (transmitter mode), \( \frac{1}{4} \leq \text{FIFO} < \frac{1}{2} \) (receiver mode)
- 011: \( \frac{1}{2} < \text{FIFO} \leq \frac{3}{4} \) (transmitter mode), \( \frac{1}{2} \leq \text{FIFO} < \frac{3}{4} \) (receiver mode)
- 100: \( \frac{3}{4} < \text{FIFO} \) but not full (transmitter mode), \( \frac{3}{4} \leq \text{FIFO} < 1 \) (receiver mode)
- 101: FIFO full (transmitter and receiver modes)
- Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

**Bit 6 LFSDET: Late frame synchronization detection.**

This bit is read only.

- 0: No error.
- 1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if LFSDETI bit is set in the SAI_xIM register.

This flag is cleared when the software sets CLFSDET in SAI_xCLRFR register

**Bit 5 AFSDET: Anticipated frame synchronization detection.**

This bit is read only.

- 0: No error.
- 1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if AFSDETI bit is set in SAI_xIM register.

This flag is cleared when the software sets CAFSDET in SAI_xCLRFR register.
Bit 4 **CNRDY**: Codec not ready.
This bit is read only.
0: External AC'97 Codec is ready
1: External AC'97 Codec is not ready
This bit is used only when the AC'97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.
It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3 **FREQ**: FIFO request.
This bit is read only.
0: No FIFO request.
1: FIFO request to read or to write the SAI_xDR.
The request depends on the audio block configuration:
- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.
This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.

Bit 2 **WCKCFG**: Wrong clock configuration flag.
This bit is read only.
0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 40.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.
This bit is read only.
0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.
This bit is read only.
0: No overrun/underrun error.
1: Overrun/underrun error detection.
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

Bits 31:7 Reserved, must be kept at reset value.

- **Bit 6 CLFSDET**: Clear late frame synchronization detection flag.  
  This bit is write only.  
  Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.  
  This bit is not used in AC’97 or SPDIF mode.  
  Reading this bit always returns the value 0.

- **Bit 5 CAFSDET**: Clear anticipated frame synchronization detection flag.  
  This bit is write only.  
  Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.  
  It is not used in AC’97 or SPDIF mode.  
  Reading this bit always returns the value 0.

- **Bit 4 CCNRDY**: Clear Codec not ready flag.  
  This bit is write only.  
  Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.  
  This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.  
  Reading this bit always returns the value 0.

- **Bit 3 Reserved, must be kept at reset value.**

- **Bit 2 CWCKCFG**: Clear wrong clock configuration flag.  
  This bit is write only.  
  Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.  
  This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.  
  Reading this bit always returns the value 0.

- **Bit 1 CMUTEDET**: Mute detection flag.  
  This bit is write only.  
  Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.  
  Reading this bit always returns the value 0.

- **Bit 0 COVRUDR**: Clear overrun / underrun.  
  This bit is write only.  
  Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.  
  Reading this bit always returns the value 0.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 MCKEN: Master clock generation enable
0: The master clock is not generated
1: The master clock is generated independently of SAIEN bit

Bit 26 OSR: Oversampling ratio for master clock
This bit is meaningful only when NODIV bit is set to 0.
0: Master clock frequency = F_FS x 256
1: Master clock frequency = F_FS x 512

Bits 25:20 MCKDIV[5:0]: Master clock divider
These bits are set and cleared by software.
000000: Divides by 1 the kernel clock input (sai_x_ker_ck).
Otherwise, The master clock frequency is calculated according to the formula given in
Section 40.4.8: SAI clock generator.
These bits have no meaning when the audio block is slave.
They have to be configured when the audio block is disabled.
Bit 19 **NODIV**: No divider
This bit is set and cleared by software.
0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512
1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0]

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable
This bit is set and cleared by software.
0: DMA disabled
1: DMA enabled
*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable
This bit is set by software.
To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.
This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.
0: SAI audio block disabled
1: SAI audio block enabled.
*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive
This bit is set and cleared by software.
0: Audio block output driven when SAIEN is set
1: Audio block output driven immediately after the setting of this bit.
*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*

Bit 12 **MONO**: Mono mode
This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.
When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are stored. Refer to *Section: Mono/stereo mode* for more details.
0: Stereo mode
1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable
These bits are set and cleared by software. They must be configured when the audio subblock is disabled.
00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode
10: Reserved.
11: Reserved
*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*
Bit 9 **CKSTR**: Clock strobing edge  
This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.  
0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.  
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first  
This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.  
0: Data are transferred with MSB first  
1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size  
These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.  
These bits must be configured when the audio block is disabled.  
000: Reserved  
001: Reserved  
010: 8 bits  
011: 10 bits  
100: 16 bits  
101: 20 bits  
110: 24 bits  
111: 32 bits

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **PRTCFG[1:0]**: Protocol configuration  
These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.  
00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.  
01: SPDIF protocol  
10: AC’97 protocol  
11: Reserved

Bits 1:0 **MODE[1:0]**: SAIx audio block mode  
These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.  
00: Master transmitter  
01: Master receiver  
10: Slave transmitter  
11: Slave receiver

*Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00). In Master transmitter mode, the audio block starts generating the FS and the clocks immediately.*
40.6.10  SAI configuration register 2 (SAI_BCR2)

Address offset: 0x0028
Reset value: 0x0000 0000

| Bit 31-16 | Reserved, must be kept at reset value. |
| Bit 15-14 | COMP[1:0]: Companding mode. |
| These bits are set and cleared by software. The µ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit. |
| The data expansion or data compression are determined by the state of bit MODE[0]. |
| The data compression is applied if the audio block is configured as a transmitter. |
| The data expansion is automatically applied when the audio block is configured as a receiver. |
| Refer to Section : Companding mode for more details. |
| 00: No companding algorithm |
| 01: Reserved. |
| 10: µ-Law algorithm |
| 11: A-Law algorithm |
| Note: Companding mode is applicable only when Free protocol mode is selected. |
| Bit 13 | CPL: Complement bit. |
| This bit is set and cleared by software. |
| It defines the type of complement to be used for companding mode |
| 0: 1’s complement representation. |
| 1: 2’s complement representation. |
| Note: This bit has effect only when the companding mode is µ-Law algorithm or A-Law algorithm. |
| Bits 12-7 | MUTECNT[5:0]: Mute counter. |
| These bits are set and cleared by software. They are used only in reception mode. |
| The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set. |
| Refer to Section : Mute mode for more details. |
Bit 6  **MUTEVAL**: Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is
lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0,
whatever the value of MUTEVAL.
if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each
slot is the one sent during the previous frame.
Refer to **Section : Mute mode** for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

Bit 5  **MUTE**: Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a
transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to
2, or equal to 0 if it is greater than 2.
Refer to **Section : Mute mode** for more details.
0: No mute mode.
1: Mute mode enabled.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

Bit 4  **TRIS**: Tristate management on data line.

This bit is set and cleared by software. It is meaningful only if the audio block is configured as a
transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be
configured when SAI is disabled.
Refer to **Section : Output data line management on an inactive slot** for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one
is inactive.

Bit 3  **FFLUSH**: FIFO flush.

This bit is set by software. It is always read as 0. This bit must be configured when the SAI is
disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read
and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or
received data lost). Before flushing, SAI DMA stream/interrupt must be disabled

Bits 2:0  **FTH[2:0]**: FIFO threshold.

This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved
40.6.11  SAI frame configuration register (SAI_BFRCR)

Address offset: 0x002C
Reset value: 0x0000 0007

Note:  This register has no meaning in AC’97 and SPDIF audio protocol

</tr>
<tr>
<td>0</td>
<td>Reserved</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:19  Reserved, must be kept at reset value.

Bit 18  FSOFF: Frame synchronization offset.

0: FS is asserted on the first bit of the slot 0.
1: FS is asserted one bit before the first bit of the slot 0.

Bit 17  FSPOL: Frame synchronization polarity.

0: FS is active low (falling edge)
1: FS is active high (rising edge)

Bit 16  FSDEF: Frame synchronization definition.

0: FS signal is a start frame signal
1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots is dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols…).

This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15  Reserved, must be kept at reset value.

Bits 14:8  FSALL[6:0]: Frame synchronization active level length.

These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.

These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.

They must be configured when the audio block is disabled.
Bits 7:0  **FRL[7:0]**: Frame length.

These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.

The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).

In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256. These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.

### 40.6.12  **SAI slot register (SAI_BSLOTR)**

Address offset: 0x0030

Reset value: 0x0000 0000

**Note:**  *This register has no meaning in AC’97 and SPDIF audio protocol.*

</tbody>
</table>

Bits 31:16 **SLOTEN[15:0]**: Slot enable.

These bits are set and cleared by software.

Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).

0: Inactive slot.
1: Active slot.

The slot must be enabled when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.

These bits are set and cleared by software.

The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.

The number of slots must be configured when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.
Bits 7:6 **SLOTSZ[1:0]:** Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to *Output data line management on an inactive slot* for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

- **00:** The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
- **01:** 16-bit
- **10:** 32-bit
- **11:** Reserved

Bit **5** Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]:** First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

### 40.6.13 SAI interrupt mask register (SAI_BIM)

<td>rw</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bit **6** **LFSDETIE:** Late frame synchronization detection interrupt enable.

This bit is set and cleared by software.

- **0:** Interrupt is disabled
- **1:** Interrupt is enabled

When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.

This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit **5** **AFSDETE:** Anticipated frame synchronization detection interrupt enable.

This bit is set and cleared by software.

- **0:** Interrupt is disabled
- **1:** Interrupt is enabled

When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.

This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.
Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC’97).
   - This bit is set and cleared by software.
   - 0: Interrupt is disabled
   - 1: Interrupt is enabled
   - When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR register is set and an interrupt is generated.
   - This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio block operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.
   - This bit is set and cleared by software.
   - 0: Interrupt is disabled
   - 1: Interrupt is enabled
   - When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
   - Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
   - This bit is set and cleared by software.
   - 0: Interrupt is disabled
   - 1: Interrupt is enabled
   - This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.
   - It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
   - **Note**: This bit is used only in Free protocol mode and is meaningless in other modes.

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
   - This bit is set and cleared by software.
   - 0: Interrupt is disabled
   - 1: Interrupt is enabled
   - When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
   - This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.
   - This bit is set and cleared by software.
   - 0: Interrupt is disabled
   - 1: Interrupt is enabled
   - When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.

</tbody>
</table>

**Note**: This bit is used only in Free protocol mode and is meaningless in other modes.
Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

- 000: FIFO empty (transmitter and receiver modes)
- 001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode)
- 010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode)
- 011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode)
- 100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode)
- 101: FIFO full (transmitter and receiver modes)

Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

**Bit 6** **LFSDET**: Late frame synchronization detection.

This bit is read only.

- 0: No error.
- 1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

**Bit 5** **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.

- 0: No error.
- 1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

**Bit 4** **CNRDY**: Codec not ready.

This bit is read only.

- 0: External AC’97 Codec is ready
- 1: External AC’97 Codec is not ready

This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

**Bit 3** **FREQ**: FIFO request.

This bit is read only.

- 0: No FIFO request.
- 1: FIFO request to read or to write the SAI_xDR.

The request depends on the audio block configuration:

- If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
- If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.

This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.

This bit is read only.

0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 40.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)

This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0. It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.

This bit is read only.

0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame

This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).

It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.

This flag is cleared when the software sets bit CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.

This bit is read only.

0: No overrun/underrun error.
1: Overrun/underrun error detection.

The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.

It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.

This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
This bit is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
It is not used in AC’97 or SPDIF mode.
Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.
This bit is write only.
Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag.
This bit is write only.
Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.
This bit is write only.
Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.
This bit is write only.
Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  Reserved, must be kept at reset value.

Bit 11  CKEN4: Clock enable of bitstream clock number 4
This bit is set and cleared by software.
0: SAI_CK4 clock disabled
1: SAI_CK4 clock enabled

Note:  It is not recommended to configure this bit when PDMEN = 1.
SAI_CK4 might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.

Bit 10  CKEN3: Clock enable of bitstream clock number 3
This bit is set and cleared by software.
0: SAI_CK3 clock disabled
1: SAI_CK3 clock enabled

Note:  It is not recommended to configure this bit when PDMEN = 1.
SAI_CK3 might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.

Bit 9  CKEN2: Clock enable of bitstream clock number 2
This bit is set and cleared by software.
0: SAI_CK2 clock disabled
1: SAI_CK2 clock enabled

Note:  It is not recommended to configure this bit when PDMEN = 1.
SAI_CK2 might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.

Bit 8  CKEN1: Clock enable of bitstream clock number 1
This bit is set and cleared by software.
0: SAI_CK1 clock disabled
1: SAI_CK1 clock enabled

Note:  It is not recommended to configure this bit when PDMEN = 1.
SAI_CK1 might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.
Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MICNBR[1:0]**: Number of microphones
   - This bit is set and cleared by software.
   - 00: Configuration with 2 microphones
   - 01: Configuration with 4 microphones
   - 10: Configuration with 6 microphones
   - 11: Configuration with 8 microphones

   *Note: It is not recommended to configure this field when PDMEN = 1.*

   *The complete set of data lines might not be available for all SAI instances. Refer to Section 40.3: SAI implementation for details.*

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PDMEN**: PDM enable
   - This bit is set and cleared by software. This bit enables to control the state of the PDM interface block.
   - Make sure that the SAI is already operating in TDM master mode before enabling the PDM interface.
   - 0: PDM interface disabled
   - 1: PDM interface enabled

Refer to Section 2.2 for the register boundary addresses.
41 Inter-integrated circuit interface (I2C)

41.1 Introduction
The I2C peripheral handles the interface between the device and the serial I²C (inter-integrated circuit) bus. It provides multimaster capability, and controls all I²C-bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

The I2C peripheral is also SMBus (system management bus) and PMBus® (power management bus) compatible.

It can use DMA to reduce the CPU load.

41.2 I2C main features
- I²C-bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit-addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy-to-use event management
  - Clock stretching (optional)
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters
- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock
- Wake-up from Stop mode on address match

For information on I2C instantiation, refer to Section 41.3: I2C implementation.
41.3 **I2C implementation**

This section provides an implementation overview with respect to the I2C instantiation.

1. X = supported.

41.4 **I2C functional description**

In addition to receiving and transmitting data, the peripheral converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The peripheral is connected to the I²C-bus through a data pin (SDA) and a clock pin (SCL). It supports Standard-mode (up to 100 kHz), Fast-mode (up to 400 kHz), and Fast-mode Plus (up to 1 MHz) I²C-bus.

The peripheral can also be connected to an SMBus, through the data pin (SDA), the clock pin (SCL), and an optional SMBus alert pin (SMBA).

The independent clock function allows the I2C communication speed to be independent of the PCLK1 frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG).

41.4.3 I2C clock requirements

The I2C kernel is clocked by I2CCLK.

The I2CCLK period $t_{I2CCLK}$ must respect the following conditions:

$$t_{I2CCLK} < \left( t_{LOW} - t_{filters} \right) / 4$$

$$t_{I2CCLK} < t_{HIGH}$$

where $t_{LOW}$ is the SCL low time, $t_{HIGH}$ is the SCL high time, and $t_{filters}$ is the sum of the analog and digital filter delays (when enabled).

The digital filter delay is $\text{DNF}[3:0] \times t_{I2CCLK}$.

The PCLK1 clock period $t_{PCLK}$ must respect the condition $t_{PCLK} < 4/3 \times t_{SCL}$, where $t_{SCL}$ is the SCL period.

**Caution:** When the I2C kernel is clocked by PCLK1, this clock must respect the conditions for $t_{I2CCLK}$.

### 41.4.4 Mode selection

The peripheral can operate as:

- slave transmitter
- slave receiver
- master transmitter
- master receiver

By default, the peripheral operates in slave mode. It automatically switches from slave to master mode upon generating START condition, and from master to slave mode upon arbitration loss or upon generating STOP condition. This allows the use of the I2C peripheral in a multimaster I2C-bus environment.

**Communication flow**

In master mode, the I2C peripheral initiates a data transfer and generates the clock signal. Serial data transfers always begin with a START condition and end with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the peripheral recognizes its own 7-bit or 10-bit address, and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first one (7-bit addressing) or two (10-bit addressing) bytes following the START condition contain the address. The address is always transmitted in master mode.
The following figure shows the transmission of a single byte. The master generates nine SCL pulses. The transmitter sends the eight data bits to the receiver with the SCL pulses 1 to 8. Then the receiver sends the acknowledge bit to the transmitter with the ninth SCL pulse.

![I²C-bus protocol](image)

The acknowledge can be enabled or disabled by software. The own addresses of the I²C peripheral can be selected by software.

### 41.4.5 I²C initialization

#### Enabling and disabling the peripheral

Before enabling the I²C peripheral, configure and enable its clock through the clock controller, and initialize its control registers.

The I²C peripheral can then be enabled by setting the PE bit of the I²C_CR1 register.

Disabling the I²C peripheral by clearing the PE bit resets the I²C peripheral. Refer to Section 41.4.6 for more details.

#### Noise filters

Before enabling the I²C peripheral by setting the PE bit of the I²C_CR1 register, the user must configure the analog and/or digital noise filters, as required.

The analog noise filter on the SDA and SCL inputs complies with the I²C-bus specification which requires, in Fast-mode and Fast-mode Plus, the suppression of spikes shorter than 50 ns. Enabled by default, it can be disabled by setting the ANOFF bit.

The digital filter is controlled through the DNF[3:0] bitfield of the I²C_CR1 register. When it is enabled, the internal SCL and SDA signals only take the level of their corresponding I²C-bus line when remaining stable for more than DNF[3:0] periods of I²CCLK. This allows suppressing spikes shorter than the filtering capacity period programmable from one to fifteen I²CCLK periods.

The following table compares the two filters.

Caution: The filter configuration cannot be changed when the I2C peripheral is enabled.

I2C timings

To ensure correct data hold and setup times, the corresponding timings must be configured through the PRESC[3:0], SCLDEL[3:0], and SDADEL[3:0] bitfields of the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.
When the SCL falling edge is internally detected, the delay $t_{SDADEL}$ (impacting the hold time $t_{HD;DAT}$) is inserted before sending SDA output:

$$t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK},$$

where $t_{PRESC} = (PRESC + 1) \times t_{I2CCLK}$.

The total SDA output delay is:

$$t_{SYNC1} + \{SDADEL \times (PRESC + 1) + 1\} \times t_{I2CCLK}$$

The $t_{SYNC1}$ duration depends upon:

- SCL falling slope
- input delay $t_{AF(min)} < t_{AF} < t_{AF(max)}$ introduced by the analog filter (if enabled)
- input delay $t_{DNF} = DNF \times t_{I2CCLK}$ introduced by the digital filter (if enabled)
- delay due to SCL synchronization to I2CCLK clock (two to three I2CCLK periods)

To bridge the undefined region of the SCL falling edge, the user must set SDADEL[3:0] so as to fulfill the following condition:

$$\frac{t_{AF(max)} - t_{HD;DAT(min)} - t_{AF(min)} - [(DNF + 3) \times t_{I2CCLK}]}{(PRESC + 1) \times t_{I2CCLK}} \leq SDADEL$$

$$SDADEL \leq \frac{t_{HD;DAT(max)} - t_{AF(max)} - [(DNF + 4) \times t_{I2CCLK}]}{(PRESC + 1) \times t_{I2CCLK}}$$
Note: \( t_{AF\text{\(min\)}} \) and \( t_{AF\text{\(max\)}} \) are only part of the condition when the analog filter is enabled. Refer to the device datasheet for \( t_{AF} \) values.

The \( t_{HD;DAT} \) time can at maximum be 3.45 \( \mu \)s for Standard-mode, 0.9 \( \mu \)s for Fast-mode, and 0.45 \( \mu \)s for Fast-mode Plus. It must be lower than the maximum of \( t_{VD;DAT} \) by a transition time. This maximum must only be met if the device does not stretch the LOW period (\( t_{LOW} \)) of the SCL signal. When it stretches SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. The previous condition then becomes:

\[
SDADEL \leq (t_{VD;DAT \text{\(max\)}} - tr \text{\(max\)}) \cdot [(DNF + 4) \times t_{I2CCLK}] / ((PRESC + 1) \times t_{I2CCLK})
\]

Note: This condition can be violated when NOSTRETCH = 0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL[3:0] value.

After \( t_{SDADEL} \), or after sending SDA output when the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, the SCL line is kept at low level during the setup time. This setup time is \( t_{SCLDEL} = (SCLDEL + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). \( t_{SCLDEL} \) impacts the setup time \( t_{SU;DAT} \).

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL[3:0] so as to fulfill the following condition:

\[
\left[ \frac{tr \text{\(max\)}}{t_{SU;DAT \text{\(min\)}}} \right] / ((PRESC + 1) \times t_{I2CCLK}) - 1 \leq SCLDEL
\]

Refer to the following table for \( tr, \text{\(Sy;DAT\)} \), and \( t_{SCLDEL} \) standard values.

Use the SDA and SCL real transition time values measured in the application to widen the scope of allowed \( SDADEL[3:0] \) and SCLDEL[3:0] values. Use the maximum SDA and SCL transition time values defined in the standard to make the device work reliably regardless of the application.

Note: At every clock pulse, after SCL falling edge detection, I2C operating as master or slave stretches SCL low during at least \( [(SDADEL + SCLDEL + 1) \times (PRESC + 1) + 1] \times t_{I2CCLK} \) in both transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDA delay elapses, the I2C peripheral keeps stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

When the NOSTRETCH bit is set in slave mode, the SCL is not stretched. The SDADEL[3:0] must then be programmed so that it ensures a sufficient setup time.

<table>

</tbody>
</table>

Refer to the following table for \( tf, tr, t_{HD;DAT}, t_{VD;DAT}, t_{SU;DAT} \) standard values.
Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0], and SCLL[7:0] bitfields of the I2C_TIMINGR register.

When the SCL falling edge is internally detected, the I2C peripheral releasing the SCL output after the delay \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). The \( t_{SCLL} \) delay impacts the SCL low time \( t_{LOW} \).

When the SCL rising edge is internally detected, the I2C peripheral forces the SCL output to low level after the delay \( t_{SCLH} = (SCLH + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). The \( t_{SCLH} \) impacts the SCL high time \( t_{HIGH} \).

Caution: Changing the timing configuration and the NOSTRETCH configuration is not allowed when the I2C peripheral is enabled. Like the timing settings, the slave NOSTRETCH settings must also be done before enabling the peripheral. Refer to I2C master initialization for more details.

Refer to I2C master initialization for more details.

---

### I2C reset

The reset of the I2C peripheral is performed by clearing the PE bit of the I2C_CR1 register. It has the effect of releasing the SCL and SDA lines. Internal state machines are reset and the communication control bits and the status bits revert to their reset values. This reset does not impact the configuration registers.

The impacted register bits are:

1. I2C_CR2 register: START, STOP, PECBYTE, and NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, PECERR, TIMEOUT, ALERT, and OVR

---

</tbody>
</table>

---

41.4.6 I2C reset
PE must be kept low during at least three APB clock cycles to perform the I2C reset. To ensure this, perform the following software sequence:

1. Write PE = 0
2. Check PE = 0
3. Write PE = 1

41.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into the I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, which means that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch occurs between the eighth and ninth SCL pulse (before the acknowledge pulse).

![Figure 634. Data reception](image-url)
Transmission

If the I2C_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on the SDA line. If TXE = 1, which means that no data is written yet in I2C_TXDR, the SCL line is stretched low until I2C_TXDR is written. The stretch starts after the ninth SCL pulse.

![Figure 635. Data transmission](image)

Hardware transfer management

The I2C features an embedded byte counter to manage byte transfer and to close the communication in various modes, such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking

In master mode, the byte counter is always used. By default, it is disabled in slave mode. It can be enabled by software, by setting the SBC (slave byte control) bit of the I2C_CR1 register.

The number of bytes to transfer is programmed in the NBYTES[7:0] bitfield of the I2C_CR2 register. If this number is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected, by setting the RELOAD bit of the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES[7:0] is transferred (when the associated counter reaches zero), and an interrupt is generated if TCIE is set. SCL is stretched as long as the TCR flag is set. TCR is cleared by software when NBYTES[7:0] is written to a non-zero value.

When NBYTES[7:0] is reloaded with the last number of bytes to transfer, the RELOAD bit must be cleared.
When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end** (AUTOEND = 1 in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bitfield is transferred.

- **Software end** (AUTOEND = 0 in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bitfield is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit of the I2C_CR2 register is set. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

**41.4.8 I2C slave mode**

**I2C slave initialization**

To work in slave mode, the user must enable at least one slave address. The I2C_OAR1 and I2C_OAR2 registers are available to program the slave own addresses OA1 and OA2, respectively.

OA1 can be configured either in 7-bit (default) or in 10-bit addressing mode, by setting the OA1MODE bit of the I2C_OAR1 register.

OA1 is enabled by setting the OA1EN bit of the I2C_OAR1 register.

If an additional slave addresses are required, the second slave address OA2 can be configured. Up to seven OA2 LSBs can be masked, by configuring the OA2MSK[2:0] bitfield of the I2C_OAR2 register. Therefore, for OA2MSK[2:0] configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6], or OA2[7] are compared with the received address. When OA2MSK[2:0] is other than 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX) and they are not acknowledged. If OA2MSK[2:0] = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

When enabled through the specific bit, the reserved addresses can be acknowledged if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK[2:0] = 0.

OA2 is enabled by setting the OA2EN bit of the I2C_OAR2 register.

The general call address is enabled by setting the GCEN bit of the I2C_CR1 register.

When the I2C peripheral is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when required, to perform software actions. If the master does not
support clock stretching, I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled, the user must read the ADDCODE[6:0] bitfield of the I2C_ISR register to check which address matched. The DIR flag must also be checked to know the transfer direction.

**Slave with clock stretching**

As long as the NOSTRETCH bit of the I2C_CR1 register is zero (default), the I2C peripheral operating as an I²C-bus slave stretches the SCL signal in the following situations:

- The ADDR flag is set and the received address matches with one of the enabled slave addresses.
  The stretch is released when the software clears the ADDR flag by setting the ADDRCF bit.
- In transmission, the previous data transmission is completed and no new data is written in I2C_TXDR register, or the first data byte is not written when the ADDR flag is cleared (TXE = 1).
  The stretch is released when the data is written to the I2C_TXDR register.
- In reception, the I2C_RXDR register is not read yet and a new data reception is completed.
  The stretch is released when I2C_RXDR is read.
- In slave byte control mode (SBC bit set) with reload (RELOAD bit set), the last data byte transfer is finished (TCR bit set).
  The stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] bitfield.
- After SCL falling edge detection.
  The stretch is released after \[(SDADEL + SCLDEL + 1) \times (PRESCL + 1) + 1\] x tI2CCLK period.

**Slave without clock stretching**

As long as the NOSTRETCH bit of the I2C_CR1 register is set, the I2C peripheral operating as an I²C-bus slave does not stretch the SCL signal.

The SCL clock is not stretched while the ADDR flag is set.

In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, it ensures that the OVR status is provided, even for the first data to be transmitted.

In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not, an overrun occurs, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.
Slave byte control mode

To allow byte ACK control in slave reception mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C_CR1 register. This is required to comply with SMBus standards.

The reload mode must be selected to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES[7:0] must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit of the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent, and the next byte can be received.

NBYTES[7:0] can be loaded with a value greater than 0x1. Receiving then continues until the corresponding number of bytes are received.

**Note:** The SBC bit must be configured when the I2C peripheral is disabled, when the slave is not addressed, or when ADDR = 1.
The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

**Caution:** The slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

**Figure 636. Slave initialization flow**

1. SBC must be set to support SMBus features.
Slave transmitter

A transmit interrupt status (TXIS) flag is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit of the I2C_CR1 register is set. The TXIS flag is cleared when the I2C_TXDR register is written with the next data byte to transmit.

When NACK is received, the NACKF flag is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit of the I2C_CR1 register is set. The slave automatically releases the SCL and SDA lines to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When STOP is received and the STOPIE bit of the I2C_CR1 register is set, the STOPF flag of the I2C_ISR register is set and an interrupt is generated. In most applications, the SBC bit is usually programmed to 0. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register, by setting the TXE bit in order to program a new data byte.

In slave byte control mode (SBC = 1), the number of bytes to transmit must be programmed in NBYTES[7:0] in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0].

Caution: When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine to program the first data byte. The first data byte to send must be previously programmed in the I2C_TXDR register:

- This data can be the one written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to send, the I2C_TXDR register can be flushed, by setting the TXE bit, to program a new data byte. The STOPF bit must be cleared only after these actions. This guarantees that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event (transmit interrupt or transmit DMA request) is required, the user must set the TXIS bit in addition to the TXE bit, to generate the event.

41.4.9 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured, by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:
- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

I2C detects its own SCL low level after a tSYNC1 delay depending on the SCL falling edge, SCL input noise filters (analog and digital), and SCL synchronization to the I2CxCLK clock.
I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bitfield of the I2C_TIMINGR register.

I2C detects its own SCL high level after a tSYNC2 delay depending on the SCL rising edge, SCL input noise filters (analog and digital), and SCL synchronization to the I2CxCLK clock.
I2C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bitfield of the I2C_TIMINGR register.

Consequently the master clock period is:

\[ t_{SCL} = t_{SYNC1} + t_{SYNC2} + \left\{ [(SCLH+1) + (SCLL+1)] \times (PRESC+1) \times t_{I2CCLK} \right\} \]

The duration of tSYNC1 depends upon:
- SCL falling slope
- input delay induced by the analog filter (when enabled)
- input delay induced by the digital filter (when enabled): DNF[3:0] \times t_{I2CCLK}
- delay due to SCL synchronization with the I2CCLK clock (two to three I2CCLK periods)

The duration of tSYNC2 depends upon:
- SCL rising slope
- input delay induced by the analog filter (when enabled)
- input delay induced by the digital filter (when enabled): DNF[3:0] \times t_{I2CCLK}
- delay due to SCL synchronization with the I2CCLK clock (two to three I2CCLK periods)

Note: The SCLL[7:0] bitfield also determines the $t_{BUF}$ and $t_{SU:STA}$ timings and SCLH[7:0] the $t_{HD:STA}$ and $t_{SU:STO}$ timings.

Refer to Section 41.4.10 for examples of I2C_TIMINGR settings versus the I2CCLK frequency.

**Master communication initialization (address phase)**

To initiate the communication with a slave to address, set the following bitfields of the I2C_CR2 register:
- ADD10: addressing mode (7-bit or 10-bit)
- SADD[9:0]: slave address to send
- RD_WRN: transfer direction
- HEAD10R: in case of 10-bit address read, this bit determines whether the header only (for direction change) or the complete address sequence is sent.
- NBYTES[7:0]: the number of bytes to transfer; if equal to or greater than 255 bytes, the bitfield must initially be set to 0xFF.

Note: Changing these bitfields is not allowed as long as the START bit is set.

Before launching the communication, make sure that the I²C-bus is idle. This can be checked using the bus idle detection function or by verifying that the IDR bits of the GPIOs selected as SDA and SCL are set. Any low-level incident on the I²C-bus lines that coincides with the START condition asserted by the I2C peripheral may cause its deadlock if not filtered out by the input filters. If such incidents cannot be prevented, design the software so that it restores the normal operation of the I2C peripheral in case of a deadlock, by toggling the PE bit of the I2C_CR1 register.
To launch the communication, set the START bit of the I2C_CR2 register. The master then automatically sends a START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after the $t_{BUF}$ delay from a previous STOP condition expires.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

**Note:** The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware upon arbitration loss.

In 10-bit addressing mode, the master automatically keeps resending the slave address in a loop until the first address byte (first seven address bits) is acknowledged by the slave. Setting the ADDRCF bit makes I2C quit that loop.

If the I2C peripheral is addressed as a slave (ADDR = 1) while the START bit is set, the I2C peripheral switches to slave mode and the START bit is cleared when the ADDRCF bit is set.

**Note:** The same procedure is applied for a repeated start condition. In this case, BUSY = 1.

---

**Initialization of a master receiver addressing a 10-bit address slave**

If the slave address is in 10-bit format, the user can choose to send the complete read sequence, by clearing the HEAD10R bit of the I2C_CR2 register. In this case, the master automatically sends the following complete sequence after the START bit is set:

(REW)START + Slave address 10-bit header Write + Slave address second byte +
(REW)START + Slave address 10-bit header Read.

---

**Figure 645. 10-bit address read access with HEAD10R = 0**

---

**Figure 644. Master initialization flow**

---
If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated START is set with the 10-bit slave address configured with HEAD10R = 1. In this case, the master sends this sequence:

RESTART + Slave address 10-bit header Read.

**Figure 646. 10-bit address read access with HEAD10R = 1**

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit of the I2C_CR1 register is set. The flag is cleared when the I2C_TXDR register is written with the next data byte to transmit.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to transmit is greater than 255, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when the NBYTES[7:0] number of data bytes is transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written with a non-zero value.

When RELOAD = 0 and the number of data bytes defined in NBYTES[7:0] is transferred:

- In automatic end mode (AUTOEND = 1), a STOP condition is automatically sent.
- In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low, to perform software actions:
  - A RESTART condition can be requested by setting the START bit of the I2C_CR2 register with the proper slave address configuration and the number of bytes to transfer. Setting the START bit clears the TC flag and sends the START condition on the bus.
  - A STOP condition can be requested by setting the STOP bit of the I2C_CR2 register. This clears the TC flag and sends a STOP condition on the bus.

When a NACK is received, the TXIS flag is not set and a STOP condition is automatically sent. the NACKF flag of the I2C_ISR register is set. An interrupt is generated if the NACKIE bit is set.

