Introduction

This document is addressed to application developers. It provides complete information on how to use the STM32G4 series microcontroller memory and peripherals. These devices come with different memory sizes, packages and peripherals, and include ST state-of-the-art patented technology.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-M4 core, refer to the Cortex®-M4 Technical Reference Manual.

1.1 General information

The STM32G4 series devices have an Arm®(a) Cortex®-M4 with FPU core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

- **read/write (rw)** Software can read and write to this bit.
- **read-only (r)** Software can only read this bit.
- **write-only (w)** Software can only write to this bit. Reading this bit returns the reset value.
- **read/clear write0 (rc_w0)** Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
- **read/clear write1 (rc_w1)** Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
- **read/clear write (rc_w)** Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
- **read/clear by read (rc_r)** Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
- **read/set by read (rs_r)** Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
- **read/set (rs)** Software can read as well as set this bit. Writing 0 has no effect on the bit value.
- **read/write once (rwo)** Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
- **toggle (t)** The software can toggle this bit by writing 1. Writing 0 has no effect.
- **read-only write trigger (rt_w1)** Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
- **Reserved (Res.)** Reserved bit, must be kept at reset value.

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **IAP (in-application programming)**: IAP is the ability to re-program the flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the flash memory.
- **AHB**: advanced high-performance bus.

1.4 Product category definition

*Table 1* gives an overview of memory density versus product line.

The present reference manual describes the superset of features for each product category. Refer to *Table 2* for the list of features per category.

2 System and memory overview

2.1 System architecture

The main system consists of 32-bit multilayer AHB bus matrix that interconnects:

- Up to five masters:
  - Cortex®-M4 with FPU core I-bus
  - Cortex®-M4 with FPU core D-bus
  - Cortex®-M4 with FPU core S-bus
  - DMA1
  - DMA2

- Up to nine slaves:
  - Internal Flash memory on ICode bus
  - Internal Flash memory on DCode bus
  - Internal SRAM1
  - Internal SRAM2
  - Internal CCM SRAM
  - AHB1 peripherals including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - Flexible static memory controller (FSMC)
  - QUAD SPI memory interface (QUADSPI)

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in Figure 1:
2.1.1 I-bus

This bus connects the instruction bus of the Cortex®-M4 with FPU core to the BusMatrix. This bus is used by the core to fetch instructions. The target of this bus is a memory containing code (either internal Flash memory, internal SRAMs or external memories through the FSMC or QUADSPI).

2.1.2 D-bus

This bus connects the data bus of the Cortex®-M4 with FPU core to the BusMatrix. This bus is used by the core for literal load and debug access. The target of this bus is a memory containing code (either internal Flash memory, internal SRAMs or external memories through the FSMC or QUADSPI).
2.1.3 **S-bus**

This bus connects the system bus of the Cortex®-M4 with FPU core to the BusMatrix. This bus is used by the core to access data located in a peripheral or SRAM area. The targets of this bus are the internal SRAM, the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the external memories through the QUADSPI or the FSMC.

The CCM SRAM is also accessible on this bus to allow continuous mapping with SRAM1 and SRAM2.

2.1.4 **DMA-bus**

This bus connects the AHB master interface of the DMA to the BusMatrix. The targets of this bus are the SRAM1, SRAM2 and CCM SRAM, the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the external memories through the QUADSPI or the FSMC.

2.1.5 **BusMatrix**

The BusMatrix manages the access arbitration between masters. The arbitration uses a Round Robin algorithm. The BusMatrix is composed of up to five masters (CPU AHB, system bus, DCode bus, ICode bus, DMA1, DMA2, ) and up to nine slaves (FLASH, SRAM1, SRAM2, CCM SRAM, AHB1 (including APB1 and APB2), AHB2, QUADSPI, and FSMC).

**AHB/APB bridges**

The two AHB/APB bridges provide full synchronous connections between the AHB and the two APB buses, allowing flexible selection of the peripheral frequency.

Refer to *Section 2.2.2: Memory map and register boundary addresses on page 82* for the address mapping of the peripherals connected to this bridge.

After each device reset, all peripheral clocks are disabled (except for the SRAM1/2 and Flash memory interface). Before using a peripheral you have to enable its clock in the RCC_AHBxENR and the RCC_APBxENR registers.

*Note:* When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.
2.2 Memory organization

2.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.
2.2.2 Memory map and register boundary addresses

Figure 2. Memory map
All areas not allocated to on-chip memories and peripherals are considered "Reserved". For the detailed mapping of available memory and register areas, refer to the following table.

Table 3 gives the boundary addresses of the peripherals available in the devices.

2.3 Bit banding

The Cortex®-M4 with FPU memory map includes two bit-band regions. These regions map each word in an alias region of memory to a bit in a bit-band region of memory. Writing to a word in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

In the STM32G4 series devices both the peripheral registers and the SRAM are mapped to a bit-band region, so that single bit-band write and read operations are allowed. The operations are available only for Cortex®-M4 with FPU accesses, and not from other bus masters (such as DMA).
A mapping formula shows how to reference each word in the alias region to a corresponding bit in the bit-band region. The mapping formula is:

\[
\text{bit\_word\_addr} = \text{bit\_band\_base} + (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)
\]

where:

- \(\text{bit\_word\_addr}\) is the address of the word in the alias memory region that maps to the targeted bit
- \(\text{bit\_band\_base}\) is the starting address of the alias region
- \(\text{byte\_offset}\) is the number of the byte in the bit-band region that contains the targeted bit
- \(\text{bit\_number}\) is the bit position (0-7) of the targeted bit

**Example**

The following example shows how to map bit 2 of the byte located at SRAM1 address 0x20000300 to the alias region:

\[0x22006008 = 0x22000000 + (0x300 \times 32) + (2 \times 4)\]

Writing to address 0x22006008 has the same effect as a read-modify-write operation on bit 2 of the byte at SRAM1 address 0x20000300.

Reading address 0x22006008 returns the value (0x01 or 0x00) of bit 2 of the byte at SRAM1 address 0x20000300 (0x01: bit set; 0x00: bit reset).

### 2.4 Embedded SRAM

Category 3 devices feature up to 128 Kbytes SRAM:
- 80 Kbytes SRAM1 (mapped at address 0x2000 0000)
- 16 Kbytes SRAM2 (mapped at address 0x2001 4000)
- 32 Kbytes CCM SRAM (mapped at address 0x1000 0000 and end of SRAM2)

Category 4 devices feature up to 112 Kbytes SRAM:
- 80 Kbytes SRAM1 (mapped at address 0x2000 0000)
- 16 Kbytes SRAM2 (mapped at address 0x2001 4000)
- 16 Kbytes CCM SRAM (mapped at address 0x1000 0000 and end of SRAM2)

Category 2 devices feature up to 32 Kbytes SRAM:
- 16 Kbytes SRAM1 (mapped at address 0x2000 0000)
- 6 Kbytes SRAM2 (mapped at address 0x2000 4000)
- 10 Kbytes CCM SRAM (mapped at address 0x1000 0000 and end of SRAM2)

These SRAM can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed at maximum system clock frequency without wait state and thus by both CPU and DMA.

The CPU can access the SRAM1 through the system bus or through the ICode/DCode buses when boot from SRAM1 is selected or when physical remap is selected (Section 10.2.1: SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller). To get the maximum performance on SRAM1 execution, physical remap should be selected (boot or software selection).

CCM SRAM is mapped at address 0x1000 0000.
Execution can be performed from CCM SRAM with maximum performance without any remap thanks to access through ICode bus. The CCM SRAM is aliased at address following the end of SRAM2 (0x2000 5800 for category 2 devices, 0x2001 8000 for category 3 devices, 0x2001 8000 for category 4 devices), offering a continuous address space with the SRAM1 and SRAM2. CCM can be accessed by DMA only by this aliased address.

2.4.1 Parity check

On category 3 and category 4 devices, a parity check is implemented on the first 32 Kbytes of SRAM1 and on the whole CCM SRAM.

On the category 2 devices, a parity check is implemented on the whole SRAM1 and CCM SRAM.

The user can enable the parity check using the option bit SRAM_PE in the user option byte (refer to Section 3.4.1: Option bytes description).

The data bus width is 36 bits because 4 bits are available for parity check (1 bit per byte) in order to increase memory robustness, as required for instance by Class B or SIL norms.

The parity bits are computed and stored when writing into the SRAM. Then, they are automatically checked when reading. If one bit fails, an NMI is generated. The same error can also be linked to the BRK_IN Break input of TIM1/TIM8/TIM15/TIM16/TIM17/TIM20, and to hrtim_sys_flt with the SPL control bit in the Section 10.2.8: SYSCFG configuration register 2 (SYSCFG_CFRG2). The SRAM parity error flag (SPF) is available in the Section 10.2.8: SYSCFG configuration register 2 (SYSCFG_CFRG2).

Note: When enabling the SRAM parity check, it is advised to initialize by software the whole SRAM memory at the beginning of the code, to avoid getting parity errors when reading non-initialized locations.

2.4.2 CCM SRAM write protection

The CCM SRAM can be write protected with a page granularity of 1 Kbyte.

</tbody>
</table>
The write protection can be enabled in Section 10.2.9: SYSCFG CCM SRAM write protection register (SYSCFG_SWP) in the SYSCFG block. This is a register with write ‘1’ once mechanism, which means by writing ‘1’ on a bit it sets up the write protection for that page of SRAM and it can be removed/cleared by a system reset only.

### 2.4.3 CCM SRAM read protection

The CCMSRAM is protected with the Read protection (RDP). Refer to Section 3.5.1: Read protection (RDP) for more details.

### 2.4.4 CCM SRAM erase

The CCMSRAM can be erased with a system reset using the option bit CCMSRAM_RST in the user option byte (refer to Section 3.4.1: Option bytes description).

The CCMSRAM erase can also be requested by software by setting the bit CCMSR in the Section 10.2.7: SYSCFG CCM SRAM control and status register (SYSCFG_SCSR).
2.5 Flash memory overview

The flash memory is composed of two distinct physical areas:
- The main flash memory block contains the application program and user data if necessary.
- The information block is composed of three parts:
  - Option bytes for hardware and memory protection user configuration.
  - System memory that contains the ST proprietary code.
  - OTP (one-time programmable) area

The flash memory interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the flash memory operations (program/erase) controlled through the flash memory registers. Refer to Section 3: Embedded flash memory (FLASH) for category 3 devices, Section 4: Embedded flash memory (FLASH) for category 4 devices, and Section 5: Embedded flash memory (FLASH) for category 2 devices for more details.

2.6 Boot configuration

2.6.1 Boot configuration

Three different boot modes can be selected through the BOOt0 pin or the nBOOT0 bit into the FLASH_OPTR register (if the nSWBOOT0 bit is cleared into the FLASH_OPTR register), and nBOOT1 bit in FLASH_OPTR register, as shown in Table 5.

</tbody>
</table>

1. When the BFB2 bit is set (for dual bank devices), the system memory remains aliased at 0x0000 0000. Aliasing system memory to 0x0000 0000 must be considered in user application - VTOR address must be remapped from default 0x0000 0000 address into real user application to properly address vector table. For further details, refer to AN2606.
The values on both BOOT0 pin (coming from the pin or the option bit) and nBOOT1 bit are latched on the 4th edge of the internal startup clock source after reset release. It is up to the user to set nBOOT1 and BOOT0 to select the required boot mode.

The BOOT0 pin or user option bit (depending on the nSWBOOT0 bit value in the FLASH_OPTR register), and nBOOT1 bit are also re-sampled when exiting from Standby mode. Consequently, they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory at 0x0000 0004.

Depending on the selected boot mode, main flash memory, system memory or SRAM1 is accessible as follows:

- Boot from main flash memory: the main flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x0800 0000). In other words, the flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.
- Boot from system memory: the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF 0000).
- Boot from the embedded SRAM1: the SRAM1 is aliased in the boot memory space (0x0000 0000), but it is still accessible from its original memory space (0x2000 0000).

PB8/BOOT0 GPIO is configured in:

- Input mode during the complete reset phase if the option bit nSWBOOT0 is set into the FLASH_OPTR register and then switches automatically in analog mode after reset is released (BOOT0 pin).
- Input mode from the reset phase to the completion of the option byte loading if the bit nSWBOOT0 is cleared into the FLASH_OPTR register (BOOT0 value coming from the option bit). It switches then automatically to the analog mode even if the reset phase is not complete.

Note: When the device boots from SRAM, in the application initialization code, you have to relocate the vector table in SRAM using the NVIC exception table and the offset register. When booting from the main flash memory, the application software can either boot from bank 1 or from bank 2 (only for category 3 devices). By default, boot from bank 1 is selected. To select boot from flash memory bank 2, set the BFB2 bit in the user option bytes. When this bit is set and the boot pins are in the boot from main flash memory configuration, the device boots from system memory, and the boot loader jumps to execute the user application programmed in flash memory bank 2. For further details, refer to AN2606. See Table 13: Access status versus protection level and execution modes for bootloader function for different RDP levels.

Forcing boot from user flash memory

Regardless the boot configuration, it is possible to force booting from a unique entry point in main flash memory.

Physical remap

Once the boot pins mode is selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller.
The following memories can be remapped:
- Main flash memory
- System memory
- Embedded SRAM1
- FSMC bank 1 (NOR/PSRAM 1 and 2)
- QUADSPI memory

1. Reserved memory area highlighted in gray.
2. When the FSMC is remapped at address 0x0000 0000, only the first two regions of bank 1 memory controller (bank 1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. When the FSMC is remapped at address 0x0000 0000, only 128 MB are remapped. In remap mode, the CPU can access the external memory via ICode bus instead of system bus, which boosts up the performance.
3. Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.

**Embedded boot loader**

The embedded boot loader is located in the system memory, programmed by ST during production. Refer to AN2606 STM32 microcontroller system memory boot mode.
3 Embedded flash memory (FLASH) for category 3 devices

3.1 Introduction

The flash memory interface manages the CPU AHB ICode and DCode accesses to the flash memory. It implements the erase and program flash memory operations and the read and write protection mechanisms.

The flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

3.2 FLASH main features

- Up to 512 Kbytes of flash memory with dual bank architecture supporting read-while-write capability (RWW).
- Flash memory read operations with two data width modes supported:
  - Single bank mode DBANK = 0: read access of 128 bits
  - Dual bank mode DBANK = 1: read access of 64 bits
- Page erase, bank erase, and mass erase (both banks)

Flash memory interface features:
- Flash memory read operations
- Flash memory program/erase operations
- Read protection activated by option (RDP)
- Four write protection areas (2 per bank when DBANK = 1 and 4 for full memory when DBANK = 0)
- Two proprietary code read protection areas (1 per bank when DBANK = 1, 2 for all memory when DBANK = 0)
- Two securable memory areas defined by option (1 per bank when DBANK = 1, 1 for all memory when DBANK = 0).
- Prefetch on ICODE
- Instruction cache: 32 cache lines of 4 x 64 or 2 x 128 bits on ICode (1 KB RAM)
- Data cache: 8 cache lines of 4 x 64 bits or 2 x 128 on DCode (256B RAM)
- Error code correction (ECC): 8 bits per 64-bit double-word
  - DBANK = 1: 8 + 64 = 72 bits, 2 bits detection, 1 bit correction
  - DBANK = 0: (8 + 64) + (8 + 64) = 144 bits, 2 bits detection, 1 bit correction
- Option byte loader
- Low-power mode
3.3  FLASH functional description

3.3.1  Flash memory organization

The flash memory has the following main features:

- Capacity up to 512 Kbytes, in single bank mode (read width of 128 bits) or in dual bank mode (read width of 64 bits)
- Supports dual boot mode thanks to the BFB2 option bit (only in dual bank mode)
- Dual bank mode when the DBANK bit is set:
  - 512 Kbytes organized in two banks for main memory
  - Page size of 2 Kbytes
  - 72 bits wide data read (64 bits plus 8 ECC bits)
  - Bank and mass erase
- Single bank mode when DBANK is reset:
  - 512 KB organized in one single bank for main memory
  - Page size of 4 Kbytes
  - 144 bits wide data read (128 bits plus 2x8 ECC bits)
  - Mass erase

The flash memory is organized as follows:

- A main memory block organized depending on the dual bank configuration bit:
  - When dual bank is enabled (DBANK bit set), the flash memory is divided in two banks of 256 KB, and each bank is organized as follows:
    The main memory block containing 128 pages of 2 Kbytes
    Each page is composed of 8 rows of 256 bytes
  - When the dual bank is disabled (DBANK bit reset), the main memory block is organized as one single bank of 512 KB as follows:
    The main memory block containing 128 pages of 4 Kbytes
    Each page is composed of 8 rows of 512 bytes

- An Information block containing:
  - System memory from which the device boots in System memory boot mode. The area is reserved for use by STMicroelectronics and contains the bootloader that is used to reprogram the flash memory through one of the following interfaces: USART, SPI, I2C, FDCAN, USB. It is programmed when the device is manufactured, and protected against spurious write/erase operations. For further details, refer to AN2606 available from www.st.com.
  - 1 Kbyte (128 double word) OTP (one-time programmable) bytes for user data. The OTP area is available in Bank 1 only. The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire double word cannot be written anymore, even with the value 0x0000 0000 0000 0000.
  - Option bytes for user configuration.

The memory is organized on a main area and an information block, as shown in Table 28.

3.3.2 Error code correction (ECC)

Dual bank mode (DBANK = 1, 64-bit data width)

Data in flash memory are 72-bit words: 8 bits are added per double word (64 bits). The ECC mechanism supports:

- One error detection and correction
- Two errors detection

When one error is detected and corrected, the flag ECCC (ECC correction) is set in Flash ECC register (FLASH_ECCR). If ECCCIE is set, an interrupt is generated.

When two errors are detected, a flag ECCD (ECC detection) is set in the FLASH_ECCR register. In this case, an NMI is generated.

When an ECC error is detected, the address of the failing double word and its associated bank are saved in ADDR_ECC[20:0] and BK_ECC in the FLASH_ECCR register. ADDR_ECC[2:0] are always cleared.

When ECC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Single bank mode (DBANK = 0, 128-bit data width)

Data in flash memory are 144-bit words: 8 bits are added per each double word. The ECC mechanism supports:

- One error detection and correction
- Two errors detection per 64 double words

The user must first check the SYSF_ECC bit, and if it is set, the user must refer to the DBANK = 1 programming model (because system flash is always on two banks). If the bit is not set, the user must refer to the following programing model:

Each double word (bits 63:0 and bits 127:64) has ECC.

When one error is detected in the 64 LSBs (bits 63:0) and corrected, a flag ECCC (ECC correction) is set in the FLASH_ECCR register.

When one error is detected in the 64 MSBs (bits 127:64) and corrected, a flag ECCC2 (ECC2 correction) is set in the FLASH_ECCR register.

If the ECCCIE is set, an interrupt is generated. The user has to read ECCC and ECCC2 to see which part of the 128-bit data has been corrected (either 63:0, 127:64, or both).

When two errors are detected in 64 LSB bits, a flag ECCD (ECC detection) is set in the FLASH_ECCR register.

When two errors are detected in the 64 MSBs, a flag ECCD2 (ECC2 detection) is set in the FLASH_ECCR register.

In this case, a NMI is generated. The user has to read ECCD and ECCD2 to see which part of the 128-bit data has error detection (either 63:0, 127:64, or both).

When an ECC error is detected, the address of the failing the two times double word is saved into ADDR_ECC[20:0] in FLASH_ECCR. ADDR_ECC[20:0] contains an address of a two times double word.

The ADDR_ECC[3:0] is always cleared. BK_ECC is not used in this mode.
When ECCC/ECCC2 or ECCD/ECCD2 is/are set, if a new ECC error occurs, the ADDR_ECC is not updated. The FLASH_ECCR is updated only if the ECC flags (ECCC/ECCC2/ECCD/ECCD2) are cleared.

**Note:** For a virgin data: 0xFF FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

### 3.3.3 Read access latency

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the *Flash access control register (FLASH_ACR)* according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device $V_{\text{CORE}}$. Refer to [Section 6.1.5: Dynamic voltage scaling management.](#)

Table 9 shows the correspondence between wait states and CPU clock frequency.

<table>
<thead>
<tr>
<th>Wait states (WS) (LATENCY)</th>
<th>HCLK (MHz)</th>
<th>$V_{\text{CORE}}$ Range 1 boost mode</th>
<th>$V_{\text{CORE}}$ Range 1 normal mode</th>
<th>$V_{\text{CORE}}$ Range 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 CPU cycles)</td>
<td>≤ 34</td>
<td>≤ 30</td>
<td>≤ 12</td>
<td></td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>≤ 68</td>
<td>≤ 60</td>
<td>≤ 24</td>
<td></td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>≤ 102</td>
<td>≤ 90</td>
<td>≤ 26</td>
<td></td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>≤ 136</td>
<td>≤ 120</td>
<td>-</td>
<td></td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>≤ 170</td>
<td>≤ 150</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 16 MHz and 1 wait state (WS) is configured in the FLASH_ACR register.

When changing the CPU frequency, the following software sequences must be applied in order to tune the number of wait states needed to access the flash memory:

**Increasing the CPU frequency:**

1. Program the new number of wait states to the LATENCY bits in the *Flash access control register (FLASH_ACR)*.
2. Check that the new number of wait states is taken into account to access the flash memory by reading the FLASH_ACR register.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in the RCC_CFGR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFGR

If some of the above two steps decreases the CPU frequency, firstly perform this step and then the rest. Otherwise, modify the CPU clock source by writing the SW bits in the
RCC_CFRGR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFRGR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFRGR register.

**Decreasing the CPU frequency:**

1. Modify the CPU clock source by writing the SW bits in the RCC_CFRGR register.
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFRGR.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in the RCC_CFRGR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFRGR

If some of the above two steps increases the CPU frequency, firstly perform another step and then this step. Otherwise, modify the CPU clock source by writing the SW bits in the RCC_CFRGR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFRGR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFRGR register.

5. Program the new number of wait states to the LATENCY bits in Flash access control register (FLASH_ACR).

6. Check that the new number of wait states is used to access the flash memory by reading the FLASH_ACR register.

### 3.3.4 Adaptive real-time memory accelerator (ART Accelerator)

The proprietary adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M4 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M4 with FPU over flash memory technologies, which normally requires the processor to wait for the flash memory at higher operating frequencies.

To release the processor to full performance, the accelerator implements an instruction prefetch queue and branch cache, which increases program execution speed from the 64-bit flash memory. Based on the CoreMark benchmark, the performance achieved thanks to the ART Accelerator is equivalent to 0 wait state program execution from flash memory at a CPU frequency up to 170 MHz.

**Instruction prefetch**

The Cortex®-M4 fetches the instruction over the ICode bus and the literal pool (constant/data) over the DCode bus. The prefetch block aims at increasing the efficiency of ICode bus accesses.

In case of Single bank mode (DBANK option bit is reset), each flash memory read operation provides 128 bits from either four instructions of 32 bits or eight instructions of 16 bits depending on the launched program. This 128-bit current instruction line is saved in a current buffer, and in case of sequential code, at least four CPU cycles are needed to execute the previous read instruction line.
When in dual bank mode (DBANK option bit is set), each flash memory read operation provides 64 bits from either two instructions of 32 bits or four instructions of 16 bits depending on the launched program. This 64-bit current instruction line is saved in a current buffer, and in the case of sequential code, at least two CPU cycles are needed to execute the previous read instruction line.

Prefetch on the ICode bus can be used to read the next sequential instruction line from the flash memory while the current instruction line is being requested by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the Flash access control register (FLASH_ACR). This feature is useful if at least one wait state is needed to access the flash memory.

*Figure 9* shows the execution of sequential 16-bit instructions with and without prefetch when 3 WS are needed to access the flash memory.
When the code is not sequential (branch), the instruction may not be present in the currently used instruction line or in the prefetched instruction line. In this case (miss), the penalty in terms of the number of cycles is at least equal to the number of wait states.
If a loop is present in the current buffer, no new flash access is performed.

**Instruction cache memory (I-Cache)**

To limit the time lost due to jumps, it is possible to retain 32 lines of 4 x 64 bits in dual bank mode or 32 lines of 2 x 128 bits in single bank mode in an instruction cache memory. This feature can be enabled by setting the instruction cache enable (ICEN) bit in the Flash access control register (FLASH_ACR). Each time a miss occurs (requested data not present in the currently used instruction line, in the prefetched instruction line or in the instruction cache memory), the line read is copied into the instruction cache memory. If some data contained in the instruction cache memory are requested by the CPU, they are provided without inserting any delay. Once all the instruction cache memory lines have been filled, the LRU (least recently used) policy is used to determine the line to replace in the instruction memory cache. This feature is particularly useful in the case of code containing loops.

The instruction cache memory is enable after system reset.

**Data cache memory (D-Cache)**

Literal pools are fetched from flash memory through the DCode bus during the execution stage of the CPU pipeline. Each DCode bus read access fetches 64 or 128 bits, which are saved in a current buffer. The CPU pipeline is consequently stalled until the requested literal pool is provided. To limit the time lost due to literal pools, accesses through the AHB databus DCode have priority over accesses through the AHB instruction bus ICode.

If some literal pools are frequently used, the data cache memory can be enabled by setting the data cache enable (DCEN) bit in the Flash access control register (FLASH_ACR). This feature works like the instruction cache memory, but the retained data size is limited to 8 rows of 4*64 bits in dual bank mode and to 8 rows of 2*128 bits in single bank mode.

The Data cache memory is enabled after system reset.

*Note: The D-Cache is active only when data is requested by the CPU (not by DMA1 and DMA2). Data in the option bytes block are not cacheable.*

### 3.3.5 Flash program and erase operations

The STM32G4 series embedded flash memory can be programmed using in-circuit programming or in-application programming.

The *in-circuit programming (ICP)* method is used to update the entire contents of the flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, *in-application programming (IAP)* can use any communication interface supported by the microcontroller (I/Os, USB, CAN, UART, I²C, SPI, etc.) to download programming data into memory. IAP allows the user to reprogram the flash memory while the application is running. Nevertheless, part of the application has to have been previously programmed in the flash memory using ICP.

The contents of the flash memory are not guaranteed if a device reset occurs during a flash memory operation.

An on-going flash memory operation does not block the CPU as long as the CPU does not access the same flash memory bank. Code or data fetches are possible on one bank while
a write/erase operation is performed to the other bank (refer to Section 3.3.8: Read-while-write (RWW) available only in dual bank mode (DBANK = 1)).

The flash memory erase and programming is only possible in the voltage scaling range 1. The VOS[1:0] bits in the PWR_CR1 must be programmed to 01b.

On the contrary, during a program/erase operation to the flash memory, any attempt to read the same flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has completed.

Unlocking the flash memory

After reset, write is not allowed in the Flash control register (FLASH_CR) to protect the flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the Flash key register (FLASH_KEYR)
2. Write KEY2 = 0xCDEF89AB in the FLASH_KEYR register.

Any wrong sequence locks up the FLASH_CR register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated.

The FLASH_CR register can be locked again by software by setting the LOCK bit in the FLASH_CR register.

Note: The FLASH_CR register cannot be written when the BSY bit in the Flash status register (FLASH_SR) is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

3.3.6 Flash main memory erase sequences

The flash memory erase operation can be performed at page level, bank level or on the whole flash memory (mass erase). Mass erase does not affect the Information block (system flash, OTP, and option bytes).

Page erase

To erase a page, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. In dual bank mode (DBANK option bit is set), set the PER bit and select the page to erase (PNB) with the associated bank (BKER) in the flash control register (FLASH_CR). In single bank mode (DBANK option bit is reset), set the PER bit and select the page to erase (PNB). The BKER bit in the flash control register (FLASH_CR) must be kept cleared.
4. Set the STRT bit in the FLASH_CR register.
5. Wait for the BSY bit to be cleared in the FLASH_SR register.
**Note:** The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when the STRT bit is cleared, except if the HSI16 is previously enabled with HSION in the RCC_CR register.

If the page erase is part of write-protected area (by WRP or PCROP), WRPERR is set and the page erase request is aborted.

**Bank 1, Bank 2 mass erase (available only in dual bank mode when DBANK = 1)**

To perform a bank mass erase, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit or MER2 (depending on the bank) in the Flash control register (FLASH_CR). Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the STRT bit in the FLACH_CR register.
5. Wait for the BSY bit to be cleared in the Flash status register (FLASH_SR).

**Mass erase**

To perform a mass erase, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit and MER2 in the flash control register (FLASH_CR).
4. Set the STRT bit in the FLACH_CR register.
5. Wait for the BSY bit to be cleared in the flash status register (FLASH_SR).

**Note:** The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in the RCC_CR register.

When DBANK = 0, if only the MERA or the MERB bit is set, PGSERR is set and no erase operation is performed.

If the bank to erase or if one of the banks to erase contains a write-protected area (by WRP or PCROP), WRPERR is set and the mass erase request is aborted (for both banks if both are selected).

**3.3.7 Flash main memory programming sequences**

The flash memory is programmed 72 bits at a time (64 bits + 8 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets the PROGERR flag in the Flash status register (FLASH_SR).
It is only possible to program double word (2 x 32-bit data).

- Any attempt to write a byte or half-word sets SIZERR flag in the FLASH_SR register.
- Any attempt to write a double word, which is not aligned with a double word address sets the PGAERR flag in the FLASH_SR register.

**Standard programming**

The flash memory programming sequence in standard mode is as follows:

1. Check that no flash main memory operation is ongoing by checking the BSY bit in the **Flash status register (FLASH_SR)**.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PG bit in the **Flash control register (FLASH_CR)**.
4. Perform the data write operation at the desired memory address, inside the main memory block or OTP area. Only a double word can be programmed.
   - Write a first word in an address aligned with a double word
   - Write the second word
5. Wait until the BSY bit is cleared in the FLASH_SR register.
6. Check that the EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
7. Clear the PG bit in the FLASH_SR register if there is no more programming request anymore.

**Note:** When the flash interface has received a good sequence (a double word), programming is automatically launched and the BSY bit is set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the user needs to program only one word, a double word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the double word to program.

**Fast programming for a row (64 double words if DBANK = 1) or for half row (64 double words if DBANK = 0)**

This mode allows to program a row (64 double words if DBANK = 1) or half row (64 double words if DBANK = 0), and to reduce the page programming time by eliminating the need for verifying the flash locations before they are programmed and to avoid rising and falling time of high voltage for each double word. During fast programming, the CPU clock frequency (HCLK) must be at least 8 MHz.

Only the main memory can be programmed in Fast programming mode.
The flash main memory programming sequence in standard mode is as follows:

1. In single bank mode (DBANK = 0), perform a mass erase. If not, PGSERR is set. The Fast programming can be performed only if the code is executed from RAM or from bootloader. In dual bank mode (DBANK = 1), perform a mass erase of the bank to program. If not, PGSERR is set.

2. Check that no flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).

3. Check and clear all error programming flag due to a previous programming.

4. Set the FSTPG bit in Flash control register (FLASH_CR).

5. Write the 64 double words to the program a row or half row. Only double words can be programmed:
   - Write a first word in an address aligned with a double word
   - Write the second word.

6. Wait until the BSY bit is cleared in the FLASH_SR register.

7. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.

8. Clear the FSTPG bit in the FLASH_SR register if there no more programming request anymore.

Note: If the flash is attempted to be written in Fast programming mode while a read operation is on going in the same bank, the programming is aborted without any system notification (no error flag is set).

When the flash interface has received the first double word, programming is automatically launched. The BSY bit is set when the high voltage is applied for the first double word, and it is cleared when the last double word has been programmed or in case of error. The internal oscillator HSI16 (16 MHz) is enabled automatically when FSTPG bit is set, and disabled automatically when FSTPG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

The 64 double word must be written successively. The high voltage is kept on the flash for all the programming. Maximum time between two double words write requests is the time programming (around 2 x 25us). If a second double word arrives after this time programming, fast programming is interrupted and MISSERR is set.

High voltage cannot exceed 8 ms for a full row between 2 erases. This is guaranteed by the sequence of 64 double words successively written with a clock system greater or equal to 8MHz. An internal time-out counter counts 7 ms when fast programming is set and stops the programming when time-out is over. In this case, the FASTERR bit is set.

If an error occurs, the high voltage is stopped and the next double word to programmed is not programmed. Anyway, all previous double words have been properly programmed.
Programming errors

Several kinds of errors are detected. In case of error, the flash operation (programming or erasing) is aborted.

- **PROGERR**: Programming Error
  In standard programming: PROGERR is set if the word to write is not previously erased (except if the value to program is full zero).

- **SIZERR**: Size Programming Error
  In standard programming or in fast programming: only double word can be programmed and only 32-bit data can be written. SIZERR is set if a byte or a half-word is written.

- **PGAERR**: Alignment Programming error
  PGAERR is set if one of the following conditions occurs:
  - In standard programming: the first word to be programmed is not aligned with a double word address, or the second word doesn’t belong to the same double word address.
  - In fast programming: the data to program doesn’t belong to the same row than the previous programmed double words, or the address to program is not greater than the previous one.

- **PGSERR**: Programming Sequence Error
  PGSERR is set if one of the following conditions occurs:
  - In the standard programming sequence or the fast programming sequence: a data is written when PG and FSTPG are cleared.
  - In the standard programming sequence or the fast programming sequence: MER1, MER2, and PER are not cleared when PG or FSTPG is set.
  - In the fast programming sequence: the mass erase is not performed before setting FSTPG bit.
  - In the mass erase sequence: PG, FSTPG, and PER are not cleared when MER1 or MER2 is set.
  - In the page erase sequence: PG, FSTPG, MER1 and MER2 are not cleared when PER is set.
  - PGSERR is set also if PROGERR, SIZERR, PGAERR, WRPERR, MISSERR, FASTERR, or PGSERR is set due to a previous programming error.
  - When DBANK = 0, in the case that only either MER1 or MER2 is set, PGSERR is set (bank mass erase is not allowed).

- **WRPERR**: Write Protection Error
  WRPERR is set if one of the following conditions occurs:
  - Attempt to program or erase in a write protected area (WRP) or in a PCROP area or in a securable memory area.
  - Attempt to perform a bank erase when one page or more is protected by WRP or PCROP.
  - The debug features are connected or the boot is executed from SRAM or from System flash when the read protection (RDP) is set to Level 1.
  - Attempt to modify the option bytes when the read protection (RDP) is set to Level 2.

- **MISSERR**: Fast Programming Data Miss Error
In fast programming: all the data must be written successively. MISSERR is set if the previous data programming is finished and the next data to program is not written yet.

- **FASTERR**: Fast Programming Error
  In fast programming: FASTERR is set if one of the following conditions occurs:
  - When FSTPG bit is set for more than 7 ms, which generates a time-out detection.
  - When the fast programming has been interrupted by a MISSERR, PGAERR, WRPERR, or SIZERR.

If an error occurs during a program or erase operation, one of the following error flags is set in the FLASH_SR register:

- PROGERR, SIZERR, PGAERR, PGSERR, MISSERR (Program error flags)
- WRPERR (Protection error flag)

In this case, if the error interrupt enable bit ERRIE is set in the Flash status register (FLASH_SR), an interrupt is generated and the operation error flag OPERR is set in the FLASH_SR register.

**Note:** If several successive errors are detected (for example, in case of DMA transfer to the flash memory), the error flags cannot be cleared until the end of the successive write requests.

### Programming and caches

If a flash memory write access concerns some data in the data cache, the flash write access modifies the data in the flash memory and the data in the cache.

If an erase operation in flash memory also concerns data in the data or instruction cache, you have to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush the caches by setting the DCRST and ICRST bits in the Flash access control register (FLASH_ACR).

**Note:** The I/D cache should be flushed only when it is disabled (I/DCEN = 0).

### 3.3.8 Read-while-write (RWW) available only in dual bank mode (DBANK = 1)

The dual bank mode is available only when the DBANK option bit is set, allowing read-while-write operations. This feature allows to perform a read operation from one bank while an erase or program operation is performed to the other bank.

**Note:** Write-while-write operations are not allowed. As an example, It is not possible to perform an erase operation on one bank while programming the other one.

#### Read from bank 1 while page erasing in bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is on going in bank 1 or bank 2).
2. Set PER bit, PSB to select the page and BKER to select the bank in the Flash control register (FLASH_CR).
3. Set the STRT bit in the FLASH_CR register.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).
Read from bank 1 while mass erasing bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa). Follow the procedure below:
1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is ongoing in bank 1 or bank 2).
2. Set MER1 or MER2 to in the Flash control register (FLASH_CR).
3. Set the STRT bit in the FLASH_CR register.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).

Read from bank 1 while programming bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2. (and vice versa). Follow the procedure below:
1. Check that no flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is ongoing on bank 1 or bank 2).
2. Set the PG bit in the Flash control register (FLASH_CR).
3. Perform the data write operations at the desired address memory inside the main memory block or OTP area.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).
3.4 **FLASH option bytes**

3.4.1 **Option bytes description**

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog can be selected in hardware or software mode (refer to Section 5.4.2).

A double word is split up as follows in the option bytes:

<table>
<thead>
<tr>
<th>63-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
<th>31-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complemented option byte 3</td>
<td>Complemented option byte 2</td>
<td>Complemented option byte 1</td>
<td>Complemented option byte 0</td>
<td>Option byte 3</td>
<td>Option byte 2</td>
<td>Option byte 1</td>
<td>Option byte 0</td>
</tr>
</tbody>
</table>

The organization of these bytes inside the information block is as shown in Table 31.

The option bytes can be read from the memory locations listed in Table 31 or from the flash memory registers:

- **Flash option register (FLASH_OPTR)**
- **Flash PCROP1 Start address register (FLASH_PCROP1SR)**
- **Flash PCROP1 End address register (FLASH_PCROP1ER)**
- **Flash WRP area A address register (FLASH_WRP1AR)**
- **Flash WRP area B address register (FLASH_WRP1BR)**
- **Flash PCROP2 Start address register (FLASH_PCROP2SR)**
- **Flash PCROP2 End address register (FLASH_PCROP2ER)**
- **Flash Bank 2 WRP area A address register (FLASH_WRP2AR)**
- **Flash Bank 2 WRP area B address register (FLASH_WRP2BR)**.

Bank 2

1. Negated values are overlined.

User and read protection option bytes
Flash memory address: 0x1FFF 7800
ST production value: 0xFFEF F8AA

| Bit 31 | Reserved, must be kept at reset value. |
| Bit 30 | IRH_EN: Internal reset holder on NRST pin |
| 0: | IRH disabled |
| 1: | IRH enabled |
| Bits 29:28 | NRST_MODE[1:0]: PG10 pad mode |
| 00: | Reset Input/Output |
| 01: | Reset Input only |
| 10: | GPIO |
| 11: | Reset Input/Output |
| Bit 27 | nBOOT0: nBOOT0 option bit |
| 0: | nBOOT0 = 0 |
| 1: | nBOOT0 = 1 |
| Bit 26 | nSWBOOT0: Software BOOT0 |
| 0: | BOOT0 taken from the option bit nBOOT0 |
| 1: | BOOT0 taken from PB8/BOOT0 pin |

110/2138 RM0440 Rev 8
Bit 25 **CCMSRAM_RST**: CCM SRAM erase when system reset
- 0: CCM SRAM erased when a system reset occurs
- 1: CCM SRAM is not erased when a system reset occurs

Bit 24 **SRAM_PE**: SRAM1 and CCM SRAM parity check enable
- 0: SRAM1 and CCM SRAM parity check enable
- 1: SRAM1 and CCM SRAM parity check disable

Bit 23 **nBOOT1**: Boot configuration
Together with the BOOT0 pin, this bit selects boot mode from the flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bit 22 **DBANK**:
- 0: Single bank mode with 128 bits data read width
- 1: Dual bank mode with 64 bits data
This bit can be written only when PCROP1/2 is disabled.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **BFB2**: Dual-bank boot
- 0: Dual-bank boot disable
- 1: Dual-bank boot enable

Bit 19 **WWDG_SW**: Window watchdog selection
- 0: Hardware window watchdog
- 1: Software window watchdog

Bit 18 **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode
- 0: Independent watchdog counter is frozen in Standby mode
- 1: Independent watchdog counter is running in Standby mode

Bit 17 **IWDG_STOP**: Independent watchdog counter freeze in Stop mode
- 0: Independent watchdog counter is frozen in Stop mode
- 1: Independent watchdog counter is running in Stop mode

Bit 16 **IWDG_SW**: Independent watchdog selection
- 0: Hardware independent watchdog
- 1: Software independent watchdog

Bit 15 Reserved, must be kept at reset value.

Bit 14 **nRST_SHDW**:
- 0: Reset generated when entering the Shutdown mode
- 1: No reset generated when entering the Shutdown mode

Bit 13 **nRST_STDBY**
- 0: Reset generated when entering the Standby mode
- 1: No reset generated when entering the Standby mode

Bit 12 **nRST_STOP**
- 0: Reset generated when entering the Stop mode
- 1: No reset generated when entering the Stop mode

Bit 11 Reserved, must be kept at reset value.
Embedded flash memory (FLASH) for category 3 devices

Bits 10:8 **BOR_LEV**: BOR reset Level  

These bits contain the VDD supply level threshold that activates/releases the reset.  

- 000: BOR Level 0. Reset level threshold is around 1.7 V  
- 001: BOR Level 1. Reset level threshold is around 2.0 V  
- 010: BOR Level 2. Reset level threshold is around 2.2 V  
- 011: BOR Level 3. Reset level threshold is around 2.5 V  
- 100: BOR Level 4. Reset level threshold is around 2.8 V  

Bits 7:0 **RDP**: Read protection level  

- 0xAA: Level 0, read protection not active  
- 0xCC: Level 2, chip read protection active  
- Others: Level 1, memories read protection active  

**PCROP1 Start address option bytes**  
Flash memory address: 0x1FFF 7808  
Reset value: 0xFFFF FFFF (ST production value)

Bits 31:15 Reserved, must be kept at reset value.  

Bits 14:0 **PCROP1_STRT[14:0]**: PCROP area start offset  

- **DBANK = 1**  
  PCROP1_STRT contains the first double-word of the PCROP area for bank1.  
- **DBANK = 0**  
  PCROP1_STRT contains the first 2xdouble-word of the PCROP area for all memory.

**PCROP1 End address option bytes**  
Flash memory address: 0x1FFF 7810  
Reset value: 0x00FF 0000 (ST production value)

**Note**: All reserved bits are set after first reprogramming (with no possibility to reset them back).
Bit 31 **PCROP_RDP**: PCROP area preserved when RDP level decreased
   This bit is set only. It is reset after a full mass erase due to a change of RDP
   from Level 1 to Level 0.
   0: PCROP area is not erased when the RDP level is decreased from Level 1 to
   Level 0.
   1: PCROP area is erased when the RDP level is decreased from Level 1 to
   Level 0 (full mass erase).

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **PCROP1_END[14:0]**: Bank 1 PCROP area end offset
   DBANK = 1
   PCROP1_END contains the last double-word of the bank 1 PCROP area.
   DBANK = 0
   PCROP1_END contains the last 2x double-word PCROP area for all memory.

### WRP1 Area A address option bytes

Flash memory address: 0x1FFF 7818
Reset value: 0xFF00 FFFF (ST production value)

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **WRP1A_END[6:0]**: WRP first area “A” end offset
   DBANK = 1
   WRP1A_END contains the last page of WRP first area in bank1.
   DBANK = 0
   WRP1A_END contains the last page of WRP first area for all memory.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **WRP1A_STRT[6:0]**: WRP first area “A” start offset
   DBANK = 1
   WRP1A_STRT contains the first page of WRP first area for bank1.
   DBANK = 0
   WRP1A_STRT contains the first page of WRP first area for all memory.

### WRP1 Area B address option bytes

Flash memory address: 0x1FFF 7820
Reset value: 0xFF00 FFFF (ST production value)

*Note: All reserved bits are set after first reprogramming (with no possibility to reset them back).*
Securable memory area Bank 1 option bytes

Flash memory address: 0xFFFF7828
Reset value: 0xFFFF FF00 (ST production value)

Note: All reserved bits are set after first reprogramming (with no possibility to reset them back).

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:16 **WRP1B_END[6:0]**: WRP second area “B” end offset
- DBANK = 1
  - WRP1B_END contains the last page of the WRP second area for bank1.
- DBANK = 0
  - WRP1B_END contains the last page of the WPR second area for all memory.

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:0 **WRP1B_STRT[6:0]**: WRP second area start offset
- DBANK = 1
  - WRP1B_STRT contains the last page of the WRP second area for bank1.
- DBANK = 0
  - WRP1B_STRT contains the last page of the WPR second area for all memory.

Securable memory area Bank 2 option bytes

Flash memory address: 0x1FFFF808
Reset value: 0xFFFF FFFF (ST production value)

Bits 31:17  Reserved, must be kept at reset value.

Bit 16 **BOOT_LOCK**: used to force boot from user area
- 0: Boot based on the pad/option bit configuration
- 1: Boot forced from main flash memory

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0 **SEC_SIZE1[7:0]**: Securable memory area size
Contains the number of securable flash memory pages

PCROP2 Start address option bytes

Flash memory address: 0x1FFFF808
Reset value: 0xFFFF FFFF (ST production value)
Embedded flash memory (FLASH) for category 3 devices

PCROP2 End address option bytes
Flash memory address: 0x1FFF F810
Reset value: 0xFF00 FFFF (ST production value)

Note: All reserved bits are set after first reprogramming (with no possibility to reset them back).

PCROP2_Start offset
Bits 31:15 Reserved, must be kept at reset value.
Bits 14:0 PCROP2_STRT[14:0]: PCROP area start offset
DBANK = 1
PCROP2_STRT contains the first double-word of the PCROP area for bank 2.
DBANK = 0
PCROP2_STRT contains the first double-word PCROP area for all memory.

PCROP2 Area A address option bytes
Flash memory address: 0x1FFF F810
Reset value: 0xFF00 FFFF (ST production value)

Note: All reserved bits are set after first reprogramming (with no possibility to reset them back).

WRP2 Area A end offset
Bits 31:15 Reserved, must be kept at reset value.
Bits 14:0 WRP2A_END[6:0]: PCROP area end offset
DBANK = 1
PCROP2_END contains the last 2xdouble-word of the PCROP area for all the memory.
DBANK = 0
PCROP2_END contains the last double-word of the PCROP area for bank 2.