EV2: TXIS ISR: wr data2

Example I2C master transmitter 2 bytes, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 2, AUTOEND=0, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2
EV3: TC ISR: program Slave address, program NBYTES = N, set START
Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit of the I2C_CR1 register is set. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to receive is greater than 255, select the reload mode, by setting the RELOAD bit of the I2C_CR2 register. In this case, when the NBYTES[7:0] number of data bytes is transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written with a non-zero value.

When RELOAD = 0 and he number of data bytes defined in NBYTES[7:0] is transferred:

- In automatic end mode (AUTOEND = 1), a NACK and a STOP are automatically sent after the last received byte.
- In software end mode (AUTOEND = 0), a NACK is automatically sent after the last received byte. The TC flag is set and the SCL line is stretched low in order to allow software actions:
  - A RESTART condition can be requested by setting the START bit of the I2C_CR2 register, with the proper slave address configuration and the number of bytes to transfer. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
  - A STOP condition can be requested by setting the STOP bit of the I2C_CR2 register. This clears the TC flag and sends a STOP condition on the bus.

41.4.11 SMBus specific features

**Introduction**

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on operation principles of the I²C-bus. The SMBus provides a control bus for system and power management related tasks.

The I2C peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices:

- **Slave** is a device that receives or responds to a command.
- **Master** is a device that issues commands, generates clocks, and terminates the transfer.
- **Host** is a specialized master that provides the main interface to the system CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

The I2C peripheral can be configured as a master or a slave device, and also as a host.

**Bus protocols**

There are eleven possible command protocols for any given device. A device can use any or all of them to communicate. The protocols are: Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write, and Block Write-Block Read Process Call. The protocols must be implemented by the user software.
For more details on these protocols, refer to the SMBus specification (http://smbus.org).

STM32CubeMX implements an SMBus stack thanks to X-CUBE-SMBUS, a downloadable software pack that allows basic SMBus configuration per I2C instance.

**Address resolution protocol (ARP)**

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. To provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique 128-bit device identifier (UDID). In the I2C peripheral, is implemented by software.

The I2C peripheral supports the Address resolution protocol (ARP). The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit of the I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details on the SMBus address resolution protocol, refer to the SMBus specification (http://smbus.org).

**Received command and data acknowledge control**

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C_CR1 register. Refer to **Slave byte control mode** for more details.

**Host notify protocol**

To enable the host notify protocol, set the SMBHEN bit of the I2C_CR1 register. The I2C peripheral then acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

**SMBus alert**

The I2C peripheral supports the SMBALERT# optional signal through the SMBA pin. With the SMBALERT# signal, an SMBus slave device can signal to the SMBus host that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device/devices which pulled SMBALERT# low acknowledges/acknowledge the alert response address.

When the I2C peripheral is configured as an SMBus slave device (SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit of the I2C_CR1 register. The alert response address is enabled at the same time.

When the I2C peripheral is configured as an SMBus host (SMBHEN = 1), the ALERT flag of the I2C_ISR register is set when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit of the I2C_CR1 register is set. When ALERTEN = 0, the alert line is considered high even if the external SMBA pin is low.

**Note:** If the SMBus alert pin is not required, keep the ALERTEN bit cleared. The SMBA pin can then be used as a standard GPIO.

**Packet error checking**

A packet error checking mechanism introduced in the SMBus specification improves reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is
calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The I2C peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match the hardware calculated PEC.

**Timeouts**

To comply with the SMBus timeout specifications, the I2C peripheral embeds hardware timers.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter</th>
<th>Limits</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t_{\text{TIMEOUT}}$</td>
<td>Detect clock low timeout</td>
<td>25</td>
<td>35</td>
</tr>
<tr>
<td>$t_{\text{LOW:SEXT}}^{(1)}$</td>
<td>Cumulative clock low extend time (slave device)</td>
<td>-</td>
<td>25</td>
</tr>
<tr>
<td>$t_{\text{LOW:MEXT}}^{(2)}$</td>
<td>Cumulative clock low extend time (master device)</td>
<td>-</td>
<td>10</td>
</tr>
</tbody>
</table>

1. $t_{\text{LOW:SEXT}}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{\text{LOW:SEXT}}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. $t_{\text{LOW:MEXT}}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than $t_{\text{LOW:MEXT}}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for \( t_{\text{IDLE}} > t_{\text{HIGH,MAX}} \) (refer to I2C timings).

This timing parameter covers the condition where a master is dynamically added to the bus, and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The I2C peripheral supports a hardware bus idle detection.

41.4.12 SMBus initialization

In addition to the I2C initialization for the I²C-bus, the use of the peripheral for the SMBus communication requires some extra initialization steps.

Received command and data acknowledge control (slave mode)

An SMBus receiver must be able to NACK each received command or data. To allow ACK control in slave mode, the slave byte control mode must be enabled, by setting the SBC bit of the I2C_CR1 register. Refer to Slave byte control mode for more details.

Specific addresses (slave mode)

The specific SMBus addresses must be enabled if required. Refer to Bus idle detection for more details.

The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit of the I2C_CR1 register.

The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit of the I2C_CR1 register.

The alert response address (0b0001100) is enabled by setting the ALERTEN bit of the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit of the I2C_CR1 register. Then the PEC transfer is managed with the help of the hardware byte counter associated with the NBYTES[7:0] bitfield of the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after transferring NBYTES[7:0] - 1 data bytes, if the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C peripheral is enabled.

</tbody>
</table>

Table 393. SMBus with PEC configuration
Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits of the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

$t_{\text{TIMEOUT}}$ check

To check the $t_{\text{TIMEOUT}}$ parameter, load the 12-bit TIMEOUTA[11:0] bitfield with the timer reload value. Keep the TIDLE bit at 0 to detect the SCL low level timeout.

Then set the TIMOUTEN bit of the I2C_TIMEOUTR register, to enable the timer.

If SCL is tied low for longer than the $(\text{TIMEOUT}A + 1) \times 2048 \times t_{\text{I2CCLK}}$ period, the TIMEOUT flag of the I2C_ISR register is set.

Refer to Table 394.

Caution: Changing the TIMEOUTA[11:0] bitfield and the TIDLE bit values is not allowed when the TIMOUTEN bit is set.

$t_{\text{LOW:SEXT}}$ and $t_{\text{LOW:MEXT}}$ check

A 12-bit timer associated with the TIMEOUTB[11:0] bitfield allows checking $t_{\text{LOW:SEXT}}$ for the I2C peripheral operating as a slave, or $t_{\text{LOW:MEXT}}$ when it operates as a master. As the standard only specifies a maximum, the user can choose the same value for both. The timer is then enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

If the SMBus peripheral performs a cumulative SCL stretch for longer than the $(\text{TIMEOUT}B + 1) \times 2048 \times t_{\text{I2CCLK}}$ period, and within the timeout interval described in Bus idle detection section, the TIMEOUT flag of the I2C_ISR register is set.

Refer to Table 395.

Caution: Changing the TIMEOUTB[11:0] bitfield value is not allowed when the TEXTEN bit is set.

Bus idle detection

To check the $t_{\text{IDLE}}$ period, the TIMEOUTA[11:0] bitfield associated with 12-bit timer must be loaded with the timer reload value. Keep the TIDLE bit at 1 to detect both SCL and SDA high level timeout. Then set the TIMOUTEN bit of the I2C_TIMEOUTR register to enable the timer.

If both the SCL and SDA lines remain high for longer than the $(\text{TIMEOUT}A + 1) \times 4 \times t_{\text{I2CCLK}}$ period, the TIMEOUT flag of the I2C_ISR register is set.

Refer to Table 396.

Caution: Changing the TIMEOUTA[11:0] bitfield and the TIDLE bit values is not allowed when the TIMOUTEN bit is set.
41.4.13 SMBus I2C_TIMEOUT register configuration examples

41.4.14 SMBus slave mode

In addition to I2C slave transfer management (refer to Section 41.4.8: I2C slave mode), this section provides extra software flowcharts to support SMBus.

**SMBus slave transmitter**

When using the I2C peripheral in SMBus mode, set the SBC bit to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case, the total number of TXIS interrupts is NBYTES[7:0] - 1, and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the transfer of the NBYTES[7:0] - 1 data bytes.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 654. Transfer sequence flow for SMBus slave transmitter N bytes + PEC

- Slave initialization
- Read ADDCODE and DIR in I2C_ISR
  - I2C_CR2.NBYTES = N + 1
  - PECBYTE=1
  - Set I2C_ICR.ADDRCF
- Write I2C_TXDR.TXDATA

Figure 655. Transfer bus diagram for SMBus slave transmitter (SBC = 1)

Example SMBus slave transmitter 2 bytes + PEC,

- ADDR
- TXIS
- TXIS
- NBYTES = 3

Legend:
- Transmission
- Reception
- SCL stretch

EV1: ADDR ISR: check ADDCODE, program NBYTES=3, set PECBYTE, set ADDRCF
EV2: TXIS ISR: wr data1
EV3: TXIS ISR: wr data2
SMBus slave receiver

When using the I2C peripheral in SMBus mode, set the SBC bit to enable the PEC checking at the end of the programmed number of data bytes. To allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to Slave byte control mode for more details.

To check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after the receipt of NBYTES[7:0] - 1 data bytes, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

Upon a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.

If no ACK software control is required, the user can set the PECBYTE bit and, in the same write operation, load NBYTES[7:0] with the number of bytes to receive in a continuous flow. After the receipt of NBYTES[7:0] - 1 bytes, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 656. Transfer sequence flow for SMBus slave receiver N bytes + PEC

1. SMBus slave reception
2. Slave initialization
3. Check if I2C_ISR.ADDR = 1?
   - No: Proceed to next step
   - Yes: Read ADDCODE and DIR in I2C_ISR
     - I2C_CR2.NBYTES = 1, RELOAD = 1
     - PECBYTE = 1
     - Set I2C_ICR.ADDRCF
4. Check if I2C_ISR.RXNE = 1? I2C_ISR.TCR = 1?
   - No: Read I2C_RXDR.RXDATA
   - Yes: Program I2C_CR2.NACK = 0
     - I2C_CR2.NBYTES = 1
     - N = N - 1
5. Check if N = 1?
   - No: Read I2C_RXDR.RXDATA
     - Program RELOAD = 0
     - NACK = 0 and NBYTES = 1
   - Yes: Read I2C_RXDR.RXDATA
8. End
41.4.15 SMBus master mode

In addition to I2C master transfer management (refer to Section 41.4.9: I2C master mode), this section provides extra software flowcharts to support SMBus.

SMBus master transmitter

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be loaded in the NBYTES[7:0] bitfield, before setting the START bit. In this case, the total number of TXIS interrupts is NBYTES[7:0] - 1. So if the PECBYTE bit is set when NBYTES[7:0] = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, the automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.
When the SMBus master wants to send a RESTART condition after the PEC, the software mode must be selected (AUTOEND = 0). In this case, once NBYTES[7:0] - 1 are transmitted, the I2C_PECR register content is transmitted. The TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 658. Bus transfer diagrams for SMBus master transmitter**

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)

- INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
- EV1: TXIS ISR: wr data1
- EV2: TXIS ISR: wr data2

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)

- INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
- EV1: TXIS ISR: wr data1
- EV2: TXIS ISR: wr data2
- EV3: TC ISR: program Slave address, program NBYTES = N, set START
**SMBus master receiver**

When the SMBus master wants to receive, at the end of the transfer, the PEC followed by a STOP condition, the automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address programmed before setting the START bit. In this case, after the receipt of NBYTES[7:0] - 1 data bytes, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive, at the end of the transfer, the PEC byte followed by a RESTART condition, the software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address programmed before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
41.4.16 Wake-up from Stop mode on address match

The I2C peripheral is able to wake up the device from Stop mode (APB clock is off), when the device is addressed. All addressing modes are supported.

The wake-up from Stop mode is enabled by setting the WUPEN bit of the I2C_CR1 register. The HSI16 oscillator must be selected as the clock source for I2CCLK to allow the wake-up from Stop mode.

In Stop mode, the HSI16 oscillator is stopped. Upon detecting START condition, the I2C interface starts the HSI16 oscillator and stretches SCL low until the oscillator wakes up. HSI16 is then used for the address reception.
If the received address matches the device own address, I2C stretches SCL low until the device wakes up. The stretch is released when the ADDR flag is cleared by software. Then the transfer goes on normally.

If the address does not match, the HSI16 oscillator is stopped again and the device does not wake up.

*Note:* When the system clock is used as I2C clock, or when WUPEN = 0, the HSI16 oscillator does not start upon receiving START condition.

Only an ADDR interrupt can wake the device up. Therefore, do not enter Stop mode when I2C is performing a transfer, either as a master or as an addressed slave after the ADDR flag is set. This can be managed by clearing the SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

*Caution:* The digital filter is not compatible with the wake-up from Stop mode feature. Before entering Stop mode with the WUPEN bit set, deactivate the digital filter, by writing zero to the DNF[3:0] bitfield.  

*Caution:* The feature is only available when the HSI16 oscillator is selected as the I2C clock.  

*Caution:* Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.  

*Caution:* If the wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

### 41.4.17 Error conditions

The following errors are the conditions that can cause the communication to fail.

**Bus error (BERR)**

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. START or STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C peripheral is involved in the transfer as master or addressed slave (that is, not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C peripheral enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag of the I2C_ISR register is set, and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.

**Arbitration loss (ARLO)**

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.

In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag of the I2C_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.
Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag of the I2C_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.

Packet error checking error (PECERR)

A PEC error is detected when the received PEC byte does not match the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag of the I2C_ISR register is set and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.

Timeout error (TIMEOUT)

A timeout error occurs for any of these conditions:

- TIDLE = 0 and SCL remains low for the time defined in the TIMEOUTA[11:0] bitfield: this is used to detect an SMBus timeout.
- TIDLE = 1 and both SDA and SCL remains high for the time defined in the TIMEOUTA[11:0] bitfield: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reaches the time defined in the TIMEOUTB[11:0] bitfield (SMBus tLOW:MEXT parameter).
- Slave cumulative clock low extend time reaches the time defined in the TIMEOUTB[11:0] bitfield (SMBus tLOW:SEXT parameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.

Alert (ALERT)

The ALERT flag is set when the I2C peripheral is configured as a host (SMBHEN = 1), the SMBAlert# signal detection is enabled (ALERTEN = 1), and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit of the I2C_CR1 register is set.
41.5 I2C in low-power modes

The following table gives the list of I2C interrupt requests.

### Table 397. Effect of low-power modes to I2C

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>

</table>

1. The ADDR match event can wake up the device from Stop mode only if the I2C instance supports the wake-up from Stop mode feature. Refer to Section 41.3: I2C implementation.
41.7 I2C DMA requests

Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit of the I2C_CR1 register. Data is loaded from an SRAM area configured through the DMA peripheral (see Section 12: Direct memory access controller (DMA)) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter.

In slave mode:
- With NOSTRETCH = 0, when all data are transferred using DMA, DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
- With NOSTRETCH = 1, the DMA must be initialized before the address match event.

The PEC transfer is managed with the counter associated to the NBYTES[7:0] bitfield. Refer to SMBus slave transmitter and SMBus master mode.

Note: If DMA is used for transmission, it is not required to set the TXIE bit.

Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit of the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured through the DMA peripheral (refer to Section 12: Direct memory access controller (DMA)) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.

The PEC transfer is managed with the counter associated to the NBYTES[7:0] bitfield. Refer to SMBus slave receiver and SMBus master receiver.

Note: If DMA is used for reception, it is not required to set the RXIE bit.

41.8 I2C debug modes

When the device enters debug mode (core halted), the SMBus timeout either continues working normally or stops, depending on the DBG_I2Cx_STOP bits in the DBG block.
41.9 I2C registers

Refer to Section 1.2 on page 73 for the list of abbreviations used in register descriptions.

The registers are accessed by words (32-bit).

41.9.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 PECEN: PEC enable
0: PEC calculation disabled
1: PEC calculation enabled

Bit 22 ALERTEN: SMBus alert enable
0: The SMBALERT# signal on SMBA pin is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the alert response address header is disabled (0001100x followed by NACK).
1: The SMBALERT# signal on SMBA pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the alert response address header is enabled (0001100x followed by ACK).

Note: When ALERTEN = 0, the SMBA pin can be used as a standard GPIO.

Bit 21 SMBDEN: SMBus device default address enable
0: Device default address disabled. Address 0b1100001x is NACKed.
1: Device default address enabled. Address 0b1100001x is ACKed.

Bit 20 SMBHEN: SMBus host address enable
0: Host address disabled. Address 0b0001000x is NACKed.
1: Host address enabled. Address 0b0001000x is ACKed.

Bit 19 GCEN: General call enable
0: General call disabled. Address 0b00000000 is NACKed.
1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 WUPEN: Wake-up from Stop mode enable
0: Wake-up from Stop mode disabled.
1: Wake-up from Stop mode enabled.

Note: WUPEN can be set only when DNF[3:0] = 0000.
Bit 17 **NOSTRETCH**: Clock stretching disable
This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.
0: Clock stretching enabled
1: Clock stretching disabled

*Note*: This bit can be programmed only when the I2C peripheral is disabled (PE = 0).

Bit 16 **SBC**: Slave byte control
This bit is used to enable hardware byte control in slave mode.
0: Slave byte control disabled
1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable
0: DMA mode disabled for reception
1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable
0: DMA mode disabled for transmission
1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF**: Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled

*Note*: This bit can be programmed only when the I2C peripheral is disabled (PE = 0).

Bits 11:8 **DNF[3:0]**: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] * tI2CCLK
0000: Digital filter disabled
0001: Digital filter enabled and filtering capability up to one tI2CCLK
... 1111: digital filter enabled and filtering capability up to fifteen tI2CCLK

*Note*: If the analog filter is enabled, the digital filter is added to it. This filter can be programmed only when the I2C peripheral is disabled (PE = 0).

Bit 7 **ERIE**: Error interrupts enable
0: Error detection interrupts disabled
1: Error detection interrupts enabled

*Note*: Any of these errors generates an interrupt:
- arbitration loss (ARLO)
- bus error detection (BERR)
- overrun/underrun (OVR)
- timeout detection (TIMEOUT)
- PEC error detection (PECERR)
- alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable
0: Transfer complete interrupt disabled
1: Transfer complete interrupt enabled

*Note*: Any of these events generates an interrupt:
Transfer complete (TC)
Transfer complete reload (TCR)
Bit 5 **STOPIE**: STOP detection interrupt enable
   0: STOP detection (STOPF) interrupt disabled
   1: STOP detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received interrupt enable
   0: Not acknowledge (NACKF) received interrupts disabled
   1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match interrupt enable (slave only)
   0: Address match (ADDR) interrupts disabled
   1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX interrupt enable
   0: Receive (RXNE) interrupt disabled
   1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX interrupt enable
   0: Transmit (TXIS) interrupt disabled
   1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable
   0: Peripheral disabled
   1: Peripheral enabled

   *Note: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.*

### 41.9.2 I2C control register 2 (I2C_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte
   This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.
   0: No PEC transfer
   1: PEC transmission/reception is requested

   *Note: Writing 0 to this bit has no effect. This bit has no effect when RELOAD is set, and in slave mode when SBC = 0.*
Bit 25  **AUTOEND**: Automatic end mode (master mode)
This bit is set and cleared by software.
0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.
*Note:*  This bit has no effect in slave mode or when the RELOAD bit is set.

Bit 24  **RELOAD**: NBYTES reload mode
This bit is set and cleared by software.
0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes
The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC = 0.
*Note:*  Changing these bits when the START bit is set is not allowed.

Bit 15  **NACK**: NACK generation (slave mode)
The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.
0: an ACK is sent after current received byte.
1: a NACK is sent after current received byte.
*Note:*  Writing 0 to this bit has no effect.
*This bit is used only in slave mode: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.*
*When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated, whatever the NACK bit value.*
*When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.*

Bit 14  **STOP**: STOP condition generation
This bit only pertains to master mode. It is set by software and cleared by hardware when a STOP condition is detected or when PE = 0.
0: No STOP generation
1: STOP generation after current byte transfer
*Note:*  Writing 0 to this bit has no effect.

Bit 13  **START**: START condition generation
This bit is set by software. It is cleared by hardware after the START condition followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software, by setting the ADDRCF bit of the I2C_ICR register.
0: No START generation
1: RESTART/START generation:
If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a repeated START condition when RELOAD = 0, after the end of the NBYTES transfer.
Otherwise, setting this bit generates a START condition once the bus is free.
*Note:*  Writing 0 to this bit has no effect.
*The START bit can be set even if the bus is BUSY or I2C is in slave mode.*
*This bit has no effect when RELOAD is set.*
Bit 12 **HEAD10R**: 10-bit address header only read direction (master receiver mode)
0: The master sends the complete 10-bit slave address read sequence: START + 2 bytes 10-bit address in write direction + RESTART + first seven bits of the 10-bit address in read direction.
1: The master sends only the first seven bits of the 10-bit address, followed by read direction. 
*Note: Changing this bit when the START bit is set is not allowed.*

Bit 11 **ADD10**: 10-bit addressing mode (master mode)
0: The master operates in 7-bit addressing mode
1: The master operates in 10-bit addressing mode
*Note: Changing this bit when the START bit is set is not allowed.*

Bit 10 **RD_WRN**: Transfer direction (master mode)
0: Master requests a write transfer
1: Master requests a read transfer
*Note: Changing this bit when the START bit is set is not allowed.*

Bits 9:0 **SADD[9:0]**: Slave address (master mode)
**Condition: In 7-bit addressing mode (ADD10 = 0):**
SADD[7:1] must be written with the 7-bit slave address to be sent. Bits SADD[9], SADD[8] and SADD[0] are don't care.

**Condition: In 10-bit addressing mode (ADD10 = 1):**
SADD[9:0] must be written with the 10-bit slave address to be sent.
*Note: Changing these bits when the START bit is set is not allowed.*

### 41.9.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

<table>

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

**Bit 15 **OA1EN**: Own address 1 enable
0: Own address 1 disabled. The received slave address OA1 is NACKed.
1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

**Bit 10 **OA1MODE**: Own address 1 10-bit mode
0: Own address 1 is a 7-bit address.
1: Own address 1 is a 10-bit address.
*Note: This bit can be written only when OA1EN = 0.*
41.9.4 I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x PCLK1 + 6 x I2CCLK.

<table>
<thead>
<tr>
<th>OA2EN</th>
<th>OA2MSK[2:0]</th>
<th>OA2[7:1]</th>
</tr>
</thead>
<tbody>

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 OA2EN: Own address 2 enable
0: Own address 2 disabled. The received slave address OA2 is NACKed.
1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 OA2MSK[2:0]: Own address 2 masks
000: No mask
001: OA2[1] is masked and don't care. Only OA2[7:2] are compared.
010: OA2[2:1] are masked and don't care. Only OA2[7:3] are compared.
100: OA2[4:1] are masked and don't care. Only OA2[7:5] are compared.
111: OA2[7] is masked and don't care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

Note: These bits can be written only when OA2EN = 0.

As soon as OA2MSK ≠ 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged, even if the comparison matches.

Bits 7:1 OA2[7:1]: Interface address
7-bit addressing mode: 7-bit address

Note: These bits can be written only when OA2EN = 0.

Bit 0 Reserved, must be kept at reset value.
41.9.5  **I2C timing register (I2C_TIMINGR)**

Address offset: 0x10
Reset value: 0x0000 0000
Access: no wait states

<table>

Bit 31  **TEXTEN**: Extended clock timeout enable
- 0: Extended clock timeout detection is disabled
- 1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than t_{LOW:EXT} is done by the I2C interface, a timeout error is detected (TIMEOUT = 1).

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  **TIMEOUTB[11:0]**: Bus timeout B
- This field is used to configure the cumulative clock extension timeout:
  - Master mode: the master cumulative clock low extend time (t_{LOW:MEXT}) is detected
  - Slave mode: the slave cumulative clock low extend time (t_{LOW:SEXT}) is detected
  \[ t_{LOW:EXT} = (\text{TIMEOUTB} + \text{TIDLE} = 01) \times 2048 \times t_{I2CCLK} \]
  
  *Note: These bits can be written only when TEXTEN = 0.*

Bit 15  **TIMOUTEN**: Clock timeout enable
- 0: SCL timeout detection is disabled
- 1: SCL timeout detection is enabled. When SCL is low for more than t_{TIMEOUT} (TIDLE = 0) or high for more than t_{IDLE} (TIDLE = 1), a timeout error is detected (TIMEOUT = 1).

Bits 14:13  Reserved, must be kept at reset value.

Bit 12  **TIDLE**: Idle clock timeout detection
- 0: TIMEOUTA is used to detect SCL low timeout
- 1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

*Note: This bit can be written only when TIMOUTEN = 0.*

Bits 11:0  **TIMEOUTA[11:0]**: Bus timeout A
- This field is used to configure:
  - The SCL low timeout condition t_{TIMEOUT} when TIDLE = 0
  \[ t_{\text{TIMEOUT}} = (\text{TIMEOUTA} + 1) \times 2048 \times t_{I2CCLK} \]
  - The bus idle condition (both SCL and SDA high) when TIDLE = 1
  \[ t_{\text{IDLE}} = (\text{TIMEOUTA} + 1) \times 4 \times t_{I2CCLK} \]

*Note: These bits can be written only when TIMOUTEN = 0.*
41.9.7 I2C interrupt and status register (I2C_ISR)

<tr>
<td></td>
<td>Note: This bit is cleared by hardware when PE = 0.</td>
</tr>
</tbody>
</table>
Bit 9 **ARLO**: Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 8 **BERR**: Bus error

This flag is set by hardware when a misplaced START or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting the BERRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 7 **TCR**: Transfer complete reload

This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE = 0.*

This flag is only for master mode, or for slave mode when the SBC bit is set.

Bit 6 **TC**: Transfer complete (master mode)

This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 5 **STOPF**: STOP detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

- as a master, provided that the STOP condition is generated by the peripheral.
- as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE ≠ 0.*

Bit 4 **NACKF**: Not acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE ≠ 0.*

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting the ADDRCF bit.

*Note: This bit is cleared by hardware when PE ≠ 0.*

Bit 2 **RXNE**: Receive data register not empty (receivers)

This bit is set by hardware when the received data is copied into the I2C_RXDR register, and is ready to be read. It is cleared when I2C_RXDR is read.

*Note: This bit is cleared by hardware when PE ≠ 0.*

Bit 1 **TXIS**: Transmit interrupt status (transmitters)

This bit is set by hardware when the I2C_TXDR register is empty and the data to be transmitted must be written in the I2C_TXDR register. It is cleared when the next data to be sent is written in the I2C_TXDR register.

This bit can be written to 1 by software only when NOSTRETCH = 1, to generate a TXIS event (interrupt if TXIE = 1 or DMA request if TXDMAEN = 1).

*Note: This bit is cleared by hardware when PE ≠ 0.*
Bit 0 **TXE**: Transmit data register empty (transmitters)
This bit is set by hardware when the I2C_TXDR register is empty. It is cleared when the next
data to be sent is written in the I2C_TXDR register.
This bit can be written to 1 by software in order to flush the transmit data register I2C_TXDR.
*Note*: This bit is set by hardware when PE = 0.

### 41.9.8 I2C interrupt clear register (I2C_ICR)

Address offset: 0x1C  
Reset value: 0x0000 0000  
Access: no wait states

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |

| Bits 31:14 | Reserved, must be kept at reset value. |
| Bit 13 | **ALERTCF**: Alert flag clear  
Writing 1 to this bit clears the ALERT flag in the I2C_ISR register. |
| Bit 12 | **TIMOUTCF**: Timeout detection flag clear  
Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register. |
| Bit 11 | **PECCF**: PEC error flag clear  
Writing 1 to this bit clears the PECERR flag in the I2C_ISR register. |
| Bit 10 | **OVRCF**: Overrun/underrun flag clear  
Writing 1 to this bit clears the OVR flag in the I2C_ISR register. |
| Bit 9 | **ARLOCF**: Arbitration lost flag clear  
Writing 1 to this bit clears the ARLO flag in the I2C_ISR register. |
| Bit 8 | **BERRCF**: Bus error flag clear  
Writing 1 to this bit clears the BERRF flag in the I2C_ISR register. |
| Bits 7:6 | Reserved, must be kept at reset value. |
| Bit 5 | **STOPCF**: STOP detection flag clear  
Writing 1 to this bit clears the STOPF flag in the I2C_ISR register. |
| Bit 4 | **NACKCF**: Not acknowledge flag clear  
Writing 1 to this bit clears the NACKF flag in I2C_ISR register. |
| Bit 3 | **ADDRCF**: Address matched flag clear  
Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register. |
| Bits 2:0 | Reserved, must be kept at reset value. |
41.9.9  **I2C PEC register (I2C_PECR)**

Address offset: 0x20
Reset value: 0x0000 0000
Access: no wait states

Refer to Section 2.2 on page 81 for the register boundary addresses.
42 Independent watchdog (IWDG)

42.1 Introduction

The devices feature an embedded watchdog peripheral (IWDG) that offers a combination of high safety level, timing accuracy, and flexibility of use. This peripheral detects and solves malfunctions due to software failure, and triggers a system reset when the counter reaches a given timeout value.

The independent watchdog is clocked by its own dedicated low-speed clock (LSI), and stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to Section 43: System window watchdog (WWDG).

42.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional reset
  - Reset (if watchdog is activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog is activated) if the downcounter is reloaded outside the window

42.3 IWDG functional description

42.3.1 IWDG block diagram

Figure 660 shows the functional blocks of the independent watchdog module.

Figure 660. Independent watchdog block diagram

1. The register interface is located in the voltage domain. The watchdog function is located in the VDD voltage domain, still functional in Standby mode.
When the independent watchdog is started by writing the value 0x0000 CCCC in the *IWDG key register (IWDG_KR)*, the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000), a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the *IWDG key register (IWDG_KR)*, the IWDG_RLR value is reloaded in the counter, and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

### 42.3.2 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the *IWDG window register (IWDG_WINR)*.

If the reload operation is performed while the counter is greater than the value stored in the *IWDG window register (IWDG_WINR)*, a reset is provided.

The default value of the *IWDG window register (IWDG_WINR)* is 0x0000 0FFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed to reset the downcounter to the *IWDG reload register (IWDG_RLR)* value, and to ease the cycle number calculation to generate the next reload.

#### Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the IWDG prescaler by programming *IWDG prescaler register (IWDG_PR)* from 0 to 7.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Write to the *IWDG window register (IWDG_WINR)*. This automatically refreshes the counter value in the *IWDG reload register (IWDG_RLR)*.

*Note:* Writing the window value allows the counter value to be refreshed by the RLR when the *IWDG status register (IWDG_SR)* is set to 0x0000 0000.

#### Configuring the IWDG when the window option is disabled

When the window option is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the prescaler by programming the *IWDG prescaler register (IWDG_PR)* from 0 to 7.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Refresh the counter value with IWDG_RLR (IWDG_KR = 0x0000 AAAA).
42.3.3 Hardware watchdog

If this feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the IWDG key register (IWDG_KR) is written by the software before the counter reaches the end of count, or if the downcounter is reloaded inside the window.

42.3.4 Low-power freeze

Depending on the IWDG_STOP and IWDG_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode, respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to User and read protection option bytes for more details.

42.3.5 Register access protection

Write access to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR), and IWDG window register (IWDG_WINR) is protected. To modify it, first write the code 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence, and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an ongoing update of the prescaler, or of the downcounter reload value, or of the window value.

42.3.6 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in DBGMCU freeze register.
42.4  IWDG registers

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

42.4.1  IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

KEY[15:0]

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  KEY[15:0]: Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 42.3.5: Register access protection)

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)
### 42.4.2 IWDG prescaler register (IWDG_PR)

Address offset: 0x04  
Reset value: 0x0000 0000

<table>
<thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **PR[2:0]: Prescaler divider**

These bits are write access protected see Section 42.3.5: Register access protection. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the **IWDG status register (IWDG_SR)** must be reset in order to be able to change the prescaler divider.

- 000: divider /4
- 001: divider /8
- 010: divider /16
- 011: divider /32
- 100: divider /64
- 101: divider /128
- 110: divider /256
- 111: divider /256

**Note:** Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the **IWDG status register (IWDG_SR)** is reset.
42.4.3  IWDG reload register (IWDG_RLR)

Address offset: 0x08
Reset value: 0x0000 0FFF (reset by Standby mode)

<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  \textbf{RL[11:0]}: Watchdog counter reload value

These bits are write access protected see Register access protection. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the IWDG key register (IWDG_KR). The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the IWDG status register (IWDG_SR) must be reset to be able to change the reload value.

\textit{Note}: Reading this register returns the reload value from the V_{DD} voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.
### 42.4.4 IWDG status register (IWDG_SR)

Address offset: 0x0C
Reset value: 0x0000 0000 (not reset by Standby mode)

<table>
<thead>
<tr>

<td>r</td>
<td>r</td>
<td>r</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2 WVU:** Watchdog counter window value update
  
  This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the V\text{DD} voltage domain (takes up to five cycles).
  
  Window value can be updated only when WVU bit is reset.

- **Bit 1 RVU:** Watchdog counter reload value update
  
  This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V\text{DD} voltage domain (takes up to five cycles).
  
  Reload value can be updated only when RVU bit is reset.

- **Bit 0 PVU:** Watchdog prescaler value update
  
  This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V\text{DD} voltage domain (takes up to five cycles).
  
  Prescaler value can be updated only when PVU bit is reset.

**Note:** If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.
42.4.5  IWDG window register (IWDG_WINR)

<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **WIN[11:0]:** Watchdog counter window value

These bits are write access protected, see Section 42.3.5, they contain the high limit of the window value to be compared with the downcounter.
To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0.
The WVU bit in the IWDG status register (IWDG_SR) must be reset in order to be able to change the reload value.

Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the IWDG status register (IWDG_SR) is reset.
### 42.4.6 IWDG register map

The following table gives the IWDG register map and reset values.

43 System window watchdog (WWDG)

43.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. An MCU reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

43.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 662)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

43.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent an MCU reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 661 for the WWDG block diagram.
43.3.1 **WWDG block diagram**

![Watchdog block diagram](image)

43.3.2 **Enabling the watchdog**

When the user option WWDG_SW selects “Software window watchdog”, the watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again, except by a reset.

When the user option WWDG_SW selects “Hardware window watchdog”, the watchdog is always enabled after a reset, it cannot be disabled.

43.3.3 **Controlling the down-counter**

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 662). The **WWDG configuration register (WWDG_CFR)** contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. Figure 662 describes the window watchdog process.

*Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).*

43.3.4 **How to program the watchdog timeout**

Use the formula in Figure 662 to calculate the WWDG timeout.
Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

The formula to calculate the timeout value is given by:

\[ t_{WWDG} = t_{PCLK} \times 4096 \times 2^{WDGTB[2:0]} \times (T[5:0] + 1) \quad (\text{ms}) \]

where:
- \( t_{WWDG} \): WWDG timeout
- \( t_{PCLK} \): APB clock period measured in ms
- 4096: value corresponding to internal divider
As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3, and T[5:0] is set to 63:

\[ t_{\text{WWDG}} = \left( \frac{1}{48000} \right) \times 4096 \times 2^3 \times (63 + 1) = 43.69 \text{ms} \]

Refer to the datasheet for the minimum and maximum values of \( t_{\text{WWDG}} \).

### 43.3.5 Debug mode

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details, refer to Section 48.16.2: Debug support for timers, RTC, watchdog, bxCAN and I\(^2\)C.

### 43.4 WWDG interrupts

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

**Note:** When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.

### 43.5 WWDG registers

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).
43.5.1  WWDG control register (WWDG_CR)

Address offset: 0x000
Reset value: 0x0000 007F

<table>
<thead>

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  WDGA: Activation bit
This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.
0: Watchdog disabled
1: Watchdog enabled

Bits 6:0  T[6:0]: 7-bit counter (MSB to LSB)
These bits contain the value of the watchdog counter, decremented every (4096 x 2^WDGTB[2:0]) PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

43.5.2  WWDG configuration register (WWDG_CFR)

Address offset: 0x004
Reset value: 0x0000 007F

</tr>
</tbody>
</table>

Bits 31:14  Reserved, must be kept at reset value.

Bits 13:11  WDGTB[2:0]: Timer base
The timebase of the prescaler can be modified as follows:
000: CK counter clock (PCLK div 4096) div 1
001: CK counter clock (PCLK div 4096) div 2
010: CK counter clock (PCLK div 4096) div 4
011: CK counter clock (PCLK div 4096) div 8
100: CK counter clock (PCLK div 4096) div 16
101: CK counter clock (PCLK div 4096) div 32
110: CK counter clock (PCLK div 4096) div 64
111: CK counter clock (PCLK div 4096) div 128

Bit 10  Reserved, must be kept at reset value.
Bit 9  **EWI**: Early wake-up interrupt enable
Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7  Reserved, must be kept at reset value.

Bits 6:0  **W[6:0]**: 7-bit window value
These bits contain the window value to be compared with the down-counter.

### 43.5.3  WWDG status register (WWDG_SR)

</tr>
</tbody>
</table>

Bits 31:1  Reserved, must be kept at reset value.

Bit 0  **EWIF**: Early wake-up interrupt flag
This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing 0. Writing 1 has no effect. This bit is also set if the interrupt is not enabled.

### 43.5.4  WWDG register map

The following table gives the WWDG register map and reset values.

| Offset | Register name  | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000  | WWDG_CR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x004  | WWDG_CFR      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x008  | WWDG_SR       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to **Section 2.2 on page 81** for the register boundary addresses.
44 FD controller area network (FDCAN)

44.1 Introduction

The controller area network (CAN) subsystem (see Figure 663) consists of one CAN module, a shared message RAM, and a configuration block. Refer to the memory map for the base address of each of these parts.

The modules (FDCAN) are compliant with ISO 11898-1: 2015 (CAN protocol specification version 2.0 part A, B) and CAN FD protocol specification version 1.0.

A 0.8-Kbyte message RAM per FDCAN instance implements filters, receive FIFOs, transmit event FIFOs, and transmit FIFOs.

The CAN subsystem I/O signals and pins are detailed, respectively, in Table 402 and Figure 663.

44.2 FDCAN main features

- Conform with CAN protocol version 2.0 part A, B, and ISO 11898-1: 2015
- CAN FD with maximum 64 data bytes supported
- CAN error logging
- AUTOSAR and J1939 support
- Improved acceptance filtering
- Two receive FIFOs of three payloads each (up to 64 bytes per payload)
- Separate signaling on reception of high priority messages
- Configurable transmit FIFO/queue of three payloads (up to 64 bytes per payload)
- Transmit event FIFO
- Programmable loop-back test mode
- Maskable module interrupts
- Two clock domains: APB bus interface and CAN core kernel clock
- Power-down support
44.3 FDCAN functional description

Dual interrupt lines

The FDCAN peripheral provides two interrupt lines, fdcan_intr0_it and fdcan_intr1_it. By programming the EINT0 and EINT1 bits of the FDCAN_ILE register, the interrupt lines can be independently enabled or disabled.

CAN core

The CAN core contains the protocol controller and receive/transmit shift registers. It handles all ISO 11898-1: 2015 protocol functions and supports both 11-bit and 29-bit identifiers.

Sync

This block synchronizes signals from the APB clock domain to the CAN kernel clock domain and vice versa.
Tx handler

The Tx handler controls the message transfer from the message RAM to the CAN core. A maximum of three Tx buffers is available for transmission. The Tx buffer can be used as Tx FIFO or as a Tx queue. Tx event FIFO stores Tx timestamps together with the corresponding message ID. Transmit cancellation is also supported.

Rx handler

The Rx handler controls the transfer of received messages from the CAN core to the external message RAM. The Rx handler supports two receive FIFOs, for storage of all messages that have passed acceptance filtering. An Rx timestamp is stored together with each message. Up to 28 filters can be defined for 11-bit IDs; up to eight filters for 29-bit IDs.

APB interface

The APB interface connects the FDCAN to the APB bus for configuration registers, controller configuration, and RAM access.

Message RAM interface

The message RAM interface connects the FDCAN access to an external 1-Kbyte message RAM through a RAM controller/arbiter.

44.3.1 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

As shown in Figure 665, its operation can be explained simply by splitting the bit time in three segments, as follows:

- Synchronization segment (SYNC_SEG): a bit change is expected to occur within this time segment, having a fixed length of one time quantum (1 \( \times t_q \)).
- Bit segment 1 (BS1): defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard. Its duration is programmable from 1 to 16 time quanta, but can be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of various nodes of the network.
- Bit segment 2 (BS2): defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard, its duration is programmable between one and eight time quanta, but can also be automatically shortened to compensate for negative phase drifts.
The baud rate is the inverse of the bit time (baud rate = 1 / bit time), which, in turn, is the sum of three components (see Figure 665):

\[ \text{bit time} = t_{\text{SyncSeg}} + t_{\text{BS1}} + t_{\text{BS2}} \]

Where:

- For the nominal bit time
  \[ t_q = (\text{NBRP}[8:0] + 1) \times t_{\text{fdcan_tq_clk}} \]
  \[ t_{\text{SyncSeg}} = 1 \times t_q \]
  \[ t_{\text{BS1}} = t_q \times (\text{NTSEG1}[7:0] + 1) \]
  \[ t_{\text{BS2}} = t_q \times (\text{NTSEG2}[6:0] + 1) \]
  Where NBRP[8:0], NTSEG1[7:0], and NTSEG2[6:0] bitfields belong to the FDCAN_NBTP register.

- For the data bit time
  \[ t_q = (\text{DBRP}[4:0] + 1) \times t_{\text{fdcan_tq_clk}} \]
  \[ t_{\text{SyncSeg}} = 1 \times t_q \]
  \[ t_{\text{BS1}} = t_q \times (\text{DTSEG1}[4:0] + 1) \]
  \[ t_{\text{BS2}} = t_q \times (\text{DTSEG2}[3:0] + 1) \]
  Where DBRP[4:0], DTSEG1[4:0], and DTSEG2[3:0] belong to the FDCAN_DBTP register.

The (re)synchronization jump width (SJW) defines an upper bound for the amount of lengthening or shortening of the bit segments. It is programmable between one and four time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level, provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNCESEG, BS1 is extended by up to SJW, so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNCESEG, BS2 is shortened by up to SJW, so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the bit timing register is only possible while the device is in Standby mode. The FDCAN_DBTP and FDCAN_NBTP registers (dedicated, respectively, to data and nominal bit timing) are only accessible when the CCE and INIT of the FDCA_CCCR register are set.

Note: For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898-1 standard.
44.3.2 Operating modes

Configuration
Access to IP version, hardware, and input clock divider configuration. When the clock divider is set to 0, the primary input clock is used as it is.

Software initialization
Software initialization is started by setting the INIT bit of the FDCAN_CCCR register, by software, by a hardware reset, or by entering bus-off state. While the INIT bit is set, message transfers from and to the CAN bus are stopped, and the status of the CAN bus output FDCAN_TX is recessive (high). The EML (error management logic) counters are unchanged. Setting the INIT bit does not change any configuration register. Clearing INIT bit of FDCAN_CCCR finishes the software initialization. Afterwards the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (bus-idle) before it can take part in bus activities and start the message transfer.

Access to the FDCAN configuration registers is only enabled when the INIT bit and the CCE bit of the FDCAN_CCCR register are both set.

The CCE bit of the FDCAN_CCCR register can only be set/cleared while the INIT bit of FDCAN_CCCR is set. The CCE bit is automatically cleared when the INIT bit is cleared.

The following registers are reset when the CCE bit of the FDCAN_CCCR register is set:
- FDCAN_HPMS: High priority message status
- FDCAN_RXF0S: Rx FIFO 0 status
- FDCAN_RXF1S: Rx FIFO 1 status
- FDCAN_TXFQS: Tx FIFO/queue status
- FDCAN_TXBRP: Tx buffer request pending
- FDCAN_TXBTO: Tx buffer transmission occurred
- FDCAN_TXBCF: Tx buffer cancellation finished
- FDCAN_TXEFS: Tx event FIFO status

The timeout counter value (TOC[15:0] bit of the FDCAN_TOCV register) is preset to the value configured by the TOP[15:0] of the FDCAN_TOCC register when the CCE bit of the FDCAN_CCCR is set.

In addition, the state machines of the Tx handler and Rx handler are held in idle state while the CCE bit is set.

The following registers can be written only when the CCE bit is cleared:
- FDCAN_TXBAR: Tx buffer add request
- FDCAN_TXBCR: Tx buffer cancellation request

The TEST and the MON bits of the FDCAN_CCCR register can be set only by software while the INIT and the CCE bits of the FDCAN_CCCR register are both set. Both bits can be reset at any time. The DAR bit of FDCAN_CCCR can only be set/cleared while the INIT and CCE bits are both set.
Normal operation

The FDCAN default operating mode after hardware reset is event-driven CAN communication. TT operation mode is not supported.

Once the FDCAN is initialized and the INIT bit of the FDCAN_CCCR register is cleared, the FDCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including message ID and DLC are stored into the Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted, the Tx FIFO or the Tx queue can be initialized or updated. Automated transmission on reception of remote frames is not supported.

CAN FD operation

There are two variants in the FDCAN protocol:

1. Long frame mode (LFM), where the data field of a CAN frame may be longer than eight bytes
2. Fast frame mode (FFM), where the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate compared to the beginning and to the end of the frame

The fast frame mode can be used in combination with the long frame mode.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are decoded as FDF bit: FDF recessive signifies a CAN FD frame, while FDF dominant signifies a classic CAN frame.

In a CAN FD frame, the two bits following FDF (res and BRS) decide whether the bit rate inside this CAN FD frame is switched. A CAN FD bit rate switch is signified by res dominant and BRS recessive. The coding of res recessive is reserved for future expansion of the protocol. In case the FDCAN receives a frame with FDF recessive and res recessive, it signals a protocol exception event by setting the PXE bit of the FDCAN_PSR register. When protocol exception handling is enabled (PXHD = 0 in FDCAN_CCCR), this causes the operation state to change from receiver (ACT[1:0] = 10 in FDCAN_PSR) to integrating (ACT[1:0] = 00 in FDCAN_PSR) at the next sample point. If protocol exception handling is disabled (PXHD = 1 in FDCAN_CCCR), the FDCAN treats a recessive res bit as a form error and responds with an error frame.

CAN FD operation is enabled by programming the FDOE bit of the FDCAN_CCCR register. In case FDOE = 1, transmission and reception of CAN FD frames are enabled. Transmission and reception of classic CAN frames are always possible. Whether a CAN FD frame or a classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx buffer element. With FDOE = 0, received frames are interpreted as classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx buffer element is set. The FDOE and BRSE bits of the FDCAN_CCCR register can only be changed while the INIT and CCE bits are both set.

With FDOE = 0, the setting of the FDF and BRSE bits is ignored, and frames are transmitted in classic CAN format. With FDOE = 1 and BRSE = 0, only the FDF bit of a Tx buffer element is evaluated. With FDOE = 1 and BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx buffer elements with FDF and BRSE bits set are transmitted in CAN FD format with bit rate switching.
A mode change during CAN operation is recommended only under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes transmit classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN partial networking have to be transmitted in classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non-CAN FD nodes are held in silent mode until programming is complete. Then all nodes switch back to classic CAN communication.

In the FDCAN format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15 (that in standard CAN all code a data field of 8 bytes) are coded according to Table 403.

<table>

In CAN FD fast frames, the bit timing is switched inside the frame, after the BRS (bit rate switch) bit, if this bit is recessive. Before the BRS bit, in the FDCAN arbitration phase, the standard CAN bit timing is used as defined by the FDCAN_DBTP register. In the following FDCAN data phase, the fast CAN bit timing is used as defined by the FDCAN_DBTP register. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the FDCAN kernel clock frequency. For example, with an FDCAN kernel clock frequency of 20 MHz and the shortest configurable bit time of four time quanta (tq), the bit rate in the data phase is 5 Mbit/s.

In both data frame formats (CAN FD long frames and CAN FD fast frames), the value of bit ESI (error status indicator) is determined by the transmitter error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames, the ESI bit is always transmitted dominant, independent of the transmitter error state. The data length code of CAN FD remote frames is transmitted as 0.

In case an FDCAN Tx buffer is configured for FDCAN transmission with DLC > 8, the first eight bytes are transmitted as configured in the Tx buffer while the remaining part of the data field is padded with 0xCC. When the FDCAN receives a FDCAN frame with DLC > 8, the first eight bytes of that frame are stored into the matching Rx FIFO. The remaining bytes are discarded.

### Transceiver delay compensation

During the data phase of an FDCAN transmission, only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin FDCAN_TX, the protocol controller receives the transmitted data from its local CAN transceiver via pin FDCAN_RX. The received data is delayed by the CAN transceiver loop.
delay. If this delay is greater than TSEG1 (time segment before sample point), and a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of an FDCAN frame is limited by the transceiver loop delay.

The FDCAN implements a delay compensation mechanism to compensate the CAN transceiver loop delay, thereby enabling transmission with higher bit rates during the FDCAN data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the secondary sample point (SSP). If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase, the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay. This is enabled by setting the TDC bit of the FDCAN_DBTP register, and described in detail in the ISO11898-1 specification.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the FDCAN transmit output pin FDCAN_TX through the transceiver to the receive input pin FDCAN_RX plus the transmitter delay compensation offset as configured by TDCO[6:0] of FDCAN_TDCR. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example, half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq (minimum time quantum, one period of fdcantq_ck clock).

The TDCV[6:0] bitfield of the FDCAN_PSR register shows the actual transmitter delay compensation value. TDCV[6:0] is cleared when the INIT is set in the FDCAN_CCCR. It is updated at each transmission of an FD frame while the TDC bit of the FDCAN_DBTP register is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the FDCAN:

- The sum of the measured delay from FDCAN_Tx to FDCAN_Rx and the configured transmitter delay compensation offset TDCO[6:0] has to be lower than 6-bit times in the data phase.
- The sum of the measured delay from FDCAN_TX to FDCAN_RX and the configured transmitter delay compensation offset TDCO[6:0] has to be lower than or equal to $127 \times mtq$. If the sum exceeds this value, the maximum value ($127 \times mtq$) is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, which stops checking received bits at the SSPs.

If transmitter delay compensation is enabled by setting the TDC bit of the FDCAN_DBTP; the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input pin FDCAN_TX of the transmitter. The resolution of this measurement is one mtq.
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit (resulting in a too early SSP position), the use of a transmitter delay compensation filter window can be enabled by programming the TDCF[6:0] bitfield of the FDCAN_TDCR register. This defines a minimum value for the SSP position. Dominant edges on FDCAN_RX that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCF[6:0] and FDCAN_RX is low.

**Restricted operation mode**

In restricted operation mode, the node is able to receive data and remote frames, and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits. Instead, it waits for the occurrence of a bus-idle condition to resynchronize itself to the CAN communication. The error counters (REC[6:0] and TEC[7:0] in FDCAN_ECR) are frozen while the error logging (CEL[7:0]) is active. The software can set the FDCAN into restricted operation mode by setting the ASM bit of FDCAN_CCCR. The bit can only be set by software when both CCE and INIT bits are set in FDCAN_CCCR. The bit can be cleared by software at any time.

Restricted operation mode is automatically entered when the Tx handler is not able to read data from the message RAM in time. To leave restricted operation mode, the software has to clear the ASM bit of FDCAN_CCCR.

The restricted operation mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after it has received a valid frame.

**Note:** The restricted operation mode must not be combined with the loop-back mode (internal or external).
**Bus monitoring mode**

The FDCAN is set in bus monitoring mode by setting the MON bit of the FDCAN_CCCR register. In bus monitoring mode (for more details refer to ISO11898-1, 10.12 bus monitoring), the FDCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the FDCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the FDCAN can monitor it, even if the CAN bus remains in recessive state. In bus monitoring mode, the FDCAN_TXBRP register is held in reset state.

The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. *Figure 667* shows the connection of FDCAN_TX and FDCAN_RX signals to the FDCAN in bus monitoring mode.

**Figure 667. Pin control in bus monitoring mode**

---

**Disabled automatic retransmission mode (DAR)**

According to the CAN specification (see ISO11898-1, 6.3.3 Recovery Management), the FDCAN provides means for automatic retransmission of frames that have lost arbitration or have been disturbed by errors during transmission. By default, automatic retransmission is enabled. The DAR mode can be disabled through the DAR bit of the FDCAN_CCCR register.

**Frame transmission in DAR mode**

In DAR mode, all transmissions are automatically canceled after they have been started on the CAN bus. A Tx buffer Tx request pending bit (TRPx in FDCAN_TXBRP) is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, when it has been aborted due to lost arbitration, or when an error has occurred during frame transmission.

- **Successful transmission**
  - The corresponding Tx buffer transmission occurred bit TOx is set in FDCAN_TXBTO register.
  - The corresponding Tx buffer cancellation finished bit CFx is cleared in the FDCAN_TXBCF register.
• Successful transmission in spite of cancellation
  – The corresponding Tx buffer transmission occurred bit TOx is set in the FDCAN_TXBTO register.
  – The corresponding Tx buffer cancellation finished bit CFx is set in the FDCAN_TXBCF register.
• Arbitration loss or frame transmission disturbed
  – The corresponding Tx buffer transmission occurred bit TOx is cleared in the FDCAN_TXBTO register.
  – The corresponding Tx buffer cancellation finished bit CFx is set in the FDCAN_TXBCF register.

In case of a successful frame transmission, and if the storage of Tx events is enabled, a Tx event FIFO element is written with event type ET = 10 (transmission in spite of cancellation).

Power-down (Sleep mode)

Power-down entry

The FDCAN can be set into power-down mode controlled by setting the CSR bit of the FDCAN_CCCR register. As long as the clock stop request is active, CSR is read as 1.

When all pending transmission requests have completed, the FDCAN waits until the bus-idle state is detected. The FDCAN then sets the INIT bit of the FDCAN_CCCR register to prevent any further CAN transfers. Now, the FDCAN acknowledges that it is ready for power-down by setting the CSA bit of the FDCAN_CCCR register. In this state, before the clocks are switched off, further register accesses can be made. A write access to the INIT bit has no effect. Now, the module clock inputs can be switched off.

Power-down exit

To leave power-down mode, the application has to turn on the module clocks before clearing the CSR bit. The FDCAN acknowledges this by clearing the CSA bit. Afterwards, the application can restart CAN communication by clearing the INIT bit.

Test modes

To enable write access to **FDCAN test register (FDCAN_TEST)**, the TEST bit of the FDCAN_CCCR register must be set, thus enabling the configuration of test modes and functions.

Four output functions are available for the CAN transmit pin FDCAN_TX by programming the TX[1:0] bitfield of the FDCAN_TEST register. In addition to its default function (the serial data output), it can drive the CAN sample point signal to monitor the FDCAN bit timing as well as drive constant dominant or recessive values. The actual value at pin FDCAN_RX can be read from the RX bit of FDCAN_TEST. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN kernel clock and APB clock domain, there can be a delay of several APB clock periods between writing to TX[1:0] until the new configuration is visible at FDCAN_TX output pin. This applies also when reading FDCAN_RX input pin via RX.

**Note:** Test modes must be used for production tests or self-test only. The software control for FDCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.
External loop-back mode

The FDCAN can be set in external loop-back mode by setting the LBCK bit of the FDCAN_TEST register. In loop-back mode, the FDCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. Figure 668 shows the connection of transmit and receive signals FDCAN_TX and FDCAN_RX to the FDCAN in external loop-back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the FDCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop-back mode. In this mode, the FDCAN performs an internal feedback from its transmit output to its receive input. The actual value of the FDCAN_RX input pin is disregarded by the FDCAN. The transmitted messages can be monitored at the FDCAN_TX transmit pin.

Internal loop-back mode

Internal loop-back mode is entered by setting both the LBCK bit of FDCAN_TEST and the MON bit of FDCAN_CCR. This mode can be used for a “hot self-test”, meaning the FDCAN can be tested without affecting a running CAN system connected to the FDCAN_TX and FDCAN_RX pins. In this mode, FDCAN_RX pin is disconnected from the FDCAN and FDCAN_TX pin is held recessive. Figure 668 shows the connection of FDCAN_TX and FDCAN_RX pins to the FDCAN in case of internal loop-back mode.

Figure 668. Pin control in loop-back mode

Timestamp generation

For timestamp generation, the FDCAN supplies a 16-bit wrap-around counter. A prescaler (TCP[3:0] of FDCAN_TSCC) can be configured to clock the counter in multiples of CAN bit times (1 to 16). The counter is readable via the TCV[15:0] bitfield of the FDCAN_TSCV register. A write access to TSCV[15:0] resets the counter to 0. When the timestamp counter wraps around, the interrupt flag (TSW bit of FDCAN_ISR) is set.

On start of frame reception/transmission, the counter value is captured and stored into the timestamp section of an Rx FIFO (RXTS[15:0]) or Tx event FIFO (TXTS[15:0]) element.
By programming TSS[1:0] of FDCAN_TSCC, a 16-bit timestamp can be used.

**Debug mode behavior**

In debug mode, the set/reset on read feature is automatically disabled during the debugger register access, and enabled during normal MCU operation.

**Timeout counter**

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO the FDCAN supplies a 16-bit timeout counter. It operates as a down-counter and uses the same prescaler controlled by TCP[3:0] of FDCAN_TSCC as the timestamp counter. The timeout counter is configured via the FDCAN_TOCC register. The actual counter value can be read from the TOC[15:0] bitfield of FDCAN_TOCV. The timeout counter can only be started while the INIT bit of FDCAN_CCCR is cleared. It is stopped when INIT is set, for example, when the FDCAN enters bus-off state.

The operation mode is selected by TOS[1:0] of FDCAN_TOCC. When operating in continuous mode, the counter starts when INIT is cleared. A write to FDCAN_TOCV presets the counter to the value configured by TOP[15:0] in FDCAN_TOCC and continues down-counting.

When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOP[15:0]. Down-counting is started when the first FIFO element is stored. Writing to FDCAN_TOCV has no effect.

When the counter reaches 0, the TOO interrupt flag is set in the FDCAN_IR register. In continuous mode, the counter is immediately restarted at TOP[15:0].

*Note: The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore, the point in time where the timeout counter is decremented may vary due to the synchronization/resynchronization mechanism of the CAN core. If the baud rate switch feature in FDCAN is used, the timeout counter is clocked differently in the arbitration and data fields.*
44.3.3 Message RAM

The message RAM is 32-bit wide, and the FDCAN module is configured to allocate up to 212 words in it. It is not necessary to configure each of the sections shown in Figure 669.

Figure 669. Message RAM configuration

When the FDCAN addresses the message RAM, it addresses 32-bit words (aligned), not a single byte. The RAM addresses are 32-bit words, that is, only bits 15 to 2 are evaluated, the two least significant bits are ignored.

In case of multiple instances, the RAM start address for the FDCANn is computed by end address + 4 of FDCANn - 1, and the FDCANn end address is computed by FDCANn start address + 0x0350 - 4.

As an example, for two instances:

- **FDCAN1:**
  - Start address 0x0000
  - End address 0x034C (as in Figure 669)

- **FDCAN2:**
  - Start address = 0x034C (FDCAN1 end address) + 4 = 0x0350
  - End address = 0x0350 (FDCAN2 start address) + 0x0350 - 4 = 0x069C.

**Rx handling**

The Rx handler controls the acceptance filtering, the transfer of received messages to one of the two Rx FIFOs, as well as the Rx FIFO put and get indices.

**Acceptance filter**

The FDCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and another for extended identifiers. These filters can be assigned to Rx FIFO 0 or Rx FIFO 1. For acceptance filtering, each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element, and the following filter elements are not evaluated for this message.
The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering.
- Each filter element can be enabled/disabled individually.
- Filters are checked sequentially, execution stops with the first matching filter element.

Related configuration registers are:

- Global filter configuration (RXGFC)
- Extended ID AND mask (XIDAM)

Depending on the configuration of the filter element (SFEC[2:0]/EFEC[2:0]), a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Reject received frame
- Set the high priority message interrupt flag HPM in FDCAN_IR
- Set the high priority message interrupt flag HPM in FDCAN_IR, and store the received frame in FIFO 0 or FIFO 1.

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx FIFO has been found, the message handler starts writing the received message data in 32-bit portions to the matching Rx FIFO. If the CAN protocol controller has detected an error condition (for example, CRC error), this message is discarded with the following impact:

- Rx FIFO
  The put index of the matching Rx FIFO is not updated, but the related Rx FIFO element is partly overwritten with the received data. For error type, see LEC[2:0] and DLEC[2:0] bitfields of the FDCAN_PSR register. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in Rx FIFO overwrite mode have to be considered.

*Note:* When an accepted message is written to one of the two Rx FIFOs, the unmodified received identifier is stored independently from the used filters. The result of the acceptance filter process strongly depends on the sequence of configured filter elements.

### Range filter

The filter matches for all received frames with message IDs in the range defined by SF1ID/SF2ID and EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- EFT[1:0] = 00: the message ID of received frames is AND-ed with the extended ID AND mask (XIDAM) before the range filter is applied.
- EFT[1:0] = 11: the extended ID AND mask (XIDAM) is not used for range filtering.
Filter for dedicated IDs

A filter element can be configured to filter for one or two specific message IDs. To filter for one specific message ID, the filter element has to be configured with SF1ID = SF2ID and EF1ID = EF2ID.

Classic bit mask filter

The classic bit mask filtering is intended to filter groups of message IDs by masking single bits of a received message ID. With classic bit mask filtering SF1ID/EF1ID is used as message ID filter, while SF2ID/EF2ID is used as filter mask.

0 bit at the filter mask masks out the corresponding bit position of the configured ID filter. For example, the value of the received message ID at that bit position is not relevant for acceptance filtering. Only the bits of the received message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

In case all mask bits are 1, a match occurs only when the received message ID and the message ID filter are identical. If all mask bits are 0, all message IDs match.

Standard message ID filtering

Figure 670 shows the flow for standard message ID (11-bit identifier) filtering. The standard message ID filter element is described in Section 44.3.8.

The standard message filtering is controlled by the FDCAN_RXGFC register. The standard message ID, the remote transmission request bit (RTR), and the identifier extension bit (IDE) of the received frames are compared against the list of configured filter elements.

Extended message ID filtering

*Figure 671* shows the flow for extended message ID (29-bit identifier) filtering. The extended message ID filter element is described in *Section 44.3.9*.

The extended message filtering is controlled by the FDCAN_RXGFC register. The extended message ID, the remote transmission request bit (RTR), and the identifier extension bit (IDE) of the received frames are compared against the list of configured filter elements.

*Figure 671. Extended message ID filter path*

The extended ID AND mask (XIDAM) is AND-ed with the received identifier before the filter list is executed.
Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can hold up to three elements each.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see Acceptance filter. The Rx FIFO element is described in Section 44.3.5.

When an Rx FIFO full condition is signaled by RFnF in FDCAN_IR (where n is the FIFO number), no further messages are written to the corresponding Rx FIFO until at least one message has been read out, and the Rx FIFO get index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded, and the interrupt flag RFnL is set in the FDCAN_IR register.

When reading from an Rx FIFO, the Rx FIFO get index (FnGl of FDCAN_RXFnS) + FIFO element size has to be added to the corresponding Rx FIFO start address (FnSA).

Rx FIFO blocking mode

The Rx FIFO blocking mode is configured by clearing the FnOM bit in the FDCAN_RXGFC register. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (FnPI = FnGI in FDCAN_RXFnS), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO get index has been incremented. An Rx FIFO full condition is signaled by FnF = 1 in FDCAN_RXFnS. In addition, the RFnF interrupt flag is set in FDCAN_IR.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded, and the message lost condition is signaled by setting RFnL bit in FDCAN_RXFnS. In addition, the RFnL interrupt flag is set in FDCAN_IR.

Rx FIFO overwrite mode

The Rx FIFO overwrite mode is configured by setting the FnOM bit of the FDCAN_RXGFC register.

When an Rx FIFO full condition (FnPI = FnGl of FDCAN_RXFnS) is signaled by FnF = 1 in FDCAN_RXFnS, the next message accepted for the FIFO overwrites the oldest FIFO message. Put and get indices are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signaled, reading from the Rx FIFO elements must start at least at get index + 1. This is because it may happen that a received message is written to the message RAM (put index) while the CPU is reading from the message RAM (get index). In this case, inconsistent data can be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO acknowledge index (FnA of FDCAN_RXFnA). This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (FnF = 0 in FDCAN_RXFnS).
Tx handling

The Tx handler handles transmission requests for the Tx FIFO and the Tx queue. It controls the transfer of transmit messages to the CAN core, the put and get indices, and the Tx event FIFO. Up to three Tx buffers can be set up for message transmission. The CAN message data field is configured to 64 bytes. The Tx FIFO allocates eighteen 32-bit words for storage of a Tx element.

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.

The Tx handler starts a Tx scan to check for the highest priority pending Tx request (Tx buffer with lowest message ID) when the Tx buffer request pending register (FDCAN_TXBRP) is updated, or when a transmission has been started.

Transmit pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are permanently specified to specific values and cannot easily be changed. These message identifiers can have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority must be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

As an example, if CAN ECU-1 has the feature enabled and is requested by its application software to transmit four messages, it waits, after the first successful message transmission, for two CAN bit times of bus-idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, these messages are started in the idle time, and they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The feature is controlled by the TXP bit of the CCCR register. If the bit is set, the FDCAN, each time it has successfully transmitted a message, pauses for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. By default, this feature is disabled (TXP = 0 in FDCAN_CCCR).
This feature loses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

**Tx FIFO**

Tx FIFO operation is configured by clearing the TFQM bit of the FDCAN_TXBC register. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the get index (TFGI[1:0] bitfield of FDCAN_TXFQS). After each transmission, the get index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same message ID from different Tx buffers in the order that these messages have been written to the Tx FIFO. The FDCAN calculates the Tx FIFO free level (TFFL[2:0] bitfield of FDCAN_TXFQS) as the difference between the get and put index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx buffer referenced by the put index (TFQPI[1:0] bitfield of FDCAN_TXFQS). An add request increments the put index to the next free Tx FIFO element. When the put index reaches the get index, Tx FIFO full (TFQF = 1 in FDCAN_TXFQS) is signaled. In this case, no further messages must be written to the Tx FIFO until the next message has been transmitted and the get index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by setting the FDCAN_TXBAR bit related to the Tx buffer referenced by the Tx FIFO put index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx buffers starting with the put index. The transmissions are then requested via the FDCA_TXBAR register. The put index is then cyclically incremented by n. The number of requested Tx buffers must not exceed the number of free Tx buffers as indicated by the Tx FIFO free level.

When a transmission request for the Tx buffer referenced by the get index is canceled, the get index is incremented to the next Tx buffer with a transmission request is pending and the Tx FIFO free level is recalculated. When transmission cancellation is applied to any other Tx buffer, the get index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates eighteen 32-bit words in the message RAM. Therefore, the start address of the next available (free) Tx FIFO buffer, is calculated by adding four times the put index TFQPI[1:0] (0 … 2) to the Tx buffer start address TBSA.

**Tx queue**

Tx queue operation is configured by setting the TFQM of the FDCAN_TXBC register. Messages stored in the Tx queue are transmitted starting with the message with the lowest message ID (highest priority).

In case of mixing of standard and extended message IDs, the standard message IDs are compared to bits [28:18] of extended message IDs.