PCROP2 Area A start offset
Bits 31:15 Reserved, must be kept at reset value.
Bits 14:0 WRP2A_STRT[6:0]: PCROP area start offset
DBANK = 1
PCROP2_STRT contains the first 2xdouble-word of the PCROP area for all the memory.
Embedded flash memory (FLASH) for category 3 devices

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:16  **WRP2A_END[6:0]**: WRP first area “B” end offset
            |  DBANK = 1  |
            |  WRP2A_END contains the last page of the WRP first area for bank2.  |
            |  DBANK = 0  |
            |  WRP2A_END contains the last page of the WRP third area for all memory.  |

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:0  **WRP2A_STRT[6:0]**: WRP first area “B” start offset
            |  DBANK = 1  |
            |  WRP2A_STRT contains the first page of the WRP first area for bank2.  |
            |  DBANK = 0  |
            |  WRP2A_STRT contains the first page of the WRP third area for all memory.  |

**WRP2 Area B address option bytes**

Flash memory address: 0x1FFF F820
Reset value: 0xFF00 FFFF (ST production value)

*Note: All reserved bits are set after first reprogramming (with no possibility to reset them back).*

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | WRP2A_END[6:0] |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|W  |

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | WRP2A_STRT[6:0] |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

|15|14|13|12|11|10|9|8|7|6|5|4|3|2|1|0|W  |

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:16  **WRP2B_END[6:0]**: WRP second area “B” end offset
            |  DBANK = 1  |
            |  WRP2B_END contains the last page of the WRP second area for bank2.  |
            |  DBANK = 0  |
            |  WRP2B_END contains the last page of the WRP fourth area for all memory.  |

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:0  **WRP2B_STRT[6:0]**: WRP second area “B” start offset
            |  DBANK = 1  |
            |  WRP2B_STRT contains the first page of the WRP second area for bank2.  |
            |  DBANK = 0  |
            |  WRP2B_STRT contains the first page of the WRP second area for all memory.  |

**Securable memory area Bank 2 option bytes**

Flash memory address: 0x1FFF F828
Reset value: 0xFF00 FF00 (ST production value)
3.4.2 Option bytes programming

After reset, the options related bits in the Flash control register (FLASH_CR) are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the Flash control register (FLASH_CR) must be cleared. The following sequence is used to unlock this register:

1. Unlock the FLASH_CR with the LOCK clearing sequence (refer to Unlocking the flash memory).
2. Write OPTKEY1 = 0x08192A3B in the Flash option key register (FLASH_OPTKEYR).
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If LOCK is set by software, OPTLOCK is automatically set too.

Modifying user options

The option bytes are programmed differently from a main memory user address. It is not possible to modify independently user options of bank 1 or bank 2. The users Options of the bank 1 are modified first.

To modify the user options value, follow the procedure below:

1. Check that no flash memory operation is going by checking the BSY bit in the Flash status register (FLASH_SR).
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers: Flash option register (FLASH_OPTR), Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash WRP area A address register (FLASH_WRP1AR), Flash PCROP2 Start address register (FLASH_PCROP2SR), Flash PCROP2 End address register (FLASH_PCROP2ER), Flash Bank 2 WRP area A address register (FLASH_WRP2AR), Flash Bank 2 WRP area B address register (FLASH_WRP2BR).
4. Set the Options Start bit OPTSTRT in the Flash control register (FLASH_CR).
5. Wait for the BSY bit to be cleared.

Note: Any modification of the value of one option is automatically performed by erasing both user option bytes pages first (bank 1 and bank 2) and then programming all the option bytes with the values contained in the flash option registers.
Option byte loading

After the BSY bit is cleared, all new options are updated into the flash but they are not applied to the system. They have effect on the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- when OBL_LAUNCH bit is set in the Flash control register (FLASH_CR).
- after a power reset (BOR reset or exit from Standby/Shutdown modes).

Option byte loader performs a read of the options block and stores the data into internal option registers. These internal registers configure the system and cannot be read with by software. Setting OBL_LAUNCH generates a reset so the option byte loading is performed under system reset.

Each option bit has also its complement in the same double word. During option loading, a verification of the option bit and its complement allows to check the loading has correctly taken place.

During option byte loading, the options are read by double word with ECC. If the word and its complement are matching, the option word/byte is copied into the option register.

If the comparison between the word and its complement fails, a status bit OPTVERR is set. Mismatch values are forced into the option registers:

- For USR OPT option, the value of mismatch is all options at ‘1’, except for BOR_LEV which is “000” (lowest threshold)
- For WRP option, the value of mismatch is the default value “No protection”
- For RDP option, the value of mismatch is the default value “Level 1”
- For PCROP, the value of mismatch is “all memory protected”

On system reset rising, internal option registers are copied into option registers which can be read and written by software (FLASH_OPTR, FLASH_PCROP1/2SR, FLASH_PCROP1/2ER, FLASH_WRP1/2AR, FLASH_WRP1/2BR). These registers are also used to modify options. If these registers are not modified by user, they reflects the options states of the system. See Modifying user options for more details.

Activating dual bank mode (switching from DBANK = 0 to DBANK = 1)

When switching from one flash mode to another (for example from single to dual bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading corrupted data from the flash when the memory organization is changed, any access (either CPU or DMAs) to flash memory should be avoided before reprogramming.

- Disable Instruction/data caches and/or prefetch if they are enabled (reset PRFTEN and ICEN/DCEN bits in the FLASH_ACR register).
- Flush instruction and data cache by setting the DCRST/ICRST bits in the FLASH_ACR register.
- Set the DBANK option bit and clear all the WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK = 1, perform a mass erase.
  - Start a new programing of code in 64 bits mode with DBANK = 1 memory mapping
  - Set the new WRP/PCROP with DBANK = 1 scheme if needed.
  - Set PRFTEN and ICEN/DCEN if needed.

The new software is ready to be run using the bank configuration.
De-activating dual bank mode (switching from DBANK = 1 to DBANK = 0)

When switching from one flash mode to another (for example from single to dual bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading corrupted data from the flash when the memory organization is changed, any access (either CPU or DMAs) to flash memory should be avoided before reprogramming.

- Disable Instruction/data caches and/or prefetch if they are enabled (reset PRFTEN and ICEN/DCEN bits in the FLASH_ACR register).
- Flush instruction and data cache by setting the DCRST/ICRST bits in the FLASH_ACR register.
- Clear the DBANK option bit and all WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK = 0, perform a mass erase.
  - Start a new programing of code in 128 bits mode with DBANK = 0 memory mapping
  - Set the new WRP/PCROP with DBANK = 0 scheme if needed. Set PRFTEN and ICEN/DCEN if needed.

The new software is ready to be run using the bank configuration.
3.5 **FLASH memory protection**

The flash main memory can be protected against external accesses with the Read protection (RDP). The pages of the flash memory can also be protected against unwanted write due to loss of program counter contexts. The write-protection (WRP) granularity is one page (2 Kbytes). Apart of the flash memory can also be protected against read and write from third parties (PCROP). The PCROP granularity is double word (64-bit).

### 3.5.1 Read protection (RDP)

The read protection is activated by setting the RDP option byte and then, by applying a system reset to reload the new RDP option byte. The read protection protects to the flash main memory, the option bytes, the backup registers (TAMP_BKPxR in the RTC) and the CCM SRAM.

**Note:** *If the read protection is set while the debugger is still connected (or had been connected since the last power on) through JTAG/SWD, apply a POR (power-on reset) instead of a system reset. If the read protection is programmed through software, don’t set the OBL_LAUNCH bit (FLASH_CR register) but perform a POR to reload the option byte. This can be done with a transition Standby (or Shutdown) mode followed by a wakeup.*

There are three levels of read protection from no protection (level 0) to maximum protection or no debug (level 2).

The flash memory is protected when the RDP option byte and its complement contain the pair of values shown in Table 32.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>RDP complement value</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>0x55</td>
<td>Level 0 (production value)</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Any value (not necessarily complementary) except 0x55 and 0x33</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>0x33</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

The System memory area is read accessible whatever the protection level. It is never accessible for program/erase operation.

**Level 0: no protection**

Read, program and erase operations into the flash main memory area are possible. The option bytes, the CCM SRAM and the backup registers are also accessible by all operations.
Level 1: Read protection

This is the default protection level when RDP option byte is erased. It is defined as well when RDP value is at any value different from 0xAA and 0xCC, or even if the complement is not correct.

- **User mode**: Code executing in user mode (Boot Flash) can access flash main memory, option bytes, CCM SRAM and backup registers with all operations.
- **Debug, boot RAM and bootloader modes**: In debug mode or when code is running from boot RAM or bootloader, the flash main memory, the backup registers (TAMP_BKPxR in the RTC) and the CCM SRAM are totally inaccessible. In these modes, a read or write access to the flash generates a bus error and a Hard Fault interrupt.

**Caution**: In case the Level 1 is configured and no PCROP area is defined, it is mandatory to set PCROP_RDP bit to 1 (full mass erase when the RDP level is decreased from Level 1 to Level 0). In case the Level 1 is configured and a PCROP area is defined, if user code needs to be protected by RDP but not by PCROP, it must not be placed in a page containing a PCROP area.

Level 2: No debug

In this level, the protection level 1 is guaranteed. In addition, the Cortex®-M4 debug port, the boot from RAM (boot RAM mode) and the boot from System memory (bootloader mode) are no more available. In user execution mode (boot FLASH mode), all operations are allowed on the flash main memory. On the contrary, only read operations can be performed on the option bytes.

Option bytes cannot be programmed nor erased. Thus, the level 2 cannot be removed at all: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag WRPERR is set in the Flash_SR register and an interrupt can be generated.

**Note**: The debug feature is also disabled under reset.
STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Changing the Read protection level

It is easy to move from level 0 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 1. Once in level 2, it is no more possible to modify the Read protection level.

When the RDP is reprogrammed to the value 0xAA to move from Level 1 to Level 0, a mass erase of the flash main memory is performed if PCROP_RDP is set in the Flash_PCROP1 End address register (FLASH_PCROP1ER). The backup registers (TAMP_BKPxR in the RTC) and the CCM SRAM are also erased. The user options except PCROP protection are set to their previous values copied from FLASH_OPTR, FLASH_WRPxyR (x=1, 2 and y =A or B). PCROP is disable. The OTP area is not affected by mass erase and remains unchanged.

If the bit PCROP_RDP is cleared in the FLASH_PCROP1ER, the full mass erase is replaced by a partial mass erase that is successive page erases in the bank where PCROP is active, except for the pages protected by PCROP. This is done in order to keep the PCROP code. If PCROP is active for both banks, both banks are erased by page erases.
Only when both banks are erased, options are re-programmed with their previous values. This is also true for FLASH_PCROPxSR and FLASH_PCROPxER registers (x=1,2).

**Note:** Full mass erase or partial mass erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase. To validate the protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in flash control register.

**Figure 4. Changing the read protection (RDP) level**

3.5.2 Proprietary code readout protection (PCROP)

Apart of the flash memory can be protected against read and write from third parties. The protected area is execute-only: it can only be reached by the STM32 CPU, as an instruction code, while all other accesses (DMA, debug and CPU data read, write and erase) are strictly prohibited. Depending of the DBANK mode, it allows either to specify one PCROP zone per bank in dual bank mode or to specify two PCROP zones for all memory. An additional option bit (PCROP_RDP) allows to select if the PCROP area is erased or not when the RDP protection is changed from Level 1 to Level 0 (refer to Changing the Read protection level).

Each PCROP area is defined by a start page offset and an end page offset related to the physical flash bank base address. These offsets are defined in the PCROP address registers Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash PCROP2 Start address register (FLASH_PCROP2SR), Flash PCROP2 End address register (FLASH_PCROP2ER).

In single bank mode (DBANK = 0):
- The PCROPx (x = 1,2) area is defined from the address: base address + [PCROPx_STRT x 16] (included) to the address: base address + [(PCROPx_END+1) x 16] (excluded). The minimum PCROP area size is two 2 x double-words (256 bits)

In dual bank mode (DBANK = 1)
- The PCROPx (x = 1,2) area is defined from the address: bank “x” base address + [PCROPx_STRT x 0x8] (included) to the address: bank “x” base address + [(PCROPx_END+1) x 0x8] (excluded). The minimum PCROP area size is two double-words (128 bits).

Table 13. Access status versus protection level and execution modes (continued)

<tr>
<td></td>
<td>2</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. When the protection level 2 is active, the Debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. The flash main memory is erased when the RDP option byte is programmed with all level protections disabled (0xAA).
4. OTP can only be written once.
5. The backup registers are erased when RDP changes from level 1 to level 0.
6. The CCM SRAM is erased when RDP changes from level 1 to level 0.
For example, to protect by PCROP from the address 0x0802 2F80 (included) to the address 0x0803 0004 (included):

- if boot in flash is done in Bank 1, FLASH_PCROP1SR and FLASH_PCROP1ER registers must be programmed with:
  - PCROP1_STRT = 0x45F0.
  - PCROP1_END = 0x6000.

- If the two banks are swapped, the protection must apply to bank 2, and FLASH_PCROP2SR and FLASH_PCROP2ER register must be programmed with:
  - PCROP2_STRT = 0x45F0.
  - PCROP2_END = 0x6000.

Any read access performed through the D-bus to a PCROP protected area triggers the RDERR flag error.

Any PCROP protected address is also write protected and any write access to one of these addresses triggers WRPERR.

Any PCROP area is also erase protected. Consequently, any erase to a page in this zone is impossible (including the page containing the start address and the end address of this zone). Moreover, a software mass erase cannot be performed if one zone is PCROP protected.

For previous example, due to erase by page, all pages from page 0x62 to 0x70 are protected in case of page erase. (All addresses from 0x0806 2000 to 0x080 70FFF can’t be erased).

Deactivation of PCROP can only occurs when the RDP is changing from level 1 to level 0. If the user options modification tries to clear PCROP or to decrease the PCROP area, the options programming is launched but PCROP area stays unchanged. On the contrary, it is possible to increase the PCROP area.

When option bit PCROP_RDP is cleared, when the RDP is changing from level 1 to level 0, Full mass erase is replaced by partial mass erase in order to keep the PCROP area (refer to Changing the Read protection level). In this case, PCROP1/2_STRT and PCROP1/2_END are also not erased.

Note: It is recommended to align PCROP area with page granularity when using PCROP_RDP, or to leave free the rest of the page where PCROP zone starts or ends.

### Table 14. PCROP protection(1)

<table>
<thead>
<tr>
<th>PCROPx registers values (x = 1,2)</th>
<th>PCROP protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCROPx_offset_strt &gt; PCROPx_offset_end</td>
<td>No PCROP area.</td>
</tr>
<tr>
<td>PCROPx_offset_strt &lt; PCROPx_offset_end</td>
<td>The area between PCROPx_offset_strt and PCROPx_offset_end is protected. It is possible to write: – PCROPx_offset_strt with a lower value – PCROPx_offset_end with a higher value.</td>
</tr>
</tbody>
</table>
The user area in flash memory can be protected against unwanted write operations. Depending on the DBANK option bit configuration, it allows either to specify:

- In single bank mode (DBANK = 0): four write-protected (WRP) areas can be defined, with page size (4 Kbytes) granularity.
- In dual bank mode (DBANK = 1): two write-protected (WRP) areas can be defined in each bank, with page (2 Kbytes) granularity.

Each area is defined by a start page offset and an end page offset related to the physical flash bank base address. These offsets are defined in the WRP address registers: Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR), Flash Bank 2 WRP area A address register (FLASH_WRP2AR), Flash Bank 2 WRP area B address register (FLASH_WRP2BR).

**3.5.3 Write protection (WRP)**

The user area in flash memory can be protected against unwanted write operations. Depending on the DBANK option bit configuration, it allows either to specify:

- In single bank mode (DBANK = 0): four write-protected (WRP) areas can be defined, with page size (4 Kbytes) granularity.
- In dual bank mode (DBANK = 1): two write-protected (WRP) areas can be defined in each bank, with page (2 Kbytes) granularity.

Each area is defined by a start page offset and an end page offset related to the physical flash bank base address. These offsets are defined in the WRP address registers: Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR), Flash Bank 2 WRP area A address register (FLASH_WRP2AR), Flash Bank 2 WRP area B address register (FLASH_WRP2BR).

**Single Bank mode (DBANK = 0)**

The WRPx “y” area (x=1,2 and y=A,B) is defined from the address: Base address + [WRPy_STRT x 0x1000] (included) to the address: Base address + [(WRPy_END+1) x 0x1000] (excluded).

**Dual bank mode (DBANK = 1)**

The bank “x” WRP “y” area (x=1,2 and y=A,B) is defined from the address: Bank “x” Base address + [WRPxy_STRT x 0x800] (included) to the address: Bank “x” Base address + [(WRPxy_END+1) x 0x800] (excluded).

For example, to protect by WRP from the address 0x0806 2800 (included) to the address 0x0807 07FF (included) with DBANK = 1:

- If the two banks are not swapped (FB_MODE=0), FLASH_WRP1AR register must be programmed with:
  - WRP1A_STRT = 0XC5
  - WRP1A_END = 0xE0
  WRP1B_STRT and WRP1B_END in FLASH_WRP1BR can be used instead (area “B” in Bank 1).

- If the two banks are swapped (FB_MODE = 1), the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  - WRP2A_STRT = 0xC5
  - WRP2A_END = 0xE0
  WRP2B_STRT and WRP2B_END in FLASH_WRP2BR can be used instead (area “B” in Bank 2).

When WRP is active, it cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.
If an erase/program operation to a write-protected part of the flash memory is attempted, the write protection error flag (WRPERR) is set in the FLASH_SR register. This flag is also set for any write access to:

- OTP area
- part of the flash memory that can never be written like the ICP
- PCROP area.

**Note:** When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase flash memory if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or System flash, even if WRP is not activated.

**Note:** To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in flash control register.

**Note:** When DBANK = 0, it is the user's responsibility to make sure that no overlapping occurs on the WRP zone.

<table>
<thead>
<tr>
<th>WRP registers values (x=1/2 y= A/B)</th>

</tr>
</tbody>
</table>

### 3.5.4 Securable memory area

This is an area of code that can be executed only once at boot, and never again unless a new reset occurs. The main purpose of the securable memory area is to protect a specific part of flash memory against undesired access. This is a mean to isolate first stage firmware boot together with its sensitive assets (keys) from the rest of the application code. This allows implementing root of trust solution such as secure boot. Securable memory area is located in the main flash memory. It is dedicated to executing trusted code. When not secured, the securable memory behaves like the remainder of main flash memory. When secured (the SEC_PROT1 (or SEC_PROT2) bit of the FLASH_CR register set), any attempt to program or erase in a secure memory area generates a write protection error (WRPERR flag is set) and any attempt to read from it generates a read error (RDERR flag is set).

The size of the securable memory area is defined by the SEC_SIZE1[7:0] (or SEC_SIZE2[7:0]) bitfield of the FLASH_SEC1R (or FLASH_SEC2R) register. It can be modified only in RDP Level 0. Its content is erased upon changing from RDP Level 1 to Level 0, even if it overlaps with PCROP pages.
The securable memory area is defined:

In case of dual bank configuration (DBANK = 1):
from the address: Bank1 base address (included) to the address: Bank1 base address + (0x800 * SEC_SIZE1) (excluded) and from the address: Bank2 base address (included) to the address: Bank2 base address + (0x800 * SEC_SIZE2) (excluded).

In case of single bank configuration DBANK = 0:
from the address: Bank base address (included) to the address: Bank base address + (0x1000 * SEC_SIZE1) (excluded).

3.5.5 Disabling core debug access

For executing sensitive code or manipulating sensitive data in securable memory area, the debug access to the core can temporarily be disabled.

In RDP level 2, the debugger is disabled by hardware, but in other RDP levels, the debugger can be disabled by software using the bit DBG_SWEN in the FLASH_ACR register. *Figure 11* gives an example of managing DBG_SWEN and SEC_PROT bits.

3.5.6 Forcing boot from flash memory

To increase the security and establish a chain of trust, the BOOT_LOCK option bit of the FLASH_SEC1R/FLASH_SEC2R register allows forcing the system to boot from the main flash memory regardless the other boot options. It is always possible to set the BOOT_LOCK bit. However, it is possible to reset it only when:

- RDP is set to Level 0, or
- RDP is set to Level 1, while Level 0 is requested and a full mass-erase is performed.

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **DBG_SWEN**: Debug software enable
   SW may use this bit to enable/disable the debugger.
   0: Debugger disabled
   1: Debugger enabled

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **SLEEP_PD**: Flash Power-down mode during Sleep or Low-power sleep mode
   This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Sleep or Low-power sleep mode.
   0: Flash in Idle mode during Sleep and Low-power sleep modes
   1: Flash in Power-down mode during Sleep and Low-power sleep modes

   **Caution**: The flash must not be put in power-down while a program or an erase operation is on-going.

Bit 13 **RUN_PD**: Flash Power-down mode during Run or Low-power run mode
   This bit is write-protected with FLASH_PDKEYR.
   This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Run or Low-power run mode. The flash memory can be put in power-down mode only when the code is executed from RAM. The flash memory must not be accessed when RUN_PD is set.
   0: Flash in Idle mode
   1: Flash in Power-down mode

   **Caution**: The flash must not be put in power-down while a program or an erase operation is on-going.

Bit 12 **DCRST**: Data cache reset
   0: Data cache is not reset
   1: Data cache is reset
   This bit can be written only when the data cache is disabled.
3.7.2 Flash Power-down key register (FLASH_PDKEYR)

</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 BSY:** Busy  
This indicates that a flash memory operation is in progress. This is set on the beginning of a flash memory operation and reset when the operation finishes or when an error occurs.

**Bit 15 OPTVERR:** Option validity error  
Set by hardware when the options read may not be the one configured by the user. If option haven’t been properly loaded, OPTVERR is set again after each system reset.  
Cleared by writing 1.

**Bit 14 RDERR:** PCROP read error  
Set by hardware when an address to be read through the D-bus belongs to a read protected area of the flash (PCROP protection). An interrupt is generated if RDERRIE is set in FLASH_CR.  
Cleared by writing 1.

Bits 13:10 Reserved, must be kept at reset value.

**Bit 9 FASTERR:** Fast programming error  
Set by hardware when a fast programming sequence (activated by FSTPG) is interrupted due to an error (alignment, size, write protection or data miss). The corresponding status bit (PGAERR, SIZERR, WRPERR or MISSERR) is set at the same time.  
Cleared by writing 1.

**Bit 8 MISSERR:** Fast programming data miss error  
In Fast programming mode, 32 double words must be sent to flash successively, and the new data must be sent to the flash logic control before the current data is fully programmed. MISSERR is set by hardware when the new data is not present in time.  
Cleared by writing 1.

**Bit 7 PGSERR:** Programming sequence error  
Set by hardware when a write access to the flash memory is performed by the code while PG or FSTPG have not been set previously. Set also by hardware when PROGERR, SIZERR, PGAERR, WRPERR, MISSERR or FASTERR is set due to a previous programming error.  
Set also when trying to perform bank erase when DBANK = 0.  
Cleared by writing 1.
Bit 6 **SIZERR**: Size error
Set by hardware when the size of the access is a byte or half-word during a program or a fast program sequence. Only double word programming is allowed (consequently: word access).
Cleared by writing 1.

Bit 5 **PGAERR**: Programming alignment error
Set by hardware when the data to program cannot be contained in the same 64-bit flash memory row in case of standard programming, or if there is a change of page during fast programming.
Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error
Set by hardware when an address to be erased/programmed belongs to a write-protected part (by WRP, PCROP or RDP level 1) of the flash memory.
Cleared by writing 1.

Bit 3 **PROGERR**: Programming error
Set by hardware when a double-word address to be programmed contains a value different from ‘0xFFFF FFFF FFFF FFFF’ before programming, except if the data to write is ‘0x0000 0000 0000 0000’.
Cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Operation error
Set by hardware when a flash memory operation (program / erase) completes unsuccessfully.
This bit is set only if error interrupts are enabled (ERRIE = 1).
Cleared by writing ‘1’.

Bit 0 **EOP**: End of operation
Set by hardware when one or more flash memory operation (programming / erase) has been completed successfully.
This bit is set only if the end of operation interrupts are enabled (EOPIE = 1).
Cleared by writing 1.

### 3.7.6 Flash control register (FLASH_CR)

Address offset: 0x14
Reset value: 0xC000 0000
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

</table>
Bit 31 **LOCK**: FLASH_CR lock

This bit is set only. When set, the FLASH_CR register is locked. It is cleared by hardware after detecting the unlock sequence. In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30 **OPTLOCK**: Options lock

This bit is set only. When set, all bits concerning user option in FLASH_CR register and so option page are locked. This bit is cleared by hardware after detecting the unlock sequence. The LOCK bit must be cleared before doing the unlock sequence for OPTLOCK bit. In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bit 29 **SEC_PROT2**: Securable memory area protection bit for bank 2.

This bit is set to lock the access to the securable area in bank 2. It is set by software when exiting the securable area, and can only be written once. In case DBANK = 0, this bit is useless.

Bit 28 **SEC_PROT1**: Securable memory area protection bit for bank 1.

This bit is set to lock the access to the securable memory area for bank 1 (or when DBANK = 0). It is set by software when exiting the securable area, and can only be written once.

Bit 27 **OBL_LAUNCH**: Force the option byte loading

When set to 1, this bit forces the option byte reloading. This bit is cleared only when the option byte loading is complete. It cannot be written if OPTLOCK is set.

0: Option byte loading complete
1: Option byte loading requested

Bit 26 **RDERRIE**: PCROP read error interrupt enable

This bit enables the interrupt generation when the RDERR bit in the FLASH_SR is set to 1.

0: PCROP read error interrupt disabled
1: PCROP read error interrupt enabled

Bit 25 **ERRIE**: Error interrupt enable

This bit enables the interrupt generation when the OPERR bit in the FLASH_SR is set to 1.

0: OPERR error interrupt disabled
1: OPERR error interrupt enabled

Bit 24 **EOPIE**: End of operation interrupt enable

This bit enables the interrupt generation when the EOP bit in the FLASH_SR is set to 1.

0: EOP Interrupt disabled
1: EOP Interrupt enabled

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **FSTPG**: Fast programming

0: Fast programming disabled
1: Fast programming enabled

Bit 17 **OPTSTRT**: Options modification start

This bit triggers an options operation when set. This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.
Bit 16 **START**: Start
This bit triggers an erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, an unpredictable behavior may occur without generating any error flag. This condition should be forbidden.
This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 15 **MER2**: Bank 2 mass erase
This bit triggers the bank 2 mass erase (all bank 2 user pages) when set.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Bank erase
DBANK = 1
0: Bank 1 is selected for page erase
1: Bank 2 is selected for page erase
DBANK = 0
Reserved, must be at reset value.

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Page number selection
These bits select the page to erase:
0000000: page 0
0000001: page 1
...
1111111: page 255

Bit 2 **MER1**: Bank 1 mass erase
This bit triggers the bank 1 mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Page erase
0: page erase disabled
1: page erase enabled

Bit 0 **PG**: Programming
0: Flash programming disabled
1: Flash programming enabled

### 3.7.7 Flash ECC register (FLASH_ECCR)

**Address offset**: 0x18

**Reset value**: 0x0000 0000

**Access**: no wait state when no flash memory operation is on going, word, half-word and byte access

**ADDR_ECC[15:0]**

| r | r | r | r | r | r | r | r | r | r | r | r | r |
Bit 31 **ECCD**: ECC detection  
DBANK = 1  
Set by hardware when two ECC errors have been detected (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). When this bit is set, a NMI is generated.  
Cleared by writing 1.  
DBANK = 0  
Set by hardware when two ECC errors have been detected on 64-bit LSB (bits 63:0) (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). When this bit is set, a NMI is generated.  
Cleared by writing 1.

Bit 30 **ECCC**: ECC correction  
DBANK = 1  
Set by hardware when one ECC error has been detected and corrected (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). An interrupt is generated if ECCCIE is set.  
Cleared by writing 1.  
DBANK = 0  
Set by hardware when one ECC error as been detected and corrected on 64-bit LSB (bits 63:0) (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared).  
Cleared by writing 1.

Bit 29 **ECCD2**: ECC2 detection  
DBANK = 0  
Set by hardware when two ECC errors have been detected on 64-bit MSB (bits127:64). This bit is set (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). When this bit is set, a NMI is generated.  
Cleared by writing 1.  
DBANK = 1  
Reserved, must be kept at reset value.

Bit 28 **ECCC2**: ECC correction  
DBANK = 0  
Set by hardware when one ECC error has been detected and corrected on 64-bit MSB (bits127:64). This bit is set (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). An interrupt is generated if ECCCIE is set.  
Cleared by writing 1.  
DBANK = 1  
Reserved, must be kept at reset value.

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **ECCCEIE**: ECC correction interrupt enable  
0: ECCC interrupt disabled  
1: ECCC interrupt enabled.  
DBANK = 0  
This bit enables the interrupt generation when the ECCC or ECCC2 bits in the FLASH_ECCR register are set.  
DBANK = 1  
This bit enables the interrupt generation when the ECC bit in the FLASH_ECCR register is set.

Bit 23 Reserved, must be kept at reset value.
Bit 22 **SYSF_ECC**: System flash ECC fail

This bit indicates that the ECC error correction or double ECC error detection is located in the system flash.

Bit 21 **BK_ECC**: ECC fail bank

DBANK = 1

This bit indicates which bank is concerned by the ECC error correction or by the double ECC error detection.

0: bank 1
1: bank 2

DBANK = 0

If SYSF_ECC is 1, it indicates which bank is concerned by the ECC error.

If SYSF_ECC is 0, reserved, must be kept cleared.

Bits 20:19 Reserved, must be kept at reset value.

Bits 18:0 **ADDR_ECC[18:0]**: ECC fail address

DBANK = 0

This bit indicates which address in the flash memory is concerned by the ECC error correction or by the double ECC error detection.

DBANK = 1

This bit indicates which address in the bank is concerned by the ECC error correction or by the double ECC error detection.

### 3.7.8 Flash option register (FLASH_OPTR)

Address offset: 0x20

Reset value: 0xFXXX XXXX. Register bits are loaded with values from flash memory at OBL.

Access: no wait state when no flash memory operation is on going, word, half-word and byte access

<table>

</table>
Bits 29:28 **NRST_MODE[1:0]:**
- 00: Reserved
- 01: Reset Input only: a low level on the NRST pin generates system reset, internal RESET not propagated to the NSRT pin
- 10: GPIO: standard GPIO pad functionality, only internal RESET possible
- 11: Bidirectional reset: NRST pin configured in reset input/output mode (legacy mode)

Bit 27 **nBOOT0**: nBOOT0 option bit
- 0: nBOOT0 = 0
- 1: nBOOT0 = 1

Bit 26 **nSWBOOT0**: Software BOOT0
- 0: BOOT0 taken from the option bit nBOOT0
- 1: BOOT0 taken from PB8/BOOT0 pin

Bit 25 **CCMSRAM_RST**: CCM SRAM Erase when system reset
- 0: CCM SRAM erased when a system reset occurs
- 1: CCM SRAM is not erased when a system reset occurs

Bit 24 **SRAM_PE**: SRAM1 and CCM SRAM parity check enable
- 0: SRAM1 and CCM SRAM parity check enable
- 1: SRAM1 and CCM SRAM parity check disable

Bit 23 **nBOOT1**: Boot configuration
Together with the BOOT0 pin, this bit selects boot mode from the flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bit 22 **DBANK**: 0: Single bank mode with 128 bits data read width
- 1: Dual bank mode with 64 bits data
This bit can only be written when PCROPA/B is disabled.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **BFB2**: Dual-bank boot
- 0: Dual-bank boot disable
- 1: Dual-bank boot enable

Bit 19 **WWDG_SW**: Window watchdog selection
- 0: Hardware window watchdog
- 1: Software window watchdog

Bit 18 **IWWDG_STDBY**: Independent watchdog counter freeze in Standby mode
- 0: Independent watchdog counter is frozen in Standby mode
- 1: Independent watchdog counter is running in Standby mode

Bit 17 **IWWDG_STOP**: Independent watchdog counter freeze in Stop mode
- 0: Independent watchdog counter is frozen in Stop mode
- 1: Independent watchdog counter is running in Stop mode

Bit 16 **IWWDG_SW**: Independent watchdog selection
- 0: Hardware independent watchdog
- 1: Software independent watchdog

Bit 15 Reserved, must be at reset value.
Bit 14 **nRST_SHDW**
0: Reset generated when entering the Shutdown mode
1: No reset generated when entering the Shutdown mode

Bit 13 **nRST_STDBY**
0: Reset generated when entering the Standby mode
1: No reset generated when entering the Standby mode

Bit 12 **nRST_STOP**
0: Reset generated when entering the Stop mode
1: No reset generated when entering the Stop mode

Bit 11 Reserved, must be at reset value.

Bits10:8 **BOR_LEV**: BOR reset Level
These bits contain the VDD supply level threshold that activates/releases the reset.
000: BOR Level 0. Reset level threshold is around 1.7 V
001: BOR Level 1. Reset level threshold is around 2.0 V
010: BOR Level 2. Reset level threshold is around 2.2 V
011: BOR Level 3. Reset level threshold is around 2.5 V
100: BOR Level 4. Reset level threshold is around 2.8 V

Bits 7:0 **RDP**: Read protection level
0xAA: Level 0, read protection not active
0xCC: Level 2, chip read protection active
Others: Level 1, memories read protection active

*Note: Take care about PCROP_RDP configuration in Level 1. Refer to Level 1: Read protection for more details.*

### 3.7.9 Flash PCROP1 Start address register (FLASH_PCROP1SR)
Address offset: 0x24
Reset value: 0xFFFF XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word access.

**RPCROP1_STRT[14:0]**

Bits 31:15 Reserved, must be kept at reset value.

**Bits 14:0** **RPCROP1_STRT[14:0]**: PCROP area start offset

DBANK = 1
PCROP1_STRT contains the first double-word of the PCROP area for bank1.
DBANK = 0
PCROP1_STRT contains the first 2xdouble-word of the PCROP area for all memory.
3.7.10 Flash PCROP1 End address register (FLASH_PCROP1ER)

Address offset: 0x28
Reset value: 0x0000 XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word, half-word access.
PCROP_RDP bit can be accessed with byte access.

### Flash PCROP1 End address register (FLASH_PCROP1ER)

Bit 31 **PCROP_RDP:** PCROP area preserved when RDP level decreased
This bit is set only. It is reset after a full mass erase due to a change of RDP from Level 1 to Level 0.
0: PCROP area is not erased when the RDP level is decreased from Level 1 to Level 0.
1: PCROP area is erased when the RDP level is decreased from Level 1 to Level 0 (full mass erase).

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **PCROP1_END[14:0]:** Bank 1 PCROP area end offset
DBANK = 1
PCROP1_END contains the last double-word of the bank 1 PCROP area.
DBANK = 0
PCROP1_END contains the last 2x double-word of the first PCROP area in all memory.

3.7.11 Flash Bank 1 WRP area A address register (FLASH_WRP1AR)

Address offset: 0x2C
Reset value: 0x00XX 00XX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

</tr>
</thead>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **BOOT_LOCK**: used to force boot from user flash area.
- 0: Boot based on the pad/option bit configuration
- 1: Boot forced from main flash memory

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **SEC_SIZE1[7:0]**: sets the number of pages used in the bank 1 securable memory area.
- Secure area starts at 0x0800 0000 and its size is SEC_SIZE1 * page size.
- This field can be changed in level0 only.
- Any attempt to modify in level1 silently fails, and does not change register value.

3.7.18 Flash securable area bank2 register (FLASH_SEC2R)

Address offset: 0x74
Reset value: 0xFFFF FFXX
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Refer to Section 2.2 on page 81 for the register boundary addresses.
4 Embedded flash memory (FLASH) for category 4 devices

4.1 Introduction

The flash memory interface manages CPU AHB ICode and DCode accesses to the flash memory. It implements the erase and program flash memory operations and the read and write protection mechanisms.

The flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

4.2 FLASH main features

- Up to 512 Kbytes of flash memory (single bank).
- Flash memory read operations with 64 bits data width
- Page erase and mass erase

Flash memory interface features:
- Flash memory read operations
- Flash memory program/erase operations
- Read protection activated by option (RDP)
- 2 Write protection areas selected by option
- Proprietary code read protection areas defined by option
- Secureable memory areas defined by option
- Prefetch on ICODE
- Instruction Cache: 32 cache lines of 4 x 64 bits on ICode (1 KB RAM)
- Data Cache: 8 cache lines of 4 x 64 bits on DCode (256B RAM)
- Error Code Correction ECC: 8 bits per 64-bit double-word
  \[8 + 64 = 72\] bits, 2 bits detection, 1 bit correction
- Option byte loader
- Low-power mode
4.3 FLASH functional description

4.3.1 Flash memory organization

The flash memory has the following main features:
- Capacity up to 512 Kbytes (read width of 64-bit)
- 512 Kbytes organized in one single bank for main memory
- Page size of 2 Kbytes
- 72 bits wide data read (64 bits plus 8 ECC bits)
- Page and mass erase
- Each page is composed of 8 rows of 256 bytes
- An Information block containing:
  - System memory from which the device boots in System memory boot mode. The area is reserved for use by STMicroelectronics and contains the bootloader that is used to reprogram the flash memory through one of the following interfaces: USART, SPI, I2C, USB. It is programmed by STMicroelectronics when the device is manufactured, and protected against spurious write/erase operations. For further details, please refer to the AN2606 available from www.st.com.
  - 1 Kbyte (128 double word) OTP (one-time programmable) bytes for user data. The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire double word cannot be written anymore, even with the value 0x0000 0000 0000 0000.
  - Option bytes for user configuration.

The memory organization is based on a main area and an information block as shown in Table 28.

| Table 18. Flash module - 256/512 Kbytes organization (64 bits read width) |
|--------------------------|-----------------------------|----------|----------|
| Flash area               | Flash memory addresses      | Size     | Name     |
| Main memory 256/512 Kbytes\(^{(1)}\) | 0x0800 0000 - 0x0800 07FF  | 2 K      | Page 0   |
|                         | 0x0800 0800 - 0x0800 0FF   | 2 K      | Page 1   |
|                         | 0x0800 1000 - 0x0800 17FF  | 2 K      | Page 2   |
|                         | 0x0800 1800 - 0x0800 1FFF  | 2 K      | Page 3   |
|                         | 0x0807 F800 - 0x0807 FFFF  | 2 K      | Page 255 |
| Information block       | 0x1FFF 0000 - 0x1FFF 6FF   | 28 K     | System memory |
|                         | 0x1FFF 7000 - 0x1FFF 73FF  | 1 K      | OTP area  |
|                         | 0x1FFF 7800 - 0x1FFF 782F  | 48       | Option bytes |

\(^{(1)}\) For 256-Kbyte devices: from page 0 to page 127.
4.3.2 Error code correction (ECC)

Data in flash memory are 72-bit words: 8 bits are added per double word (64 bits). The ECC mechanism supports:

- One error detection and correction
- Two errors detection

When one error is detected and corrected, the flag ECCC (ECC correction) is set in **Flash ECC register (FLASH_ECCR)**. If ECCCIE is set, an interrupt is generated.

When two errors are detected, a flag ECCD (ECC detection) is set in **FLASH_ECCR** register. In this case, a NMI is generated.

When an ECC error is detected, the address of the failing double word is saved in ADDR_ECC[20:0] in the **FLASH_ECCR** register. ADDR_ECC[2:0] are always cleared.

When ECC or ECCD is set, ADDR_ECC is not updated if a new ECC error occurs. **FLASH_ECCR** is updated only when ECC flags are cleared.

**Note:** For a virgin data: 0xFFF FFFF FFFF FFFF FFF, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

4.3.3 Read access latency

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the **Flash access control register (FLASH_ACR)** according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device V\textsubscript{CORE}. Refer to **Section 6.1.5: Dynamic voltage scaling management.** Table 19 shows the correspondence between wait states and CPU clock frequency.

<table>
<thead>
<tr>
<th>Wait states (WS) (LATENCY)</th>
<th>HCLK (MHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>V\textsubscript{CORE} Range 1 boost mode</td>
</tr>
<tr>
<td>0 WS (1 CPU cycles)</td>
<td>\leq 34</td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>\leq 68</td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>\leq 102</td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>\leq 136</td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>\leq 170</td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 16 MHz and 1 wait state (WS) is configured in the **FLASH_ACR** register.

When changing the CPU frequency, the following software sequences must be applied in order to tune the number of wait states needed to access the flash memory:
Increasing the CPU frequency:

1. Program the new number of wait states to the LATENCY bits in the Flash access control register (FLASH_ACR).
2. Check that the new number of wait states is taken into account to access the flash memory by reading the FLASH_ACR register.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in RCC_CFGR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFGR

If some of above two steps decreases the CPU frequency, firstly perform this step and then the rest. Otherwise modify The CPU clock source by writing the SW bits in the RCC_CFGR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.

Decreasing the CPU frequency:

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGR register.
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in RCC_CFGR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFGR

If some of above two steps increases the CPU frequency, firstly perform another step and then this step. Otherwise modify The CPU clock source by writing the SW bits in the RCC_CFGR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.

5. Program the new number of wait states to the LATENCY bits in Flash access control register (FLASH_ACR).

6. Check that the new number of wait states is used to access the flash memory by reading the FLASH_ACR register.

4.3.4 Adaptive real-time memory accelerator (ART Accelerator)

The proprietary Adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M4 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M4 with FPU over flash memory technologies, which normally requires the processor to wait for the flash memory at higher operating frequencies.

To release the processor full performance, the accelerator implements an instruction prefetch queue and branch cache which increases program execution speed from the 64-bit flash memory. Based on CoreMark benchmark, the performance achieved thanks to the ART accelerator is equivalent to 0 wait state program execution from flash memory at a CPU frequency up to 170 MHz.
Instruction prefetch

The Cortex®-M4 fetches the instruction over the ICode bus and the literal pool (constant/data) over the DCode bus. The prefetch block aims at increasing the efficiency of ICode bus accesses.

Each flash memory read operation provides 64 bits from either two instructions of 32 bits or four instructions of 16 bits depending on the launched program. This 64-bit current instruction line is saved in a current buffer, and in case of sequential code, at least two CPU cycles are needed to execute the previous read instruction line.

Prefetch on the ICode bus can be used to read the next sequential instruction line from the flash memory while the current instruction line is being requested by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the Flash access control register (FLASH_ACR). This feature is useful if at least one wait state is needed to access the flash memory.

Figure 9 shows the execution of sequential 16-bit instructions with and without prefetch when 3 WS are needed to access the flash memory.
When the code is not sequential (branch), the instruction may not be present in the currently used instruction line or in the prefetched instruction line. In this case (miss), the penalty in terms of number of cycles is at least equal to the number of wait states.
If a loop is present in the current buffer, no new flash access is performed.

**Instruction cache memory (I-Cache)**

To limit the time lost due to jumps, it is possible to retain 32 lines of 4 x 64 bits in an instruction cache memory. This feature can be enabled by setting the instruction cache enable (ICEN) bit in the *Flash access control register (FLASH_ACR)*. Each time a miss occurs (requested data not present in the currently used instruction line, in the prefetched instruction line or in the instruction cache memory), the line read is copied into the instruction cache memory. If some data contained in the instruction cache memory are requested by the CPU, they are provided without inserting any delay. Once all the instruction cache memory lines have been filled, the LRU (least recently used) policy is used to determine the line to replace in the instruction memory cache. This feature is particularly useful in case of code containing loops.

The Instruction cache memory is enable after system reset.

**Data cache memory (D-Cache)**

Literal pools are fetched from flash memory through the DCode bus during the execution stage of the CPU pipeline. Each DCode bus read access fetches 64 bits which are saved in a current buffer. The CPU pipeline is consequently stalled until the requested literal pool is provided. To limit the time lost due to literal pools, accesses through the AHB databus DCode have priority over accesses through the AHB instruction bus ICode.

If some literal pools are frequently used, the data cache memory can be enabled by setting the data cache enable (DCEN) bit in the *Flash access control register (FLASH_ACR)*. This feature works like the instruction cache memory, but the retained data size is limited to 8 rows of 4*64 bits.

The Data cache memory is enable after system reset.

*Note:*  *The D-Cache is active only when data is requested by the CPU (not by DMA1 and DMA2).*

*Data in option bytes block are not cacheable.*

### 4.3.5 Flash program and erase operations

The STM32G4 series embedded flash memory can be programmed using in-circuit programming or in-application programming.

The *in-circuit programming (ICP)* method is used to update the entire contents of the flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, *in-application programming (IAP)* can use any communication interface supported by the microcontroller (I/Os, USB, CAN, UART, I²C, SPI, etc.) to download programming data into memory. IAP allows the user to reprogram the flash memory while the application is running. Nevertheless, part of the application has to have been previously programmed in the flash memory using ICP.

The contents of the flash memory are not guaranteed if a device reset occurs during a flash memory operation.

The flash erase and programming is only possible in the voltage scaling range 1. The VOS[1:0] bits in the PWR_CR1 must be programmed to 01b.
During a program/erase operation to the flash memory, any attempt to read the flash memory stalls the bus. The read operation proceeds correctly once the program/erase operation has completed.

**Unlocking the flash memory**

After reset, write is not allowed in the *Flash control register (FLASH_CR)* to protect the flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write \( \text{KEY1} = 0x45670123 \) in the *Flash key register (FLASH_KEYR)*
2. Write \( \text{KEY2} = 0xCDEF89AB \) in the FLASH_KEYR register.

Any wrong sequence locks up the FLASH_CR register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated.

The FLASH_CR register can be locked again by software by setting the LOCK bit in the FLASH_CR register.

*Note:* The FLASH_CR register cannot be written when the BSY bit in the *Flash status register (FLASH_SR)* is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

### 4.3.6 Flash main memory erase sequences

The flash memory erase operation can be performed at page level or on the whole flash memory (mass erase). Mass erase does not affect the Information block (system flash, OTP and option bytes).

#### Page erase

To erase a page, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the *Flash status register (FLASH_SR)*.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PER bit and select the page to erase (PNB).
4. Set the STRT bit in the FLASH_CR register.
5. Wait for the BSY bit to be cleared in the FLASH_SR register.

*Note:* The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the page erase is part of write-protected area (by WRP or PCROP), WRPERR is set and the page erase request is aborted.

#### Mass erase

To perform a mass erase, follow the procedure below:
1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit in the flash memory control register (FLASH_CR).
4. Set the STRT bit in the FLACH_CR register.
5. Wait for the BSY bit to be cleared in the flash status register (FLASH_SR).

**Note:** The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the Flash memory contains a write-protected area (by WRP or PCROP), WRPERR is set and the mass erase request is aborted.

### 4.3.7 Flash main memory programming sequences

The flash memory is programmed 72 bits at a time (64 bits + 8 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets PROGERR flag in the Flash status register (FLASH_SR).

It is only possible to program double word (2 x 32-bit data).

- Any attempt to write byte or half-word sets SIZERR flag in the FLASH_SR register.
- Any attempt to write a double word which is not aligned with a double word address sets PGAERR flag in the FLASH_SR register.

#### Standard programming

The flash memory programming sequence in standard mode is as follows:

1. Check that no flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PG bit in the Flash control register (FLASH_CR).
4. Perform the data write operation at the desired memory address, inside main memory block or OTP area. Only double word can be programmed.
   - Write a first word in an address aligned with double word
   - Write the second word
5. Wait until the BSY bit is cleared in the FLASH_SR register.
6. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
7. Clear the PG bit in the FLASH_SR register if there no more programming request anymore.