In case multiple queue buffers are configured with the same message ID, the queue buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx buffer referenced by the put index (TFQPI[1:0] in FDCAN_TXFQS). An add request cyclically increments the put index to the next free Tx buffer. In case the Tx queue is full (TFQF = 1 in FDCAN_TXFQS), the put index is not valid and no further message must be written to the Tx queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.
The application can use the FDCAN_TXBRP register instead of the put index and can place messages to any Tx buffer without pending transmission request.

A Tx queue buffer allocates eighteen 32-bit words in the message RAM. The start address of Therefore, the next available (free) Tx queue buffer is calculated by adding four times the Tx queue put index TFQPI[1:0] (0 ... 2) to the Tx buffer start address TBSA.

Transmit cancellation

The FDCAN supports transmit cancellation. To cancel a requested transmission from a Tx queue buffer, the host has to write 1 to the corresponding bit position (= number of Tx buffer) of the FDCAN_TXBCR register. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the FDCAN_TXBCF register.

In case a transmit cancellation is requested while a transmission from a Tx buffer is already ongoing, the corresponding FDCAN_TXBRP bit remains set as long as the transmission is in progress. If the transmission is successful, the corresponding FDCAN_TXBTO and FDCAN_TXBCF bits are set. If the transmission is not successful, it is not repeated and only the corresponding FDCAN_TXBCF bit is set.

Note: In case a pending transmission is canceled immediately before it has been started, there is a short time window where no transmission is started even if another message is pending in the node. This can enable another node to transmit a message that can have a priority lower than that of the second message in the node.

Tx event handling

To support Tx event handling the FDCAN has implemented a Tx event FIFO. After the FDCAN has transmitted a message on the CAN bus, message ID and timestamp are stored in a Tx event FIFO element. To link a Tx event to a Tx event FIFO element, the message marker from the transmitted Tx buffer is copied into the Tx event FIFO element.

The Tx event FIFO is configured to three elements. The Tx event FIFO element is described in Tx FIFO.

The purpose of the Tx event FIFO is to decouple handling transmit status information from transmit message handling that is, a Tx buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx buffer before overwriting that Tx buffer.

When a Tx event FIFO full condition is signaled by the TEFF bit of the FDCAN_IR, no further elements are written to the Tx event FIFO until at least one element has been read out and the Tx event FIFO get index has been incremented. In case a Tx event occurs while the Tx event FIFO is full, this event is discarded and the TEFL interrupt flag is set in the FDCAN_IR register.

When reading from the Tx event FIFO, the Tx event FIFO get index (EFGI[1:0] of FDCAN_TXEFS) has to be added twice to the Tx event FIFO start address EFSA.
44.3.4 FIFO acknowledge handling

The get indices of Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO are controlled by writing to the corresponding FIFO acknowledge index (see Section 44.4.23 and Section 44.4.25). Writing to the FIFO acknowledge index sets the FIFO get index to the FIFO acknowledge index plus one and thereby updates the FIFO fill level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the get index), this get index value is written to the FIFO acknowledge index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO acknowledge index only once at the end of that read sequence (value = index of the last element read), to update the FIFO get index.

Because the CPU has free access to the FDCAN message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (get index not considered). This might be useful when reading a high priority message from one of the two Rx FIFOs. In this case, the FIFO acknowledge index must not be written because this would set the get index to a wrong position and alter the FIFO fill level. In this case, some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO acknowledge index. The FDCAN does not check for erroneous values.

44.3.5 FDCAN Rx FIFO element

Two Rx FIFOs are configured in the message RAM. Each Rx FIFO section can be configured to store up to three received messages. The structure of an Rx FIFO element is described in Table 405. The description is provided in Table 406.

### 44.3.6 FDCAN Tx buffer element

The Tx buffers section (three elements) can be configured to hold Tx FIFO or Tx queue. The Tx handler distinguishes between Tx FIFO and Tx queue using the Tx buffer configuration TFQM bit of the FDCAN_TXBC register. The element size is configured for storage of CAN FD messages with up to 64-byte data.

44.3.7 FDCAN Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx event, FIFO the host CPU gets this information in the order that the messages were transmitted. Status information about the Tx event FIFO can be obtained from FDCAN_TXEFS register.

1. The ESI bit of the transmit buffer is OR-ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node can optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.

2. When RTR = 1, the FDCAN transmits a remote frame according to ISO11898-1, even if the transmission in CAN FD format is enabled by the FDOE bit of the FDCAN_CCCR.

3. Bits ESI, FDF, and BRS are only evaluated when CAN FD operation is enabled by setting the FDOE bit of the FDCAN_CCCR. Bit BRS is only evaluated when in addition BRSE bit is set in FDCAN_CCCR.

</tbody>
</table>

Bits 31:0 ETV[31:0]: Endianness test value
The endianness test value is 0x8765 4321.

Note: The register read must give the reset value to ensure no endianness issue.

44.4.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP)

Address offset: 0x000C
Reset value: 0x0000 0A33

This register is only writable if the CCE and INIT bits of the FDCAN_CCCR are set. The CAN time quantum can be programmed in the range of 1 to 32 FDCAN clock periods:
\[ t_q = (DBRP[4:0] + 1) \text{ FDCAN clock periods} \]
DTSEG1[4:0] is the sum of PROP_SEG and PHASE_SEG1. DTSEG2[3:0] is PHASE_SEG2. Therefore, the length of the bit time is (programmed values) \times [\text{DTSEG1}[4:0] + \text{DTSEG2}[3:0] + 3] \times t_q \text{ or } (\text{functional values}) \times [\text{SYNC_SEG} + \text{PROP_SEG} + \text{PHASE_SEG1} + \text{PHASE_SEG2}] \times t_q.

The information processing time (IPT) is 0, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With an FDCAN clock of 8 MHz, the reset value 0x0000 0A33 configures the FDCAN for a fast bit rate of 500 kbit/s. The data phase bit rate must be higher than or equal to the nominal bit rate.

44.4.4 FDCAN test register (FDCAN_TEST)

Write access to this register is enabled by setting the TEST bit of the FDCAN_CCCR register. All register functions are set to their reset values when this bit is cleared.

Loop-back mode and software control of Tx pin FDCANx_TX are hardware test modes. Programming TX[1:0] differently from 00 can disturb the message transfer on the CAN bus.

Address offset: 0x0010
Reset value: 0x0000 0000
44.4.5 FDCAN RAM watchdog register (FDCAN_RWD)

The RAM watchdog monitors the READY output of the message RAM. A message RAM access starts the message RAM watchdog counter with the value configured through the WDC[7:0] bitfield of the FDCAN_RWD register.

The counter is reloaded with WDC[7:0] when the message RAM signals successful completion by activating its READY output. In case there is no response from the message RAM until the counter has counted down to 0, the counter stops, and the interrupt flag WDI is set in the FDCAN_IR register. The RAM watchdog counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 WDV[7:0]: Watchdog value
Actual message RAM watchdog counter value.
Bits 7:0  **WDC[7:0]**: Watchdog configuration
   Start value of the message RAM watchdog counter. With the reset value of 00, the counter is disabled.
   This bitfield is write-protected (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

### 44.4.6 FDCAN CC control register (FDCAN_CCCR)

**Address offset**: 0x0018

**Reset value**: 0x0000 0001

For details about setting and clearing single bits, see *Software initialization*.

</table>

Bits 31:16  **Reserved**, must be kept at reset value.

**Bit 15  **NISO**: Non-ISO operation
   If this bit is set, the FDCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.
   0: CAN FD frame format according to ISO11898-1
   1: CAN FD frame format according to Bosch CAN FD Specification V1.0

**Bit 14  **TXP**: Transmit pause enable
   If this bit is set, the FDCAN pauses for two CAN bit times before starting the next transmission after successfully transmitting a frame.
   0: Disabled
   1: Enabled

**Bit 13  **EFBI**: Edge filtering during bus integration
   0: Edge filtering disabled
   1: Two consecutive dominant $t_d$ required to detect an edge for hard synchronization

**Bit 12  **PXHD**: Protocol exception handling disable
   0: Protocol exception handling enabled
   1: Protocol exception handling disabled

Bits 11:10  **Reserved**, must be kept at reset value.

**Bit 9  **BRSE**: FDCAN bit rate switching
   0: Bit rate switching for transmissions disabled
   1: Bit rate switching for transmissions enabled

**Bit 8  **FDOE**: FD operation enable
   0: FD operation disabled
   1: FD operation enabled

**Bit 7  **TEST**: Test mode enable
   0: Normal operation, FDCAN_TEST holds reset values
   1: Test mode, write access to FDCAN_TEST enabled
Bit 6  **DAR**: Disable automatic retransmission
0: Automatic retransmission of messages not transmitted successfully enabled
1: Automatic retransmission disabled

Bit 5  **MON**: Bus monitoring mode
This bit can only be set by software when both CCE and INIT are set. The bit can be cleared by the host at any time.
0: Bus monitoring mode disabled
1: Bus monitoring mode enabled

Bit 4  **CSR**: Clock stop request
0: No clock stop requested
1: Clock stop requested. When clock stop is requested, first INIT and then CSA is set after all pending transfer requests have been completed and the CAN bus is idle.

Bit 3  **CSA**: Clock stop acknowledge
0: No clock stop acknowledged
1: FDCAN can be set in power-down by stopping APB clock and kernel clock.

Bit 2  **ASM**: ASM restricted operation mode
The restricted operation mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the restricted operation mode after it has received a valid frame. In the optional restricted operation mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus-idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by software when both CCE and INIT are set. The bit can be cleared by the software at any time.
0: Normal CAN operation
1: Restricted operation mode active

Bit 1  **CCE**: Configuration change enable
0: The CPU has no write access to the protected configuration registers.
1: The CPU has write access to the protected configuration registers (while INIT set in FDCAN_CCCR).

Bit 0  **INIT**: Initialization
0: Normal operation
1: Initialization started

**Note:** Due to the synchronization mechanism between the two clock domains, there can be a delay until the value written to INIT can be read back. Therefore, the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

### 44.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP)

Address offset: 0x001C

Reset value: 0x0600 0A03

This register is only writable if the CCE and INIT bits of the FDCAN_CCCR register are both set. The CAN bit time can be programmed in the range of 4 to $81 \times t_q$. The CAN time quantum can be programmed in the range of 1 to 1024 FDCAN kernel clock periods:

$$t_q = (BRP + 1) \times \text{FDCA}n \text{ clock period fdcan_ker_ck}.$$
NTSEG1[7:0] is the sum of PROP_SEG and PHASE_SEG1. NTSEG2[6:0] is PHASE_SEG2. Therefore, the length of the bit time is
(programmed values) × [NTSEG1[7:0] + NTSEG2[6:0] + 3] × tq or
(functional values) × [SYNC_SEG + PROP_SEG + PHASE_SEG1 + PHASE_SEG2] × tq.

The information processing time (IPT) is 0, meaning the data for the next bit is available at the first clock edge after the sample point.

Bits 31:25 **NSJW[6:0]**: Nominal (re)synchronization jump width
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that the used value is the one programmed incremented by one.
This bitfield is write-protected (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 24:16 **NBRP[8:0]**: Bit rate prescaler
Value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum. Valid values are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
This bitfield is write-protected (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 15:8 **NTSEG1[7:0]**: Nominal time segment before sample point
Valid values are 0 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
This bitfield is write-protected write (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **NTSEG2[6:0]**: Nominal time segment after sample point
Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

**Note:** With a CAN kernel clock of 48 MHz, the reset value of 0x0600 0A03 configures the FDCAN for a bit rate of 3 Mbit/s.
44.4.8 FDCAN timestamp counter configuration register (FDCAN_TSCC)

</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 TCP[3:0]: Timestamp counter prescaler
Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1…16].
The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
In CAN FD mode, the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase. Thus CAN FD requires an external counter for timestamp generation (TSS[1:0] = 10).
This bitfield is write-protected (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 TSS[1:0]: Timestamp select
00: Timestamp counter value always 0x0000
01: Timestamp counter value incremented according to TCP
10: External timestamp counter from TIM3 value (tim3_cnt[0:15])
11: Same as 00.
These bits are write-protected write (P): write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

44.4.9 FDCAN timestamp counter value register (FDCAN_TSCV)

Address offset: 0x0024
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.
44.4.10 FDCAN timeout counter configuration register (FDCAN_TOCC)

Address offset: 0x0028
Reset value: 0xFFFF 0000

Bits 15:0  **TSC[15:0]: Timestamp counter**

The internal/external timestamp counter value is captured on start of frame (both Rx and Tx). When TSS[1:0] = 01 in FDCAN_TSCC, the timestamp counter is incremented in multiples of CAN bit times [1 ... 16] depending on the configuration of TCP[3:0] in FDCAN_TSCC. A wrap around sets the TSW interrupt flag in FDCAN_IR. Write access resets the counter to 0. When TSS[1:0] = 10, TSC[15:0] reflects the external timestamp counter value. A write access has no impact.

**Note:** A “wrap around” is a change of the timestamp counter value from non-0 to 0 that is not caused by write access to FDCAN_TSCV.

Bits 31:16 **TOP[15:0]: Timeout period**

Start value of the timeout counter (down-counter). Configures the timeout period.

Bits 15:3 Reserved, must be kept at reset value.

Bits 2:1 **TOS[1:0]: Timeout select**

When operating in continuous mode, a write to FDCAN_TOCV presets the counter to the value configured by TOP[15:0] in FDCAN_TOCC and continues down-counting. When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOP[15:0]. Down-counting is started when the first FIFO element is stored.

00: Continuous operation
01: Timeout controlled by Tx event FIFO
10: Timeout controlled by Rx FIFO 0
11: Timeout controlled by Rx FIFO 1

This bitfield is write-protected (P), write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

**Bit 0 ETOC: Timeout counter enable**

0: Timeout counter disabled
1: Timeout counter enabled

This bit is write-protected (P), write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

For more details, see *Timeout counter.*
44.4.11 FDCAN timeout counter value register (FDCAN_TOCV)

Address offset: 0x002C
Reset value: 0x0000 FFFF

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | TOC[15:0]: Timeout counter |
| The timeout counter is decremented in multiples of CAN bit times [1 ... 16] depending on the configuration of the TCP[3:0] bitfield of the FDCAN_TSCC register. When decremented to 0, the TOO interrupt flag is set in FDCAN_IR and the timeout counter is stopped. Start and reset/restart conditions are configured via TOS[1:0] in FDCAN_TOCC. |

44.4.12 FDCAN error counter register (FDCAN_ECR)

Address offset: 0x0040
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:16 | CEL[7:0]: CAN error logging |
| The counter is incremented each time when a CAN protocol error causes the transmit error counter or the receive error counter to be incremented. It is reset by read access to CEL[7:0]. The counter stops at 0xFF; the next increment of TEC[7:0] or REC[6:0] sets the ELO interrupt flag in FDCAN_IR. Access type is rc_r: cleared on read. |

Bit 15 | RP: Receive error passive |
| 0: The receive error counter is below the error passive level of 128. |
| 1: The receive error counter has reached the error passive level of 128. |

Bits 14:8 | REC[6:0]: Receive error counter |
| Actual state of the receive error counter, values between 0 and 127. |

Bits 7:0 | TEC[7:0]: Transmit error counter |
| Actual state of the transmit error counter, values between 0 and 255. When the ASM bit of the FDCAN_CCCR is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL[7:0] is still incremented. |
44.4.13  FDCAN protocol status register (FDCAN_PSR)

Address offset: 0x0044
Reset value: 0x0000 0707

- **TDCV[6:0]:** Transmitter delay compensation value
  - Position of the secondary sample point, defined by the sum of the measured delay from FDCAN_TX to FDCAN_RX and TDCO[6:0] in FDCAN_TDCR. The SSP position is, in the data phase, the number of minimum time quanta (mtq) between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 × mtq.

- **Bit 15** Reserved, must be kept at reset value.

- **Bits 22:16** TDCV[6:0]: Transmitter delay compensation value
  - Position of the secondary sample point, defined by the sum of the measured delay from FDCAN_TX to FDCAN_RX and TDCO[6:0] in FDCAN_TDCR. The SSP position is, in the data phase, the number of minimum time quanta (mtq) between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 × mtq.

- **Bit 14** PXE: Protocol exception event
  - 0: No protocol exception event occurred since last read access
  - 1: Protocol exception event occurred

- **Bit 13** REDL: Received FDCAN message
  - This bit is set independent of acceptance filtering.
  - 0: Since this bit was cleared by the CPU, no FDCAN message has been received.
  - 1: Message in FDCAN format with EDL flag set has been received.
  - Access type is rc_r: cleared on read.

- **Bit 12** RBRS: BRS flag of last received FDCAN message
  - This bit is set together with REDL, independent of acceptance filtering.
  - 0: Last received FDCAN message did not have its BRS flag set.
  - 1: Last received FDCAN message had its BRS flag set.
  - Access type is rc_r: cleared on read.

- **Bit 11** RESI: ESI flag of last received FDCAN message
  - This bit is set together with REDL, independent of acceptance filtering.
  - 0: Last received FDCAN message did not have its ESI flag set.
  - 1: Last received FDCAN message had its ESI flag set.
  - Access type is rc_r: cleared on read.

- **Bits 10:8** DLEC[2:0]: Data last error code
  - Type of last error that occurred in the data phase of a FDCAN format frame with its BRS flag set. Coding is the same as for LEC[2:0]. This field is cleared when a FDCAN format frame with its BRS flag set has been transferred (reception or transmission) without error.
  - Access type is rs: set on read.

- **Bit 7** BO: Bus-off status
  - 0: The FDCAN is not in bus-off state.
  - 1: The FDCAN is in bus-off state.
Bit 6  **EW**: Warning status  
0: Both error counters are below the error-warning limit of 96.  
1: At least one of error counter has reached the error-warning limit of 96.

Bit 5  **EP**: Error passive  
0: The FDCAN is in the error-active state. It normally takes part in bus communication and sends an active error flag when an error has been detected.  
1: The FDCAN is in the error-passive state.

Bits 4:3  **ACT[1:0]**: Activity  
Monitors the module’s CAN communication state.  
00: Synchronizing: node is synchronizing on CAN communication.  
01: Idle: node is neither receiver nor transmitter.  
10: Receiver: node is operating as receiver.  
11: Transmitter: node is operating as transmitter.

Bits 2:0  **LEC[2:0]**: Last error code  
LEC[2:0] indicates the type of the last error to occur on the CAN bus. This bitfield is cleared when a message has been transferred (reception or transmission) without error.  
000: No error occurred since LEC[2:0] has been cleared by successful reception or transmission.  
001: Stuff error. More than five equal bits in a sequence have occurred in a part of a received message where this is not allowed.  
010: Form error. A fixed format part of a received frame has the wrong format.  
011: Ack error. The message transmitted by the FDCAN was not acknowledged by another node.  
100: Bit1 error. During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.  
101: Bit0 error. During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During bus-off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the bus-off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).  
110: CRC error. The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.  
111: No change. Any read access to the protocol status register reinitializes LEC[2:0] to 7. When the LEC[2:0] shows the value 7, no CAN bus event was detected since the last CPU read access to the protocol status register.  
Access type is rs: set on read.

Note: When a frame in FDCAN format has reached the data phase with the BRS flag set, the next CAN event (error or valid frame) is shown in DLEC[2:0] instead of LEC[2:0]. An error in a fixed stuff bit of an FDCAN CRC sequence is shown as a form error, not as a stuff error.

The bus-off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or clearing the INIT bit of the FDCAN_CCCR register. If the device enters bus-off, it sets the INIT bit of its own, stopping all bus activities. Once INIT has been cleared by the CPU, the device waits for 129 occurrences of bus-idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error management counters are reset. During the waiting time after clearing INIT, each time a sequence of 11 recessive bits has been monitored, a bit0 error code is written to LEC[2:0] of FDCAN_PSR, enabling the CPU to check up whether the CAN bus is...
stuck at dominant or continuously disturbed, and to monitor the bus-off recovery sequence. The REC[6:0] bitfield of the FDCAN_ECR register is used to count these sequences.

44.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR)

Address offset: 0x0048
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</table>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 TDCO[6:0]: Transmitter delay compensation offset
Offset value defining the distance between the measured delay from FDCAN_TX to FDCAN_RX and the secondary sample point. Valid values are 0 to 127 × mtq.
This bitfield is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 TDCF[6:0]: Transmitter delay compensation filter window length
Defines the minimum value for the SSP position, dominant edges on FDCAN_RX that would result in an earlier SSP position are ignored for transmitter delay measurements.
This bitfield is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

44.4.15 FDCAN interrupt register (FDCAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the host clears them. A flag is cleared by writing 1 to the corresponding bit position.

Writing 0 has no effect. A hard reset clears the register. The configuration of FDCAN_IE controls whether an interrupt is generated. The configuration of FDCAN_ILS controls on which interrupt line an interrupt is signaled.

Address offset: 0x0050
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.
Bit 23  **ARA**: Access to reserved address
0: No access to reserved address occurred
1: Access to reserved address occurred

Bit 22  **PED**: Protocol error in data phase (data bit time is used)
0: No protocol error in data phase
1: Protocol error in data phase detected (DLEC[2:0] different from 0 and 7 in FDCAN_PSR)

Bit 21  **PEA**: Protocol error in arbitration phase (nominal bit time is used)
0: No protocol error in arbitration phase
1: Protocol error in arbitration phase detected (LEC[2:0] different from 0 and 7 in FDCAN_PSR)

Bit 20  **WDI**: Watchdog interrupt
0: No message RAM watchdog event occurred
1: Message RAM watchdog event due to missing READY

Bit 19  **BO**: Bus-off status
0: Bus-off status unchanged
1: Bus-off status changed

Bit 18  **EW**: Warning status
0: Error-warning status unchanged
1: Error-warning status changed

Bit 17  **EP**: Error passive
0: Error-passive status unchanged
1: Error-passive status changed

Bit 16  **ELO**: Error logging overflow
0: CAN error logging counter did not overflow.
1: Overflow of CAN error logging counter occurred.

Bit 15  **TOO**: Timeout occurred
0: No timeout
1: Timeout reached

Bit 14  **MRAF**: Message RAM access failure
The flag is set when the Rx handler:
- has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx handler starts processing of the following message.
- was unable to write a message to the message RAM. In this case message storage is aborted.

In both cases the FIFO put index is not updated. The partly stored message is overwritten when the next message is stored to this location.

The flag is also set when the Tx handler was not able to read a message from the message RAM in time. In this case message transmission is aborted. In case of a Tx handler access failure, the FDCAN is switched into restricted operation mode (see *Restricted operation mode*). To leave restricted operation mode, the host CPU has to clear the ASM of the FDCAN_CCCR register.

0: No message RAM access failure occurred
1: Message RAM access failure occurred
Bit 13 **TSW**: Timestamp wraparound  
0: No timestamp counter wrap-around  
1: Timestamp counter wrapped around

Bit 12 **TEFL**: Tx event FIFO element lost  
0: No Tx event FIFO element lost  
1: Tx event FIFO element lost

Bit 11 **TEFF**: Tx event FIFO full  
0: Tx event FIFO Not full  
1: Tx event FIFO full

Bit 10 **TEFN**: Tx event FIFO new entry  
0: Tx event FIFO unchanged  
1: Tx handler wrote Tx event FIFO element.

Bit 9 **TFE**: Tx FIFO empty  
0: Tx FIFO non-empty  
1: Tx FIFO empty

Bit 8 **TCF**: Transmission cancellation finished  
0: No transmission cancellation finished  
1: Transmission cancellation finished

Bit 7 **TC**: Transmission completed  
0: No transmission completed  
1: Transmission completed

Bit 6 **HPM**: High-priority message  
0: No high-priority message received  
1: High-priority message received

Bit 5 **RF1L**: Rx FIFO 1 message lost  
0: No Rx FIFO 1 message lost  
1: Rx FIFO 1 message lost

Bit 4 **RF1F**: Rx FIFO 1 full  
0: Rx FIFO 1 not full  
1: Rx FIFO 1 full

Bit 3 **RF1N**: Rx FIFO 1 new message  
0: No new message written to Rx FIFO 1  
1: New message written to Rx FIFO 1

Bit 2 **RF0L**: Rx FIFO 0 message lost  
0: No Rx FIFO 0 message lost  
1: Rx FIFO 0 message lost

Bit 1 **RF0F**: Rx FIFO 0 full  
0: Rx FIFO 0 not full  
1: Rx FIFO 0 full

Bit 0 **RF0N**: Rx FIFO 0 new message  
0: No new message written to Rx FIFO 0  
1: New message written to Rx FIFO 0
### 44.4.16 FDCAN interrupt enable register (FDCAN_IE)

The settings in the interrupt enable register determine which status changes in the interrupt register are signaled on an interrupt line.

**Address offset:** 0x0054

### 44.4.17 FDCAN interrupt line select register (FDCAN_ILS)

This register assigns an interrupt generated by a specific group of interrupt flags from the interrupt register to one of the two module interrupt lines. For interrupt generation, the respective interrupt line has to be enabled via the EINT0 and EINT1 bit of the FDCAN_ILE register.

Address offset: 0x0058

**Bits 31:28 Reserved, must be kept at reset value.**
Bits 27:24 **LSE[3:0]**: Number of extended filter elements in the list
- 0: No extended message ID filter
- 1 to 8: Number of extended message ID filter elements
- > 8: Values greater than 8 are interpreted as 8.

This bitfield is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 23:21 **Reserved**, must be kept at reset value.

Bits 20:16 **LSS[4:0]**: Number of standard filter elements in the list
- 0: No standard message ID filter
- 1 to 28: Number of standard message ID filter elements
- > 28: Values greater than 28 are interpreted as 28.

This bitfield is write-protected (P), which means that write access by the bits is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 15:10 **Reserved**, must be kept at reset value.

Bit 9 **F0OM**: FIFO 0 operation mode (overwrite or blocking)
- This bit is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bit 8 **F1OM**: FIFO 1 operation mode (overwrite or blocking)
- This bit is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 7:6 **Reserved**, must be kept at reset value.

Bits 5:4 **ANFS[1:0]**: Accept Non-matching frames standard
- Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated.
  - 00: Accept in Rx FIFO 0
  - 01: Accept in Rx FIFO 1
  - 10: Reject
  - 11: Reject

This bitfield is write-protected (P), which means write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 3:2 **ANFE[1:0]**: Accept non-matching frames extended
- Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated.
  - 00: Accept in Rx FIFO 0
  - 01: Accept in Rx FIFO 1
  - 10: Reject
  - 11: Reject

This bitfield is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bit 1 **RRFS**: Reject remote frames standard
- 0: Filter remote frames with 11-bit standard IDs
- 1: Reject all remote frames with 11-bit standard IDs

This bit is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.
Bit 0 **RRFE**: Reject remote frames extended  
0: Filter remote frames with 29-bit standard IDs  
1: Reject all remote frames with 29-bit standard IDs  
This bit is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

**EIDM[28:0]**  
For acceptance filtering of extended frames the extended ID AND mask is AND-ed with the message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set, the mask is not active.  
This bitfield is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:0 **EIDM[28:0]**: Extended ID mask

### 44.4.21 FDCAN high-priority message status register (FDCAN_HPMS)

This register is updated every time a message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Address offset: 0x0088  
Reset value: 0x0000 0000

**FLST**  
Indicates the filter list of the matching filter element:  
0: Standard filter list  
1: Extended filter list  
Bits 14:13 Reserved, must be kept at reset value.
Bits 12:8 **FIDX[4:0]**: Filter index
- Index of matching filter element.
- Range: 0 to LSS[4:0] - 1 or LSE[3:0] - 1 in FDCAN_RXGFC.

Bits 7:6 **MSI[1:0]**: Message storage indicator
- 00: No FIFO selected
- 01: FIFO overrun
- 10: Message stored in FIFO 0
- 11: Message stored in FIFO 1

Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **BIDX[2:0]**: Buffer index
- Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = 1.

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 F0AI[2:0]: Rx FIFO 0 acknowledge index

After the host has read a message or a sequence of messages from Rx FIFO 0, it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI[2:0]. This sets the Rx FIFO 0 get index (F0GI[1:0] of FDCAN_RXF0S) to F0AI[2:0] + 1 and updates the FIFO 0 fill level (F0FL[3:0] FDCAN_RXF0S).

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 RF1L: Rx FIFO 1 message lost
This bit is a copy of the RF1L interrupt flag of the FDCAN_IR register. When RF1L is cleared, this bit is also cleared.
0: No Rx FIFO 1 message lost
1: Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size 0

Bit 24 F1F: Rx FIFO 1 full
0: Rx FIFO 1 not full
1: Rx FIFO 1 full

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 F1PI[1:0]: Rx FIFO 1 put index
Rx FIFO 1 write index pointer.
Range: 0 to 2.

Bits 15:10 Reserved, must be kept at reset value.
44.4.25 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A)

Address offset: 0x009C
Reset value: 0x0000 0000

Bits 9:8 **F1GI[1:0]**: Rx FIFO 1 get index
Rx FIFO 1 read index pointer.
Range: 0 to 2.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **F1FL[3:0]**: Rx FIFO 1 fill level
Number of elements stored in Rx FIFO 1.
Range: 0 to 3.

After the host has read a message or a sequence of messages from Rx FIFO 1, it has to write the buffer index of the last element read from Rx FIFO 1 to **F1AI[2:0]**. This sets the Rx FIFO 1 get index (**F1GI[1:0]**) of FDCAN_RXF1S to **F1AI[2:0]** + 1 and updates the FIFO 1 fill level (**F1FL[3:0]** FDCAN_RXF1S).

**44.4.26 FDCAN Tx buffer configuration register (FDCAN_TXBC)**

Address offset: 0x00C0
Reset value: 0x0000 0000

Bit 24 **TFQM**: Tx FIFO/queue mode
0: Tx FIFO operation
1: Tx queue operation.
This bit is write-protected (P), which means that write access is possible only when the CCE and INIT bits of the FDCAN_CCCR register are both set.

Bits 23:0 Reserved, must be kept at reset value.
### 44.4.27 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS)

The Tx FIFO/queue status is related to the pending Tx requests listed in the FDCAN_TXBRP register. Therefore, the effect of add/cancellation requests can be delayed due to a running Tx scan (FDCAN_TXBRP not yet updated).

Address offset: 0x00C4
Reset value: 0x0000 0003

| Bit 31:22 Reserved, must be kept at reset value. |
| Bit 21 **TFQF**: Tx FIFO/queue full |
| 0: Tx FIFO/queue not full |
| 1: Tx FIFO/queue full |

Bits 20:18 Reserved, must be kept at reset value.

| Bits 17:16 **TFQPI[1:0]**: Tx FIFO/queue put index |
| Tx FIFO/queue write index pointer, range 0 to 3 |

Bits 15:10 Reserved, must be kept at reset value.

| Bits 9:8 **TFGI[1:0]**: Tx FIFO get index |
| Tx FIFO read index pointer, range 0 to 3. Read as 0 when Tx queue operation is configured (TFQM = 1 in FDCAN_TXBC) |

Bits 7:3 Reserved, must be kept at reset value.

| Bits 2:0 **TFFL[2:0]**: Tx FIFO free level |
| Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 3. Read as 0 when Tx queue operation is configured (TFQM = 1 in FDCAN_TXBC). |

### 44.4.28 FDCAN Tx buffer request pending register (FDCAN_TXBRP)

Address offset: 0x00C8
Reset value: 0x0000 0000

| Bit 31:3 Reserved, must be kept at reset value. |
| Bit 21 **TRP[2:0]**: |

Bits 20:16 Reserved, must be kept at reset value.
Bits 2:0 **TRP[2:0]**: Transmission request pending

Each Tx buffer has its own transmission request pending bit. The bits are set via the FDCAN_TXBAR register. The bits are cleared after a requested transmission has completed or has been canceled via the FDCAN_TXBCR register.

After the FDCAN_TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx buffer with lowest message ID).

A cancellation request resets the corresponding transmission request pending bit of the FDCAN_TXBRP register. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are directly cleared after the corresponding FDCAN_TXBRP bit has been cleared.

After a cancellation has been requested, a finished cancellation is signaled via the FDCAN_TXBCF in the following cases:

- after successful transmission together with the corresponding TXBTO bit
- when the transmission has not yet been started at the point of cancellation
- when the transmission has been aborted due to lost arbitration
- when an error occurred during frame transmission

In DAR mode, all transmissions are automatically canceled if they are not successful. The corresponding FDCAN_TXBCF bit is set for all unsuccessful transmissions.

0: No transmission request pending
1: Transmission request pending

**Note:** FDCAN_TXBRP bits set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx buffer, this add request is canceled immediately. The corresponding FDCAN_TXBRP bit is cleared.

### 44.4.29 FDCAN Tx buffer add request register (FDCAN_TXBAR)

Address offset: 0x00CC

Reset value: 0x0000 0000

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **AR[2:0]**: Add request

Each Tx buffer has its own add request bit. Writing a 1 sets the corresponding add request bit; writing a 0 has no impact. This enables the host to set transmission requests for multiple Tx buffers with one write to FDCAN_TXBAR. When no Tx scan is running, the bits are cleared immediately, else the bits remain set until the Tx scan process has completed.

0: No transmission request added
1: Transmission requested added.

**Note:** If an add request is applied for a Tx buffer with pending transmission request (corresponding FDCAN_TXBRP bit already set), the request is ignored.
44.4.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR)

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 TO[2:0]: Transmission occurred.

Each Tx buffer has its own TO bit. The bits are set when the corresponding FDCAN_TXBRP bit is cleared after a successful transmission. The bits are cleared when a new transmission is requested by writing a 1 to the corresponding bit of register FDCAN_TXBAR.