**Note:** When the flash interface has received a good sequence (a double word), programming is automatically launched and BSY bit is set. The internal oscillator HSI16 (16 MHz) is enabled
automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the user needs to program only one word, double word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the double word to program.

**Fast programming**

This mode allows to program a row (32 double words), and to reduce the page programming time by eliminating the need for verifying the flash locations before they are programmed and to avoid rising and falling time of high voltage for each double word. During fast programming, the CPU clock frequency (HCLK) must be at least 8 MHz.

Only the main memory can be programmed in Fast programming mode.

The flash main memory programming sequence in standard mode is as follows:

1. Perform a mass erase. If not, PGSERR is set.
2. Check that no flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
3. Check and clear all error programming flag due to a previous programming.
4. Set the FSTPG bit in Flash control register (FLASH_CR).
5. Write the 32 double words to program a row. Only double words can be programmed:
   - Write a first word in an address aligned with double word
   - Write the second word.
6. Wait until the BSY bit is cleared in the FLASH_SR register.
7. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
8. Clear the FSTPG bit in the FLASH_SR register if there no more programming request anymore.

**Note:** If the flash is attempted to be written in Fast programming mode while a read operation is ongoing, the programming is aborted without any system notification (no error flag is set).

When the flash interface has received the first double word, programming is automatically launched. The BSY bit is set when the high voltage is applied for the first double word, and it is cleared when the last double word has been programmed or in case of error. The internal oscillator HSI16 (16 MHz) is enabled automatically when FSTPG bit is set, and disabled automatically when FSTPG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

The 32 double word must be written successively. The high voltage is kept on the flash for all the programming. Maximum time between two double words write requests is the time programming (around 2 x 25us). If a second double word arrives after this time programming, fast programming is interrupted and MISSERR is set.

High voltage cannot exceed 8 ms for a full row between 2 erases. This is guaranteed by the sequence of 32 double words successively written with a clock system greater or equal to 8MHz. An internal time-out counter counts 7ms when Fast programming is set and stops the programming when time-out is over. In this case the FASTERR bit is set.

If an error occurs, high voltage is stopped and next double word to programmed is not programmed. Anyway, all previous double words have been properly programmed.
Programming errors

Several kinds of errors can be detected. In case of error, the flash memory operation (programming or erasing) is aborted.

- **PROGERR**: Programming Error
  
  In standard programming: PROGERR is set if the word to write is not previously erased (except if the value to program is full zero).

- **SIZERR**: Size Programming Error
  
  In standard programming or in fast programming: only double word can be programmed and only 32-bit data can be written. SIZERR is set if a byte or an half-word is written.

- **PGAERR**: Alignment Programming Error
  
  PGAERR is set if one of the following conditions occurs:
  - In standard programming: the first word to be programmed is not aligned with a double word address, or the second word doesn’t belong to the same double word address.
  - In fast programming: the data to program doesn’t belong to the same row than the previous programmed double words, or the address to program is not greater than the previous one.

- **PGSERR**: Programming Sequence Error
  
  PGSERR is set if one of the following conditions occurs:
  - In the standard programming sequence or the fast programming sequence: a data is written when PG and FSTPG are cleared.
  - In the standard programming sequence or the fast programming sequence: MER1, and PER are not cleared when PG or FSTPG is set.
  - In the fast programming sequence: the mass erase is not performed before setting FSTPG bit.
  - In the mass erase sequence: PG, FSTPG, and PER are not cleared when MER1 is set.
  - In the page erase sequence: PG, FSTPG, MER1 are not cleared when PER is set.
  - PGSERR is set also if PROGERR, SIZERR, PGAERR, WRPERR, MISSERR, FASTERR or PGSERR is set due to a previous programming error.

- **WRPERR**: Write Protection Error
  
  WRPERR is set if one of the following conditions occurs:
  - Attempt to program or erase in a write protected area (WRP) or in a PCROP area or in a securable memory area.
  - Attempt to perform an erase when one page or more is protected by WRP or PCROP.
  - The debug features are connected or the boot is executed from SRAM or from System flash when the read protection (RDP) is set to Level 1.
  - Attempt to modify the option bytes when the read protection (RDP) is set to Level 2.

- **MISSERR**: Fast Programming Data Miss Error
  
  In fast programming: all the data must be written successively. MISSERR is set if the previous data programmation is finished and the next data to program is not written yet.

- **FASTERR**: Fast Programming Error
In fast programming: FASTERR is set if one of the following conditions occurs:
- When FSTPG bit is set for more than 7ms which generates a time-out detection.
- When the fast programming has been interrupted by a MISSERR, PGAERR, WRPERR or SIZERR.

If an error occurs during a program or erase operation, one of the following error flags is set in the FLASH_SR register:
- PROGERR, SIZERR, PGAERR, PGSERR, MISSERR (Program error flags),
- WRPERR (Protection error flag)

In this case, if the error interrupt enable bit ERRIE is set in the Flash status register (FLASH_SR), an interrupt is generated and the operation error flag OPERR is set in the FLASH_SR register.

Note: If several successive errors are detected (for example, in case of DMA transfer to the flash memory), the error flags cannot be cleared until the end of the successive write requests.

Programming and caches

If a flash memory write access concerns some data in the data cache, the flash write access modifies the data in the flash memory and the data in the cache.

If an erase operation in flash memory also concerns data in the data or instruction cache, you have to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush the caches by setting the DCRST and ICRST bits in the Flash access control register (FLASH_ACR).

Note: The I/D cache should be flushed only when it is disabled (I/DCEN = 0).
4.4 FLASH option bytes

4.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog can be selected in hardware or software mode (refer to Section 5.4.2: Option bytes programming).

A double word is split up as follows in the option bytes:

<table>
<thead>
<tr>
<th>Table 20. Option byte format</th>
</tr>
</thead>
<tbody>
<tr>
<td>63-24</td>
</tr>
<tr>
<td>Complemented option byte 3</td>
</tr>
</tbody>
</table>

The organization of these bytes inside the information block is as shown in Table 31: Option byte organization.

The option bytes can be read from the memory locations listed in Table 31: Option byte organization or from the Option byte registers:

- Flash option register (FLASH_OPTR)
- Flash PCROP1 Start address register (FLASH_PCROP1SR)
- Flash PCROP1 End address register (FLASH_PCROP1ER)
- Flash WRP area A address register (FLASH_WRP1AR)
- Flash WRP area B address register (FLASH_WRP1BR)

<table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 \textbf{BOOT\_LOCK}: used to force boot from user area
0: Boot based on the pad/option bit configuration
1: Boot forced from main flash memory

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 \textbf{SEC\_SIZE1[8:0]}: Securable memory area size
Contains the number of securable flash memory pages
4.4.2 Option bytes programming

After reset, the options related bits in the Flash control register (FLASH_CR) are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the Flash control register (FLASH_CR) must be cleared. The following sequence is used to unlock this register:

1. Unlock the FLASH_CR with the LOCK clearing sequence (refer to Unlocking the flash memory).
2. Write OPTKEY1 = 0x08192A3B in the Flash option key register (FLASH_OPTKEYR).
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

*Note:* If LOCK is set by software, OPTLOCK is automatically set too.

Modifying user options

The option bytes are programmed differently from a main memory user address. To modify the user options value, follow the procedure below:

1. Check that no flash memory operation is on going by checking the BSY bit in the Flash status register (FLASH_SR).
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers: Flash option register (FLASH_OPTR), Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR).
4. Set the Options Start bit OPTSTRT in the Flash control register (FLASH_CR).
5. Wait for the BSY bit to be cleared.

*Note:* Any modification of the value of one option is automatically performed by erasing both user option bytes pages first and then programming all the option bytes with the values contained in the flash option registers.

Option byte loading

After the BSY bit is cleared, all new options are updated into the flash but they are not applied to the system. They have effect on the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- when OBL_LAUNCH bit is set in the Flash control register (FLASH_CR).
- after a power reset (BOR reset or exit from Standby/Shutdown modes).

Option byte loader performs a read of the options block and stores the data into internal option registers. These internal registers configure the system and cannot be read with by software. Setting OBL_LAUNCH generates a reset so the option byte loading is performed under system reset.

Each option bit has also its complement in the same double word. During option loading, a verification of the option bit and its complement allows to check the loading has correctly taken place.

During option byte loading, the options are read by double word with ECC. If the word and its complement are matching, the option word/byte is copied into the option register.
If the comparison between the word and its complement fails, a status bit OPTVERR is set. Mismatch values are forced into the option registers:

- For USR OPT option, the value of mismatch is all options at ‘1’, except for BOR.LEV which is “000” (lowest threshold)
- For WRP option, the value of mismatch is the default value “No protection”
- For RDP option, the value of mismatch is the default value “Level 1”
- For PCROP, the value of mismatch is “all memory protected”

On system reset rising, internal option registers are copied into option registers which can be read and written by software (FLASH_OPTR, FLASH_PCROP1SR, FLASH_PCROP1ER, FLASH_WRP1AR, FLASH_WRP1BR). These registers are also used to modify options. If these registers are not modified by user, they reflects the options status of the system. See Section : Modifying user options for more details.

4.5 FLASH memory protection

The flash main memory can be protected against external accesses with the Read protection (RDP). The pages of the flash memory can also be protected against unwanted write due to loss of program counter contexts. The write-protection (WRP) granularity is one page (2 Kbytes). Apart of the flash memory can also be protected against read and write from third parties (PCROP). The PCROP granularity is double word (64-bit).

4.5.1 Read protection (RDP)

The read protection is activated by setting the RDP option byte and then, by applying a system reset to reload the new RDP option byte. The read protection protects to the flash main memory, the option bytes, the backup registers (TAMP_BKPxR in the RTC) and the CCM SRAM.

Note: If the read protection is set while the debugger is still connected (or had been connected since the last power on) through JTAG/SWD, apply a POR (power-on reset) instead of a system reset. If the read protection is programmed through software, don't set the OBL.LAUNCH bit (FLASH_CR register) but perform a POR to reload the option byte. This can be done with a transition Standby (or Shutdown) mode followed by a wakeup.

There are three levels of read protection from no protection (level 0) to maximum protection or no debug (level 2).

The flash memory is protected when the RDP option byte and its complement contain the pair of values shown in Table 32.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>RDP complement value</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>0x55</td>
<td>Level 0 (production value)</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Any value (not necessarily complementary) except 0x55 and 0x33</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>0x33</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

The System memory area is read accessible whatever the protection level. It is never accessible for program/erase operation.
Level 0: no protection

Read, program and erase operations into the flash main memory area are possible. The option bytes, the CCM SRAM and the backup registers are also accessible by all operations.

Level 1: Read protection

This is the default protection level when RDP option byte is erased. It is defined as well when RDP value is at any value different from 0xAA and 0xCC, or even if the complement is not correct.

- **User mode**: Code executing in user mode (Boot Flash) can access flash main memory, option bytes, CCM SRAM and backup registers with all operations.
- **Debug, boot RAM and bootloader modes**: In debug mode or when code is running from boot RAM or bootloader, the flash main memory, the backup registers (TAMP_BKxR in the RTC) and the CCM SRAM are totally inaccessible. In these modes, a read or write access to the flash generates a bus error and a Hard Fault interrupt.

**Caution**: In case the Level 1 is configured and no PCROP area is defined, it is mandatory to set PCROP_RDP bit to 1 (full mass erase when the RDP level is decreased from Level 1 to Level 0). In case the Level 1 is configured and a PCROP area is defined, if user code needs to be protected by RDP but not by PCROP, it must not be placed in a page containing a PCROP area.

Level 2: No debug

In this level, the protection level 1 is guaranteed. In addition, the Cortex®-M4 debug port (boundary scan TAP and Cortex®-M4 with FPU TAP), the boot from RAM (boot RAM mode) and the boot from System memory (bootloader mode) are no more available. In user execution mode (boot FLASH mode), all operations are allowed on the flash main memory. On the contrary, only read operations can be performed on the option bytes.

Option bytes cannot be programmed nor erased. Thus, the level 2 cannot be removed at all: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag WRPERR is set in the Flash_SR register and an interrupt can be generated.

**Note**: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Changing the Read protection level

It is easy to move from level 0 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 1. Once in level 2, it is no more possible to modify the Read protection level.

When the RDP is reprogrammed to the value 0xAA to move from Level 1 to Level 0, a mass erase of the flash main memory is performed if PCROP_RDP is set in the Flash PCROP1 End address register (FLASH_PCROP1ER). The backup registers (TAMP_BKxR in the RTC) and the CCM SRAM are also erased. The user options except PCROP protection are set to their previous values copied from FLASH_OPTR, FLASH_WRPxyR (x=1 and y =A or B). PCROP is disable. The OTP area is not affected by mass erase and remains unchanged.
If the bit PCROP_RDP is cleared in the FLASH_PCROP1ER, the full mass erase is replaced by a partial mass erase that is successive page erases, except for the pages protected by PCROP. This is done in order to keep the PCROP code. Only when the flash memory is erased, options are re-programmed with their previous values. This is also true for FLASH_PCROPxSR and FLASH_PCROPxER registers (x=1).

**Note:** Full mass erase or partial mass erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase. To validate the protection level change, the option bytes must be re-loaded through the OBL_LAUNCH bit in flash control register.

</tbody>
</table>

(1) ST recommends using the BOOT_FROM_RAM flags only in BootFromLoader mode.
(2) The code pages in System memory are protected against mass erase.
(3) The value in Flash main memory is the production value.
Apart of the flash memory can be protected against read and write from third parties. The protected area is execute-only: it can only be reached by the STM32 CPU, as an instruction code, while all other accesses (DMA, debug and CPU data read, write and erase) are strictly prohibited. The PCROP area has a double word (64-bit) granularity. An additional option bit (PCROP_RDP) allows to select if the PCROP area is erased or not when the RDP protection is changed from Level 1 to Level 0 (refer to Changing the Read protection level).

Each PCROP area is defined by a start page offset and an end page offset related to the physical flash memory address. These offsets are defined in the PCROP address registers

- Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER).

- The PCROPx (x = 1) area is defined from the address: flash memory base address + [PCROPx_STRT x 0x8] (included) to the address: flash memory base address + [(PCROPx_END+1) x 0x8] (excluded). The minimum PCROP area size is two double-words (128 bits).

For example, to protect by PCROP from the address 0x0806 2F80 (included) to the address 0x0807 0004 (included):

- if boot in flash is selected, FLASH_PCROP1SR and FLASH_PCROP1ER registers must be programmed with:
  - PCROP1_STRT = 0xC5F0.
  - PCROP1_END = 0xE000.
Any read access performed through the D-bus to a PCROP protected area triggers RDERR flag error.

Any PCROP protected address is also write protected and any write access to one of these addresses triggers WRPERR.

Any PCROP area is also erase protected. Consequently, any erase to a page in this zone is impossible (including the page containing the start address and the end address of this zone). A software mass erase cannot be performed if one zone is PCROP protected.

For previous example, due to erase by page, all pages from page 0xC5 to 0xE0 are protected in case of page erase. (All addresses from 0x0806 2800 to 0x0807 07FF can't be erased).

Deactivation of PCROP can only occurs when the RDP is changing from level 1 to level 0. If the user options modification tries to clear PCROP or to decrease the PCROP area, the options programming is launched but PCROP area stays unchanged. On the contrary, it is possible to increase the PCROP area.

When option bit PCROP_RDP is cleared, when the RDP is changing from level 1 to level 0, mass erase is replaced by partial mass erase to keep the PCROP area (refer to Changing the Read protection level). In this case, PCROP1_STRT and PCROP1_END are also not erased.

Note: It is recommended to align PCROP area with page granularity when using PCROP_RDP, or to leave free the rest of the page where PCROP zone starts or ends.

<table>
<thead>
<tr>
<th>PCROPx registers values (x = 1)</th>
<th>PCROP protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCROPx_offset_strt &gt; PCROPx_offset_end</td>
<td>No PCROP area.</td>
</tr>
<tr>
<td>PCROPx_offset_strt &lt; PCROPx_offset_end</td>
<td>The area between PCROPx_offset_strt and PCROPx_offset_end is protected. It is possible to write:</td>
</tr>
<tr>
<td></td>
<td>– PCROPx_offset_strt with a lower value</td>
</tr>
<tr>
<td></td>
<td>– PCROPx_offset_end with a higher value.</td>
</tr>
</tbody>
</table>

1. The minimum PCROP area size is 2xdouble words: PCROPx_offset_strt and PCROPx_offset_end.

4.5.3 Write protection (WRP)

The user area in flash memory can be protected against unwanted write operations. It allows either to specify:
- Two write-protected (WRP) areas can be defined, with page (2 Kbytes) granularity.

Each area is defined by a start page offset and an end page offset related to the physical flash base address. These offsets are defined in the WRP address registers: Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR).

The WRP "y" area (x=1 and y=A,B) is defined from the address: Flash memory Base address + [WRPxy_STRT x 0x800] (included) to the address: Flash memory Base address + [(WRPxy_END+1) x 0x800] (excluded).
For example, to protect by WRP from the address 0x0801 2800 (included) to the address 0x0801 87FF (included):

- if boot in flash is selected, FLASH_WRP1AR register must be programmed with:
  - WRP1A_STRT = 0x25.
  - WRP1A_END = 0x30.

WRP1B_STRT and WRP1B_END in FLASH_WRP1BR can be used instead (area “B” in the flash memory).

When WRP is active, it cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the flash memory is attempted, the write protection error flag (WRPERR) is set in the FLASH_SR register. This flag is also set for any write access to:

- OTP area
- part of the flash memory that can never be written like the ICP
- PCROP area.

Note: When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase flash memory if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or System flash, even if WRP is not activated.

Note: To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in flash control register.

### Table 25. WRP protection

<table>
<thead>
<tr>
<th>WRP registers values (x=1 y= A/B)</th>
<th>WRP protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRPxy_STRT = WRPxy_END</td>
<td>Page WRPxy is protected.</td>
</tr>
<tr>
<td>WRPxy_STRT &gt; WRPxy_END</td>
<td>No WRP area.</td>
</tr>
<tr>
<td>WRPxy_STRT &lt; WRPxy_END</td>
<td>The pages from WRPxy_STRT to WRPxy_END are protected.</td>
</tr>
</tbody>
</table>

#### 4.5.4 Securable memory area

This is an area of code that can be executed only once at boot, and never again unless a new reset occurs. The main purpose of the securable memory area is to protect a specific part of flash memory against undesired access. This allows implementing software security services such as secure key storage or safe boot. Securable memory area is located in the main flash memory. It is dedicated to executing trusted code. When not secured, the securable memory behaves like the remainder of main flash memory. When secured (the SEC_PROT1 bit of the FLASH_CR register set), any attempt to program or erase in a secure memory area generates a write protection error (WRPERR flag is set) and any attempt to read from it generates a read error (RDERR flag is set).

The size of the securable memory area is defined by the SEC_SIZE1[8:0] bitfield of the FLASH_SEC register. It can be modified only in RDP Level 0. Its content is erased upon changing from RDP Level 1 to Level 0, even if it overlaps with PCROP pages.
The securable memory area is defined from the address: Bank base address (included) to the address: Bank base address + (0x800 * SEC_SIZE1) (excluded).

### 4.5.5 Disabling core debug access

For executing sensitive code or manipulating sensitive data in securable memory area, the debug access to the core can temporarily be disabled.

In RDP level 2, the debugger is disabled by hardware, but in other RDP levels, the debugger can be disabled by software using the bit DBG_SWEN in the FLASH_ACR register.

*Figure 11* gives an example of managing DBG_SWEN and SEC_PROT bits.

**Figure 8. Example of disabling core debug access**

![Diagram of core debug access](MSv42192V1)

### 4.5.6 Forcing boot from flash memory

To increase the security and establish a chain of trust, the BOOT_LOCK option bit of the FLASH_SEC1R/FLASH_SEC2R register allows forcing the system to boot from the main flash memory regardless the other boot options. It is always possible to set the BOOT_LOCK bit. However, it is possible to reset it only when:

- RDP is set to Level 0, or
- RDP is set to Level 1, while Level 0 is requested and a full mass-erase is performed.

### 4.6 FLASH interrupts

**Table 26. Flash interrupt request**

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Event flag/interrupt clearing method</th>
<th>Interrupt enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>End of operation</td>
<td>EOP(1)</td>
<td>Write EOP=1</td>
<td>EOPIE</td>
</tr>
<tr>
<td>Operation error</td>
<td>OPERR(2)</td>
<td>Write OPERR=1</td>
<td>ERRIE</td>
</tr>
<tr>
<td>Read error</td>
<td>RDERR</td>
<td>Write RDERR=1</td>
<td>RDERRIE</td>
</tr>
<tr>
<td>ECC correction</td>
<td>ECC</td>
<td>Write ECC=1</td>
<td>ECCCIE</td>
</tr>
</tbody>
</table>

1. EOP is set only if EOPIE is set.
2. OPERR is set only if ERRIE is set.
## 4.7 FLASH registers

### 4.7.1 Flash access control register (FLASH_ACR)

**Address offset:** 0x00  
**Reset value:** 0x0004 0601  
**Access:** no wait state, word, half-word and byte access

<table>
<thead>
<tr>
<th>Bit 31:19 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 18 <strong>DBG_SWN:</strong> Debug software enable</td>
</tr>
<tr>
<td>SW may use this bit to enable/disable the debugger.</td>
</tr>
<tr>
<td>0: Debugger disabled</td>

<tr>
<td>1: Debugger enabled</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 17:15 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 14 <strong>SLEEP_PD:</strong> Flash Power-down mode during Sleep or Low-power sleep mode</td>
</tr>
<tr>
<td>This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Sleep or Low-power sleep mode.</td>
</tr>
<tr>
<td>0: Flash in Idle mode during Sleep and Low-power sleep modes</td>
</tr>
<tr>
<td>1: Flash in Power-down mode during Sleep and Low-power sleep modes</td>
</tr>
<tr>
<td><strong>Caution:</strong> The flash must not be put in power-down while a program or an erase operation is on-going.</td>
</tr>
</tbody>
</table>

| Bit 13 **RUN_PD:** Flash Power-down mode during Run or Low-power run mode |
| This bit is write-protected with FLASH_PDKEYR. |
| This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Run or Low-power run mode. The flash memory can be put in power-down mode only when the code is executed from RAM. The flash must not be accessed when RUN_PD is set. |
| 0: Flash in Idle mode |
| 1: Flash in Power-down mode |
| **Caution:** The flash must not be put in power-down while a program or an erase operation is on-going. |

| Bit 12 **DCRST:** Data cache reset |
| 0: Data cache is not reset |
| 1: Data cache is reset |
| This bit can be written only when the data cache is disabled. |
4.7.2 Flash Power-down key register (FLASH_PDKEYR)

Address offset: 0x04
Reset value: 0x0000 0000
Access: no wait state, word access

Bits 31:0 PDKEYR[31:0]: Power-down in Run mode flash key
The following values must be written consecutively to unlock the RUN_PD bit in FLASH_ACR:
PDKEY1: 0x0415 2637
PDKEY2: 0xFAFB FCFD
4.7.3  Flash key register (FLASH_KEYR)

Address offset: 0x08
Reset value: 0x0000 0000
Access: no wait state, word access

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

</tr>
</tbody>
</table>

Bits 31:0  **KEYR[31:0]**: Flash key

The following values must be written consecutively to unlock the FLACH_CR register allowing flash programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

4.7.4  Flash option key register (FLASH_OPTKEYR)

Address offset: 0x0C
Reset value: 0x0000 0000
Access: no wait state, word access

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

</tr>
</tbody>
</table>

Bits 31:0  **OPTKEYR[31:0]**: Option byte key

The following values must be written consecutively to unlock the FLACH_OPTR register allowing option byte programming/erasing operations:
KEY1: 0x0819 2A3B
KEY2: 0x4C5D 6E7F

4.7.5  Flash status register (FLASH_SR)

Address offset: 0x10
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access
# Embedded flash memory (FLASH) for category 4 devices

<table>
<thead>

<td></td>
</tr>
<tr>
<td>Cleared by writing 1.</td>
<td></td>
</tr>
</tbody>
</table>
Bit 5 **PGAERR**: Programming alignment error
Set by hardware when the data to program cannot be contained in the same 64-bit flash memory row in case of standard programming, or if there is a change of page during fast programming.
Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error
Set by hardware when an address to be erased/programmed belongs to a write-protected part (by WRP, PCROP or RDP level 1) of the flash memory.
Cleared by writing 1.