0: No transmission occurred
1: Transmission occurred
44.4.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF)

Address offset: 0x00D8
Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **CF[2:0]**: Cancellation finished

Each Tx buffer has its own CF bit. The bits are set when the corresponding FDCAN_TXBRP bit is cleared after a cancellation was requested via FDCAN_TXBCR. In case the corresponding FDCAN_TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are cleared when a new transmission is requested by writing a 1 to the corresponding bit of the FDCAN_TXBAR register.

0: No transmit buffer cancellation
1: Transmit buffer cancellation finished

44.4.33 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE)

45 Universal serial bus full-speed device interface (USB)

45.1 Introduction
The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB1 bus.

USB suspend/resume are supported, which allows to stop the device clocks for low-power consumption.

45.2 USB main features

- USB specification version 2.0 full-speed compliant
- Configurable number of endpoints from 1 to 8
- Dedicated packet buffer memory (SRAM) of 1024 bytes
- Cyclic redundancy check (CRC) generation/checking, Non-return-to-zero Inverted (NRZI) encoding/decoding and bit-stuffing
- Isochronous transfers support
- Double-buffered bulk/isochronous endpoint support
- USB Suspend/Resume operations
- Frame locked clock pulse generation
- USB 2.0 Link Power Management support
- Battery Charging Specification Revision 1.2 support
- USB connect / disconnect capability (controllable embedded pull-up resistor on USB_DP line)

45.3 USB implementation

Table 416 describes the USB implementation in the devices.

45.4 USB functional description

Figure 672 shows the block diagram of the USB peripheral.

The USB peripheral provides an USB-compliant connection between the host PC and the
function implemented by the microcontroller. Data transfer between the host PC and the
system memory occurs through a dedicated packet buffer memory accessed directly by the
USB peripheral. This dedicated memory size is 1024 bytes, and up to 16 mono-directional
or 8 bidirectional endpoints can be used. The USB peripheral interfaces with the USB host,
detecting token packets, handling data transmission/reception, and processing handshake
packets as required by the USB standard. Transaction formatting is performed by the
hardware, including CRC generation and checking.

Each endpoint is associated with a buffer description block indicating where the
endpoint-related memory area is located, how large it is or how many bytes must be
transmitted. When a token for a valid function/endpoint pair is recognized by the USB
peripheral, the related data transfer (if required and if the endpoint is configured) takes
place. The data buffered by the USB peripheral is loaded in an internal 16-bit register and memory access to the dedicated buffer is performed. When all the data has been transferred, if needed, the proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint-specific interrupt is generated, reading status registers and/or using different interrupt response routines. The microcontroller can determine:

- which endpoint has to be served,
- which type of transaction took place, if errors occurred (bit stuffing, format, CRC, protocol, missing ACK, over/underrun, etc.).

Special support is offered to isochronous transfers and high throughput bulk transfers, implementing a double buffer usage, which allows to always have an available buffer for the USB peripheral while the microcontroller uses the other one.

The unit can be placed in low-power mode (SUSPEND mode), by writing in the control register, whenever required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wake-up line to allow the system to immediately restart the normal clock generation and/or support direct clock start/stop.

### 45.4.1 Description of USB blocks

The USB peripheral implements all the features related to USB interfacing, which include the following blocks:

- **USB Physical Interface (USB PHY):** This block is maintaining the electrical interface to an external USB host. It contains the differential analog transceiver itself, controllable embedded pull-up resistor (connected to USB_DP line) and support for Battery Charging Detection (BCD), multiplexed on same USB_DP and USB_DM lines. The output enable control signal of the analog transceiver (active low) is provided externally on USB_NOE. It can be used to drive some activity LED or to provide information about the actual communication direction to some other circuitry.

- **Serial Interface Engine (SIE):** The functions of this block include: synchronization pattern recognition, bit-stuffing, CRC generation and checking, PID verification/generation, and handshake evaluation. It must interface with the USB transceivers and uses the virtual buffers provided by the packet buffer interface for local data storage. This unit also generates signals according to USB peripheral events, such as Start of Frame (SOF), USB_Reset, Data errors etc. and to Endpoint related events like end of transmission or correct reception of a packet; these signals are then used to generate interrupts.

- **Timer:** This block generates a start-of-frame locked clock pulse and detects a global suspend (from the host) when no traffic has been received for 3 ms.

- **Packet Buffer Interface:** This block manages the local memory implementing a set of buffers in a flexible way, both for transmission and reception. It can choose the proper buffer according to requests coming from the SIE and locate them in the memory addresses pointed by the Endpoint registers. It increments the address after each exchanged byte until the end of packet, keeping track of the number of exchanged bytes and preventing the buffer to overrun the maximum capacity.
• Endpoint-Related Registers: Each endpoint has an associated register containing the endpoint type and its current status. For mono-directional/single-buffer endpoints, a single register can be used to implement two distinct endpoints. The number of registers is 8, allowing up to 16 mono-directional/single-buffer or up to 7 double-buffer endpoints in any combination. For example the USB peripheral can be programmed to have 4 double buffer endpoints and 8 single-buffer/mono-directional endpoints.

• Control Registers: These are the registers containing information about the status of the whole USB peripheral and used to force some USB events, such as resume and power-down.

• Interrupt Registers: These contain the Interrupt masks and a record of the events. They can be used to inquire an interrupt reason, the interrupt status or to clear the status of a pending interrupt.

*Endpoint 0 is always used for control transfer in single-buffer mode.*

Note: The USB peripheral is connected to the APB1 bus through an APB1 interface, containing the following blocks:

• Packet Memory: This is the local memory that physically contains the Packet Buffers. It can be used by the Packet Buffer interface, which creates the data structure and can be accessed directly by the application software. The size of the Packet Memory is 1024 bytes, structured as 512 half-words of 16 bits.

• Arbiter: This block accepts memory requests coming from the APB1 bus and from the USB interface. It resolves the conflicts by giving priority to APB1 accesses, while always reserving half of the memory bandwidth to complete all USB transfers. This time-duplex scheme implements a virtual dual-port SRAM that allows memory access, while an USB transaction is happening. Multiword APB1 transfers of any length are also allowed by this scheme.

• Register Mapper: This block collects the various byte-wide and bit-wide registers of the USB peripheral in a structured 16-bit wide half-word set addressed by the APB1.

• APB1 Wrapper: This provides an interface to the APB1 for the memory and register. It also maps the whole USB peripheral in the APB1 address space.

• Interrupt Mapper: This block is used to select how the possible USB events can generate interrupts and map them to the NVIC.

45.5 Programming considerations

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to ease application software development.

45.5.1 Generic USB device programming

This part describes the main tasks required of the application software in order to obtain USB compliant behavior. The actions related to the most general USB events are taken into account and paragraphs are dedicated to the special cases of double-buffered endpoints and Isochronous transfers. Apart from system reset, action is always initiated by the USB peripheral, driven by one of the USB events described below.
45.5.2 System and power-on reset

Upon system and power-on reset, the first operation the application software should perform is to provide all required clock signals to the USB peripheral and subsequently de-assert its reset signal so to be able to access its registers. The whole initialization sequence is hereafter described.

As a first step application software needs to activate register macrocell clock and de-assert macrocell specific reset signal using related control bits provided by device clock management logic.

After that, the analog part of the device related to the USB transceiver must be switched on using the PDWN bit in CNTR register, which requires a special handling. This bit is intended to switch on the internal voltage references that supply the port transceiver. This circuit has a defined startup time (tSTARTUP specified in the datasheet) during which the behavior of the USB transceiver is not defined. It is thus necessary to wait this time, after setting the PDWN bit in the CNTR register, before removing the reset condition on the USB part (by clearing the FRES bit in the CNTR register). Clearing the ISTR register then removes any spurious pending interrupt before any other macrocell operation is enabled.

At system reset, the microcontroller must initialize all required registers and the packet buffer description table, to make the USB peripheral able to properly generate interrupts and data transfers. All registers not specific to any endpoint must be initialized according to the needs of application software (choice of enabled interrupts, chosen address of packet buffers, etc.). Then the process continues as for the USB reset case (see further paragraph).

USB reset (RESET interrupt)

When this event occurs, the USB peripheral is put in the same conditions it is left by the system reset after the initialization described in the previous paragraph: communication is disabled in all endpoint registers (the USB peripheral will not respond to any packet). As a response to the USB reset event, the USB function must be enabled, having as USB address 0, implementing only the default control endpoint (endpoint address is 0 too). This is accomplished by setting the Enable Function (EF) bit of the USB_DADDR register and initializing the EP0R register and its related packet buffers accordingly. During USB enumeration process, the host assigns a unique address to this device, which must be written in the ADD[6:0] bits of the USB_DADDR register, and configures any other necessary endpoint.

When a RESET interrupt is received, the application software is responsible to enable again the default endpoint of USB function 0 within 10 ms from the end of reset sequence which triggered the interrupt.

Structure and usage of packet buffers

Each bidirectional endpoint may receive or transmit data from/to the host. The received data is stored in a dedicated memory buffer reserved for that endpoint, while another memory buffer contains the data to be transmitted by the endpoint. Access to this memory is performed by the packet buffer interface block, which delivers a memory access request and waits for its acknowledgment. Since the packet buffer memory has to be accessed by the microcontroller also, an arbitration logic takes care of the access conflicts, using half APB1 cycle for microcontroller access and the remaining half for the USB peripheral access. In this way, both the agents can operate as if the packet memory is a dual-port SRAM, without being aware of any conflict even when the microcontroller is performing
back-to-back accesses. The USB peripheral logic uses a dedicated clock. The frequency of this dedicated clock is fixed by the requirements of the USB standard at 48 MHz, and this can be different from the clock used for the interface to the APB1 bus. Different clock configurations are possible where the APB1 clock frequency can be higher or lower than the USB peripheral one.

**Note:** For USB throughput and system performance reasons during USB active bus connection it is recommended to run APB1 clock no lower than 48 MHz.

Each endpoint is associated with two packet buffers (usually one for transmission and the other one for reception). Buffers can be placed anywhere inside the packet memory because their location and size is specified in a buffer description table, which is also located in the packet memory at the address indicated by the USB_BTABLE register. Each table entry is associated to an endpoint register and it is composed of four 16-bit half-words so that table start address must always be aligned to an 8-byte boundary (the lowest three bits of USB_BTABLE register are always “000”). Buffer descriptor table entries are described in the Section 45.6.2: Buffer descriptor table. If an endpoint is unidirectional and it is neither an Isochronous nor a double-buffered bulk, only one packet buffer is required (the one related to the supported transfer direction). Other table locations related to unsupported transfer directions or unused endpoints, are available to the user. Isochronous and double-buffered bulk endpoints have special handling of packet buffers (Refer to Section 45.5.4: Isochronous transfers and Section 45.5.3: Double-buffered endpoints respectively). The relationship between buffer description table entries and packet buffer areas is depicted in Figure 673.

**Figure 673. Packet buffer areas with examples of buffer description table locations**
Each packet buffer is used either during reception or transmission starting from the bottom. The USB peripheral will never change the contents of memory locations adjacent to the allocated memory buffers; if a packet bigger than the allocated buffer length is received (buffer overrun condition) the data are copied to the memory only up to the last available location.

**Endpoint initialization**

The first step to initialize an endpoint is to write appropriate values to the ADDRn_TX/ADDRn_RX registers so that the USB peripheral finds the data to be transmitted already available and the data to be received can be buffered. The EP_TYPE bits in the USB_EPnR register must be set according to the endpoint type, eventually using the EP_KIND bit to enable any special required feature. On the transmit side, the endpoint must be enabled using the STAT_TX bits in the USB_EPnR register and COUNTn_TX must be initialized. For reception, STAT_RX bits must be set to enable reception and COUNTn_RX must be written with the allocated buffer size using the BL_SIZE and NUM_BLOCK fields. Unidirectional endpoints, except Isochronous and double-buffered bulk endpoints, need to initialize only bits and registers related to the supported direction. Once the transmission and/or reception are enabled, register USB_EPnR and locations ADDRn_TX/ADDRn_RX, COUNTn_TX/COUNTn_RX (respectively), should not be modified by the application software, as the hardware can change their value on the fly. When the data transfer operation is completed, notified by a CTR interrupt event, they can be accessed again to re-enable a new operation.

**IN packets (data transmission)**

When receiving an IN token packet, if the received address matches a configured and valid endpoint, the USB peripheral accesses the contents of ADDRn_TX and COUNTn_TX locations inside the buffer descriptor table entry related to the addressed endpoint. The content of these locations is stored in its internal 16 bit registers ADDR and COUNT (not accessible by software). The packet memory is accessed again to read the first byte to be transmitted (Refer to *Structure and usage of packet buffers on page 2019*) and starts sending a DATA0 or DATA1 PID according to USB_EPnR bit DTOG_TX. When the PID is completed, the first byte, read from buffer memory, is loaded into the output shift register to be transmitted on the USB bus. After the last data byte is transmitted, the computed CRC is sent. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the data packet, according to STAT_TX bits in the USB_EPnR register.

The ADDR internal register is used as a pointer to the current buffer memory location while COUNT is used to count the number of remaining bytes to be transmitted. Each half-word read from the packet buffer memory is transmitted over the USB bus starting from the least significant byte. Transmission buffer memory is read starting from the address pointed by ADDRn_TX for COUNTn_TX/2 half-words. If a transmitted packet is composed of an odd number of bytes, only the lower half of the last half-word accessed is used.

On receiving the ACK receipt by the host, the USB_EPnR register is updated in the following way: DTOG_TX bit is toggled, the endpoint is made invalid by setting STAT_TX=10 (NAK) and bit CTR_TX is set. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP_ID and DIR bits in the USB_ISTR register. Servicing of the CTR_TX event starts clearing the interrupt bit; the application software then prepares another buffer full of data to be sent, updates the COUNTn_TX table location with the number of byte to be transmitted during the next transfer, and finally sets STAT_TX to ‘11 (VALID) to re-enable transmissions. While the STAT_TX bits are equal to ‘10 (NAK), any IN request addressed to that endpoint is NAKed.
indicating a flow control condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second IN transaction addressed to the same endpoint immediately following the one which triggered the CTR interrupt.

**OUT and SETUP packets (data reception)**

These two tokens are handled by the USB peripheral more or less in the same way; the differences in the handling of SETUP packets are detailed in the following paragraph about control transfers. When receiving an OUT/SETUP PID, if the address matches a valid endpoint, the USB peripheral accesses the contents of the ADDRn_RX and COUNTn_RX locations inside the buffer descriptor table entry related to the addressed endpoint. The content of the ADDRn_RX is stored directly in its internal register ADDR. While COUNT is now reset and the values of BL_SIZE and NUM_BLOCK bit fields, which are read within COUNTn_RX content are used to initialize BUF_COUNT, an internal 16 bit counter, which is used to check the buffer overrun condition (all these internal registers are not accessible by software). Data bytes subsequently received by the USB peripheral are packed in half-words (the first byte received is stored as least significant byte) and then transferred to the packet buffer starting from the address contained in the internal ADDR register while BUF_COUNT is decremented and COUNT is incremented at each byte transfer. When the end of DATA packet is detected, the correctness of the received CRC is tested and only if no errors occurred during the reception, an ACK handshake packet is sent back to the transmitting host.

In case of wrong CRC or other kinds of errors (bit-stuff violations, frame errors, etc.), data bytes are still copied in the packet memory buffer, at least until the error detection point, but ACK packet is not sent and the ERR bit in USB_ISTR register is set. However, there is usually no software action required in this case: the USB peripheral recovers from reception errors and remains ready for the next transaction to come. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the ACK, according to bits STAT_RX in the USB_EPhR register and no data is written in the reception memory buffers.

Reception memory buffer locations are written starting from the address contained in the ADDRn_RX for a number of bytes corresponding to the received data packet length, CRC included (i.e. data payload length + 2), or up to the last allocated memory location, as defined by BL_SIZE and NUM_BLOCK, whichever comes first. In this way, the USB peripheral never writes beyond the end of the allocated reception memory buffer area. If the length of the data packet payload (actual number of bytes used by the application) is greater than the allocated buffer, the USB peripheral detects a buffer overrun condition. In this case, a STALL handshake is sent instead of the usual ACK to notify the problem to the host, no interrupt is generated and the transaction is considered failed.

When the transaction is completed correctly, by sending the ACK handshake packet, the internal COUNT register is copied back in the COUNTn_RX location inside the buffer description table entry, leaving unaffected BL_SIZE and NUM_BLOCK fields, which normally do not require to be re-written, and the USB_EPhR register is updated in the following way: DTOG_RX bit is toggled, the endpoint is made invalid by setting STAT_RX = ‘10 (NAK) and bit CTR_RX is set. If the transaction has failed due to errors or buffer overrun condition, none of the previously listed actions take place. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP_ID and DIR bits in the USB_ISTR register. The CTR_RX event is serviced by first determining the transaction type (SETUP bit in the USB_EPhR register); the application software must clear the interrupt flag bit and get the number of received bytes reading the COUNTn_RX location inside the buffer description table entry related to the endpoint being
processed. After the received data is processed, the application software should set the STAT_RX bits to ‘11 (Valid) in the USB_EPnR, enabling further transactions. While the STAT_RX bits are equal to ‘10 (NAK), any OUT request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second OUT transaction addressed to the same endpoint following immediately the one which triggered the CTR interrupt.

Control transfers

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only and are very similar to OUT ones (data reception) except that the values of DTOG_TX and DTOG_RX bits of the addressed endpoint registers are set to 1 and 0 respectively, to initialize the control transfer, and both STAT_TX and STAT_RX are set to ‘10 (NAK) to let software decide if subsequent transactions must be IN or OUT depending on the SETUP contents. A control endpoint must check SETUP bit in the USB_EPnR register at each CTR_RX event to distinguish normal OUT transactions from SETUP ones. A USB device can determine the number and direction of data stages by interpreting the data transferred in the SETUP stage, and is required to STALL the transaction in the case of errors. To do so, at all data stages before the last, the unused direction should be set to STALL, so that, if the host reverses the transfer direction too soon, it gets a STALL as a status stage.

While enabling the last data stage, the opposite direction should be set to NAK, so that, if the host reverses the transfer direction (to perform the status stage) immediately, it is kept waiting for the completion of the control operation. If the control operation completes successfully, the software will change NAK to VALID, otherwise to STALL. At the same time, if the status stage is an OUT, the STATUS_OUT (EP_KIND in the USB_EPnR register) bit should be set, so that an error is generated if a status transaction is performed with not-zero data. When the status transaction is serviced, the application clears the STATUS_OUT bit and sets STAT_RX to VALID (to accept a new command) and STAT_TX to NAK (to delay a possible status stage immediately following the next setup).

Since the USB specification states that a SETUP packet cannot be answered with a handshake different from ACK, eventually aborting a previously issued command to start the new one, the USB logic doesn’t allow a control endpoint to answer with a NAK or STALL packet to a SETUP token received from the host.

When the STAT_RX bits are set to ‘01 (STALL) or ‘10 (NAK) and a SETUP token is received, the USB accepts the data, performing the required data transfers and sends back an ACK handshake. If that endpoint has a previously issued CTR_RX request not yet acknowledged by the application (i.e. CTR_RX bit is still set from a previously completed reception), the USB discards the SETUP transaction and does not answer with any handshake packet regardless of its state, simulating a reception error and forcing the host to send the SETUP token again. This is done to avoid losing the notification of a SETUP transaction addressed to the same endpoint immediately following the transaction, which triggered the CTR_RX interrupt.
45.5.3 Double-buffered endpoints

All different endpoint types defined by the USB standard represent different traffic models, and describe the typical requirements of different kind of data transfer operations. When large portions of data are to be transferred between the host PC and the USB function, the bulk endpoint type is the most suited model. This is because the host schedules bulk transactions so as to fill all the available bandwidth in the frame, maximizing the actual transfer rate as long as the USB function is ready to handle a bulk transaction addressed to it. If the USB function is still busy with the previous transaction when the next one arrives, it will answer with a NAK handshake and the host PC will issue the same transaction again until the USB function is ready to handle it, reducing the actual transfer rate due to the bandwidth occupied by re-transmissions. For this reason, a dedicated feature called ‘double-buffering’ can be used with bulk endpoints.

When ‘double-buffering’ is activated, data toggle sequencing is used to select, which buffer is to be used by the USB peripheral to perform the required data transfers, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to always have a complete buffer to be used by the application, while the USB peripheral fills the other one. For example, during an OUT transaction directed to a ‘reception’ double-buffered bulk endpoint, while one buffer is being filled with new data coming from the USB host, the other one is available for the microcontroller software usage (the same would happen with a ‘transmission’ double-buffered bulk endpoint and an IN transaction).

Since the swapped buffer management requires the usage of all 4 buffer description table locations hosting the address pointer and the length of the allocated memory buffers, the USB_EPnR registers used to implement double-buffered bulk endpoints are forced to be used as unidirectional ones. Therefore, only one STAT bit pair must be set at a value different from '00 (Disabled): STAT_RX if the double-buffered bulk endpoint is enabled for reception, STAT_TX if the double-buffered bulk endpoint is enabled for transmission. In case it is required to have double-buffered bulk endpoints enabled both for reception and transmission, two USB_EPnR registers must be used.

To exploit the double-buffering feature and reach the highest possible transfer rate, the endpoint flow control structure, described in previous chapters, has to be modified, in order to switch the endpoint status to NAK only when a buffer conflict occurs between the USB peripheral and application software, instead of doing it at the end of each successful transaction. The memory buffer which is currently being used by the USB peripheral is defined by the DTOG bit related to the endpoint direction: DTOG_RX (bit 14 of USB_EPnR register) for ‘reception’ double-buffered bulk endpoints or DTOG_TX (bit 6 of USB_EPnR register) for ‘transmission’ double-buffered bulk endpoints. To implement the new flow control scheme, the USB peripheral should know which packet buffer is currently in use by the application software, so to be aware of any conflict. Since in the USB_EPnR register, there are two DTOG bits but only one is used by USB peripheral for data and buffer sequencing (due to the unidirectional constraint required by double-buffering feature) the other one can be used by the application software to show which buffer it is currently using. This new buffer flag is called SW_BUF. In the following table the correspondence between USB_EPnR register bits and DTOG/SW_BUF definition is explained, for the cases of ‘transmission’ and ‘reception’ double-buffered bulk endpoints.
The memory buffer which is currently being used by the USB peripheral is defined by DTOG buffer flag, while the buffer currently in use by application software is identified by SW_BUF buffer flag. The relationship between the buffer flag value and the used packet buffer is the same in both cases, and it is listed in the following table.

<table>
<thead>
<tr>
<th>Buffer flag</th>
<th>‘Transmission’ endpoint</th>
<th>‘Reception’ endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>DTOG</td>
<td>DTOG_TX (USB_EPnR bit 6)</td>
<td>DTOG_RX (USB_EPnR bit 14)</td>
</tr>
<tr>
<td>SW_BUF</td>
<td>USB_EPnR bit 14</td>
<td>USB_EPnR bit 6</td>
</tr>
</tbody>
</table>

Double-buffering feature for a bulk endpoint is activated by:

- Writing EP_TYPE bit field at ‘00 in its USB_EPnR register, to define the endpoint as a bulk, and
- Setting EP_KIND bit at ‘1 (DBL_BUF), in the same register.

The application software is responsible for DTOG and SW_BUF bits initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. The end of the first transaction occurring after having set DBL_BUF, triggers the special flow control of double-buffered bulk endpoints, which is used for all other transactions addressed to this endpoint until DBL_BUF remain set. At the end of each transaction the CTR_RX or CTR_TX bit of the addressed endpoint USB_EPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_EPnR register is hardware toggled making the USB peripheral buffer swapping completely software independent. Unlike common transactions, and the first one after
DBL_BUF setting, STAT bit pair is not affected by the transaction termination and its value remains ‘11 (Valid). However, as the token packet of a new transaction is received, the actual endpoint status is masked as ‘10 (NAK) when a buffer conflict between the USB peripheral and the application software is detected (this condition is identified by DTOG and SW_BUF having the same value, see Table 418 on page 2025). The application software responds to the CTR event notification by clearing the interrupt flag and starting any required handling of the completed transaction. When the application packet buffer usage is over, the software toggles the SW_BUF bit, writing ‘1 to it, to notify the USB peripheral about the availability of that buffer. In this way, the number of NAKed transactions is limited only by the application elaboration time of a transaction data: if the elaboration time is shorter than the time required to complete a transaction on the USB bus, no re-transmissions due to flow control will take place and the actual transfer rate is limited only by the host PC.

The application software can always override the special flow control implemented for double-buffered bulk endpoints, writing an explicit status different from ‘11 (Valid) into the STAT bit pair of the related USB_EPnR register. In this case, the USB peripheral will always use the programmed endpoint status, regardless of the buffer usage condition.

45.5.4 Isochronous transfers

The USB standard supports full speed peripherals requiring a fixed and accurate data production/consume frequency, defining this kind of traffic as ‘Isochronous’. Typical examples of this data are: audio samples, compressed video streams, and in general any sort of sampled data having strict requirements for the accuracy of delivered frequency. When an endpoint is defined to be ‘isochronous’ during the enumeration phase, the host allocates in the frame the required bandwidth and delivers exactly one IN or OUT packet each frame, depending on endpoint direction. To limit the bandwidth requirements, no re-transmission of failed transactions is possible for Isochronous traffic; this leads to the fact that an isochronous transaction does not have a handshake phase and no ACK packet is expected or sent after the data packet. For the same reason, Isochronous transfers do not support data toggle sequencing and always use DATA0 PID to start any data packet.

The Isochronous behavior for an endpoint is selected by setting the EP_TYPE bits at ‘10 in its USB_EPnR register; since there is no handshake phase the only legal values for the STAT_RX/STAT_TX bit pairs are ‘00 (Disabled) and ‘11 (Valid), any other value will produce results not compliant to USB standard. Isochronous endpoints implement double-buffering to ease application software development, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to have always a complete buffer to be used by the application, while the USB peripheral fills the other.

The memory buffer which is currently used by the USB peripheral is defined by the DTOG bit related to the endpoint direction (DTOG_RX for ‘reception’ isochronous endpoints, DTOG_TX for ‘transmission’ isochronous endpoints, both in the related USB_EPnR register) according to Table 419.
As it happens with double-buffered bulk endpoints, the USB_EPnR registers used to implement Isochronous endpoints are forced to be used as unidirectional ones. In case it is required to have Isochronous endpoints enabled both for reception and transmission, two USB_EPnR registers must be used.

The application software is responsible for the DTOG bit initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. At the end of each transaction, the CTR_RX or CTR_TX bit of the addressed endpoint USB_EPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_EPnR register is hardware toggled making buffer swapping completely software independent. STAT bit pair is not affected by transaction completion; since no flow control is possible for Isochronous transfers due to the lack of handshake phase, the endpoint remains always ‘11 (Valid). CRC errors or buffer-overrun conditions occurring during Isochronous OUT transfers are anyway considered as correct transactions and they always trigger an CTR_RX event. However, CRC errors will anyway set the ERR bit in the USB_ISTR register to notify the software of the possible data corruption.

### 45.5.5 Suspend/Resume events

The USB standard defines a special peripheral state, called SUSPEND, in which the average current drawn from the USB bus must not be greater than 2.5 mA. This requirement is of fundamental importance for bus-powered devices, while self-powered devices are not required to comply to this strict power consumption constraint. In suspend mode, the host PC sends the notification by not sending any traffic on the USB bus for more than 3 ms: since a SOF packet must be sent every 1 ms during normal operations, the USB peripheral detects the lack of 3 consecutive SOF packets as a suspend request from the host PC and set the SUSP bit to ‘1 in USB_ISTR register, causing an interrupt if enabled. Once the device is suspended, its normal operation can be restored by a so called RESUME sequence, which can be started from the host PC or directly from the peripheral itself, but it is always terminated by the host PC. The suspended USB peripheral must be anyway able to detect a RESET sequence, reacting to this event as a normal USB reset event.
The actual procedure used to suspend the USB peripheral is device dependent since according to the device composition, different actions may be required to reduce the total consumption.

A brief description of a typical suspend procedure is provided below, focused on the USB-related aspects of the application software routine responding to the SUSP notification of the USB peripheral:

1. Set the FSUSP bit in the USB_CNTR register to 1. This action activates the suspend mode within the USB peripheral. As soon as the suspend mode is activated, the check on SOF reception is disabled to avoid any further SUSP interrupts being issued while the USB is suspended.
2. Remove or reduce any static power consumption in blocks different from the USB peripheral.
3. Set LP_MODE bit in USB_CNTR register to 1 to remove static power consumption in the analog USB transceivers but keeping them able to detect resume activity.
4. Optionally turn off external oscillator and device PLL to stop any activity inside the device.

When an USB event occurs while the device is in SUSPEND mode, the RESUME procedure must be invoked to restore nominal clocks and regain normal USB behavior. Particular care must be taken to insure that this process does not take more than 10 ms when the waking event is an USB reset sequence (See “Universal Serial Bus Specification” for more details). The start of a resume or reset sequence, while the USB peripheral is suspended, clears the LP_MODE bit in USB_CNTR register asynchronously. The resume procedure should be run just after the end of the suspend one, so its code is immediately executed as soon as the system clock restarts. It is therefore never necessary to handle a WKUP event as an interrupt. If multiple events could have caused the system resume (via EXTI) it is recommended to restart the USB 48 MHz clock as soon as possible.

The following is a list of actions a resume procedure should address:

1. Optionally turn on external oscillator and/or device PLL, and further wait for USB 48 MHz clock activation (this is required before making any USB register accesses).
2. Clear FSUSP bit of USB_CNTR register, and further wait for USB 48 MHz clock activation (this is required before making any USB register access).
3. If the resume triggering event has to be identified, bits RXDP and RXDM in the USB_FNR register can be used according to Table 420, which also lists the intended software action in all the cases. If required, the end of resume or reset sequence can be detected monitoring the status of the above mentioned bits by checking when they reach the “10” configuration, which represent the Idle bus state; moreover at the end of a reset sequence the RESET bit in USB_ISTR register is set to 1, issuing an interrupt if enabled, which should be handled as usual.

<table>
<thead>
<tr>
<th>[RXDP,RXDM] status</th>
<th>Wake-up event</th>
<th>Required resume software action</th>
</tr>
</thead>
<tbody>
<tr>
<td>“00”</td>
<td>Root reset</td>
<td>None</td>
</tr>
<tr>
<td>“10”</td>
<td>None (noise on bus)</td>
<td>Go back in Suspend mode</td>
</tr>
</tbody>
</table>
A device may require to exit from suspend mode as an answer to particular events not directly related to the USB protocol (e.g. a mouse movement wakes up the whole system). In this case, the resume sequence can be started by setting the RESUME bit in the USB_CNTR register to 1 and resetting it to 0 after an interval between 1 ms and 15 ms (this interval can be timed using ESOF interrupts, occurring with a 1 ms period when the system clock is running at nominal frequency). Once the RESUME bit is clear, the resume sequence is completed by the host PC and its end can be monitored again using the RXDP and RXDM bits in the USB_FNR register.

**Note:** The RESUME bit must be anyway used only after the USB peripheral has been put in suspend mode, setting the FSUSP bit in USB_CNTR register to 1.

If multiple events could have cause the system resume (via EXTI) it is recommended to re-start the USB 48 MHz clock as soon as possible. Once this clock is active it is possible to confirm if the event source was the USB resume (for instance WKUP bit).

Table 420. Resume event detection (continued)
45.6 USB and USB SRAM registers

The USB peripheral registers can be divided into the following groups:
- Common Registers: Interrupt and Control registers
- Endpoint Registers: Endpoint configuration and status

The USB SRAM registers cover:
- Buffer Descriptor Table: Location of packet memory used to locate data buffers (see Section 2.2: Memory organization to find USB SRAM base address).

All register addresses are expressed as offsets with respect to the USB peripheral registers base address, except the buffer descriptor table locations, which starts at the USB SRAM base address offset by the value specified in the USB_BTABLE register.

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

45.6.1 Common registers

These registers affect the general behavior of the USB peripheral defining operating mode, interrupt handling, device address and giving access to the current frame number updated by the host PC.

**USB control register (USB_CNTR)**

Address offset: 0x40
Reset value: 0x0003

</tbody>
</table>
Bit 11 **SUSPM**: Suspend mode interrupt mask
0: Suspend Mode Request (SUSP) Interrupt disabled.
1: SUSP Interrupt enabled, an interrupt request is generated when the corresponding bit in the USBISTR register is set.

Bit 10 **RESETM**: USB reset interrupt mask
0: RESET Interrupt disabled.
1: RESET Interrupt enabled, an interrupt request is generated when the corresponding bit in the USBISTR register is set.

Bit 9 **SOFM**: Start of frame interrupt mask
0: SOF Interrupt disabled.
1: SOF Interrupt enabled, an interrupt request is generated when the corresponding bit in the USBISTR register is set.

Bit 8 **ESOFM**: Expected start of frame interrupt mask
0: Expected Start of Frame (ESOF) Interrupt disabled.
1: ESOF Interrupt enabled, an interrupt request is generated when the corresponding bit in the USBISTR register is set.

Bit 7 **L1REQM**: LPM L1 state request interrupt mask
0: LPM L1 state request (L1REQ) Interrupt disabled.
1: L1REQ Interrupt enabled, an interrupt request is generated when the corresponding bit in the USBISTR register is set.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **L1RESUME**: LPM L1 Resume request
The microcontroller can set this bit to send a LPM L1 Resume signal to the host. After the signaling ends, this bit is cleared by hardware.

Bit 4 **RESUME**: Resume request
The microcontroller can set this bit to send a Resume signal to the host. It must be activated, according to USB specifications, for no less than 1 ms and no more than 15 ms after which the Host PC is ready to drive the resume sequence up to its end.

Bit 3 **FSUSP**: Force suspend
Software must set this bit when the SUSP interrupt is received, which is issued when no traffic is received by the USB peripheral for 3 ms.
0: No effect.
1: Enter suspend mode. Clocks and static power dissipation in the analog transceiver are left unaffected. If suspend power consumption is a requirement (bus-powered device), the application software should set the LP_MODE bit after FSUSP as explained below.