Bit 3 **PROGERR**: Programming error
Set by hardware when a double-word address to be programmed contains a value different from '0xFFFF FFFF FFFF FFFF' before programming, except if the data to write is '0x0000 0000 0000 0000'.
Cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Operation error
Set by hardware when a flash memory operation (program / erase) completes unsuccessfully.
This bit is set only if error interrupts are enabled (ERRIE = 1).
Cleared by writing ‘1’.

Bit 0 **EOP**: End of operation
Set by hardware when one or more flash memory operation (programming / erase) has been completed successfully.
This bit is set only if the end of operation interrupts are enabled (EOPIE = 1).
Cleared by writing 1.

### 4.7.6 Flash control register (FLASH_CR)

Address offset: 0x14
Reset value: 0xC000 0000
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

```

Bit 31 **LOCK**: FLASH_CR lock
This bit is set only. When set, the FLASH_CR register is locked. It is cleared by hardware after detecting the unlock sequence.
In case of an unsuccessful unlock operation, this bit remains set until the next system reset.
Bit 30 **OPTLOCK**: Options lock
   This bit is set only. When set, all bits concerning user option in FLASH_CR
   register and so option page are locked. This bit is cleared by hardware after
detecting the unlock sequence. The LOCK bit must be cleared before doing the
unlock sequence for OPTLOCK bit.
   In case of an unsuccessful unlock operation, this bit remains set until the next
reset.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **SEC_PROT1**: Securable memory area protection bit.
   This bit is set to lock the access to the securable memory area. It is set by software
when exiting the securable memory area, and can only be written once.

Bit 27 **OBL_LAUNCH**: Force the option byte loading
   When set to 1, this bit forces the option byte reloading. This bit is cleared only
when the option byte loading is complete. It cannot be written if OPTLOCK is set.
   0: Option byte loading complete
   1: Option byte loading requested

Bit 26 **RDERRIE**: PCROP read error interrupt enable
   This bit enables the interrupt generation when the RDERR bit in the FLASH_SR
   is set to 1.
   0: PCROP read error interrupt disabled
   1: PCROP read error interrupt enabled

Bit 25 **ERRIE**: Error interrupt enable
   This bit enables the interrupt generation when the OPERR bit in the FLASH_SR
   is set to 1.
   0: OPERR error interrupt disabled
   1: OPERR error interrupt enabled

Bit 24 **EOPIE**: End of operation interrupt enable
   This bit enables the interrupt generation when the EOP bit in the FLASH_SR is
   set to 1.
   0: EOP Interrupt disabled
   1: EOP Interrupt enabled

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **FSTPG**: Fast programming
   0: Fast programming disabled
   1: Fast programming enabled

Bit 17 **OPTSTRT**: Options modification start
   This bit triggers an options operation when set.
   This bit is set only by software, and is cleared when the BSY bit is cleared in
FLASH_SR.

Bit 16 **START**: Start
   This bit triggers an erase operation when set. If MER1, MER2 and PER bits are
reset and the STRT bit is set, an unpredictable behavior may occur without
generating any error flag. This condition should be forbidden.
   This bit is set only by software, and is cleared when the BSY bit is cleared in
FLASH_SR.

Bits 15:11 Reserved, must be kept at reset value.
4.7.7 Flash ECC register (FLASH_ECCR)

Address offset: 0x18
Reset value: 0x0000 0000
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>ECCD: ECC detection</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Set by hardware when two ECC errors have been detected (only if ECCC/ECCD are previously cleared). When this bit is set, a NMI is generated. Cleared by writing 1.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 30</th>
<th>ECCC: ECC correction</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Set by hardware when one ECC error has been detected and corrected (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). An interrupt is generated if ECCCIE is set. Cleared by writing 1.</td>
</tr>
</tbody>
</table>

| Bits 29:25 | Reserved, must be kept at reset value. |
| Bit 24 | ECCCIE: ECC correction interrupt enable |
| 0: ECCC interrupt disabled |
| 1: ECCC interrupt enabled. This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is set. |
| Bit 23 | Reserved, must be kept at reset value. |
### 4.7.8 Flash option register (FLASH_OPTR)

**Address offset:** 0x20  
**Reset value:** 0xFXXX XXXX. Register bits are loaded with values from flash memory at OBL.  
**Access:** no wait state when no flash memory operation is on going, word, half-word and byte access

- **Bit 22** SYSF_ECC: System flash ECC fail  
  This bit indicates that the ECC error correction or double ECC error detection is located in the System flash.
- **Bits 21:19** Reserved, must be kept at reset value.
- **Bits 18:0** ADDR_ECC[18:0]: ECC fail address  
  This bit indicates which address in the flash memory is concerned by the ECC error correction or by the double ECC error detection.

#### Bit 22 SYSF_ECC: System flash ECC fail
This bit indicates that the ECC error correction or double ECC error detection is located in the System flash.

#### Bits 21:19 Reserved, must be kept at reset value.

#### Bits 18:0 ADDR_ECC[18:0]: ECC fail address
This bit indicates which address in the flash memory is concerned by the ECC error correction or by the double ECC error detection.

#### 4.7.8 Flash option register (FLASH_OPTR)

**Address offset:** 0x20  
**Reset value:** 0xFXXX XXXX. Register bits are loaded with values from flash memory at OBL.  
**Access:** no wait state when no flash memory operation is on going, word, half-word and byte access

</tbody>
</table>
Bit 24 **SRAM_PE**: SRAM1 and CCM SRAM parity check enable
- 0: SRAM1 and CCM SRAM parity check enable
- 1: SRAM1 and CCM SRAM parity check disable

Bit 23 **nBOOT1**: Boot configuration
Together with the BOOT0 pin, this bit selects boot mode from the flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bit 22 **PB4_PUPEN**: PB4 pull-up enable
- 0: USB power delivery dead-battery enabled/ NJTRST pull-up deactivated
- 1: USB power delivery dead-battery disabled/ NJTRST pull-up activated

*Note: Only for Category 4 devices (otherwise Reserved)*

Bits: 21:20 Reserved, must be reset value.

Bit 19 **WWDG_SW**: Window watchdog selection
- 0: Hardware window watchdog
- 1: Software window watchdog

Bit 18 **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode
- 0: Independent watchdog counter is frozen in Standby mode
- 1: Independent watchdog counter is running in Standby mode

Bit 17 **IWDG_STOP**: Independent watchdog counter freeze in Stop mode
- 0: Independent watchdog counter is frozen in Stop mode
- 1: Independent watchdog counter is running in Stop mode

Bit 16 **IWDG_SW**: Independent watchdog selection
- 0: Hardware independent watchdog
- 1: Software independent watchdog

Bit 15 Reserved, must be reset value.

Bit 14 **nRST_SHDW**
- 0: Reset generated when entering the Shutdown mode
- 1: No reset generated when entering the Shutdown mode

Bit 13 **nRST_STDBY**
- 0: Reset generated when entering the Standby mode
- 1: No reset generate when entering the Standby mode

Bit 12 **nRST_STOP**
- 0: Reset generated when entering the Stop mode
- 1: No reset generated when entering the Stop mode
4.7.9 Flash PCROP1 Start address register (FLASH_PCROP1SR)
Address offset: 0x24
Reset value: 0xFFFF XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word access.

- **Bits 31:16** Reserved, must be kept at reset value.
- **Bits 15:0** PCROP1_STRT[15:0]: PCROP area start offset
  PCROP1_STRT contains the first double-word of the PCROP area.

4.7.10 Flash PCROP1 End address register (FLASH_PCROP1ER)
Address offset: 0x28
Reset value: 0xAAAA XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word, half-word access.
PCROP1_RDP bit can be accessed with byte access.
4.7.11 Flash WRP area A address register (FLASH_WRP1AR)

Address offset: 0x2C

Reset value: 0x00XX 00XX

Register bits are loaded with values from flash memory at OBL.

Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Bit 31 **PCROP_RDP:** PCROP area preserved when RDP level decreased
This bit is set only. It is reset after a full mass erase due to a change of RDP from Level 1 to Level 0.
0: PCROP area is not erased when the RDP level is decreased from Level 1 to Level 0.
1: PCROP area is erased when the RDP level is decreased from Level 1 to Level 0 (full mass erase).

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **WRP1A_END[15:0]:** WRP first area “A” end offset
WRP1A_END contains the last page of WRP first area.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **WRP1A_START[7:0]:** WRP first area “A” start offset
WRP1A_START contains the first page of WRP first area.
4.7.12 Flash WRP area B address register (FLASH_WRP1BR)

Address offset: 0x30
Reset value: 0x00XX 00XX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Reset values shown are in hexadecimal format.

Note: XXX represents a reserved bit or a bit that is not available or is not implemented.

- **Offset** indicates the memory location of each register.
- **Register** lists the names of the registers.
- **Reset value** column shows the hexadecimal reset value of each register.

**Table notes:**
- **LATENCY [3:0]** is a 4-bit field representing the latency of the flash operation.
- **ADDR_ECC[18:0]** is a 18-bit field for ECC address.
- **RDP[7:0]** is a 8-bit field for read depth parameter.
- **PCROP1_STRT[15:0]** is a 16-bit field for the start address of the PCROP1 region.
- **PCROP1_END[15:0]** is a 16-bit field for the end address of the PCROP1 region.
- **WRP1A_END[7:0]** is a 8-bit field for the end address of the WRP1A region.
- **WRP1A_STRT[7:0]** is a 8-bit field for the start address of the WRP1A region.

5 Embedded flash memory (FLASH) for category 2 devices

5.1 Introduction

The flash memory interface manages CPU AHB ICode and DCode accesses to the flash memory. It implements the erase and program flash memory operations and the read and write protection mechanisms.

The flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

5.2 FLASH main features

- Up to 128 Kbytes of flash memory (single bank).
- Flash memory read operations with 64 bits data width
- Page erase and mass erase

Flash memory interface features:

- Flash memory read operations
- Flash memory program/erase operations
- Read protection activated by option (RDP)
- 2 Write protection areas selected by option
- Proprietary code read protection areas defined by option
- Securable memory areas defined by option
- Prefetch on ICODE
- Instruction Cache: 32 cache lines of 4 x 64 bits on ICode (1 KB RAM)
- Data Cache: 8 cache lines of 4 x 64 bits on DCode (256B RAM)
- Error Code Correction ECC: 8 bits per 64-bit double-word
  - $8 + 64 = 72$ bits, 2 bits detection, 1 bit correction
- Option byte loader
- Low-power mode
5.3 FLASH functional description

5.3.1 Flash memory organization

The flash memory has the following main features:

- Capacity up to 128 Kbytes (read width of 64-bit)
- 128 KB organized in one single bank for main memory
- Page size of 2 Kbytes
- 72 bits wide data read (64 bits plus 8 ECC bits)
- Page and mass erase
- Each page is composed of 8 rows of 256 bytes
- An Information block containing:
  - System memory from which the device boots in System memory boot mode. The area is reserved for use by STMicroelectronics and contains the bootloader that is used to reprogram the flash memory through one of the following interfaces: USART, SPI, I2C, USB. It is programmed by STMicroelectronics when the device is manufactured, and protected against spurious write/erase operations. For further details, please refer to the AN2606 available from [www.st.com](http://www.st.com).
  - 1 Kbyte (128 double word) OTP (one-time programmable) bytes for user data. The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire double word cannot be written anymore, even with the value 0x0000 0000 0000 0000.
  - Option bytes for user configuration.

The memory organization is based on a main area and an information block as shown in Table 28.

1. For 64-Kbyte devices: from page 0 to page 31.
5.3.2 Error code correction (ECC)

Data in flash memory are 72-bit words: 8 bits are added per double word (64 bits). The ECC mechanism supports:

- One error detection and correction
- Two errors detection

When one error is detected and corrected, the flag ECCC (ECC correction) is set in Flash ECC register (FLASH_ECCR). If ECCCIE is set, an interrupt is generated.

When two errors are detected, a flag ECCD (ECC detection) is set in FLASH_ECCR register. In this case, a NMI is generated.

When an ECC error is detected, the address of the failing double word is saved in ADDR_ECC[20:0] in the FLASH_ECCR register. ADDR_ECC[2:0] are always cleared.

When ECC or ECCD is set, ADDR_ECC is not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Note: For a virgin data: 0xFF FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

5.3.3 Read access latency

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH_ACR) according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device VCORE. Refer to Section 6.1.5: Dynamic voltage scaling management. Table 29 shows the correspondence between wait states and CPU clock frequency.

<table>
<thead>
<tr>
<th>Wait states (WS) (LATENCY)</th>
<th>HCLK (MHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>VCORE Range 1 boost mode</td>
</tr>
<tr>
<td>0 WS (1 CPU cycles)</td>
<td>≤ 34</td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>≤ 68</td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>≤ 102</td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>≤ 136</td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>≤ 170</td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 16 MHz and 1 wait state (WS) is configured in the FLASH_ACR register.

When changing the CPU frequency, the following software sequences must be applied in order to tune the number of wait states needed to access the flash memory:
Increasing the CPU frequency:

1. Program the new number of wait states to the LATENCY bits in the Flash access control register (FLASH_ACR).
2. Check that the new number of wait states is taken into account to access the flash memory by reading the FLASH_ACR register.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in RCC_CFGFR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFGFR

If some of above two steps decreases the CPU frequency, firstly perform this step and then the rest. Otherwise modify The CPU clock source by writing the SW bits in the RCC_CFGFR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGFR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGFR register.

Decreasing the CPU frequency:

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGFR register.
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGFR.
3. Analyze the change of CPU frequency change caused either by:
   - changing clock source defined by SW bits in RCC_CFGFR register
   - or by CPU clock prescaler defined by HPRE bits in RCC_CFGFR

If some of above two steps increases the CPU frequency, firstly perform another step and then this step. Otherwise modify The CPU clock source by writing the SW bits in the RCC_CFGFR register and then (if needed) modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGFR.

4. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGFR register.

5. Program the new number of wait states to the LATENCY bits in Flash access control register (FLASH_ACR).
6. Check that the new number of wait states is used to access the flash memory by reading the FLASH_ACR register.

5.3.4 Adaptive real-time memory accelerator (ART Accelerator)

The proprietary Adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M4 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M4 with FPU over flash memory technologies, which normally requires the processor to wait for the flash memory at higher operating frequencies.

To release the processor full performance, the accelerator implements an instruction prefetch queue and branch cache which increases program execution speed from the 64-bit flash memory. Based on CoreMark benchmark, the performance achieved thanks to the ART accelerator is equivalent to 0 wait state program execution from flash memory at a CPU frequency up to 170 MHz.
Instruction prefetch

The Cortex®-M4 fetches the instruction over the ICode bus and the literal pool (constant/data) over the DCode bus. The prefetch block aims at increasing the efficiency of ICode bus accesses.

Each flash memory read operation provides 64 bits from either two instructions of 32 bits or four instructions of 16 bits depending on the launched program. This 64-bit current instruction line is saved in a current buffer, and in case of sequential code, at least two CPU cycles are needed to execute the previous read instruction line.

Prefetch on the ICode bus can be used to read the next sequential instruction line from the flash memory while the current instruction line is being requested by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the Flash access control register (FLASH_ACR). This feature is useful if at least one wait state is needed to access the flash memory.

*Figure 9* shows the execution of sequential 16-bit instructions with and without prefetch when 3 WS are needed to access the flash memory.
When the code is not sequential (branch), the instruction may not be present in the currently used instruction line or in the prefetched instruction line. In this case (miss), the penalty in terms of number of cycles is at least equal to the number of wait states.
If a loop is present in the current buffer, no new flash access is performed.

**Instruction cache memory (I-Cache)**

To limit the time lost due to jumps, it is possible to retain 32 lines of 4 x 64 bits in an instruction cache memory. This feature can be enabled by setting the instruction cache enable (ICEN) bit in the *Flash access control register (FLASH_ACR)*. Each time a miss occurs (requested data not present in the currently used instruction line, in the prefetched instruction line or in the instruction cache memory), the line read is copied into the instruction cache memory. If some data contained in the instruction cache memory are requested by the CPU, they are provided without inserting any delay. Once all the instruction cache memory lines have been filled, the LRU (least recently used) policy is used to determine the line to replace in the instruction memory cache. This feature is particularly useful in case of code containing loops.

The Instruction cache memory is enable after system reset.

**Data cache memory (D-Cache)**

Literal pools are fetched from flash memory through the DCode bus during the execution stage of the CPU pipeline. Each DCode bus read access fetches 64 bits which are saved in a current buffer. The CPU pipeline is consequently stalled until the requested literal pool is provided. To limit the time lost due to literal pools, accesses through the AHB databus DCode have priority over accesses through the AHB instruction bus ICode.

If some literal pools are frequently used, the data cache memory can be enabled by setting the data cache enable (DCEN) bit in the *Flash access control register (FLASH_ACR)*. This feature works like the instruction cache memory, but the retained data size is limited to 8 rows of 4*64 bits.

The Data cache memory is enable after system reset.

*Note:* The D-Cache is active only when data is requested by the CPU (not by DMA1 and DMA2). Data in option bytes block are not cacheable.

### 5.3.5 Flash program and erase operations

The STM32G4 series embedded flash memory can be programmed using in-circuit programming or in-application programming.

The **in-circuit programming (ICP)** method is used to update the entire contents of the flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, **in-application programming (IAP)** can use any communication interface supported by the microcontroller (I/Os, USB, CAN, UART, I²C, SPI, etc.) to download programming data into memory. IAP allows the user to reprogram the flash memory while the application is running. Nevertheless, part of the application has to have been previously programmed in the flash memory using ICP.

The contents of the flash memory are not guaranteed if a device reset occurs during a flash memory operation.

The flash erase and programming is only possible in the voltage scaling range 1. The VOS[1:0] bits in the PWR_CR1 must be programmed to 01b.
During a program/erase operation to the flash memory, any attempt to read the flash memory stalls the bus. The read operation proceeds correctly once the program/erase operation has completed.

**Unlocking the flash memory**

After reset, write is not allowed in the *Flash control register (FLASH_CR)* to protect the flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the *Flash key register (FLASH_KEYR)*
2. Write KEY2 = 0xCDEF89AB in the FLASH_KEYR register.

Any wrong sequence locks up the FLASH_CR register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated.

The FLASH_CR register can be locked again by software by setting the LOCK bit in the FLASH_CR register.

*Note:* The FLASH_CR register cannot be written when the BSY bit in the *Flash status register (FLASH_SR)* is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

**5.3.6 Flash main memory erase sequences**

The flash memory erase operation can be performed at page level or on the whole memory (mass erase). Mass erase does not affect the Information block (system flash, OTP and option bytes).

**Page erase**

To erase a page, follow the procedure below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the *Flash status register (FLASH_SR).*
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PER bit and select the page to erase (PNB).
4. Set the STRT bit in the FLASH_CR register.
5. Wait for the BSY bit to be cleared in the FLASH_SR register.

*Note:* The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the page erase is part of write-protected area (by WRP or PCROP), WRPERR is set and the page erase request is aborted.

**Mass erase**

To perform a mass erase, follow the procedure below:
1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit in the Flash control register (FLASH_CR).
4. Set the STRT bit in the FLASH_CR register.
5. Wait for the BSY bit to be cleared in the Flash status register (FLASH_SR).

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the flash memory contains a write-protected area (by WRP or PCROP), WRPERR is set and the mass erase request is aborted.

5.3.7 Flash main memory programming sequences

The flash memory is programmed 72 bits at a time (64 bits + 8 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets PROGERR flag in the Flash status register (FLASH_SR).

It is only possible to program double word (2 x 32-bit data).
- Any attempt to write byte or half-word sets SIZERR flag in the FLASH_SR register.
- Any attempt to write a double word which is not aligned with a double word address sets PGAERR flag in the FLASH_SR register.

Standard programming

The flash memory programming sequence in standard mode is as follows:
1. Check that no flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PG bit in the Flash control register (FLASH_CR).
4. Perform the data write operation at the desired memory address, inside main memory block or OTP area. Only double word can be programmed.
   - Write a first word in an address aligned with double word
   - Write the second word
5. Wait until the BSY bit is cleared in the FLASH_SR register.
6. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
7. Clear the PG bit in the FLASH_SR register if there no more programming request anymore.

Note: When the flash interface has received a good sequence (a double word), programming is automatically launched and BSY bit is set. The internal oscillator HSI16 (16 MHz) is enabled
automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the user needs to program only one word, double word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the double word to program.

**Fast programming**

This mode allows to program a row (32 double words), and to reduce the page programming time by eliminating the need for verifying the flash locations before they are programmed and to avoid rising and falling time of high voltage for each double word.

During fast programming, the CPU clock frequency (HCLK) must be at least 8 MHz.

Only the main memory can be programmed in Fast programming mode.

The flash main memory programming sequence in standard mode is as follows:

1. Perform a mass erase. If not, PGSERR is set.
2. Check that no flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
3. Check and clear all error programming flag due to a previous programming.
4. Set the FSTPG bit in Flash control register (FLASH_CR).
5. Write the 32 double words to program a row. Only double words can be programmed:
   - Write a first word in an address aligned with double word
   - Write the second word.
6. Wait until the BSY bit is cleared in the FLASH_SR register.
7. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
8. Clear the FSTPG bit in the FLASH_SR register if there no more programming request anymore.

**Note:** If the flash is attempted to be written in Fast programming mode while a read operation is ongoing, the programming is aborted without any system notification (no error flag is set).

When the flash interface has received the first double word, programming is automatically launched. The BSY bit is set when the high voltage is applied for the first double word, and it is cleared when the last double word has been programmed or in case of error. The internal oscillator HSI16 (16 MHz) is enabled automatically when FSTPG bit is set, and disabled automatically when FSTPG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

The 32 double word must be written successively. The high voltage is kept on the flash for all the programming. Maximum time between two double words write requests is the time programming (around 2 x 25us). If a second double word arrives after this time programming, fast programming is interrupted and MISSERR is set.