Bit 2 **LP_MODE**: Low-power mode
This mode is used when the suspend-mode power constraints require that all static power dissipation is avoided, except the one required to supply the external pull-up resistor. This condition should be entered when the application is ready to stop all system clocks, or reduce their frequency in order to meet the power consumption requirements of the USB suspend condition. The USB activity during the suspend mode (WKUP event) asynchronously resets this bit (it can also be reset by software).
0: No Low-power mode.
1: Enter Low-power mode.
USB interrupt status register (USB_ISTR)

Address offset: 0x44
Reset value: 0x0000 0000

This register contains the status of all the interrupt sources allowing application software to determine, which events caused an interrupt request.

The upper part of this register contains single bits, each of them representing a specific event. These bits are set by the hardware when the related event occurs; if the corresponding bit in the USB_CNTR register is set, a generic interrupt request is generated. The interrupt routine, examining each bit, will perform all necessary actions, and finally it will clear the serviced bits. If any of them is not cleared, the interrupt is considered to be still pending, and the interrupt line is kept high again. If several bits are set simultaneously, only a single interrupt is generated.

Endpoint transaction completion can be handled in a different way to reduce interrupt response latency. The CTR bit is set by the hardware as soon as an endpoint successfully completes a transaction, generating a generic interrupt request if the corresponding bit in USB_CNTR is set. An endpoint dedicated interrupt condition is activated independently from the CTRM bit in the USB_CNTR register. Both interrupt conditions remain active until software clears the pending bit in the corresponding USB_EPnR register (the CTR bit is actually a read only bit). For endpoint-related interrupts, the software can use the Direction of Transaction (DIR) and EP_ID read-only bits to identify, which endpoint made the last interrupt request and called the corresponding interrupt service routine.

The user can choose the relative priority of simultaneously pending USB_ISTR events by specifying the order in which software checks USB_ISTR bits in an interrupt service routine. Only the bits related to events, which are serviced, are cleared. At the end of the service routine, another interrupt is requested, to service the remaining conditions.

To avoid spurious clearing of some bits, it is recommended to clear them with a load instruction where all bits which must not be altered are written with 1, and all bits to be cleared are written with ‘0 (these bits can only be cleared by software). Read-modify-write cycles should be avoided because between the read and the write operations another bit
could be set by the hardware and the next write will clear it before the microprocessor has the time to serve the event.

The following describes each bit in detail:

Bit 15 CTR: Correct transfer
This bit is set by the hardware to indicate that an endpoint has successfully completed a transaction; using DIR and EP_ID bits software can determine which endpoint requested the interrupt. This bit is read-only.

Bit 14 PMAOVR: Packet memory area over / underrun
This bit is set if the microcontroller has not been able to respond in time to an USB memory request. The USB peripheral handles this event in the following way: During reception an ACK handshake packet is not sent, during transmission a bit-stuff error is forced on the transmitted stream; in both cases the host will retry the transaction. The PMAOVR interrupt should never occur during normal operations. Since the failed transaction is retried by the host, the application software has the chance to speed-up device operations during this interrupt handling, to be ready for the next transaction retry; however this does not happen during Isochronous transfers (no Isochronous transaction is anyway retried) leading to a loss of data in this case. This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 13 ERR: Error
This flag is set whenever one of the errors listed below has occurred:
NANS: No ANSwer. The timeout for a host response has expired.
CRC: Cyclic Redundancy Check error. One of the received CRCs, either in the token or in the data, was wrong.
BST: Bit Stuffing error. A bit stuffing error was detected anywhere in the PID, data, and/or CRC.
FVIO: Framing format Violation. A non-standard frame was received (EOP not in the right place, wrong token sequence, etc.).
The USB software can usually ignore errors, since the USB peripheral and the PC host manage retransmission in case of errors in a fully transparent way. This interrupt can be useful during the software development phase, or to monitor the quality of transmission over the USB bus, to flag possible problems to the user (e.g. loose connector, too noisy environment, broken conductor in the USB cable and so on). This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 12 WKUP: Wake-up
This bit is set to 1 by the hardware when, during suspend mode, activity is detected that wakes up the USB peripheral. This event asynchronously clears the LP_MODE bit in the CTRLR register and activates the USB_WAKEUP line, which can be used to notify the rest of the device (e.g. wake-up unit) about the start of the resume process. This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 11 SUSP: Suspend mode request
This bit is set by the hardware when no traffic has been received for 3 ms, indicating a suspend mode request from the USB bus. The suspend condition check is enabled immediately after any USB reset and it is disabled by the hardware when the suspend mode is active (FSUSP=1) until the end of resume sequence. This bit is read/write but only '0 can be written and writing '1 has no effect.
Bit 10  **RESET:** USB reset request
Set when the USB peripheral detects an active USB RESET signal at its inputs. The USB peripheral, in response to a RESET, just resets its internal protocol state machine, generating an interrupt if RESETM enable bit in the USB_CNTR register is set. Reception and transmission are disabled until the RESET bit is cleared. All configuration registers do not reset: the microcontroller must explicitly clear these registers (this is to ensure that the RESET interrupt can be safely delivered, and any transaction immediately followed by a RESET can be completed). The function address and endpoint registers are reset by an USB reset event.
This bit is read/write but only '0' can be written and writing '1' has no effect.

Bit 9  **SOF:** Start of frame
This bit signals the beginning of a new USB frame and it is set when a SOF packet arrives through the USB bus. The interrupt service routine may monitor the SOF events to have a 1 ms synchronization event to the USB host and to safely read the USB_FNR register which is updated at the SOF packet reception (this could be useful for isochronous applications).
This bit is read/write but only '0' can be written and writing '1' has no effect.

Bit 8  **ESOF:** Expected start of frame
This bit is set by the hardware when an SOF packet is expected but not received. The host sends an SOF packet each 1 ms, but if the device does not receive it properly, the Suspend Timer issues this interrupt. If three consecutive ESOF interrupts are generated (i.e. three SOF packets are lost) without any traffic occurring in between, a SUSP interrupt is generated. This bit is set even when the missing SOF packets occur while the Suspend Timer is not yet locked. This bit is read/write but only '0' can be written and writing '1' has no effect.

Bit 7  **L1REQ:** LPM L1 state request
This bit is set by the hardware when LPM command to enter the L1 state is successfully received and acknowledged. This bit is read/write but only '0' can be written and writing '1' has no effect.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4  **DIR:** Direction of transaction
This bit is written by the hardware according to the direction of the successful transaction, which generated the interrupt request.
If DIR bit=0, CTR_TX bit is set in the USB_EPnR register related to the interrupting endpoint. The interrupting transaction is of IN type (data transmitted by the USB peripheral to the host PC).
If DIR bit=1, CTR_RX bit or both CTR_TX/CTR_RX are set in the USB_EPnR register related to the interrupting endpoint. The interrupting transaction is of OUT type (data received by the USB peripheral from the host PC) or two pending transactions are waiting to be processed.
This information can be used by the application software to access the USB_EPnR bits related to the triggering transaction since it represents the direction having the interrupt pending. This bit is read-only.
Bits 3:0  **EP_ID[3:0]: Endpoint Identifier**

These bits are written by the hardware according to the endpoint number, which generated the interrupt request. If several endpoint transactions are pending, the hardware writes the endpoint identifier related to the endpoint having the highest priority defined in the following way: Two endpoint sets are defined, in order of priority: Isochronous and double-buffered bulk endpoints are considered first and then the other endpoints are examined. If more than one endpoint from the same set is requesting an interrupt, the EP_ID bits in USBISTR register are assigned according to the lowest requesting endpoint register, EP0R having the highest priority followed by EP1R and so on. The application software can assign a register to each endpoint according to this priority scheme, so as to order the concurring endpoint requests in a suitable way. These bits are read only.

Bits 15:8  Reserved

Bit 7  EF: Enable function

This bit is set by the software to enable the USB device. The address of this device is contained in the following ADD[6:0] bits. If this bit is at '0' no transactions are handled, irrespective of the settings of USB_EPnR registers.

Bits 6:0  ADD[6:0]: Device address

These bits contain the USB function address assigned by the host PC during the enumeration process. Both this field and the Endpoint Address (EA) field in the associated USB_EPnR register must match with the information contained in a USB token in order to handle a transaction to the required endpoint.

Bits 15:3  BTABLE[15:3]: Buffer table

These bits contain the start address of the buffer allocation table inside the dedicated packet memory. This table describes each endpoint buffer location and size and it must be aligned to an 8 byte boundary (the 3 least significant bits are always '0'). At the beginning of every transaction addressed to this device, the USB peripheral reads the element of this table related to the addressed endpoint, to get its buffer start location and the buffer size (Refer to Structure and usage of packet buffers on page 2019).

Bits 2:0  Reserved, forced by hardware to 0.
Battery charging detector (USB_BCDR)

Address offset: 0x58
Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:4 **BESL[3:0]**: BESL value
These bits contain the BESL value received with last ACKed LPM Token

Bit 3 **REMWAKE**: bRemoteWake value
This bit contains the bRemoteWake value received with last ACKed LPM Token

Bit 2 Reserved

Bit 1 **LPMACK**: LPM Token acknowledge enable
- 0: the valid LPM Token is NYET.
- 1: the valid LPM Token is ACK.
The NYET/ACK is returned only on a successful LPM transaction:
No errors in both the EXT token and the LPM token (else ERROR)
A valid bLinkState = 0001B (L1) is received (else STALL)

Bit 0 **LPMEN**: LPM support enable
This bit is set by the software to enable the LPM support within the USB device. If this bit is at '0' no LPM transactions are handled.

**Bit 15** **DPPU**: DP pull-up control
This bit is set by software to enable the embedded pull-up on the DP line. Clearing it to ‘0’ can be used to signalize disconnect to the host when needed by the user software.

**Bits 14:8** Reserved, must be kept at reset value.

**Bit 7** **PS2DET**: DM pull-up detection status
This bit is active only during PD and gives the result of comparison between DM voltage level and VLGc threshold. In normal situation, the DM level should be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
- 0: Normal port detected (connected to SDP, ACA, CDP or DCP).
- 1: PS2 port or proprietary charger detected.

**Bit 6** **SDET**: Secondary detection (SD) status
This bit gives the result of SD.
- 0: CDP detected.
- 1: DCP detected.

**Bit 5** **PDET**: Primary detection (PD) status
This bit gives the result of PD.
- 0: no BCD support detected (connected to SDP or proprietary device).
- 1: BCD support detected (connected to ACA, CDP or DCP).
Bit 4  **DCDET**: Data contact detection (DCD) status  
This bit gives the result of DCD.  
  0: data lines contact not detected.  
  1: data lines contact detected.  

Bit 3  **SDEN**: Secondary detection (SD) mode enable  
This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.  

Bit 2  **PDEN**: Primary detection (PD) mode enable  
This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.  

Bit 1  **DCDEN**: Data contact detection (DCD) mode enable  
This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.  

Bit 0  **BCDEN**: Battery charging detector (BCD) enable  
This bit is set by the software to enable the BCD support within the USB device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD should be placed in OFF mode by clearing this bit to ‘0’ in order to allow the normal USB operation.

**Endpoint-specific registers**

The number of these registers varies according to the number of endpoints that the USB peripheral is designed to handle. The USB peripheral supports up to 8 bidirectional endpoints. Each USB device must support a control endpoint whose address (EA bits) must be set to 0. The USB peripheral behaves in an undefined way if multiple endpoints are enabled having the same endpoint number value. For each endpoint, an USB_EPnR register is available to store the endpoint specific information.

**USB endpoint n register (USB_EPnR), n=[0..7]**

They are also reset when an USB reset is received from the USB bus or forced through bit FRES in the CTLR register, except the CTR_RX and CTR_TX bits, which are kept unchanged to avoid missing a correct packet notification immediately followed by an USB reset event. Each endpoint has its USB_EPnR register where \( n \) is the endpoint identifier.

Read-modify-write cycles on these registers should be avoided because between the read and the write operations some bits could be set by the hardware and the next write would modify them before the CPU has the time to detect the change. For this purpose, all bits affected by this problem have an ‘invariant’ value that must be used whenever their modification is not required. It is recommended to modify these registers with a load instruction where all the bits, which can be modified only by the hardware, are written with their ‘invariant’ value.
Bit 15 **CTR_RX**: Correct transfer for reception  
This bit is set by the hardware when an OUT/SETUP transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated. The type of occurred transaction, OUT or SETUP, can be determined from the SETUP bit described below. A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches. This bit is read/write but only ‘0’ can be written, writing 1 has no effect.

Bit 14 **DTOG_RX**: Data toggle, for reception transfers  
If the endpoint is not Isochronous, this bit contains the expected value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be received. Hardware toggles this bit, when the ACK handshake is sent to the USB host, following a data packet reception having a matching data PID value; if the endpoint is defined as a control one, hardware clears this bit at the reception of a SETUP PID addressed to this endpoint. If the endpoint is using the double-buffering feature this bit is used to support packet buffer swapping too (Refer to Section 45.5.3: Double-buffered endpoints). If the endpoint is Isochronous, this bit is used only to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to Section 45.5.4: Isochronous transfers). Hardware toggles this bit just after the end of data packet reception, since no handshake is used for isochronous transfers. This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force specific data toggle/packet buffer usage. When the application software writes ‘0’, the value of DTOG_RX remains unchanged, while writing ‘1’ makes the bit value toggle. This bit is read/write but it can be only toggled by writing 1.

Bits 13:12 **STAT_RX [1:0]**: Status bits, for reception transfers  
These bits contain information about the endpoint status, which are listed in Table 421: Reception status encoding on page 2041. These bits can be toggled by software to initialize their value. When the application software writes ‘0’, the value remains unchanged, while writing ‘1’ makes the bit value toggle. Hardware sets the STAT_RX bits to NAK when a correct transfer has occurred (CTR_RX=1) corresponding to a OUT or SETUP (control only) transaction addressed to this endpoint, so the software has the time to elaborate the received data before it acknowledge a new transaction. Double-buffered bulk endpoints implement a special transaction flow control, which control the status based upon buffer availability condition (Refer to Section 45.5.3: Double-buffered endpoints). If the endpoint is defined as Isochronous, its status can be only "VALID" or "DISABLED", so that the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT_RX bits to ‘STALL’ or ‘NAK’ for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing ‘1’.

Bit 11 **SETUP**: Setup transaction completed  
This bit is read-only and it is set by the hardware when the last completed transaction is a SETUP. This bit changes its value only for control endpoints. It must be examined, in the case of a successful receive transaction (CTR_RX event), to determine the type of transaction occurred. To protect the interrupt service routine from the changes in SETUP bits due to next incoming tokens, this bit is kept frozen while CTR_RX bit is at 1; its state changes when CTR_RX is at 0. This bit is read-only.
Bits 10:9 **EP_TYPE[1:0]: Endpoint type**

These bits configure the behavior of this endpoint as described in Table 422: Endpoint type encoding on page 2041. Endpoint 0 must always be a control endpoint and each USB function must have at least one control endpoint which has address 0, but there may be other control endpoints if required. Only control endpoints handle SETUP transactions, which are ignored by endpoints of other kinds. SETUP transactions cannot be answered with NAK or STALL. If a control endpoint is defined as NAK, the USB peripheral will not answer, simulating a receive error, in the receive direction when a SETUP transaction is received. If the control endpoint is defined as STALL in the receive direction, then the SETUP packet is accepted anyway, transferring data and issuing the CTR interrupt. The reception of OUT transactions is handled in the normal way, even if the endpoint is a control one.

Bulk and interrupt endpoints have very similar behavior and they differ only in the special feature available using the EP_KIND configuration bit.

The usage of Isochronous endpoints is explained in Section 45.5.4: Isochronous transfers.

Bit 8 **EP_KIND: Endpoint kind**

The meaning of this bit depends on the endpoint type configured by the EP_TYPE bits. Table 423 summarizes the different meanings.

DBL_BUF: This bit is set by the software to enable the double-buffering feature for this bulk endpoint. The usage of double-buffered bulk endpoints is explained in Section 45.5.3: Double-buffered endpoints.

STATUS_OUT: This bit is set by the software to indicate that a status out transaction is expected: in this case all OUT transactions containing more than zero data bytes are answered ‘STALL’ instead of ‘ACK’. This bit may be used to improve the robustness of the application to protocol errors during control transfers and its usage is intended for control endpoints only. When STATUS_OUT is reset, OUT transactions can have any number of bytes, as required.

Bit 7 **CTR_TX: Correct Transfer for transmission**

This bit is set by the hardware when an IN transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in the USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated.

A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

This bit is read/write but only ‘0’ can be written.

Bit 6 **DTOG_TX: Data Toggle, for transmission transfers**

- If the endpoint is non-isochronous, this bit contains the required value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be transmitted. Hardware toggles this bit when the ACK handshake is received from the USB host, following a data packet transmission. If the endpoint is defined as a control one, hardware sets this bit to 1 at the reception of a SETUP PID addressed to this endpoint.
- If the endpoint is using the double buffer feature, this bit is used to support packet buffer swapping too (Refer to Section 45.5.3: Double-buffered endpoints).
- If the endpoint is Isochronous, this bit is used to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to Section 45.5.4: Isochronous transfers). Hardware toggles this bit just after the end of data packet transmission, since no handshake is used for Isochronous transfers.
- This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force a specific data toggle/packet buffer usage. When the application software writes ‘0’, the value of DTOG_TX remains unchanged, while writing ‘1’ makes the bit value toggle. This bit is read/write but it can only be toggled by writing 1.
Bits 5:4 **STAT_TX [1:0]:** Status bits, for transmission transfers

These bits contain the information about the endpoint status, listed in Table 424. These bits can be toggled by the software to initialize their value. When the application software writes ‘0’, the value remains unchanged, while writing ‘1’ makes the bit value toggle. Hardware sets the STAT_TX bits to NAK, when a correct transfer has occurred (CTR_TX=1) corresponding to an IN or SETUP (control only) transaction addressed to this endpoint. It then waits for the software to prepare the next set of data to be transmitted.

Double-buffered bulk endpoints implement a special transaction flow control, which controls the status based on buffer availability condition (Refer to Section 45.5.3: Double-buffered endpoints).

If the endpoint is defined as Isochronous, its status can only be “VALID” or “DISABLED”. Therefore, the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT_TX bits to ‘STALL’ or ‘NAK’ for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing ‘1’.

Bits 3:0 **EA[3:0]:** Endpoint address

Software must write in this field the 4-bit address used to identify the transactions directed to this endpoint. A value must be written before enabling the corresponding endpoint.

45.6.2 Buffer descriptor table

**Note:**
The buffer descriptor table is located inside the packet buffer memory in the separate "USB SRAM" address space.

Although the buffer descriptor table is located inside the packet buffer memory ("USB SRAM" area), its entries can be considered as additional registers used to configure the location and size of the packet buffers used to exchange data between the USB macro cell and the device.

The first packet memory location is located at USB SRAM base address. The buffer descriptor table entry associated with the USB_EPnR registers is described below. The packet memory should be accessed only by byte (8-bit) or half-word (16-bit) accesses. Word (32-bit) accesses are not allowed.

A thorough explanation of packet buffers and the buffer descriptor table usage can be found in *Structure and usage of packet buffers on page 2019.*

Transmission buffer address n (USB_ADDRn_TX)

Address offset: [USB_BTABLE] + n*8

**Note:**
*In case of double-buffered or isochronous endpoints in the IN direction, this address location is referred to as USB_ADDRn_TX_0.*

*In case of double-buffered or isochronous endpoints in the OUT direction, this address location is used for USB_ADDRn_RX_0.*

</tr>
</thead>
</table>

Bits 15:1 **ADDRn_TX[15:1]:** Transmission buffer address

These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint associated with the USB_EPnR register at the next IN token addressed to it.

Bit 0 Must always be written as '0 since packet memory is half-word wide and all packet buffers must be half-word aligned.

Transmission byte count n (USB_COUNTn_TX)

Address offset: [USB_BTABLE] + n*8 + 2

**Note:**
*In case of double-buffered or isochronous endpoints in the IN direction, this address location is referred to as USB_COUNTn_TX_0.*

*In case of double-buffered or isochronous endpoints in the OUT direction, this address location is used for USB_COUNTn_RX_0.*

</thead>
</table>

Bits 15:1 **ADDRn_TX[15:1]:** Transmission buffer address

These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint associated with the USB_EPnR register at the next IN token addressed to it.

Bit 0 Must always be written as '0 since packet memory is half-word wide and all packet buffers must be half-word aligned.
Bits 15:10  These bits are not used since packet size is limited by USB specifications to 1023 bytes. Their value is not considered by the USB peripheral.

Bits 9:0  COUNTn_TX[9:0]: Transmission byte count
These bits contain the number of bytes to be transmitted by the endpoint associated with the USB_EPnR register at the next IN token addressed to it.

Reception buffer address n (USB_ADDRn_RX)
Address offset: [USB_BTABLE] + n*8 + 4

Note:  In case of double-buffered or isochronous endpoints in the OUT direction, this address location is referred to as USB_ADDRn_RX_1.
In case of double-buffered or isochronous endpoints in the IN direction, this address location is used for USB_ADDRn_TX_1.

<table>
<thead>
<tr>
<th>ADDRn_RX[15:1]</th>
<th>-</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:1  ADDRn_RX[15:1]: Reception buffer address
These bits point to the starting address of the packet buffer, which will contain the data received by the endpoint associated with the USB_EPnR register at the next OUT/SETUP token addressed to it.

Bit 0  This bit must always be written as '0 since packet memory is half-word wide and all packet buffers must be half-word aligned.

Reception byte count n (USB_COUNTn_RX)
Address offset: [USB_BTABLE] + n*8 + 6

Note:  In case of double-buffered or isochronous endpoints in the OUT direction, this address location is referred to as USB_COUNTn_RX_1.
In case of double-buffered or isochronous endpoints in the IN direction, this address location is used for USB_COUNTn_TX_1.

<table>
<thead>

<th>COUNTn_RX[9:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint descriptor and it is normally defined during the
enumeration process according to its maxPacketSize parameter value (See “Universal Serial Bus Specification”).

Bit 15 **BL_SIZE**: Block size

This bit selects the size of memory block used to define the allocated buffer area.

- If BL_SIZE=0, the memory block is 2-byte large, which is the minimum block allowed in a half-word wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BL_SIZE=1, the memory block is 32-byte large, which allows to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size theoretically ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications. However, the applicable size is limited by the available buffer memory.

Bits 14:10 **NUM_BLOCK[4:0]**: Number of blocks

These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BL_SIZE value as illustrated in Table 425.

Bits 9:0 **COUNTn_RX[9:0]**: Reception byte count

These bits contain the number of bytes received by the endpoint associated with the USB_EPnR register during the last OUT/SETUP transaction addressed to it.

The reset values for each register are provided in the table. Each register is described in detail in the accompanying text, including offset values and their respective bits for various control and status functions.
Refer to *Section 2.2 on page 81* for the register boundary addresses.
46 USB Type-C®/USB Power Delivery interface (UCPD)

46.1 Introduction

The USB Type-C/USB Power Delivery interface complies with:

- Universal Serial Bus Type-C Cable and Connector Specification: release 2.2, Oct 2022
- Universal Serial Bus Power Delivery specifications:
  - revision 2.0, version 1.3, January 12, 2017
  - revision 3.1, version 1.6, October 2022

It integrates the physical layer of the Power Delivery (PD) specification, with CC signaling method (no VBUS), for operation with Type-C cables.

46.2 UCPD main features

- Compliance with USB Type-C specification release 2.2
- Compliance with USB Power Delivery specifications revision 2.0 and 3.1
  - Enabling advanced applications such as PPS (programmable power supply)
- Stop mode low-power operation support
- Built-in analog PHY
  - USB Type-C pull-up (Rp, all values) and pull-down (Rd) resistors
  - “Dead battery” Rd support
  - USB Power Delivery message transmission and reception
  - FRS (fast role swap) Rx support
- Digital controller
  - BMC (bi-phase mark coding) encode and decode
  - 4b5b encode and decode
  - USB Type-C level detection with de-bounce, generating interrupts
  - FRS signaling
  - FRS detection, generating an interrupt
  - DMA-compatible byte-level interface for USB Power Delivery payload, generating interrupts
  - USB Power Delivery clock pre-scaler / dividers
  - CRC generation/checking
  - Support of ordered sets, with a programmable ordered set mask at receive
  - Clock recovery from incoming Rx stream

46.3 UCPD implementation

The devices have one UCPD controller to support one USB Type-C port.
### 46.4 UCPD functional description

The UCPD peripheral provides hardware support for the USB Power Delivery control interface specification, using I/Os specifically designed for that purpose.

The built-in PHY directly detects Type-C voltage levels, supports Power Delivery BIST carrier mode 2 (Tx only), BIST test data (Tx and Rx), and Power Delivery Rx FRS signaling.

For Power Delivery FRS Tx signaling, the device can be configured to control, through UCPD_FRSTX pin (alternate function), external NMOS transistors that ensure low-resistance pull-down on CC lines.

The UCPD transmitter BMC (bi-phase mark) encodes and transmits data: preamble, SOP, payload data from protocol layer (after 4b5b-encoding), CRC, and EOP on the Type-C connector CC lines. It automatically inserts inter-frame gap and executes “Hard Reset”.

The UCPD receiver detects SOP, BMC-decodes the incoming stream, recovers the preamble, 4b5b-decodes payload data, detects EOP, and checks CRC. It automatically detects five K-code SOP and two Reset ordered sets, plus two software-defined patterns (allows for only three out of four K-codes being correctly received, as defined by the standard).

In Stop mode, the peripheral maintains the ability to detect incoming USB Power Delivery messages and FRS signaling, which allows low-power operation.
46.4.1 UCPD block diagram

46.4.2 UCPD reset and clocks

The peripheral has a single reset signal (APB bus reset).

The register section is clocked with the APB clock (ucpd_pclk).

The main functional part of the transmitter is clocked with ucpd_clk clock, pre-scaled from the ucpd_ker_ck clock according to the PSC_UCPDCLK[2:0] bitfield of the UCPD_CFGR1 register. The main functional part of the receiver is clocked with the ucpd_rx_clk recovered from the incoming bitstream.

The receiver is designed to work in the clock frequency range from 6 to 18 MHz. However, the optimum performance is ensured in the range from 6 to 12 MHz.

The following diagram shows the clocking and timing elements of the UCPD peripheral.

Refer to the USB PD specification in order to set appropriate delays. For \( t_{TransitionWindow} \) and especially for \( t_{InterFrameGap} \), the clock frequency uncertainty must be taken into account so as to respect specified timings in all cases.
46.4.3 Physical layer protocol

The physical layer covers the signaling underlying the USB Power Delivery specification. On the transmitter side its main function is to form packets according to the defined packet format including generally:
- preamble
- start of packet (SOP, ordered set)
- payload header
- payload data
- cyclic redundancy check (CRC) information
- end of packet (EOP)

Before going on the CC line, the data stream is BMC-encoded, respecting specified timing restrictions.

On the receive side, the principle task is to:
- extract start of packet (SOP, ordered set) information
- extract payload header
- extract payload data
- receive and check CRC
- receive end of packet (EOP)

The receive is basically a reverse of the transmit process, thus starting with BMC data stream decoding.

Symbol encoding

Apart from the preamble all symbols are encoded with a 4b5b scheme according to the specification shown in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>4b</th>

</tbody>
</table>
Ordered sets

An ordered set consists of four K-codes as shown in the following figure.

![Figure 676. K-code transmission](image)

The following table lists the defined ordered sets, including all possible SOP* sequences. At the physical layer, the Hard Reset has higher priority than the other ordered sets so it can interrupt an ongoing Tx message.

<table>
<thead>
<tr>
<th>Ordered set name</th>
<th>K-code #1</th>
<th>K-code #2</th>
<th>K-code #3</th>
<th>K-code #4</th>
</tr>
</thead>
<tbody>

<td>20-bits</td>
</tr>
<tr>
<td>DWord</td>
<td>32-bits</td>
<td>40-bits</td>
</tr>
</tbody>
</table>

The bit transmission order is shown in the following figure.

Figure 677. Transmit order for various sizes of data
Packet format

Messages other than Hard Reset and Cable Reset

The packet format is shown in the following figure, with information on 4b5b encode and data source.

**Figure 678. Packet format**

![Packet format diagram]

**Hard Reset**

The physical layer handles the Hard Reset signaling differently than the other types of message as it has higher priority to be able to interrupt an ongoing transfer. The physical layer specification implies the following sequence in the case of an ongoing Tx message:

1. Terminate the message by sending an EOP K-code and discard the rest of the message.
2. Wait for \( t_{InterFrameGap} \) time.
3. If the CC line is not idle, wait until it goes idle.
4. Send the preamble followed by the four K-codes of Hard Reset signaling.
5. Disable the CC channel (stop sending and receiving), reset the physical layer and inform the protocol layer that the physical layer is reset.
6. Re-enable the channel when requested by the protocol layer.

**Figure 679. Line format of Hard Reset**

![Hard Reset line format diagram]
Cable Reset

Cable Reset shown in the following figure is similar in format to Hard Reset, but unlike Hard Reset it does not require a specific high-priority treatment.

Figure 680. Line format of Cable Reset

Collision avoidance

The physical layer respects the $t_{InterFrameGap}$ delay between end of last-transmitted bit of a Tx message, and the first bit of a following message.

It also checks the idle state of the CC line before starting transmission. The CC line is considered idle if it shows less than three ($n_{TransitionCount}$) transitions within $t_{TransitionWindow}$ (12 to 20 $\mu$s). The Power Delivery specification revision 3.1 also requires to manage the Rp value (source) and monitor Type-C voltage level for these Rp modifications (at the sink).

Physical layer signaling schemes

The bit are signaled with bi-phase mark coding (BMC).

BIST

Depending on the BIST action required by the protocol layer, either of the following can be run:

- a Tx BIST pattern test, achieved by writing TXMODE and TXSEND
- an Rx BIST pattern test, achieved by writing RXMODE to the correct value for RXBIST.

The two possible patterns supported in UCPD (corresponding to "BMC" mode) are:

- BIST Test Data (192 bit pattern), applies to Tx and Rx. In the case of Rx, the message is received (but discarded rather than passing to the protocol layer, which must nevertheless still generate a GoodCRC Tx message in acknowledgment).
- BIST Carrier Mode 2 (single pattern, infinite length message), applies to Tx only. As opposed to Tx, the receiver in this mode simply ignores the CC line during this state.

BIST test data pattern

The test data pattern is not viewed as a special case in UCPD.
The BIST test data packet frame format is shown in the following figure.

**Figure 681. BIST test data frame**

<table>

This is a fixed length test data pattern. In reality the only aspect that marks its difference from the general packet format already shown in *Figure 678: Packet format* is the contents of the Header. As UCPD receives the Tx Header contents via programming (it is simply viewed as part of the payload), it is only this programming (and not the block’s behavior) that differentiates the general packet from the BIST Test Data packet.

**BIST Carrier Mode 2**

When required, this BIST test mode sends an alternating pattern of 1010 that is continually repeated. As this mode is intended for signal analysis it is stable condition with (in V1.0 of the USB PD specification) no defined length. Starting from V1.1 of the USB PD specification, the protocol layer defines a counter that indicates when to exit this mode.

The way to quit the infinite 1010 sequence (according to requirements of the USB PD specification) is to disable the UCPD peripheral via the UCPDEN bit.

**Figure 682. BIST Carrier Mode 2 frame**

<table>
<thead>

**46.4.4 UCPD BMC transmitter**

The BMC transmitter comprises 4b5b encoding, CRC generation, and BMC encode, as shown in the following figure. Its output goes to the analog PHY through a channel switch.
**BMC encoder**

The half-bit clock hbit_clk is derived from ucpd_clk through a simple divider controlled by the HBITCLKDIV[5:0] bitfield of the UCPD_CFGR1 register. This ensures the same duration of high and low half-bit periods (if neglecting a small difference due to different rising and falling edge duration and due to jitter), and the same bit duration (if neglecting jitter).

**Transmitter timing and collision avoidance**

Hardware support of collision avoidance is made as a function of the half bit time for the transmitter. Two counters are implemented:

- \( t_{InterFrameGap} \): via IFRGAP (pre-defined value, can be altered)
- \( t_{TransitionWindow} \): via TRANSWIN (pre-defined value, can be altered)

These two counters once set correctly generates the interframe gap.

**Hard Reset in transmitter**

In order to facilitate generation of a Hard Reset, a special code of TXMODE field is used. No other fields need to be written.

On writing the correct code, the hardware forces Hard Reset Tx under the correct (optimal) timings with respect to an ongoing Tx message, which (if still in progress) is cleanly terminated by truncating the current message and directly appending an EOP K-code sequence. No specific interrupt is generated relating to this truncation event.

**Transmitter behavior in the case of errors**

The under-run condition (TXUND interrupt) may happen by accident and in this case, the UCPD is starved of (the correct) Tx payload and is not able to complete the Tx message correctly. This is a serious error (for this to happen the software fails to respond in time). As a result the hardware ensures the CRC is incorrect at the end of the message, thus guaranteeing the message to be discarded at the receiver.
46.4.5 UCPD BMC receiver

The UCPD BMC receiver performs:

- Clock recovery
- Preamble detection / timing derivation
- BMC decoding
- 4b5b decoding
- K-code ordered set recognition
- CRC checking
- SOP detection
- EOP detection

The receiver is activated as soon as the UCPD peripheral is enabled (via UCPDEN), but it waits for an idle CC line state before attempting to receive a message.

The following figure shows the UCPD BMC receiver high-level architecture.

CRC checker

The received bits are fed into a CRC checker which evolves a 32-bit state during the received the payload bitstream. At the end the 32 bits of the CRC also fed into the logic.

The EOP detection (5 bits) halts the process and a check is performed for the fixed residual state which confirms correct reception of the payload (in fact the residual is 0xC704DD78).

At this point the UCPD raises interrupt RXMSGEND. If the CRC was not correct then RXERR is set true and the receive data must be discarded.

Under normal operation, this interrupt would previously have been acknowledged and thus cleared. If this is not the case, a different interrupt RXOVR is generated in place of RXMSGEND.
Ordered set detection

This function detects the different ordered sets each consisting of four 5-bit K-codes.

Once we are in the preamble we open a sliding window detection of the ordered set (4 words of 5 bits).

The ordered sets detected include all SOP* codes (SOP, SOP’, and SOP’’), but also Hard Reset, Cable Reset, SOP’_Debug, SOP’’_Debug, and two extensions defined by registers UCPD_RX_ORDEXT1 and UCPD_RX_ORDEXT2.

EOP detection and Hard Reset exception handling

EOP is a fixed 5-bit K-code marking the end of a message.

The way in which a transmitter is required to send a Hard Reset (if a previous message transmit is still in progress) is that this previous message is truncated early with an EOP.

If Hard Reset were ignored, then the EOP detection can be done only at the expected time. However, due to the Hard Reset issue, the EOP detector must be active while an Rx message is arriving. When an “early EOP” is detected, the truncated Rx message is immediately discarded.

Truncated or corrupted message exception

Once the ordered set has been detected, depending on the message, there may be data bytes to be received which is completed with a CRC and EOP. If at any point during these phases an error condition happens:

- the line becomes static for a time significantly longer than one “UI” period (the exact threshold for this condition is not critical but the exception must occur before three UIs),
- or

- the message goes to the end but it is not recognized (for example EOP is corrupted).

In both cases, the receiver quits the current message, raising RXMSGEND and RXERR flags.

Short preamble or incomplete ordered set exception

In the exceptional case of the receiver seeing less than half of the expected preamble, the frequency estimation allowing correct BMC-decode becomes impossible. Even if the full preamble is seen, allowing frequency estimation, but the ordered set is not fully received before the line becomes static, the receiver state machine does not start.

In both of these cases, the clock-recovery/BMC decoder re-starts, checking initially for an IDLE condition, followed by a preamble, and then estimating frequency.

46.4.6 UCPD Type-C pull-ups (Rp) and pull-downs (Rd)

UCPD offers simple control of these resistors via ANAMODE and ANASUBMODE[1:0]. In case only one of the CC lines is to be used, it is possible to optimize power consumption by disabling control on the other line, through the CCENABLE[1:0] bitfield.

When the MCU is unpowered, it still presents the “dead battery” Rd, provided that UCPDx_DBCC1 and UCPDx_DBCC2 pins are each connected to UCPDx_CC1 and UCPDx_CC2 pins, respectively.

If dead battery behavior is not required (for example for source only products), then UCPDx_DBCC1 and UCPDx_DBCC2 pins must both be tied to ground.
After power arrives and the MCU boots, the desired behavior (for example source) must be programmed into ANAMODE and ANASUBMODE[1:0] before setting the UCPD1_DBDIS bit of the PWR_CR3 register to remove dead battery pull-down resistor and allow the values just programmed to take effect.

Use of Standby low-power mode is possible for sinks in the unattached state.

### 46.4.7 UCPD Type-C voltage monitoring and de-bouncing

For correct operation of the Type-C state machine and for detecting the cable orientation, the CC1/2 lines must be monitored for voltage level, while ignoring fast events such as peaks.

Thresholds between voltage levels on the CC1/2 lines are determined through PHY threshold detector settings.

The TYPEC_VSTATE_CC1/2[1:0] bitfields reflect the CC1/2 line levels processed with a hardware de-bouncing filter that suppresses high-speed line events such as peaks. The PHYCCSEL bit selects the line, CC1 or CC2, to be used for Power Delivery signaling.

For minimizing the power consumption, it is recommended to use the polling method, with the Type-C detectors only turned on for the instant of polling, rather than keeping the Type-C detectors permanently on and wake the device up from Stop mode upon CC1/2 line events.

### 46.4.8 UCPD fast role swap (FRS)

**FRS signaling**

The FRS condition (a pulse of a specific length), is generated upon setting the FRSTX bit.

For the duration of FRS condition, the I/O configured as UCPD_FRSTX (alternate function) controls, with high level, the gate of an external NMOS transistor that pulls the active CC line down.

**FRS detection**

FRS monitoring is enabled by setting the bit FRSRXEN, after writing PHYCCSEL that selects the active CC line depending on the cable orientation detected.

### 46.4.9 UCPD DMA Interface

DMA is implemented in the UCPD and when it is enabled the byte-level interrupts to handle UCPD1_TXDR and UCPD1_RXDR registers (Tx and Rx data register, each one byte) are no longer needed.

By enabling bits TXDMAEN and/or RXDMAEN, DMA can be activated independently for Tx and/or Rx functionality.

### 46.4.10 Wake-up from Stop mode

For power consumption optimization, it is useful to use Stop mode and wait for events on CC lines to wake the MCU up.

In order for this to work, it must be first enabled by writing a 1 to WUPEN.
The events causing the wake-up can be:
- Events on the BMC receiver (RXORDDET, RXHRSTDET), hardware enable PHYRXEN
- Event on the FRS detector (FRSEVT), hardware enable FRSRXEN
- Events on the Type-C detectors (TYPECEVT1, TYPECEVT2), hardware enables CC1TCDIS, CC2TCDIS

46.5 UCPD programming sequences

The normal sequence of use of the UCPD unit is:
1. Configure UCPD.
2. Enable UCPD.
3. Concurrently:
   - On demand from protocol layer, send Tx message
   - Intercept (poll or wait for interrupt) relevant Rx messages and recover detail to hand off to protocol layer

Repeat the last point infinitely.

46.5.1 Initialization phase

Use the following sequence for a clean startup:
1. Prepare all initial clock divider values, by writing the UCPD_CFG register.
2. Enable the unit, by setting the UCPDEN bit.

46.5.2 Type-C state machine handling

For the general application cases of source, sink, or dual-role port (the last alternating the source and the sink), the software must implement a corresponding USB Type-C state machine. The basic coding is in the following table.

<table>
<thead>
<tr>
<th>ANAMODE</th>
<th>ANASUBMODE[1:0]</th>
<th>Notes</th>
<th>TYPEC_VSTATE_CCx[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>00: Disabled</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0: Source</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>01: Default USB Rp</td>
<td>-</td>
<td>vRa[Def] vRd[Def] vOPEN[Def]</td>
</tr>
<tr>
<td></td>
<td>10: 1.5A Rp</td>
<td>-</td>
<td>vRa[1.5] vRd[1.5] vOPEN[1.5]</td>
</tr>
<tr>
<td>1: Sink</td>
<td>xx</td>
<td>-</td>
<td>vRa vRd-USB vRd-1.5 vRd-3.0</td>
</tr>
</tbody>
</table>

The CCENABLE[1:0] bitfield can disable pull-up/pull-downs on one of the CC lines.

Note: The Type-C state machine depends not only on CC line levels, but also on VBUS presence detection (sink mode) and, when in source mode, determines VCONN generation and VBUS state (ON/OFF/+voltage level; discharge). UCPD does not directly control VBUS generation circuitry nor VCONN load switch (enabling VCONN supply generator to be
connected to the CC line), but the application needs these inputs and controls, to function correctly.

General programming sequence (with UCPD configured then enabled)

1. Set ANAMODE and ANASUBMODE[1:0] based on the current position in USB Type-C state machine (and also the current advertisement in the case of a source). This turns on the appropriate pull-ups/pull-downs on the CC lines, and defines the voltage levels that the TYPEC_VSTATE fields represent. Note that before programming, the PHY is effectively off.

2. Read TYPEC_VSTATE_CC1/2 to determine the initial Type-C state (for example whether the local source is connected to a remote sink).

3. In the case of no connection, wait for a connection event.

4. Assuming a connection is detected and assuming a local Power Delivery functionality is implemented, start sending/receiving Power Delivery messages.

5. When a new interrupt/event occurs on PHYEVT1/2 indicating a change in stable voltage, re-evaluate the implications and give this input to the Type-C state machine.

Case of a source that needs to change between one of the three possible Rp values (Default-USB / 1.5A / 3.0A) and the sink connected to it:

- [Source] Simply reprogram ANASUBMODE[1:0]
- [Sink behavior from that time] PHYEVT1/2 occurs and the TYPEC_VSTATE1/2 changes accordingly

Programming for a dual-role port (DRP) toggling from source to sink:

- Simply re-program ANAMODE and ANASUBMODE[1:0] to start the new behavior
46.5.3 USB PD transmit

On reception of a message from the protocol layer (that is, to be sent), prepare Tx message contents by writing the UCPD_TX_ORDSET and UCPD_TX_PAYSZ registers.

The message transmission is triggered by setting the TXSEND bit, with an appropriate value of the TXMODE bitfield.

When the data byte is transmitted, the TXIS flag is raised to request a new data write to the UCPD_TXDR register.

This re-iterates until the entire payload of data is transmitted.
Upon sending the CRC packet, the TXMSGSENT flag is set to indicate the completion of the message transmission.

**Hard Reset transmission**

As soon as it is known that a Hard Reset needs to be transmitted, setting the TXHRST bit of the UCPD_CR register forces the internal state machine to generate the correct sequence. The value of UCPD_TX_ORDSET does not require update in this precise case (the correct code for Hard Reset is sent by UCPD).

The USB Power Delivery specification requires that in the case of an ongoing message transmission, the Hard Reset takes precedence. In this case, for example, UCPD truncates the payload of the current message, appending EOP to the end. No notification is available via the registers (for example through the TXMSGSEND flag). This is justified by the fact that the Hard Reset takes precedence over any previous activity (for which it is therefore no longer important to know if it is completed).

**Use of DMA for transmission**

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the UCPD_CR register.

For each message:
- Prepare the whole message in memory (starting with two header bytes)
- Program the DMA operation with a length corresponding to the two header bytes plus a number of data bytes corresponding to the number of data words multiplied by four
- Write TXSEND to initiate the message transfer
- If TXMSGDISC then go back to previous line (TXSEND)
- Wait for DMA transfer complete interrupt (that is, when last Tx byte written to UCPD)
- Double-check subsequent TXMSGSENT interrupt appears

**46.5.4 USB PD receive**

Notification of start of the receive message sequence is triggered by an interrupt on UCPD_SR (bit RXORDDET).

The information is recovered by reading:
- UCPD_RX_SOP (on interrupt RXORDDET)
- UCPD_RXDR (on interrupt RXNE, repeats for each byte)
- UCPD_RXPAYSZ (on interrupt RXMSGEND)

The data previously read from UCPD_RXDR above must be discarded at this point if the RXERR flag is set.

If the CRC is valid, the received data is transferred to the protocol layer.

For debug purposes, it may be desirable to track statistics of the number of incorrect K-codes received (this is done only when 3/4 K-codes were valid as defined in the specification). This is facilitated through:
- RXSOP3OF4 bit indicating the presence of at least one invalid K-code
- RXSOPKINVALID bitfield identifying the order of invalid K-code in the ordered set
Use of DMA for reception

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the UCPD_CR register.

Whenever a Rx message is expected:
- Program a DMA receive operation (and spare buffer) a little longer than the maximum possible message (length depends on extended message support).
- After receiving RXORDDET, DMA operation starts working in the background.
- On reception of RXMSGEND interrupt, read RXPAYSZ.
- Double-check RXPAYSZ vs. the number of DMA Rx bytes (must correspond but DMA read of RXDR is slightly after RXDR gets last byte).
- Process the DMA Rx buffer.
- Prepare next Rx DMA buffer as soon as possible in order to be ready.

46.6 UCPD low-power modes

A summary of low-power modes is shown below in Table 436: Effect of low power modes on the UCPD.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect</td>
</tr>
<tr>
<td>Stop</td>
<td>Detection of events (Type-C, BMC Rx, FRS detection) remains operational and</td>
</tr>
<tr>
<td></td>
<td>can wake up the MCU.</td>
</tr>
<tr>
<td>Standby</td>
<td>UCPD is not operating, and cannot wake up the MCU. Pull-downs remain active</td>
</tr>
<tr>
<td></td>
<td>if configured.</td>
</tr>
<tr>
<td>Unpowered</td>
<td>Dead battery pull-downs remain active.</td>
</tr>
</tbody>
</table>

The UCPD is able to wake up the MCU from Stop mode when it recognizes a relevant event, either:
- Type-C event relating to a change in the voltage range seen on either of the CC lines, visible in TYPEC_VSTATE_CCx
- Power delivery receive message with an ordered set matching those filtered according to RXORDSETEN[8:0], visible by reading RXORDSET

Wake-up from Stop mode is enabled by setting the WUPEN bit in the UCPD_CFG2 register.

At UCPD level three types of event requiring kernel clock activity may occur during Stop mode:
- Activity on the analog PHY voltage threshold detectors which can later be confirmed to be a stable change between voltage ranges defined in the Type-C specification
- Activity on Power Delivery BMC receiver (coming from the selected CC line) which can potentially generate an Rx message event (that is, RXORDSET) later
- Activity on Power Delivery FRS detector which can potentially generate an FRS signaling detection event (that is, FRSEVT) later
It order to function correctly with the RCC, the clock request signal is activated (conditional on WUPEN) when there is asynchronous activity on:

- Type-C voltage threshold detectors (coming from either CC line)
- Power Delivery receiver signal (from the selected CC line)
- FRS detection signal (from the selected CC line)

### 46.7 UCPD interrupts

The table below lists the UCPD event flags, with the associated flag clear bits and interrupt enable bits.

<table>

</tbody>
</table>

When an interrupt from the UCPD is received, then the software has to check what is the source of the interrupt by reading the UCPD_SR register.

Depending on which bit is at 1, the ISR must handle that condition and clear the bit by a write to the appropriate bit of the UCPD_ICR register.
46.8 UCPD registers

46.8.1 UCPD configuration register 1 (UCPD_CFRG1)

Address offset: 0x000
Reset value: 0x0000 0000

General configuration of the peripheral. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>UCPDEN</th>
<th>General enable of the UCPD peripheral. 0: Disable 1: Enable Upon disabling, the peripheral instantly quits any ongoing activity and all control bits and bitfields default to their reset values. They must be set to their desired values each time the peripheral transits from disabled to enabled state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 30</td>
<td>RXDMAEN</td>
<td>Reception DMA mode enable 0: Disable 1: Enable When set, the bit enables DMA mode for reception.</td>
</tr>
<tr>
<td>Bit 29</td>
<td>TXDMAEN</td>
<td>Transmission DMA mode enable 0: Disable 1: Enable When set, the bit enables DMA mode for transmission.</td>
</tr>
<tr>
<td>Bits 28:20</td>
<td>RXORDSETEN[8:0]</td>
<td>Receiver ordered set enable The bitfield determines the types of ordered sets that the receiver must detect. When set/cleared, each bit enables/disables a specific function: 0bXXXXXXXX1: SOP detect enabled 0bXXXXXXX1X: SOP' detect enabled 0bXXXXX1XX: SOP'' detect enabled 0bXXXX1XXX: Hard Reset detect enabled 0bXXX1XXXX: Cable Detect reset enabled 0bXX1XXXXX: SOP'_Debug enabled 0bX1XXXXXX: SOP''_Debug enabled 0b1XXXXXXX: SOP extension#1 enabled 0b1XXXXXXX: SOP extension#2 enabled</td>
</tr>
</tbody>
</table>
Bits 19:17 **PSC\_UCPDCLK[2:0]**: Pre-scaler division ratio for generating ucpd\_clk

The bitfield determines the division ratio of a kernel clock pre-scaler producing UCPD peripheral clock (ucpd\_clk).

- 0x0: 1 (bypass)
- 0x1: 2
- 0x2: 4
- 0x3: 8
- 0x4: 16

It is recommended to use the pre-scaler so as to set the ucpd\_clk frequency in the range from 6 to 9 MHz.

Bit 16 Reserved, must be kept at reset value.

Bits 15:11 **TRANSWIN[4:0]**: Transition window duration

The bitfield determines the division ratio (the bitfield value minus one) of a hbit\_clk divider producing \( t\_\text{TransitionWindow} \) interval.

- 0x00: Not supported
- 0x01: 2
- 0x09: 10 (recommended)
- 0x1F: 32

Set a value that produces an interval of 12 to 20 us, taking into account the ucpd\_clk frequency and the HBITCLKDIV[5:0] bitfield setting.

Bits 10:6 **IFRGAP[4:0]**: Division ratio for producing inter-frame gap timer clock

The bitfield determines the division ratio (the bitfield value minus one) of a ucpd\_clk divider producing inter-frame gap timer clock (\( t\_\text{InterFrameGap} \)).

- 0x00: Not supported
- 0x01: 2
- 0x0D: 14
- 0x0E: 15
- 0x0F: 16
- 0x1F: 32

The division ratio 15 is to apply for Tx clock at the USB PD 2.0 specification nominal value. The division ratios below 15 are to apply for Tx clock below nominal, and the division ratios above 15 for Tx clock above nominal.

Bits 5:0 **HBITCLKDIV[5:0]**: Division ratio for producing half-bit clock

The bitfield determines the division ratio (the bitfield value plus one) of a ucpd\_clk divider producing half-bit clock (hbit\_clk).

- 0x00: 1 (bypass)
- 0x1A: 27
- 0x3F: 64
46.8.2 UCPD configuration register 2 (UCPD_CFGR2)

Address offset: 0x004

Reset value: 0x0000 0000

Configuration of the UCPD Rx signal filtering. Writing to this register is only effective when UCPD is disabled (UCPDEN = 0).

</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **WUPEN**: Wake-up from Stop mode enable

Setting the bit enables the UCPD_ASYNC_INT signal.
0: Disable
1: Enable

Bit 2 **FORCECLK**: Force ClkReq clock request

0: Do not force clock request
1: Force clock request

Bit 1 **RXFILT2N3**: BMC decoder Rx pre-filter sampling method

Number of consistent consecutive samples before confirming a new value.
0: 3 samples
1: 2 samples

Bit 0 **RXFILTDIS**: BMC decoder Rx pre-filter enable

0: Enable
1: Disable

The sampling clock is that of the receiver (that is, after pre-scaler).
46.8.3 UCPD control register (UCPD_CR)

Address offset: 0x00C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

<table>
<thead>
<tr>
<th>Bit 31:22</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

Bit 21 **CC2TCDIS**: CC2 Type-C detector disable
The bit disables the Type-C detector on the CC2 line.
0: Enable
1: Disable
When enabled, the Type-C detector for CC2 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 20 **CC1TCDIS**: CC1 Type-C detector disable
The bit disables the Type-C detector on the CC1 line.
0: Enable
1: Disable
When enabled, the Type-C detector for CC1 is configured through ANAMODE and ANASUBMODE[1:0].

Bit 19 Reserved, must be kept at reset value.

Bit 18 **RDCH**: Rdch condition drive
The bit drives Rdch condition on the CC line selected through the PHYCCSEL bit (thus associated with VCONN), by remaining set during the source-only UnattachedWait.SRC state, to respect the Type-C state. Refer to "USB Type-C ECN for Source VCONN Discharge". The CCENABLE[1:0] bitfield must be set accordingly, too.
0: No effect
1: Rdch condition drive

Bit 17 **FRSTX**: FRS Tx signaling enable.
Setting the bit enables FRS Tx signaling.
0: No effect
1: Enable
The bit is cleared by hardware after a delay respecting the USB Power Delivery specification Revision 3.1.
Bit 16 **FRSRXEN**: FRS event detection enable

Setting the bit enables FRS Rx event (FRSEVT) detection on the CC line selected through the PHYCCSEL bit.

- 0: Disable
- 1: Enable

Clear the bit when the device is attached to an FRS- incapable source/sink.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:10 **CCENABLE[1:0]**: CC line enable

- This bitfield enables CC1 and CC2 line analog PHYs (pull-ups and pull-downs) according to ANAMODE and ANASUBMODE[1:0] setting.
- 0x0: Disable both PHYs
- 0x1: Enable CC1 PHY
- 0x2: Enable CC2 PHY
- 0x3: Enable CC1 and CC2 PHY

A single line PHY can be enabled when, for example, the other line is driven by VCONN via an external VCONN switch. Enabling both PHYs is the normal usage for sink/source.

Bit 9 **ANAMODE**: Analog PHY operating mode

- 0: Source
- 1: Sink

The use of CC1 and CC2 depends on CCENABLE. Refer to Table 434: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield in conjunction with ANASUBMODE[1:0].

Bits 8:7 **ANASUBMODE[1:0]**: Analog PHY sub-mode

Refer to Table 434: Coding for ANAMODE, ANASUBMODE and link with TYPEC_VSTATE_CCx for the effect of this bitfield.

Bit 6 **PHYCCSEL**: CC1/CC2 line selector for USB Power Delivery signaling

- 0: Use CC1 IO for Power Delivery communication
- 1: Use CC2 IO for Power Delivery communication

The selection depends on the cable orientation as discovered at attach.

Bit 5 **PHYRXEN**: USB Power Delivery receiver enable

- 0: Disable
- 1: Enable

Both CC1 and CC2 receivers are disabled when the bit is cleared. Only the CC receiver selected via the PHYCCSEL bit is enabled when the bit is set.

Bit 4 **RXMODE**: Receiver mode

- Determines the mode of the receiver.
- 0: Normal receive mode
- 1: BIST receive mode (BIST test data mode)

When the bit is set, RXORDSET behaves normally, RXDR no longer receives bytes yet the CRC checking still proceeds as for a normal message. As this mode prevents reception of the header (containing MessageID), software has to auto-increment a received MessageID counter for inclusion in the GoodCRC acknowledge that must still be transmitted during this test.
46.8.4 UCPD interrupt mask register (UCPD_IMR)

Address offset: 0x010

Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

46.8.5 UCPD status register (UCPD_SR)

Address offset: 0x014
Reset value: 0x0000 0000

The flags (single-bit status bitfields) are associated with interrupt request. Interrupt is generated if enabled by the corresponding bit of the UCPD_IMR register.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **FRSEVT**: FRS detection event
The flag is cleared by setting the FRSEVT_CF bit.
0: No new event
1: New FRS receive event occurred

Bits 19:18 **TYPEC_VSTATE_CC2[1:0]**: CC2 line voltage level
The status bitfield indicates the voltage level on the CC2 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest
The voltage variation on the CC2 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bits 17:16 **TYPEC_VSTATE_CC1[1:0]**:
The status bitfield indicates the voltage level on the CC1 line in its steady state.
0x0: Lowest
0x1: Low
0x2: High
0x3: Highest
The voltage variation on the CC1 line during USB PD messages due to the BMC PHY modulation does not impact the bitfield value.

Bit 15 **TYPECEVT2**: Type-C voltage level event on CC2 line
The flag indicates a change of the **TYPEC_VSTATE_CC2[1:0]** bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECEVT2_CF bit.
0: No new event
1: A new Type-C event
Bit 14 **TYPECVEVT1**: Type-C voltage level event on CC1 line

The flag indicates a change of the TYPEC_VSTATE_CC1[1:0] bitfield value, which corresponds to a new Type-C event. It is cleared by setting the TYPECVEVT2CF bit.

0: No new event
1: A new Type-C event

Bit 13 **RXERR**: Receive message error

The flag indicates errors of the last Rx message declared (via RXMSGEND), such as incorrect CRC or truncated message (a line becoming static before EOP is met). It is asserted whenever the RXMSGEND flag is set.

0: No error detected
1: Error(s) detected

Bit 12 **RXMSGEND**: Rx message received

The flag indicates whether a message (except Hard Reset message) has been received, regardless the CRC value. The flag is cleared by setting the RXMSGENDCF bit.

0: No new Rx message received
1: A new Rx message received

The RXERR flag set when the RXMSGEND flag goes high indicates errors in the last-received message.

Bit 11 **RXOVR**: Rx data overflow detection

The flag indicates Rx data buffer overflow. It is cleared by setting the RXOVRCF bit.

0: No overflow
1: Overflow

The buffer overflow can occur if the received data are not read fast enough.

Bit 10 **RXHRSTDET**: Rx Hard Reset receipt detection

The flag indicates the receipt of valid Hard Reset message. It is cleared by setting the RXHRSTDETCF bit.

0: Hard Reset not received
1: Hard Reset received

Bit 9 **RXORDDET**: Rx ordered set (4 K-codes) detection

The flag indicates the detection of an ordered set. The relevant information is stored in the RXORDSET[2:0] bitfield of the UCPD_RX_ORDSET register. It is cleared by setting the RXORDDETCF bit.

0: No ordered set detected
1: A new ordered set detected

Bit 8 **RXNE**: Receive data register not empty detection

The flag indicates that the UCPD_RXDR register is not empty. It is automatically cleared upon reading UCPD_RXDR.

0: Rx data register empty
1: Rx data register not empty

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TXUND**: Tx data underrun detection

The flag indicates that the Tx data register (UCPD_TXDR) was not written in time for a transmit message to execute normally. It is cleared by setting the TXUNDCF bit.

0: No Tx data underrun detected
1: Tx data underrun detected
Bit 5  **HRSTSENT**: Hard Reset message sent
The flag indicates that the Hard Reset message is sent. The flag is cleared by setting the HRSTSENTCF bit.
0: No Hard Reset message sent
1: Hard Reset message sent

Bit 4  **HRSTDISC**: Hard Reset discarded
The flag indicates that the Hard Reset message is discarded. The flag is cleared by setting the HRSTDISCCF bit.
0: No Hard Reset discarded
1: Hard Reset discarded

Bit 3  **TXMSGABT**: Transmit message abort
The flag indicates that a Tx message is aborted due to a subsequent Hard Reset message send request taking priority during transmit. It is cleared by setting the TXMSGABTCF bit.
0: No transmit message abort
1: Transmit message abort

Bit 2  **TXMSGSENT**: Message transmission completed
The flag indicates the completion of packet transmission. It is cleared by setting the TXMSGSENTCF bit.
0: No Tx message completed
1: Tx message completed
In the event of a message transmission interrupted by a Hard Reset, the flag is not raised.

Bit 1  **TXMSGDISC**: Message transmission discarded
The flag indicates that a message transmission was dropped. The flag is cleared by setting the TXMSGDISCCF bit.
0: No Tx message discarded
1: Tx message discarded
Transmission of a message can be dropped if there is a concurrent receive in progress or at excessive noise on the line. After a Tx message is discarded, the flag is only raised when the CC line becomes idle.

Bit 0  **TXIS**: Transmit interrupt status
The flag indicates that the UCPD_TXDR register is empty and new data write is required (as the amount of data sent has not reached the payload size defined in the TXPAYSZ bitfield). The flag is cleared with the data write into the UCPD_TXDR register.
0: New Tx data write not required
1: New Tx data write required
### 46.8.6 UCPD interrupt clear register (UCPD_ICR)

Address offset: 0x018

Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

Bit 3 **TXMSGABTCF**: Tx message abort flag (TXMSGABT) clear
Setting the bit clears the TXMSGABT flag in the UCPD_SR register.

Bit 2 **TXMSGSENTCF**: Tx message send flag (TXMSGSENT) clear
Setting the bit clears the TXMSGSENT flag in the UCPD_SR register.

Bit 1 **TXMSGDISCCF**: Tx message discard flag (TXMSGDISC) clear
Setting the bit clears the TXMSGDISC flag in the UCPD_SR register.

Bit 0 Reserved, must be kept at reset value.

### 46.8.7 UCPD Tx ordered set type register (UCPD_TX_ORDSETR)

Address offset: 0x01C
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1) and no packet transmission is in progress (TXSEND and TXHRST bits are both low).

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **TXORDSET[19:0]**: Ordered set to transmit
The bitfield determines a full 20-bit sequence to transmit, consisting of four K-codes, each of five bits, defining the packet to transmit. The bit 0 (bit 0 of K-code1) is the first, the bit 19 (bit 4 of K-code4) the last.

### 46.8.8 UCPD Tx payload size register (UCPD_TX_PAYSZR)

Address offset: 0x020
Reset value: 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

</tr>
</tbody>
</table>

Bits 31:10 Reserved, must be kept at reset value.
Bits 9:0 **TXPAYSZ[9:0]**: Payload size yet to transmit

The bitfield is modified by software and by hardware. It contains the number of bytes of a payload (including header but excluding CRC) yet to transmit: each time a data byte is written into the UCPD_TXDR register, the bitfield value decrements and the TXIS bit is set, except when the bitfield value reaches zero. The enumerated values are standard payload sizes before the start of transmission.

- 0x2: 2 bytes - the size of Control message from the protocol layer
- 0x6: 6 bytes - the shortest Data message allowed from the protocol layer
- 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
- 0x106: 262 bytes - the longest possible extended message
- 0x3FF: 1024 bytes - the longest possible payload (for future expansion)

### 46.8.9 UCPD Tx data register (UCPD_TXDR)

**Address offset:** 0x024  
**Reset value:** 0x0000 0000

Writing to this register is only effective when the peripheral is enabled (UCPDEN = 1).

</table>

Bits 31:10 Reserved, must be kept at reset value.

**Bits 9:0 RXPAYSZ[9:0]: Rx payload size received**

This bitfield contains the number of bytes of a payload (including header but excluding CRC) received: each time a new data byte is received in the UCPD_RXDR register, the bitfield value increments and the RXMSGEND flag is set (and an interrupt generated if enabled).

- 0x2: 2 bytes - the size of Control message from the protocol layer
- 0x6: 6 bytes - the shortest Data message allowed from the protocol layer
- 0x1E: 30 bytes - the longest non-extended Data message allowed from the protocol layer
- 0x106: 262 bytes - the longest possible extended message
- 0x3FF: 1024 bytes - the longest possible payload (for future expansion)

The bitfield may return a spurious value when a byte reception is ongoing (the RXMSGEND flag is low).

Refer to Section 2.2 on page 81 for the register boundary addresses.
47 Debug support (DBG)

47.1 Overview

The STM32G4 series devices are built around a Cortex®-M4 with FPU core which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint). When stopped, the core’s internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32G4 series MCUs.

Two interfaces for debug are available:
- Serial wire
- JTAG debug port

![Figure 685. Block diagram of STM32 MCU and Cortex®-M4 with FPU-level debug support](image)

**Note:** The debug features embedded in the Cortex®-M4 with FPU core are a subset of the Arm® CoreSight Design Kit.
The Arm® Cortex®-M4 with FPU core provides integrated on-chip debug support. It is comprised of:
- SWJ-DP: Serial wire / JTAG debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchdog trigger
- TPU: Trace port unit interface (available on larger packages, where the corresponding pins are mapped)
- ETM: Embedded Trace Macrocell (available only on STM32G4 series devices larger packages, where the corresponding pins are mapped)

It also includes debug features dedicated to the STM32G4 series:
- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

**Note:** For further information on debug functionality supported by the Arm® Cortex®-M4 with FPU core, refer to the Cortex®-M4 with FPU r0p1 Technical Reference Manual and to the CoreSight Design Kit r0p1 TRM (see Section 47.2: Reference Arm® documentation).

### 47.2 Reference Arm® documentation
- Arm® Debug Interface V5
- Arm® CoreSight Design Kit revision r0p1 Technical Reference Manual

### 47.3 SWJ debug port (serial wire and JTAG)

The STM32G4 series core integrates the Serial Wire / JTAG Debug Port (SWJ-DP). It is an Arm® standard CoreSight debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.
- The JTAG Debug Port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port.
- The Serial Wire Debug Port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port.

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.
47.3.1 **Mechanism to select the JTAG-DP or the SW-DP**

By default, the JTAG-Debug Port is active.

If the debugger host wants to switch to the SW-DP, it must provide a dedicated JTAG sequence on TMS/TCK (respectively mapped to SWDIO and SWCLK) which disables the JTAG-DP and enables the SW-DP. This way it is possible to activate the SWDP using only the SWCLK and SWDIO pins.

This sequence is:

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111100111100111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

47.4 **Pinout and debug port pins**

The STM32G4 series MCUs are available in various packages with different numbers of available pins. As a result, some functionalities (ETM) related to pin availability may differ between packages.
47.4.1 SWJ debug port pins

Five pins are used as outputs from the STM32G4 series for the SWJ-DP as alternate functions of general-purpose I/Os. These pins are available on all packages.

<table>
<thead>
<tr>
<th>Table 439. SWJ debug port pins</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>JTCK/SWCLK</td>
</tr>
<tr>
<td>JTDI</td>
</tr>
<tr>
<td>JTDI/TRACE SWO</td>
</tr>
<tr>
<td>NJTRST</td>
</tr>
</tbody>
</table>

47.4.2 Flexible SWJ-DP pin assignment

After RESET (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32G4 series MCUs offer the possibility of disabling some or all of the SWJ-DP ports, and therefore the possibility of releasing (in gray in the table below) the associated pins for general-purpose I/O (GPIO) usage, except for NJTRST that can be left disconnected but cannot be used as general purpose GPIO without losing debugger connection. For more details on how to disable SWJ-DP port pins, please refer to Section 9.3.2: I/O pin alternate function multiplexer and mapping.

</tbody>
</table>
47.4.3 Internal pull-up and pull-down on JTAG pins

It is necessary to ensure that the JTAG input pins are not floating since they are directly connected to flip-flops to control the debug mode features. Special care must be taken with the SWCLK/TCK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled IO levels, the device embeds internal pull-ups and pull-downs on the JTAG input pins:

- NJTRST: internal pull-up
- JTDI: internal pull-up
- JTMS/SWDIO: internal pull-up
- TCK/SWCLK: internal pull-down

Once a JTAG IO is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the I/Os in the equivalent state:

- NJTRST: input pull-up
- JTDI: input pull-up
- JTMS/SWDIO: input pull-up
- JTCK/SWCLK: input pull-down
- JTDO: input floating

The software can then use these I/Os as standard GPIOs.