High voltage cannot exceed 8 ms for a full row between two erases. This is guaranteed by the sequence of 32 double words successively written with a clock system greater or equal to 8 MHz. An internal time-out counter counts 7 ms when Fast programming is set and stops the programming when time-out is over. In this case the FASTERR bit is set.

If an error occurs, high voltage is stopped and next double word to programmed is not programmed. Anyway, all previous double words have been properly programmed.
Programming errors

Several kinds of errors can be detected. In case of error, the flash operation (programming or erasing) is aborted.

- **PROGERR**: Programming error
  - In standard programming: PROGERR is set if the word to write is not previously erased (except if the value to program is full zero).

- **SIZERR**: Size programming error
  - In standard programming or in fast programming: only double word can be programmed and only 32-bit data can be written. SIZERR is set if a byte or an half-word is written.

- **PGAERR**: Alignment programming error
  - PGAERR is set if one of the following conditions occurs:
    - In standard programming: the first word to be programmed is not aligned with a double word address, or the second word doesn’t belong to the same double word address.
    - In fast programming: the data to program doesn’t belong to the same row than the previous programmed double words, or the address to program is not greater than the previous one.

- **PGSERR**: Programming sequence error
  - PGSERR is set if one of the following conditions occurs:
    - In the standard programming sequence or the fast programming sequence: a data is written when PG and FSTPG are cleared.
    - In the standard programming sequence or the fast programming sequence: MER1, and PER are not cleared when PG or FSTPG is set.
    - In the fast programming sequence: the mass erase is not performed before setting FSTPG bit.
    - In the mass erase sequence: PG, FSTPG, and PER are not cleared when MER1 is set.
    - In the page erase sequence: PG, FSTPG, MER1 are not cleared when PER is set.
    - PGSERR is set also if PROGERR, SIZERR, PGAERR, WRPERR, MISSERR, FASTERR or PGSERR is set due to a previous programming error.

- **WRPERR**: Write protection error
  - WRPERR is set if one of the following conditions occurs:
    - Attempt to program or erase in a write protected area (WRP) or in a PCROP area or in a securable memory area.
    - Attempt to perform an erase when one page or more is protected by WRP or PCROP.
    - The debug features are connected or the boot is executed from SRAM or from System flash when the read protection (RDP) is set to Level 1.
    - Attempt to modify the option bytes when the read protection (RDP) is set to Level 2.

- **MISSERR**: Fast programming data miss error
  - In fast programming: all the data must be written successively. MISSERR is set if the previous data programmation is finished and the next data to program is not written yet.

- **FASTERR**: Fast programming error
In fast programming: FASTERR is set if one of the following conditions occurs:
- When FSTPG bit is set for more than 7ms which generates a time-out detection.
- When the fast programming has been interrupted by a MISSERR, PGAERR, WRPERR or SIZERR.

If an error occurs during a program or erase operation, one of the following error flags is set in the FLASH_SR register:
- PROGERR, SIZERR, PGAERR, PGSERR, MISSERR (Program error flags),
- WRPERR (Protection error flag)

In this case, if the error interrupt enable bit ERRIE is set in the Flash status register (FLASH_SR), an interrupt is generated and the operation error flag OPERR is set in the FLASH_SR register.

**Note:** If several successive errors are detected (for example, in case of DMA transfer to the flash memory), the error flags cannot be cleared until the end of the successive write requests.

**Programming and caches**

If a flash memory write access concerns some data in the data cache, the write access modifies the data in the flash memory and the data in the cache.

If an erase operation also concerns data in the data or instruction cache, you have to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush the caches by setting the DCRST and ICRST bits in the Flash access control register (FLASH_ACR).

**Note:** The I/D cache should be flushed only when it is disabled (I/DCEN = 0).
5.4 FLASH option bytes

5.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog can be selected in hardware or software mode (refer to Section 5.4.2: Option bytes programming).

A double word is split up as follows in the option bytes:

<table>
<thead>
<tr>
<th>Address</th>

Bit 31 Reserved, must be kept at reset value.

Bit 30 **IRH_EN**: Internal reset holder on NRST pin

0: IRH disabled

1: IRH enabled

Bits 29:28 **NRST_MODE**: PG10 pad mode

00: Reset Input/Output

01: Reset Input only

10: GPIO

11: Reset Input/Output

Bit 27 **nBOOT0**: nBOOT0 option bit

0: nBOOT0 = 0

1: nBOOT0 = 1

Bit 26 **nSWBOOT0**: Software BOOT0

0: BOOT0 taken from the option bit nBOOT0

1: BOOT0 taken from PB8/BOOT0 pin

Bit 25 **CCMSRAM_RST**: CCM SRAM erase when system reset

0: CCM SRAM erased when a system reset occurs

1: CCM SRAM is not erased when a system reset occurs

Bit 24 **SRAM_PE**: SRAM1 and CCM SRAM parity check enable

0: SRAM1 and CCM SRAM parity check enable

1: SRAM1 and CCM SRAM parity check disable

Bit 23 **nBOOT1**: Boot configuration

Together with the BOOT0 pin, this bit selects boot mode from the Flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bits 22:20 Reserved, must be kept at reset value.

Bit 19 **WWGD_SW**: Window watchdog selection

0: Hardware window watchdog

1: Software window watchdog

Bit 18 **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode

0: Independent watchdog counter is frozen in Standby mode

1: Independent watchdog counter is running in Standby mode

Bit 17 **IWDG_STOP**: Independent watchdog counter freeze in Stop mode

0: Independent watchdog counter is frozen in Stop mode

1: Independent watchdog counter is running in Stop mode
Bit 16 **IWDG_SW**: Independent watchdog selection
- 0: Hardware independent watchdog
- 1: Software independent watchdog

Bit 15 Reserved, must be kept at reset value.

Bit 14 **nRST_SHDW**
- 0: Reset generated when entering the Shutdown mode
- 1: No reset generated when entering the Shutdown mode

Bit 13 **nRST_STDBY**
- 0: Reset generated when entering the Standby mode
- 1: No reset generated when entering the Standby mode

Bit 12 **nRST_STOP**
- 0: Reset generated when entering the Stop mode
- 1: No reset generated when entering the Stop mode

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **BOR_LEV**: BOR reset Level
- These bits contain the VDD supply level threshold that activates/releases the reset.
  - 000: BOR Level 0. Reset level threshold is around 1.7 V
  - 001: BOR Level 1. Reset level threshold is around 2.0 V
  - 010: BOR Level 2. Reset level threshold is around 2.2 V
  - 011: BOR Level 3. Reset level threshold is around 2.5 V
  - 100: BOR Level 4. Reset level threshold is around 2.8 V

Bits 7:0 **RDP**: Read protection level
- 0xAA: Level 0, read protection not active
- 0xCC: Level 2, chip read protection active
- Others: Level 1, memories read protection active

**PCROP1 Start address option bytes**

Flash memory address: 0x1FFF 7808
Reset value: 0xFFFF FFFF (ST production value)

0: Boot based on the pad/option bit configuration

1: Boot forced from Main flash memory

Bits 15:7: Reserved, must be kept at reset value.

Bits 6:0 **SEC_SIZE1[6:0]:** Securable memory area size

Contains the number of securable flash memory pages
5.4.2 Option bytes programming

After reset, the options related bits in the Flash control register (FLASH_CR) are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the Flash control register (FLASH_CR) must be cleared. The following sequence is used to unlock this register:

1. Unlock the FLASH_CR with the LOCK clearing sequence (refer to Unlocking the flash memory).
2. Write OPTKEY1 = 0x08192A3B in the Flash option key register (FLASH_OPTKEYR).
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If LOCK is set by software, OPTLOCK is automatically set too.

Modifying user options

The option bytes are programmed differently from a main memory user address. To modify the user options value, follow the procedure below:

1. Check that no flash memory operation is on going by checking the BSY bit in the Flash status register (FLASH_SR).
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers: Flash option register (FLASH_OPR), Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR).
4. Set the Options Start bit OPTSTRT in the Flash control register (FLASH_CR).
5. Wait for the BSY bit to be cleared.

Note: Any modification of the value of one option is automatically performed by erasing both user option bytes pages first and then programming all the option bytes with the values contained in the flash option registers.

Option byte loading

After the BSY bit is cleared, all new options are updated into the flash but they are not applied to the system. They have effect on the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

– when OBL_LAUNCH bit is set in the Flash control register (FLASH_CR).
– after a power reset (BOR reset or exit from Standby/Shutdown modes).

Option byte loader performs a read of the options block and stores the data into internal option registers. These internal registers configure the system and cannot be read with by software. Setting OBL_LAUNCH generates a reset so the option byte loading is performed under system reset.

Each option bit has also its complement in the same double word. During option loading, a verification of the option bit and its complement allows to check the loading has correctly taken place.

During option byte loading, the options are read by double word with ECC. If the word and its complement are matching, the option word/byte is copied into the option register.
If the comparison between the word and its complement fails, a status bit OPTVERR is set. Mismatch values are forced into the option registers:

- For USR OPT option, the value of mismatch is all options at ‘1’, except for BOR_LEV which is “000” (lowest threshold)
- For WRP option, the value of mismatch is the default value “No protection”
- For RDP option, the value of mismatch is the default value “Level 1”
- For PCROP, the value of mismatch is “all memory protected”

On system reset rising, internal option registers are copied into option registers which can be read and written by software (FLASH_OPTR, FLASH_PCIEP1SR, FLASH_PCIEP1ER, FLASH_WRP1AR, FLASH_WRP1BR). These registers are also used to modify options. If these registers are not modified by user, they reflects the options states of the system. See Section: Modifying user options for more details.

5.5 FLASH memory protection

The flash main memory can be protected against external accesses with the Read protection (RDP). The pages can also be protected against unwanted write due to loss of program counter contexts. The write-protection (WRP) granularity is one page (2 Kbytes). Apart of the flash memory can also be protected against read and write from third parties (PCROP). The PCROP granularity is double word (64-bit).

5.5.1 Read protection (RDP)

The read protection is activated by setting the RDP option byte and then, by applying a system reset to reload the new RDP option byte. The read protection protects to the flash main memory, the option bytes, the backup registers (TAMP_BKPxR in the RTC) and the CCM SRAM.

Note: If the read protection is set while the debugger is still connected (or had been connected since the last power on) through JTAG/SWD, apply a POR (power-on reset) instead of a system reset. If the read protection is programmed through software, don’t set the OBL_LAUNCH bit (FLASH_CR register) but perform a POR to reload the option byte. This can be done with a transition Standby (or Shutdown) mode followed by a wakeup.

There are three levels of read protection from no protection (level 0) to maximum protection or no debug (level 2).

The flash memory is protected when the RDP option byte and its complement contain the pair of values shown in Table 32.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>RDP complement value</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>0x55</td>
<td>Level 0 (production value)</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Any value (not necessarily complementary) except 0x55 and 0x33</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>0x33</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

The System memory area is read accessible whatever the protection level. It is never accessible for program/erase operation.
Level 0: no protection

Read, program and erase operations into the flash main memory area are possible. The option bytes, the CCM SRAM and the backup registers are also accessible by all operations.

Level 1: Read protection

This is the default protection level when RDP option byte is erased. It is defined as well when RDP value is at any value different from 0xAA and 0xCC, or even if the complement is not correct.

- **User mode**: Code executing in user mode (Boot Flash) can access flash main memory, option bytes, CCM SRAM and backup registers with all operations.

- **Debug, boot RAM and bootloader modes**: In debug mode or when code is running from boot RAM or bootloader, the flash main memory, the backup registers (TAMP_BKpXR in the RTC) and the CCM SRAM are totally inaccessible. In these modes, a read or write access to the flash generates a bus error and a Hard Fault interrupt.

**Caution**: In case the Level 1 is configured and no PCROP area is defined, it is mandatory to set PCROP_RDP bit to 1 (full mass erase when the RDP level is decreased from Level 1 to Level 0). In case the Level 1 is configured and a PCROP area is defined, if user code needs to be protected by RDP but not by PCROP, it must not be placed in a page containing a PCROP area.

Level 2: No debug

In this level, the protection level 1 is guaranteed. In addition, the Cortex®-M4 debug port, the boot from RAM (boot RAM mode) and the boot from System memory (bootloader mode) are no more available. In user execution mode (boot FLASH mode), all operations are allowed on the main memory. On the contrary, only read operations can be performed on the option bytes.

Option bytes cannot be programmed nor erased. Thus, the level 2 cannot be removed at all: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag WRPERR is set in the Flash_SR register and an interrupt can be generated.

**Note**: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Changing the Read protection level

It is easy to move from level 0 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 1. Once in level 2, it is no more possible to modify the Read protection level.

When the RDP is reprogrammed to the value 0xAA to move from Level 1 to Level 0, a mass erase of the flash main memory is performed if PCROP_RDP is set in the Flash PCROP1 End address register (FLASH_PCROP1ER). The backup registers (TAMP_BKpXR in the RTC) and the CCM SRAM are also erased. The user options except PCROP protection are set to their previous values copied from FLASH_OPTR, FLASH_WRPxyR (x=1 and y=A or B). PCROP is disable. The OTP area is not affected by mass erase and remains unchanged.
If the bit PCROP_RDP is cleared in the FLASH_PCROP1ER, the full mass erase is replaced by a partial mass erase that is successive page erases, except for the pages protected by PCROP. This is done in order to keep the PCROP code. Only when the flash memory is erased, options are re-programmed with their previous values. This is also true for FLASH_PCROPxSR and FLASH_PCROPxER registers (x=1).

**Note:** Full mass erase or partial mass erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase. To validate the protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash control register.

**Figure 10. Changing the read protection (RDP) level**

Embedded flash memory (FLASH) for category 2 devices

5.5.2 Proprietary code readout protection (PCROP)

Apart of the flash memory can be protected against read and write from third parties. The protected area is execute-only: it can only be reached by the STM32 CPU, as an instruction code, while all other accesses (DMA, debug and CPU data read, write and erase) are strictly prohibited. The PCROP area has a double word (64-bit) granularity. An additional option bit (PCROP_RDP) allows to select if the PCROP area is erased or not when the RDP protection is changed from Level 1 to Level 0 (refer to Changing the Read protection level).

Each PCROP area is defined by a start page offset and an end page offset related to the physical flash address. These offsets are defined in the PCROP address registers Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER).

- The PCROPx (x = 1) area is defined from the address: Flash memory base address + [PCROPx_STRT x 0x8] (included) to the address: Flash memory base address + [(PCROPx_END+1) x 0x8] (excluded). The minimum PCROP area size is two double-words (128 bits).

For example, to protect by PCROP from the address 0x0800 2F80 (included) to the address 0x0801 0004 (included):
- if boot in flash is selected, FLASH_PCROP1SR and FLASH_PCROP1ER registers must be programmed with:
  - PCROP1_STRT = 0x05F0.
  - PCROP1_END = 0x2000.
Any read access performed through the D-bus to a PCROP protected area triggers RDERR flag error.

Any PCROP protected address is also write protected and any write access to one of these addresses triggers WRPERR.

Any PCROP area is also erase protected. Consequently, any erase to a page in this zone is impossible (including the page containing the start address and the end address of this zone). Moreover, a software mass erase cannot be performed if one zone is PCROP protected.

For previous example, due to erase by page, all pages from page 0xC5 to 0xE0 are protected in case of page erase. (All addresses from 0x0806 2800 to 0x0807 07FF can’t be erased).

Deactivation of PCROP can only occurs when the RDP is changing from level 1 to level 0. If the user options modification tries to clear PCROP or to decrease the PCROP area, the options programming is launched but PCROP area stays unchanged. On the contrary, it is possible to increase the PCROP area.

When option bit PCROP_RDP is cleared, when the RDP is changing from level 1 to level 0, Full mass erase is replaced by partial mass erase in order to keep the PCROP area (refer to Changing the Read protection level). In this case, PCROP1_STRT and PCROP1_END are also not erased.

**Note:** It is recommended to align PCROP area with page granularity when using PCROP_RDP, or to leave free the rest of the page where PCROP zone starts or ends.

<table>
<thead>
<tr>
<th>PCROPx registers values (x = 1)</th>
<th>PCROP protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCROPx_offset_strt &gt; PCROPx_offset_end</td>
<td>No PCROP area.</td>
</tr>
<tr>
<td>PCROPx_offset_strt &lt; PCROPx_offset_end</td>
<td>The area between PCROPx_offset_strt and PCROPx_offset_end is protected.</td>
</tr>
<tr>

<td>it is possible to write:</td>
</tr>
<tr>
<td></td>
<td>– PCROPx_offset_strt with a lower value</td>
</tr>
<tr>
<td></td>
<td>– PCROPx_offset_end with a higher value.</td>
</tr>
</tbody>
</table>

1. The minimum PCROP area size is 2xdouble words: PCROPx_offset_strt and PCROPx_offset_end.

### 5.5.3 Write protection (WRP)

The user area can be protected against unwanted write operations. It allows either to specify:

- Two write-protected (WRP) areas can be defined, with page (2 Kbytes) granularity.

Each area is defined by a start page offset and an end page offset related to the physical Flash base address. These offsets are defined in the WRP address registers: Flash WRP area A address register (FLASH_WRP1AR), Flash WRP area B address register (FLASH_WRP1BR).

The WRP "y" area (x=1 and y=A,B) is defined from the address: Flash memory Base address + [WRPxy_STRT x 0x800] (included) to the address: Flash memory Base address + [(WRPxy_END+1) x 0x800] (excluded).
For example, to protect by WRP from the address 0x0801 2800 (included) to the address 0x0801 87FF (included):

- if boot in flash is selected, FLASH_WRP1AR register must be programmed with:
  - WRP1A_STRT = 0x25.
  - WRP1A_END = 0x30.

WRP1B_STRT and WRP1B_END in FLASH_WRP1BR can be used instead (area “B” in Flash memory).

When WRP is active, it cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the flash memory is attempted, the write protection error flag (WRPERR) is set in the FLASH_SR register. This flag is also set for any write access to:

- OTP area
- part of the flash memory that can never be written like the ICP
- PCROP area.

**Note:** When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase flash memory if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or System flash, even if WRP is not activated.

**Note:** To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash control register.

### Table 35. WRP protection

</tr>
<tr>
<td>WRPxy_STRT &lt; WRPxy_END</td>
<td>The pages from WRPxy_STRT to WRPxy_END are protected.</td>
</tr>
</tbody>
</table>

### 5.5.4 Securable memory area

This is an area of code that can be executed only once at boot, and never again unless a new reset occurs. The main purpose of the securable memory area is to protect a specific part of the memory against undesired access. This allows implementing software security services such as secure key storage or safe boot. Securable memory area is located in the main memory. It is dedicated to executing trusted code. When not secured, the securable memory behaves like the remainder of the main memory. When secured (the SEC_PROT1 bit of the FLASH_CR register set), any attempt to program or erase in a secure memory area generates a write protection error (WRPERR flag is set) and any attempt to read from it generates a read error (RDERR flag is set).

The size of the securable memory area is defined by the SEC_SIZE1[6:0] bitfield of the FLASH_SEC register. It can be modified only in RDP Level 0. Its content is erased upon changing from RDP Level 1 to Level 0, even if it overlaps with PCROP pages.
The securable memory area is defined from the address: Bank base address (included) to the address: Bank base address + (0x800 * SEC_SIZE1) (excluded).

5.5.5 Disabling core debug access

For executing sensitive code or manipulating sensitive data in securable memory area, the debug access to the core can temporarily be disabled.

In RDP level 2, the debugger is disabled by hardware, but in other RDP levels, the debugger can be disabled by software using the bit DBG_SWEN in the FLASH_ACR register.

*Figure 11* gives an example of managing DBG_SWEN and SEC_PROT bits.

![Figure 11. Example of disabling core debug access](image)

5.5.6 Forcing boot from flash memory

To increase the security and establish a chain of trust, the BOOT_LOCK option bit of the FLASH_SEC1R/FLASH_SEC2R register allows forcing the system to boot from the Main flash memory regardless the other boot options. It is always possible to set the BOOT_LOCK bit. However, it is possible to reset it only when:

- RDP is set to Level 0, or
- RDP is set to Level 1, while Level 0 is requested and a full mass-erase is performed.
## 5.6 FLASH interrupts

|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Bits 31:19  Reserved, must be kept at reset value.

Bit 18  **DBG_SWEN**: Debug software enable

SW may use this bit to enable/disable the debugger.

0: Debugger disabled
1: Debugger enabled

Bits 17:15  Reserved, must be kept at reset value.

Bit 14  **SLEEP_PD**: Flash Power-down mode during Sleep or Low-power sleep mode

This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Sleep or Low-power sleep mode.

0: Flash in Idle mode during Sleep and Low-power sleep modes
1: Flash in Power-down mode during Sleep and Low-power sleep modes

**Caution**: The flash must not be put in power-down while a program or an erase operation is on-going.

Bit 13  **RUN_PD**: Flash Power-down mode during Run or Low-power run mode

This bit is write-protected with FLASH_PDKEYR.

This bit determines whether the flash memory is in Power-down mode or Idle mode when the device is in Run or Low-power run mode. The flash memory can be put in power-down mode only when the code is executed from RAM. The flash must not be accessed when RUN_PD is set.

0: Flash in Idle mode
1: Flash in Power-down mode

**Caution**: The flash must not be put in power-down while a program or an erase operation is on-going.

Bit 12  **DCRST**: Data cache reset

0: Data cache is not reset
1: Data cache is reset

This bit can be written only when the data cache is disabled.
5.7.2  Flash Power-down key register (FLASH_PDKEYR)

Address offset: 0x04
Reset value: 0x0000 0000
Access: no wait state, word access

<table>
<thead>
<tr>
<th>Bit 31:0 PDKEYR[31:0]: Power-down in Run mode flash key</th>

**Bits 31:0** \(\text{KEYR}[31:0]\): Flash key

- The following values must be written consecutively to unlock the \(\text{FLACH\_CR}\) register allowing flash programming/erasing operations:
  - \(\text{KEY1}: 0x4567 0123\)
  - \(\text{KEY2}: 0xCDEF 89AB\)

### 5.7.4 Flash option key register (FLASH_OPTKEYR)

- **Address offset:** 0x0C
- **Reset value:** 0x0000 0000
- **Access:** no wait state, word access

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| w | w | w | w | w | w | w | w | w | w | w | w | w | w | w |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|   |   |   |   |   |   |   |   |   |   |   |   |   |   |

**Bits 31:0** \(\text{OPTKEYR}[31:0]\): Option byte key

- The following values must be written consecutively to unlock the \(\text{FLACH\_OPTR}\) register allowing option byte programming/erasing operations:
  - \(\text{KEY1}: 0x0819 2A3B\)
  - \(\text{KEY2}: 0x4C5D 6E7F\)

### 5.7.5 Flash status register (FLASH_SR)

- **Address offset:** 0x10
- **Reset value:** 0x0000 0000
- **Access:** no wait state, word, half-word and byte access
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **BSY**: Busy

This indicates that a flash operation is in progress. This is set on the beginning of a flash operation and reset when the operation finishes or when an error occurs.

Bit 15  **OPTVERR**: Option validity error

Set by hardware when the options read may not be the one configured by the user. If option haven’t been properly loaded, OPTVERR is set again after each system reset.

Cleared by writing 1.

Bit 14  **RDERR**: PCROP read error