Note: The JTAG IEEE standard recommends to add pull-ups on TDI, TMS and nTRST but there is no special recommendation for TCK. However, for JTCK, the device needs an integrated pull-down.

Having embedded pull-ups and pull-downs removes the need to add external resistors.

The NJTRST (PB4) pin has also UCPD_CC2 functionality which implements internal UCPD pull-down resistor (5.1 KΩ) which is controlled by voltage on UCPD_DBCC2 pin (PA10). In order to use the JTAG, the pull down effect on the CC lines must be removed by using the UCPD1_DBDIS bit (USB Type-C and power delivery dead battery disable) in the PWR_CR3 register (see Section 46.4.6: UCPD Type-C pull-ups (Rp) and pull-downs (Rd)).
47.4.4 Using serial wire and releasing the unused debug pins as GPIOs

To use the serial wire DP to release some GPIOs, the user software must change the GPIO (PA15, PB3 and PB4) configuration mode in the GPIO_MODER register. This releases PA15, PB3 and PB4 which now become available as GPIOs.

When debugging, the host performs the following actions:

- Under system reset, all SWJ pins are assigned (JTAG-DP + SW-DP).
- Under system reset, the debugger host sends the JTAG sequence to switch from the JTAG-DP to the SW-DP.
- Still under system reset, the debugger sets a breakpoint on vector reset.
- The system reset is released and the Core halts.
- All the debug communications from this point are done using the SW-DP. The other JTAG pins can then be reassigned as GPIOs by the user software.

Note: For user software designs, note that:

To release the debug pins, remember that they are first configured either in input-pull-up (nTRST, TMS, TDI) or pull-down (TCK) or output tristate (TDO) for a certain duration after reset until the instant when the user software releases the pins.

When debug pins (JTAG or SW or TRACE) are mapped, changing the corresponding IO pin configuration in the IOPORT controller has no effect.

47.5 STM32G4 series JTAG TAP connection

The STM32G4 series MCUs integrate two serially connected JTAG TAPs, the boundary scan TAP (IR is 5-bit wide) and the Cortex®-M4 with FPU TAP (IR is 4-bit wide).

To access the TAP of the Cortex®-M4 with FPU for debug purposes:

1. First, it is necessary to shift the BYPASS instruction of the boundary scan TAP.
2. Then, for each IR shift, the scan chain contains 9 bits (=5+4) and the unused TAP instruction must be shifted by using the BYPASS instruction.
3. For each data shift, the unused TAP, which is in BYPASS mode, adds 1 extra data bit in the data scan chain.

Note: Important: Once Serial-Wire is selected using the dedicated Arm® JTAG sequence, the boundary scan TAP is automatically disabled (JTMS forced high).
47.6 ID codes and locking mechanism

There are several ID codes inside the STM32G4 series MCUs. ST strongly recommends tools designers to lock their debuggers using the MCU DEVICE ID code located in the external PPB memory map at address 0xE0042000.
### 47.6.1 MCU device ID code

The STM32G4 series MCUs integrate an MCU ID code. This ID identifies the ST MCU part-number and the die revision. It is part of the DBG_MCU component and is mapped on the external PPB bus (see Section 47.16 on page 2106). This code is accessible using the JTAG debug port (4 to 5 pins) or the SW debug port (two pins) or by the user software. It is even accessible while the MCU is under system reset.

Only the DEV_ID(11:0) should be used for identification by the debugger/programmer tools.

**DBGMCU_IDCODE**

Address: 0xE004 2000

Only 32-bits access supported. Read-only

#### REV_ID[15:0]

This field indicates the revision of the device.

- 0x1000: Revision A
- 0x1001: Revision Z (Category 4 devices only)
- 0x2000: Revision B
- 0x2001: Revision Z
- 0x2002: Revision Y
- 0x2003: Revision X

Bits 15:12 Reserved, must be kept at reset value.

#### DEV_ID[11:0]

The device ID is:

- 0x468: Category 2 devices (See Table 1: STM32G4 series memory density)
- 0x469: Category 3 devices (See Table 1: STM32G4 series memory density)
- 0x479: Category 4 devices (See Table 1: STM32G4 series memory density)

### 47.6.2 Boundary scan TAP

#### JTAG ID code

The TAP of the STM32G4 series BSC (boundary scan) integrates a JTAG ID code equal to 16469041 (category 3 devices), 16468041 (category 2 devices), 16479041 (category 4 devices).

### 47.6.3 Cortex®-M4 with FPU TAP

#### JTAG ID code

The TAP of the Arm® Cortex®-M4 with FPU integrates a JTAG ID code. This ID code is the Arm® default one and has not been modified. This code is only accessible by the JTAG Debug Port.
This code is \texttt{0x4BA00477} (corresponds to Cortex®-M4 with FPU r0p1, see \textit{Section 47.2: Reference Arm® documentation}).

\subsection*{47.6.4 Cortex®-M4 with FPU JEDEC-106 ID code}

The Arm® Cortex®-M4 with FPU integrates a JEDEC-106 ID code. It is located in the 4KB ROM table mapped on the internal PPB bus at address 0xE00FF000_0xE00FFFFF.

This code is accessible by the JTAG Debug Port (4 to 5 pins) or by the SW Debug Port (two pins) or by the user software.

\subsection*{47.7 JTAG debug port}

A standard JTAG state machine is implemented with a 4-bit instruction register (IR) and five data registers (for full details, refer to the Cortex®-M4 with FPU with FPU r0p1 Technical Reference Manual (TRM), for references, please see \textit{Section 47.2: Reference Arm® documentation}).

- Debug port access register
  - This initiates a debug port and allows access to a debug port register.
  - When transferring data IN:
    - Bits 34:3 = DATA[31:0] = 32-bit data to transfer for a write request
    - Bit 0 = RnW = Read request (1) or write request (0).
  - When transferring data OUT:
    - Bits 34:3 = DATA[31:0] = 32-bit data which is read following a read request
    - Bits 2:0 = ACK[2:0] = 3-bit Acknowledge:
      - 010 = OK/FAULT
      - 001 = WAIT
      - OTHER = reserved
  - Refer to \textit{Table 442} for a description of the A(3:2) bits
### Access port access register

Initiates an access port and allows access to an access port register.

- **When transferring data IN:**
  - Bits 34:3 = DATA[31:0] = 32-bit data to shift in for a write request
  - Bits 2:1 = A[3:2] = 2-bit address (sub-address AP registers).
  - Bit 0 = RnW= Read request (1) or write request (0).

- **When transferring data OUT:**
  - Bits 34:3 = DATA[31:0] = 32-bit data which is read following a read request
  - Bits 2:0 = ACK[2:0] = 3-bit Acknowledge:
    - 010 = OK/FAULT
    - 001 = WAIT
    - OTHER = reserved

There are many AP Registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

### Abort register

- Bits 31:1 = Reserved
- Bit 0 = DAPABORT: write 1 to generate a DAP abort.

47.8 SW debug port

47.8.1 SW protocol introduction

This synchronous serial protocol uses two pins:
- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 kΩ recommended by Arm®).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

47.8.2 SW protocol sequence

Each sequence consist of three phases:
1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

Refer to the Cortex®-M4 with FPU r0p1 TRM for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.

47.8.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default Arm® one and is set to 0x2BA01477 (corresponding to Cortex®-M4 with FPU r0p1).

Note: Note that the SW-DP state machine is in active until the target reads this ID code.

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles.
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is mandatory to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the target issues a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the Cortex®-M4 with FPU r0p1 TRM and the CoreSight Design Kit r0p1 TRM.

47.8.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result. The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is “WAIT”. With the exception of
IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.

- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state).
  This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it fails.

### 47.8.5 SW-DP registers

Access to these registers are initiated when APnDP=0

<table>

</table>
47.8.6 **SW-AP registers**

Access to these registers are initiated when APnDP=1.

There are many AP Registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

47.9 **AHB-AP (AHB access port) - valid for both JTAG-DP and SW-DP**

**Features:**

- System access is independent of the processor status.
- Either SW-DP or JTAG-DP accesses AHB-AP.
- The AHB-AP is an AHB master into the Bus Matrix. Consequently, it can access all the data buses (Dcode Bus, System Bus, internal and external PPB bus) but the ICode bus.
- Bitband transactions are supported.
- AHB-AP transactions bypass the FPB.

The address of the 32-bits AHP-AP resisters are 6-bits wide (up to 64 words or 256 bytes) and consists of:

- Bits [3:2] = the 2 address bits of A(3:2) of the 35-bit packet request for SW-DP.

The AHB-AP of the Cortex®-M4 with FPU includes 9 x 32-bits registers:

<table>

Refer to the *Cortex®-M4 with FPU r0p1 TRM* for further details.
47.10 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the Advanced High-performance Bus (AHB-AP) port. The processor can access these registers directly over the internal Private Peripheral Bus (PPB).

It consists of 4 registers:

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCSR</td>
<td>The 32-bit Debug Halting Control and Status Register:</td>
</tr>
<tr>
<td></td>
<td>This provides status information about the state of the processor enable core debug halt and step the processor.</td>
</tr>
<tr>
<td>DCRSR</td>
<td>The 17-bit Debug Core Register Selector Register:</td>
</tr>
<tr>
<td></td>
<td>This selects the processor register to transfer data to or from.</td>
</tr>
<tr>
<td>DCRDR</td>
<td>The 32-bit Debug Core Register Data Register:</td>
</tr>
<tr>
<td></td>
<td>This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.</td>
</tr>
<tr>
<td>DEMCR</td>
<td>The 32-bit Debug Exception and Monitor Control Register:</td>
</tr>
<tr>
<td></td>
<td>This provides Vector Catching and Debug Monitor Control. This register contains a bit named TRCENA which enable the use of a TRACE.</td>
</tr>
</tbody>
</table>

Note: Important: these registers are not reset by a system reset. They are only reset by a power-on reset.

Refer to the Cortex®-M4 with FPU r0p1 TRM for further details.

To Halt on reset, it is necessary to:
- enable the bit0 (VC_CORRESET) of the Debug and Exception Monitor Control Register
- enable the bit0 (C_DEBUGEN) of the Debug Halting Control and Status Register.

47.11 Capability of the debugger host to connect under system reset

The STM32G4 series MCUs' reset system comprises the following reset sources:
- POR (power-on reset) which asserts a RESET at each power-up
- Internal watchdog reset
- Software reset
- External reset.

The Cortex®-M4 with FPU differentiates the reset of the debug part (generally PORRESEItn) and the other one (SYSRESEItn).

This way, it is possible for the debugger to connect under System Reset, programming the Core Debug Registers to halt the core when fetching the reset vector. Then the host can release the system reset and the core immediately halts without having executed any instructions. In addition, it is possible to program any debug features under System Reset.
Note:  It is highly recommended for the debugger host to connect (set a breakpoint in the reset vector) under system reset.

47.12 FPB (Flash patch breakpoint)

The FPB unit:
• implements hardware breakpoints
• patches code and data from code space to system space. This feature gives the possibility to correct software bugs located in the Code Memory Space.

The use of a Software Patch or a Hardware Breakpoint is exclusive.

The FPB consists of:
• 2 literal comparators for matching against literal loads from Code Space and remapping to a corresponding area in the System Space
• 6 instruction comparators for matching against instruction fetches from Code Space. They can be used either to remap to a corresponding area in the System Space or to generate a Breakpoint Instruction to the core.

47.13 DWT (data watchpoint trigger)

The DWT unit consists of four comparators. They are configurable as:
• a hardware watchpoint or
• a trigger to an ETM or
• a PC sampler or
• a data address sampler

The DWT also provides some means to give some profiling informations. For this, some counters are accessible to give the number of:
• Clock cycle
• Folded instructions
• Load store unit (LSU) operations
• Sleep cycles
• CPI (clock per instructions)
• Interrupt overhead
47.14 ITM (instrumentation trace macrocell)

47.14.1 General description

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated as:

- **Software trace.** Software can write directly to the ITM stimulus registers to emit packets.
- ** Hardware trace.** The DWT generates these packets, and the ITM emits them.
- **Time stamping.** Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex®-M4 with FPU clock or the bit clock rate of the Serial Wire Viewer (SWV) output clocks the counter.

The packets emitted by the ITM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to TPIU) and then output the complete packets sequence to the debugger host.

The bit TRCEN of the Debug Exception and Monitor Control Register must be enabled before you program or use the ITM.

47.14.2 Time stamp packets, synchronization and overflow packets

Time stamp packets encode time stamp information, generic control and synchronization. It uses a 21-bit timestamp counter (with possible prescalers) which is reset at each time stamp packet emission. This counter can be either clocked by the CPU clock or the SWV clock.

A synchronization packet consists of 6 bytes equal to 0x80_00_00_00_00_00 which is emitted to the TPIU as 00 00 00 00 00 80 (LSB emitted first).

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger.

For this, the DWT must be configured to trigger the ITM: the bit CYCCNTENA (bit0) of the DWT Control Register must be set. In addition, the bit2 (SYNCENA) of the ITM Trace Control Register must be set.

*Note:* If the SYNENA bit is not set, the DWT generates Synchronization triggers to the TPIU which sends only TPIU synchronization packets and not ITM synchronization packets.

An overflow packet consists is a special timestamp packets which indicates that data has been written but the FIFO was full.
Example of configuration

To output a simple value to the TPIU:

- Configure the TPIU and assign TRACE I/Os by configuring the DBGMCU_CR (refer to Section 47.17.2: TRACE pin assignment and Section 47.16.3: Debug MCU configuration register (DBGMCU_CR))
- Write 0xC5ACCE55 to the ITM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00010005 to the ITM Trace Control Register to enable the ITM with Synchronous enabled and an ATB ID different from 0x00
- Write 0x1 to the ITM Trace Enable Register to enable the Stimulus Port 0
- Write 0x1 to the ITM Trace Privilege Register to unmask Stimulus Ports 7:0
- Write the value to output in the Stimulus Port Register 0: this can be done by software (using a printf function)
47.15 ETM (Embedded Trace Macrocell™)

47.15.1 General description

The ETM enables the reconstruction of program execution. Data are traced using the Data Watchpoint and Trace (DWT) component or the Instruction Trace Macrocell (ITM) whereas instructions are traced using the Embedded Trace Macrocell (ETM).

The ETM transmits information as packets and is triggered by embedded resources. These resources must be programmed independently and the trigger source is selected using the Trigger Event Register (0xE0041008). An event could be a simple event (address match from an address comparator) or a logic equation between 2 events. The trigger source is one of the four comparators of the DWT module, The following events can be monitored:

- Clock cycle matching
- Data address matching

For more informations on the trigger resources refer to Section 47.13: DWT (data watchpoint trigger).

The packets transmitted by the ETM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to Section 47.17: TPIU (trace port interface unit)) and then outputs the complete packet sequence to the debugger host.

47.15.2 Signal protocol, packet types

This part is described in the section 7 ETMv3 Signal Protocol of the Arm® IHI 0014N document.

47.15.3 Main ETM registers

For more information on registers refer to the chapter 3 of the Arm® IHI 0014N specification.

<table>

</tr>
</tbody>
</table>
47.15.4 Configuration example

To output a simple value to the TPIU:

- Configure the TPIU and enable the I/O_TRACEN to assign TRACE I/Os in the STM32G4 series debug configuration register
- Write 0xC5ACCE55 to the ETM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00001D1E to the control register (configure the trace)
- Write 0000406F to the Trigger Event register (define the trigger event)
- Write 0000006F to the Trace Enable Event register (define an event to start/stop)
- Write 0000191E to the ETM Control Register (end of configuration)

47.16 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog, \( \text{I}^2\text{C} \) and bxCAN during a breakpoint
- Control of the trace pins assignment

47.16.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG_SLEEP bit of DBGMCU_CR register must be previously set by the debugger. This feeds HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG_STOP must be previously set by the debugger. This enables the internal RC oscillator clock to feed FCLK and HCLK in Stop mode.
- In Standby mode, the bit DBG_STANDBY must be previously set by the debugger. This keeps the regulators on, and enable the internal RC oscillator clock to feed FCLK and HCLK in Standby mode. A system reset is generated internally so that exiting from Standby is identical than fetching from reset.

The DBGMCU_CR register can be written by the debugger under system reset. If the debugger host does not support these features, it is still possible to write this register by software.
47.16.2 Debug support for timers, RTC, watchdog and I²C

During a breakpoint, it is necessary to choose how the counter of timers, RTC and watchdog should behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the I²C, the user can choose to block the SMBUS timeout during a breakpoint.

The DBGMCU freeze registers can be written by the debugger under system reset. If the debugger host does not support these features, it is still possible to write these registers by software.

47.16.3 Debug MCU configuration register (DBGMCU_CR)

Address: 0xE004 2004
Power-on reset: 0x0000 0000
System reset: not affected
Access: Only 32-bit access supported

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:5  TRACE_MODE[1:0] and TRACE_IOEN: Trace pin assignment control

- With TRACE_IOEN=0:
  - TRACE_MODE=xx: TRACE pins not assigned (default state)
- With TRACE_IOEN=1:
  - TRACE_MODE=00: TRACE pin assignment for Asynchronous Mode
  - TRACE_MODE=01: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 1
  - TRACE_MODE=10: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 2
  - TRACE_MODE=11: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 4

Bits 4:3  Reserved, must be kept at reset value.
Bit 2 **DBG_STANDBY**: Debug Standby mode
0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.
From software point of view, exiting from Standby is identical than fetching reset vector
(except a few status bit indicated that the MCU is resuming from Standby)
1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and
HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU
generate a system reset during Standby mode so that exiting from Standby is identical than
fetching from reset.

Bit 1 **DBG_STOP**: Debug Stop mode
0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including
HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the
one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI16)). Consequently,
the software must reprogram the clock controller to enable the PLL, the Xtal, etc.
1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are
provided by the internal RC oscillator which remains active in STOP mode. When exiting
STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal,
etc. (in the same way it would do in case of DBG_STOP=0)

Bit 0 **DBG_SLEEP**: Debug Sleep mode
0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as
previously configured by the software while HCLK is disabled.
In Sleep mode, the clock controller configuration is not reset and remains in the previously
programmed state. Consequently, when exiting from Sleep mode, the software does not
need to reconfigure the clock controller.
1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same
clock that is provided to FCLK (system clock as previously configured by the software).

Bits 10:0  Reserved, must be kept at reset value.
47.17 TPIU (trace port interface unit)

47.17.1 Introduction

The TPIU acts as a bridge between the on-chip trace data from the ITM and the ETM. The output data stream encapsulates the trace source ID, that is then captured by a trace port analyzer (TPA).

The core embeds a simple TPIU, especially designed for low-cost debug (consisting of a special version of the CoreSight TPIU).

Figure 688. TPIU block diagram

47.17.2 TRACE pin assignment

- Asynchronous mode
  The asynchronous mode requires 1 extra pin and is available on all packages. It is only available if using Serial Wire mode (not in JTAG mode).

<table>
<thead>
<tr>
<th>TPUI pin name</th>
<th>Trace synchronous mode</th>
<th>STM32G4 series pin assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRACESWO</td>
<td>O</td>
<td>TRACE Asynchronous Data Output</td>
</tr>
</tbody>
</table>

- Synchronous mode
  The synchronous mode requires from 2 to 6 extra pins depending on the data trace size and is only available in the larger packages. In addition it is available in JTAG mode and in Serial Wire mode and provides better bandwidth output capabilities than asynchronous trace.
Table 452. Synchronous TRACE pin assignment

<table>
<thead>
<tr>
<th>TPUI pin name</th>
<th>Trace synchronous mode</th>
<th>STM32G4 series pin assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>TRACECK</td>
<td>O</td>
<td>TRACE Clock</td>
</tr>
<tr>
<td>TRACED[3:0]</td>
<td>O</td>
<td>TRACE Synchronous Data Outputs Can be 1, 2 or 4.</td>
</tr>
</tbody>
</table>

TPUI TRACE pin assignment

By default, these pins are NOT assigned. They can be assigned by setting the TRACE_IOEN and TRACE_MODE bits in the Debug MCU configuration register (DBGMCU_CR). This configuration has to be done by the debugger host.

In addition, the number of pins to assign depends on the trace configuration (asynchronous or synchronous).

- **Asynchronous mode**: 1 extra pin is needed
- **Synchronous mode**: from 2 to 5 extra pins are needed depending on the size of the data trace port register (1, 2 or 4):
  - TRACECK
  - TRACED(0) if port size is configured to 1, 2 or 4
  - TRACED(1) if port size is configured to 2 or 4
  - TRACED(2) if port size is configured to 4
  - TRACED(3) if port size is configured to 4

To assign the TRACE pin, the debugger host must program the bits TRACE_IOEN and TRACE_MODE[1:0] of the Debug MCU configuration register (DBGMCU_CR). By default the TRACE pins are not assigned.

This register is mapped on the external PPB and is reset by the PORESET (and not by the SYSTEM reset). It can be written by the debugger under SYSTEM reset.

Table 453. Flexible TRACE pin assignment

<table>
<thead>
<tr>
<th>DBGMCU_CR register</th>
<th>Pins assigned for:</th>
<th>TRACE IO pin assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>XX</td>
<td>Released (1)</td>
</tr>
<tr>
<td>1</td>
<td>00</td>
<td>Asynchronous Trace</td>
</tr>
</tbody>
</table>
Note: By default, the TRACECLKIN input clock of the TPIU is tied to GND. It is assigned to HCLK two clock cycles after the bit TRACE_IOEN has been set.

The debugger must then program the Trace Mode by writing the PROTOCOL[1:0] bits in the SPP_R (Selected Pin Protocol) register of the TPIU:

- PROTOCOL=00: Trace Port Mode (synchronous)
- PROTOCOL=01 or 10: Serial Wire (Manchester or NRZ) Mode (asynchronous mode).
  Default state is 01

It then also configures the TRACE port size by writing the bits [3:0] in the CPSPS_R (Current Synchronous Port Size Register) of the TPIU:

- 0x1 for 1 pin (default state)
- 0x2 for 2 pins
- 0x8 for 4 pins

### 47.17.3 TPUI formatter

The formatter protocol outputs data in 16-byte frames:

- seven bytes of data
- eight bytes of mixed-use bytes consisting of:
  - 1 bit (LSB) to indicate it is a DATA byte ('0) or an ID byte ('1).
  - 7 bits (MSB) which can be data or change of source ID trace.
- one byte of auxiliary bits where each bit corresponds to one of the eight mixed-use bytes:
  - if the corresponding byte was a data, this bit gives bit0 of the data.
  - if the corresponding byte was an ID change, this bit indicates when that ID change takes effect.

Note: Refer to the Arm® CoreSight Architecture Specification v1.0 (Arm IHI 0029B) for further information
47.17.4 TPUI frame synchronization packets

The TPUI can generate two types of synchronization packets:

- The Frame Synchronization packet (or Full Word Synchronization packet)
  It consists of the word: 0x7F_FF_FF_FF (LSB emitted first). This sequence can not occur at any other time provided that the ID source code 0x7F has not been used.
  It is output periodically between frames.
  In continuous mode, the TPA must discard all these frames once a synchronization frame has been found.
- The Half-Word Synchronization packet
  It consists of the half word: 0x7F_FF (LSB emitted first).
  It is output periodically between or within frames.
  These packets are only generated in continuous mode and enable the TPA to detect that the TRACE port is in IDLE mode (no TRACE to be captured). When detected by the TPA, it must be discarded.

47.17.5 Transmission of the synchronization frame packet

There is no Synchronization Counter register implemented in the TPIU of the core. Consequently, the synchronization trigger can only be generated by the DWT. Refer to the registers DWT Control Register (bits SYNCTAP[11:10]) and the DWT Current PC Sampler Cycle Count Register.

The TPUI Frame synchronization packet (0x7F_FF_FF_FF) is emitted:

- after each TPIU reset release. This reset is synchronously released with the rising edge of the TRACECLKIN clock. This means that this packet is transmitted when the TRACE IOEN bit in the DBGMCU_CFG register is set. In this case, the word 0x7F_FF_FF_FF is not followed by any formatted packet.
- at each DWT trigger (assuming DWT has been previously configured). Two cases occur:
  - If the bit SYNENA of the ITM is reset, only the word 0x7F_FF_FF_FF is emitted without any formatted stream which follows.
  - If the bit SYNENA of the ITM is set, then the ITM synchronization packets follow (0x80_00_00_00_00_00), formatted by the TPUI (trace source ID added).

47.17.6 Synchronous mode

The trace data output size can be configured to 4, 2 or 1 pin: TRACED(3:0)

The output clock is output to the debugger (TRACECK)

Here, TRACECLKIN is driven internally and is connected to HCLK only when TRACE is used.

Note: In this synchronous mode, it is not required to provide a stable clock frequency.

The TRACE I/Os (including TRACECK) are driven by the rising edge of TRACCLKIN (equal to HCLK). Consequently, the output frequency of TRACECK is equal to HCLK/2.
47.17.7 Asynchronous mode

This is a low cost alternative to output the trace using only 1 pin: this is the asynchronous output pin TRACESWO. Obviously there is a limited bandwidth.

TRACESWO is multiplexed with JTD0 when using the SW-DP pin. This way, this functionality is available in all STM32G4 series packages.

This asynchronous mode requires a constant frequency for TRACECLKIN. For the standard UART (NRZ) capture mechanism, 5% accuracy is needed. The Manchester encoded version is tolerant up to 10%.

47.17.8 TRACECLKIN connection inside the STM32G4 series

In the STM32G4 series, this TRACECLKIN input is internally connected to HCLK. This means that when in asynchronous trace mode, the application is restricted to use time frames where the CPU frequency is stable.

Note: Important: when using asynchronous trace: it is important to be aware that:

The default clock of the STM32G4 series MCUs is the internal RC oscillator. Its frequency under reset is different from the one after reset release. This is because the RC calibration is the default one under system reset and is updated at each system reset release.

Consequently, the trace port analyzer (TPA) should not enable the trace (with the TRACE_IOEN bit) under system reset, because a synchronization frame packet is issued with a different bit time than trace packets which are transmitted after reset release.
### 47.17.9 TPIU registers

The TPIU APB registers can be read and written only if the bit TRCENA of the Debug Exception and Monitor Control Register (DEMCR) is set. Otherwise, the registers are read as zero (the output of this bit enables the PCLK of the TPIU).

#### Table 454. Important TPIU registers

<table>
<thead>
<tr>

<td>Bit 1: Port size = 2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: Port size = 3, not supported</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3: Port Size = 4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Only 1 bit must be set. By default, the port size is one bit. (0x00000001)</td>
</tr>
<tr>
<td>0xE00400F0</td>
<td>Selected pin protocol</td>
<td>Allows the Trace Port Protocol to be selected:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit1:0 = 00: Synchronous Trace Port Mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>01: Serial Wire Output - manchester (default value)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10: Serial Wire Output - NRZ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>11: reserved</td>
</tr>
<tr>
<td>0xE0040300</td>
<td>Formatter and flush control</td>
<td>Bit 31-9 = always '0’</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 8 = TrigIn = always ‘1’ to indicate that triggers are indicated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 7-4 = always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3-2 = always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1 = EnFCont. In Synchronous Trace mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(Select_Pin_Protocol register bit1:0 = 00), this bit is forced to ‘1’:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the formatter is automatically enabled in continuous mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In asynchronous mode (Select_Pin_Protocol register bit1:0 &lt;&gt; 00), this bit</td>
</tr>
<tr>
<td></td>
<td></td>
<td>can be written to activate or not the formatter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 0 = always '0’</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The resulting default value is 0x102</td>
</tr>
</tbody>
</table>

**Note:** In synchronous mode, because the TRACECTL pin is not mapped outside the chip, the formatter is always enabled in continuous mode; this way the formatter inserts some control packets to identify the source of the trace packets.

<table>
<thead>
<tr>
<th>Address</th>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xE0040300</td>
<td>Formatter and flush status</td>
<td>Not used in Cortex®-M4 with FPU, always read as 0x00000008</td>
</tr>
</tbody>
</table>
47.17.10 Example of configuration

- Set the bit TRCENA in the Debug Exception and Monitor Control Register (DEMCR)
- Write the TPIU Current Port Size Register to the desired value (default is 0x1 for a 1-bit port size)
- Write TPIU Formatter and Flush Control Register to 0x102 (default value)
- Write the TPIU Select Pin Protocol to select the synchronous or asynchronous mode. Example: 0x2 for asynchronous NRZ mode (UART like)
- Write the DBGMCU control register to 0x20 (bit IO_TRACEN) to assign TRACE I/Os for asynchronous mode. A TPIU Synchronous packet is emitted at this time (FF_FF_FF_7F)
- Configure the ITM and write the ITM Stimulus register to output a value

1. The reset value is product dependent. For more information, refer to Section 47.6.1: MCU device ID code.
Device electronic signature

The device electronic signature is stored in the System memory area of the Flash memory module, and can be read using the debug interface or by the CPU. It contains factory-programmed identification and calibration data that allow the user firmware or other external devices to automatically match to the characteristics of the STM32G4 series microcontroller.

48.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as part of the security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits cannot be altered by the user.

Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.

- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.

- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.

- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.

- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

|            |          | Peripherals interconnect matrix section:  
|            |          | – Updated Table 60: STM32G4 series peripherals interconnect matrix  
| 26-Mar-2020| 3        |
DMA request multiplexer (DMAMUX) section:
- Updated Section 13.3.2: DMAMUX mapping;

Analog digital converter section:
Updated:
- Section 21.2: ADC main features.
- Figure 83: ADC clock scheme.
- Figure 86: ADC3 connectivity.
- Section 21.4.7: Single-ended and differential input channels.

Comparator section:
Updated Figure 168: Comparator block diagram.

Operational amplifier section:
Updated:
- Table 201: Operational amplifier possible connection.
- Section 25.3.7: Calibration procedure.
- Section 25.3.8: Timer controlled Multiplexer mode procedure.
- Section 25.5.1: OPAMP1 control/status register (OPAMP1_CSR).
- Section 25.5.2: OPAMP2 control/status register (OPAMP2_CSR).
- Section 25.5.3: OPAMP3 control/status register (OPAMP3_CSR).
- Section 25.5.4: OPAMP4 control/status register (OPAMP4_CSR).
- Section 25.5.5: OPAMP5 control/status register (OPAMP5_CSR).
- Section 25.5.6: OPAMP6 control/status register (OPAMP6_CSR).

FD controller area network section:
Updated Section 44.4.7: FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) note.

Debug support section:
Updated:
- Section 47.4.3: Internal pull-up and pull-down on JTAG pins.
- Section 47.6.1: MCU device ID code.
- Section 47.6.2: Boundary scan TAP.

Device electronic signature section:
- Added Section 48.3: Package data register.

</table>
| 12-Feb-2024| 8        | Updated Section 2.2.2: Memory map and register boundary addresses, Section 3.5.1: Read protection (RDP), Section 5.7.6: Flash control register (FLASH_CR), Section 7.4.1: Clock control register (RCC_CR), Section 7.4.20: AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR), Section 9.3: GPIO functional description, Section 8.7.1: CRS control register (CRS_CR), Section 12.2: DMA main features, Section 21.4.10: Constraints when writing the ADC control bits, Section 21.7.16: ADC injected sequence register (ADC_JSQR), Section 24.5: COMP interrupts, Section 27.2: Main features, Section 27.3.17: Fault protection, Section 29.5.10: TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 2 to 5), Section 30.7.3: TIM15 slave mode control register (TIM15_SMCR), Section 35.3.4: Clock and prescalers, note in sections 35.6.18 and 35.6.19, Section 38.4.2: LPUART signals, Section 39.3: I2S main features, Section 39.7.1: I2S general description, Power-down (Sleep mode), Rx handling, Standard message ID filtering, Extended message ID filtering, and Section 44.3.4: FIFO acknowledge handling.  
Updated User and read protection option bytes in sections 3, 4, and 5.  
Reorganized description of registers in Section 27: High-resolution timer (HRTIM) and in Section 40: Serial audio interface (SAI).  
Updated Table 11: Option byte organization, Table 31: Option byte organization, Table 51: RCC register map and reset values, Table 53: Effect of low-power modes on CRS, Table 97: STM32G4 series vector table, tables 163 to 166, Table 195: VREFBUF register map and reset values, tables in Section 27.3.2: HRTIM pins and internal signals, Table 245: HRTIM register map and reset values – common functions, Table 402: CAN subsystem I/O signals, Table 418: Bulk double-buffering memory buffers usage, and Table 435: Type-C sequence (source: 3A); cable/sink connected (Rd on CC1; Ra on CC2).  
Added footnote to Table 5: Boot modes.  
Added Table 346: USART/UART input/output pins, Table 347: USART internal input/output signals, Table 356: LPUART input/output pins, and Table 357: LPUART internal input/output signals.  
Updated figures in Section 20: Quad-SPI interface (QUADSPI), Figure 83: ADC clock scheme, figures 99 to 104, Figure 156: Dual-channel DAC block diagram, Figure 171: Standalone mode: external gain setting mode, Figure 217: Latency to external events (counter reset and output set), Figure 218: Latency to external events (output reset on external event), Figure 358: General-purpose timer block diagram, Figure 558: LPUART block diagram, Figure 639: Transfer bus diagrams for I2C slave transmitter (mandatory events only), Figure 642: Transfer bus diagrams for I2C slave receiver (mandatory events only), Figure 649: Transfer bus diagrams for I2C master transmitter (mandatory events only), Figure 652: Transfer bus diagrams for I2C master receiver (mandatory events only), Figure 660: Independent watchdog block diagram, and Figure 663: CAN subsystem.  
Added Section 49: Important security notice.  
Minor text edits across the whole document.