Set by hardware when an address to be read through the D-bus belongs to a read protected area of the flash (PCROP protection). An interrupt is generated if RDERRIE is set in FLASH_CR.

Cleared by writing 1.

Bits 13:10  Reserved, must be kept at reset value.

Bit 9  **FASTERR**: Fast programming error

Set by hardware when a fast programming sequence (activated by FSTPG) is interrupted due to an error (alignment, size, write protection or data miss). The corresponding status bit (PGAERR, SIZERR, WRPERR or MISSERR) is set at the same time.

Cleared by writing 1.

Bit 8  **MISSERR**: Fast programming data miss error

In Fast programming mode, 32 double words must be sent to flash successively, and the new data must be sent to the flash logic control before the current data is fully programmed. MISSERR is set by hardware when the new data is not present in time.

Cleared by writing 1.

Bit 7  **PGSERR**: Programming sequence error

Set by hardware when a write access to the flash memory is performed by the code while PG or FSTPG have not been set previously. Set also by hardware when PROGERR, SIZERR, PGAERR, WRPERR, MISSERR or FASTERR is set due to a previous programming error.

Cleared by writing 1.

Bit 6  **SIZERR**: Size error

Set by hardware when the size of the access is a byte or half-word during a program or a fast program sequence. Only double word programming is allowed (consequently: word access).

Cleared by writing 1.
Bit 5 **PGAERR**: Programming alignment error
Set by hardware when the data to program cannot be contained in the same 64-bit flash memory row in case of standard programming, or if there is a change of page during fast programming.
Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error
Set by hardware when an address to be erased/programmed belongs to a write-protected part (by WRP, PCROP or RDP level 1) of the flash memory.
Cleared by writing 1.

Bit 3 **PROGERR**: Programming error
Set by hardware when a double-word address to be programmed contains a value different from '0xFFFF FFFF FFFF FFFF' before programming, except if the data to write is '0x0000 0000 0000 0000'.
Cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Operation error
Set by hardware when a flash memory operation (program / erase) completes unsuccessfully.
This bit is set only if error interrupts are enabled (ERRIE = 1).
Cleared by writing ‘1’.

Bit 0 **EOP**: End of operation
Set by hardware when one or more flash memory operation (programming / erase) has been completed successfully.
This bit is set only if the end of operation interrupts are enabled (EOPIE = 1).
Cleared by writing 1.

### 5.7.6 Flash control register (FLASH_CR)
Address offset: 0x14
Reset value: 0xC000 0000
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Bit 31 **LOCK**: FLASH_CR lock
This bit is set only. When set, the FLASH_CR register is locked. It is cleared by hardware after detecting the unlock sequence.
In case of an unsuccessful unlock operation, this bit remains set until the next system reset.
Bit 30 **OPTLOCK**: Options lock
This bit is set only. When set, all bits concerning user option in FLASH_CR register and so option page are locked. This bit is cleared by hardware after detecting the unlock sequence. The LOCK bit must be cleared before doing the unlock sequence for OPTLOCK bit.
In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **SEC_PROT1**: Securable memory area protection bit.
This bit is set to lock the access to the securable memory area. It is set by software when exiting the securable memory area, and can only be written once.

Bit 27 **OBL_LAUNCH**: Force the option byte loading
When set to 1, this bit forces the option byte reloading. This bit is cleared only when the option byte loading is complete. It cannot be written if OPTLOCK is set.
0: Option byte loading complete
1: Option byte loading requested

Bit 26 **RDERRIE**: PCROP read error interrupt enable
This bit enables the interrupt generation when the RDERR bit in the FLASH_SR is set to 1.
0: PCROP read error interrupt disabled
1: PCROP read error interrupt enabled

Bit 25 **ERRIE**: Error interrupt enable
This bit enables the interrupt generation when the OPERR bit in the FLASH_SR is set to 1.
0: OPERR error interrupt disabled
1: OPERR error interrupt enabled

Bit 24 **EOPIE**: End of operation interrupt enable
This bit enables the interrupt generation when the EOP bit in the FLASH_SR is set to 1.
0: EOP Interrupt disabled
1: EOP Interrupt enabled

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **FSTPG**: Fast programming
0: Fast programming disabled
1: Fast programming enabled

Bit 17 **OPTSTRRT**: Options modification start
This bit triggers an options operation when set.
This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 16 **START**: Start
This bit triggers an erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, an unpredictable behavior may occur without generating any error flag. This condition should be forbidden.
This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bits 15:9 Reserved, must be kept at reset value.
5.7.7 Flash ECC register (FLASH_ECCR)

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state when no flash memory operation is on going, word, half-word and byte access

</tbody>
</table>

Bit 31 **ECCD**: ECC detection
Set by hardware when two ECC errors have been detected (only if ECCC/ECCD are previously cleared). When this bit is set, a NMI is generated.
Cleared by writing 1.

Bit 30 **ECCC**: ECC correction
Set by hardware when one ECC error has been detected and corrected (only if ECCC/ECCC2/ECCD/ECCD2 are previously cleared). An interrupt is generated if ECCCIE is set.
Cleared by writing 1.

Bits 29:25 Reserved, must be kept at reset value.

Bit 24 **ECCCIE**: ECC correction interrupt enable
0: ECCC interrupt disabled
1: ECCC interrupt enabled.
This bit enables the interrupt generation when the ECC bit in the FLASH_ECCR register is set.

Bit 23 Reserved, must be kept at reset value.
### 5.7.8 Flash option register (FLASH_OPTR)

Address offset: 0x20

Reset value: 0xFXXX XXXX. Register bits are loaded with values from flash memory at OBL.

Access: no wait state when no flash memory operation is on going, word, half-word and byte access

</table>

- **Bit 22** `SYSF_ECC`: System flash ECC fail
  - This bit indicates that the ECC error correction or double ECC error detection is located in the System flash.

- **Bits 21:19** Reserved, must be kept at reset value.

- **Bits 18:0** `ADDR_ECC`: ECC fail address
  - This bit indicates, which address in the flash memory is concerned by the ECC error correction or by the double ECC error detection.

- **Bit 31** Reserved, must be kept at reset value.

- **Bit 30** `IRHEN`: Internal reset holder enable bit
  - 0: Internal resets are propagated as simple pulse on NRST pin
  - 1: Internal resets drives NRST pin low until it is seen as low level

- **Bits 29:28** `NRST_MODE[1:0]`:
  - 00: Reserved
  - 01: Reset Input only: a low level on the NRST pin generates system reset, internal RESET not propagated to the NSRT pin
  - 10: GPIO: standard GPIO pad functionality, only internal RESET possible
  - 11: Bidirectional reset: NRST pin configured in reset input/output mode (legacy mode)

- **Bit 27** `nBOOT0`: nBOOT0 option bit
  - 0: nBOOT0 = 0
  - 1: nBOOT0 = 1

- **Bit 26** `nSWBOOT0`: Software BOOT0
  - 0: BOOT0 taken from the option bit nBOOT0
  - 1: BOOT0 taken from PB8/BOOT0 pin

- **Bit 25** `CCMSRAM_RST`: CCM SRAM Erase when system reset
  - 0: CCM SRAM erased when a system reset occurs
  - 1: CCM SRAM is not erased when a system reset occurs
Bit 24 **SRAM_PE**: SRAM1 and CCM SRAM parity check enable
   0: SRAM1 and CCM SRAM parity check enable
   1: SRAM1 and CCM SRAM parity check disable

Bit 23 **nBOOT1**: Boot configuration
   Together with the BOOT0 pin, this bit selects boot mode from the flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bits: 22:20 Reserved, must be reset value.

Bit 19 **WWDG_SW**: Window watchdog selection
   0: Hardware window watchdog
   1: Software window watchdog

Bit 18 **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode
   0: Independent watchdog counter is frozen in Standby mode
   1: Independent watchdog counter is running in Standby mode

Bit 17 **IWDG_STOP**: Independent watchdog counter freeze in Stop mode
   0: Independent watchdog counter is frozen in Stop mode
   1: Independent watchdog counter is running in Stop mode

Bit 16 **IWDG_SW**: Independent watchdog selection
   0: Hardware independent watchdog
   1: Software independent watchdog

Bit 15 Reserved, must be reset value.

Bit 14 **nRST_SHDW**
   0: Reset generated when entering the Shutdown mode
   1: No reset generated when entering the Shutdown mode

Bit 13 **nRST_STDBY**
   0: Reset generated when entering the Standby mode
   1: No reset generated when entering the Standby mode

Bit 12 **nRST_STOP**
   0: Reset generated when entering the Stop mode
   1: No reset generated when entering the Stop mode

Bit 11 Reserved, must be reset value.

Bits10:8 **BOR_LEV**: BOR reset Level
   These bits contain the VDD supply level threshold that activates/releases the reset.
   000: BOR Level 0. Reset level threshold is around 1.7 V
   001: BOR Level 1. Reset level threshold is around 2.0 V
   010: BOR Level 2. Reset level threshold is around 2.2 V
   011: BOR Level 3. Reset level threshold is around 2.5 V
   100: BOR Level 4. Reset level threshold is around 2.8 V

Bits 7:0 **RDP**: Read protection level
   0xAA: Level 0, read protection not active
   0xCC: Level 2, chip read protection active
   Others: Level 1, memories read protection active

*Note: Take care about PCROP_RDP configuration in Level 1. Refer to Level 1: Read protection for more details.*
5.7.9  Flash PCROP1 Start address register (FLASH_PCROP1SR)

Address offset: 0x24
Reset value: 0xFFFF XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word access.

<table>

PCROP1_STRT[14:0]

Bits 31:15  Reserved, must be kept at reset value.
Bits 14:0  PCROP1_STRT[14:0]: PCROP area start offset
           PCROP1_STRT contains the first double-word of the PCROP area.

5.7.10 Flash PCROP1 End address register (FLASH_PCROP1ER)

Address offset: 0x28
Reset value: 0x0000 XXXX
Register bits are loaded with values from flash memory at OBL.
Access: no wait state when no flash memory operation is on going, word, half-word access.
PCROP_RDP bit can be accessed with byte access.

Bit 31  PCROP_RDP: PCROP area preserved when RDP level decreased
        This bit is set only. It is reset after a full mass erase due to a change of RDP
        from Level 1 to Level 0.
        0: PCROP area is not erased when the RDP level is decreased from Level 1 to
        Level 0.
        1: PCROP area is erased when the RDP level is decreased from Level 1 to
        Level 0 (full mass erase).

Bits 30:15  Reserved, must be kept at reset value.
Bits 14:0  PCROP1_END[14:0]: PCROP area end offset
           PCROP1_END contains the last double-word of the PCROP area.
### Flash WRP area A address register (FLASH_WRP1AR)

Address offset: 0x2C  
Reset value: 0x00XX 00XX  
Register bits are loaded with values from flash memory at OBL.  
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **WRP1A_END[5:0]**: WRP first area “A” end offset  
WRP1A_END contains the last page of WRP first area.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **WRP1A_STRT[5:0]**: WRP first area “A” start offset  
WRP1A_STRT contains the first page of WRP first area.

### Flash WRP area B address register (FLASH_WRP1BR)

Address offset: 0x30  
Reset value: 0x00XX 00XX  
Register bits are loaded with values from flash memory at OBL.  
Access: no wait state when no flash memory operation is on going, word, half-word and byte access

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **WRP1B_END[5:0]**: WRP second area “B” end offset  
WRP1B_END contains the last page of the WRP second area.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **WRP1B_STRT[5:0]**: WRP second area “B” start offset  
WRP1B_STRT contains the last page of the WRP second area.
5.7.13 Flash securable area register (FLASH_SEC1R)

</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 BOOT_LOCK: used to force boot from user Flash area
0: Boot based on the pad/option bit configuration
1: Boot forced from main flash memory

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 SEC_SIZE1[6:0]: sets the number of pages used in the securable area.
Secure area starts at 0x0800 0000 and its size is SEC_SIZE1 * page size.
This field can be changed in level0 only.
Any attempt to modify in level1 silently fails, and does not change register value.
# 5.7.14 FLASH register map

## Table 37. Flash interface - Register map and reset values

| Offset | Register          | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to *Section 2.2 on page 81* for the register boundary addresses.
6  Power control (PWR)

6.1  Power supplies

The STM32G4 series devices require a 1.71 V to 3.6 V operating supply voltage (VDD). Analog peripherals are supplied through independent power domain VDDA.

- **VDD** = 1.71 V to 3.6 V
  
  VDD is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through VDD pins.

- **VDDA** = 1.62 V (ADC/ COMP) / 1.71 V (DAC 1MSPS / DAC 15MSPS) / 2 V (OPAMP) / 2.4 V (VREFBUF)

  VDDA is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The VDDA voltage level is independent from the VDD voltage. VDDA should be preferably connected to VDD when these peripherals are not used.

  During power up and power down, the following power sequence is required:
  
  - When VDD is below 1 V, then VDDA supply must remain below VDD + 300 mV
  - When VDD is above 1 V, all power supplies became independent.

  During power down phase, VDD can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power down transient phase.

- **VBAT** = 1.55 V to 3.6 V

  VBAT is the power supply for RTC, external clock 32 kHz oscillator and backup registers (through power switch) when VDD is not present. VBAT is internally bonded to VDD for small packages without dedicated pin.

- **VREF-, VREF+**

  VREF+ is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  When VDDA < 2 V, VREF+ must be equal to VDDA.

  When VDDA ≥ 2 V, VREF+ must be between 2 V and VDDA.

  VREF+ can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports three output voltages, which are configured with VRS bit in the VREFBUF_CSR register:

  - VREF+ around 2.048 V. This requires VDDA equal to or higher than 2.4 V.
  - VREF+ around 2.5 V. This requires VDDA equal to or higher than 2.8 V.
  - VREF+ around 2.9 V. This requires VDDA equal to or higher than 3.135 V.

  VREF+ pin is not available on all packages. When not available on the package, it is bonded to VDDA. When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer (VREFBUF) is not available and must be kept disable (refer to related device datasheet for packages pinout description).

  VREF- is internally double bonded with VSSA.
An embedded linear voltage regulator is used to supply the internal digital power $V_{\text{CORE}}$. $V_{\text{CORE}}$ is the power supply for digital peripherals SRAM1, SRAM2 and CCM SRAM. The Flash is supplied by $V_{\text{CORE}}$ and $V_{\text{DD}}$.

#### 6.1.1 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply which can be separately filtered and shielded from noise on the PCB.
- The analog peripherals voltage supply input is available on a separate $V_{\text{DDA}}$ pin.
- An isolated supply ground connection is provided on $V_{\text{SSA}}$ pin.

The $V_{\text{DDA}}$ supply voltage can be different from $V_{\text{DD}}$. The presence of $V_{\text{DDA}}$ must be checked before enabling any of the analog peripherals supplied by $V_{\text{DDA}}$ (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

The $V_{\text{DDA}}$ supply can be monitored by the Peripheral Voltage Monitoring, and compared with thresholds. Refer to Section 6.2.3: Peripheral Voltage Monitoring (PVM) for more details.

When a single supply is used, $V_{\text{DDA}}$ can be externally connected to $V_{\text{DD}}$ through the external filtering circuit in order to ensure a noise-free $V_{\text{DDA}}$ reference voltage.
ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to $V_{REF+}$ a separate reference voltage lower than $V_{DDA}$. $V_{REF+}$ is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

$V_{REF+}$ can be provided either by an external reference or by an internal buffered voltage reference ($V_{REFBUF}$).

The internal buffered voltage reference ($V_{REFBUF}$) is enabled by setting the ENVR bit in the Section 23.4.1: $V_{REFBUF}$ control and status register ($V_{REFBUF}$_CSR). The internal buffered voltage reference ($V_{REFBUF}$) is set to 2.048 V, 2.5 V or 2.9 V according the VRS[1:0] bits setting. The internal buffered voltage reference can also provide the voltage to external components through $V_{REF+}$ pin. Refer to the device datasheet and to Section 23: Voltage reference buffer ($V_{REFBUF}$) for further information.

6.1.2 USB transceivers supply

The USB transceivers are supplied from $V_{DD}$ power supply pin. $V_{DD}$ range for USB usage is from 3.0 V to 3.6 V.

6.1.3 Battery backup domain

To retain the content of the Backup registers and supply the RTC function when $V_{DD}$ is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The VBAT pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The switch to the VBAT supply is controlled by the power-down reset embedded in the Reset block.

---

**Warning:** During $t_{RSTTEMPO}$ (temporization at $V_{DD}$ startup) or after a PDR has been detected, the power switch between VBAT and $V_{DD}$ remains connected to VBAT. During the startup phase, if $V_{DD}$ is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into VBAT through an internal diode connected between $V_{DD}$ and the power switch (VBAT).

If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

---

If no external battery is used in the application, it is recommended to connect VBAT externally to $V_{DD}$ with a 100 nF external ceramic decoupling capacitor.

When the backup domain is supplied by $V_{DD}$ (analog switch connected to $V_{DD}$), the following pins are available:

- PC13, PC14 and PC15, which can be used as GPIO pins
- PC13, PC14 and PC15, which can be configured by RTC or LSE (refer to Section 35.3:
RTC functional description

- PA0/RTC_TAMP2 and PE6/RTC_TAMP3 when they are configured by the RTC as tamper pins

Note: As the analog switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed must be limited to 2 MHz with a maximum load of 30 pF, and these I/Os must not be used as a current source (e.g. to drive a LED).

When the backup domain is supplied by V_{BAT} (analog switch connected to V_{BAT} because V_{DD} is not present), the following functions are available:

- PC13, PC14 and PC15 can be controlled only by RTC or LSE (refer to Section 35.3: RTC functional description)

Backup domain access

After a system reset, the backup domain (RTC registers and backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the APB1 peripheral clock enable register 1 (RCC_APB1ENR1)
2. Set the DBP bit in the Power control register 1 (PWR_CR1) to enable access to the backup domain
3. Select the RTC clock source in the RTC domain control register (RCC_BDCR).

VBAT battery charging

When VDD is present, it is possible to charge the external battery on V_{BAT} through an internal resistance.

The V_{BAT} charging is done either through a 5 kOhm resistor or through a 1.5 kOhm resistor depending on the VBRS bit value in the PWR_CR4 register.

The battery charging is enabled by setting VBE bit in the PWR_CR4 register. It is automatically disabled in V_{BAT} mode.

6.1.4 Voltage regulator

Two embedded linear voltage regulators supply all the digital circuitries, except for the Standby circuitry and the backup domain. The main regulator output voltage (V_{CORE}) can be programmed by software to two different power ranges (Range 1 and Range 2) in order to optimize the consumption depending on the system's maximum operating frequency (refer to Section 7.2.8: Clock source frequency versus voltage scaling and to Section 3.3.3: Read access latency).

The voltage regulators are always enabled after a reset. Depending on the application modes, the V_{CORE} supply is provided either by the main regulator (MR) or by the low-power regulator (LPR).

- In Run, Sleep and Stop 0 modes, both regulators are enabled and the main regulator...
(MR) supplies full power to the \( V_{\text{CORE}} \) domain (core, memories and digital peripherals).

- In low-power run and low-power sleep modes, the main regulator is off and the low-power regulator (LPR) supplies low power to the \( V_{\text{CORE}} \) domain, preserving the contents of the registers, SRAM1, SRAM2 and CCM SRAM.

- In Stop 1 modes, the main regulator is off and the low-power regulator (LPR) supplies low power to the \( V_{\text{CORE}} \) domain, preserving the contents of the registers, SRAM1, SRAM2 and CCM SRAM.

- In Standby mode with SRAM2 content preserved (RRS bit is set in the PWR_CR3 register), the main regulator (MR) is off and the low-power regulator (LPR) provides the supply to SRAM2 only. The core, digital peripherals (except Standby circuitry and backup domain) SRAM1 and CCM SRAM are powered off.

- In Standby mode, both regulators are powered off. The contents of the registers, SRAM1, SRAM2 and CCM SRAM is lost except for the Standby circuitry and the backup domain.

- In Shutdown mode, both regulators are powered off. When exiting from Shutdown mode, a power-on reset is generated. Consequently, the contents of the registers, SRAM1, SRAM2 and CCM SRAM is lost, except for the backup domain.

### 6.1.5 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique which consists in increasing or decreasing the voltage used for the digital peripherals \( (V_{\text{CORE}}) \), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase \( V_{\text{CORE}} \) is known as overvolting. It allows to improve the device performance.

Dynamic voltage scaling to decrease \( V_{\text{CORE}} \) is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

- Range 1: High-performance range.

In range 1, the main regulator operates in two modes following the R1MODE bit in the PWR_CR5 register:

- Main regulator range 1 normal mode: provides a typical output voltage at 1.2 V. It is used when the system clock frequency is up to 150 MHz. The Flash access time for read access is minimum, write and erase operations are possible.

- Main regulator range 1 boost mode: provides a typical output voltage at 1.28 V. It is used when the system clock frequency is up to 170 MHz. The Flash access time for read access is minimum, write and erase operations are possible. To optimize the power consumption it is recommended to select the range1 boost mode when the system clock frequency is greater than 150 MHz. See Table 38.

<table>
<thead>
<tr>
<th>System frequency</th>
<th>SYSCLK ≤ 150 MHz</th>
<th>SYSCLK ≤ 170 MHz</th>
</tr>
</thead>
<tbody>
<tr>
<td>R1MODE bit configuration</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

- Range 2: Low-power range.
The main regulator provides a typical output voltage at 1.0 V. The system clock frequency can be up to 26 MHz. The Flash access time for a read access is increased as compared to Range 1; write and erase operations are not possible.

Voltage scaling is selected through the VOS bit in the Section 6.4.1: Power control register 1 (PWR_CR1) register.

The sequence to go from Range 1 (Normal/Boost) to Range 2 is:
1. In case of switching from Range 1 boost mode to Range 2, the system clock must be divided by 2 using the AHB prescaler before switching to a lower system frequency for at least 1us and then reconfigure the AHB prescaler.
2. Reduce the system frequency to a value lower than 26 MHz.
3. Adjust number of wait states according new frequency target in Range 2 (LATENCY bits in the FLASH_ACR).
4. Program the VOS bits to “10” in the PWR_CR1 register.

The sequence to go from Range 2 to Range 1 (normal/boost mode) is:
1. Program the VOS bits to “01” in the PWR_CR1 register.
2. Wait until the VOSF flag is cleared in the PWR_SR2 register.
3. Adjust number of wait states according new frequency target in Range 1 (LATENCY bits in the FLASH_ACR).
4. Increase the system frequency by following below procedure:
   • If the system frequency is 26 MHz < SYSCLK ≤ 150 MHz:
     – Select the Range 1 normal mode by setting R1MODE bit in the PWR_CR5 register.
     – Configure and switch to PLL for a new system frequency.
   • If the system frequency is SYSCLK > 150 MHz:
     – The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
     – Select the Range 1 boost mode by clearing the R1MODE bit is in the PWR_CR5 register.
     – Configure and switch to PLL for a new system frequency.
     – Wait for at least 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range1 normal mode to Range1 boost mode is:
1. The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
2. Clear the R1MODE bit is in the PWR_CR5 register.
3. Adjust the number of wait states according to the new frequency target in range1 boost mode
4. Configure and switch to new system frequency.
5. Wait for at least 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range1 boost mode to Range1 normal mode is:
1. Set the R1MODE bit in the PWR_CR5 register.
2. Adjust the number of wait states according to the new frequency target in Range1 default mode.
3. Configure and switch to the new system frequency.

6.2 Power supply supervisor

6.2.1 Power-on reset (POR) / power-down reset (PDR) / brown-out reset (BOR)

The device has an integrated power-on reset (POR) / power-down reset (PDR), coupled with a brown-out reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

Five BOR thresholds can be selected through option bytes.

During power-on, the BOR keeps the device under reset until the supply voltage $V_{DD}$ reaches the specified $V_{BORx}$ threshold. When $V_{DD}$ drops below the selected threshold, a device reset is generated. When $V_{DD}$ is above the $V_{BORx}$ upper limit, the device reset is released and the system can start.

For more details on the brown-out reset thresholds, refer to the electrical characteristics section in the datasheet.
1. The reset temporization \( t_{\text{RSTTEMPO}} \) is present only for the BOR lowest threshold \( (V_{\text{BOR0}}) \).

### 6.2.2 Programmable voltage detector (PVD)

You can use the PVD to monitor the \( V_{\text{DD}} \) power supply by comparing it to a threshold selected by the \( \text{PLS}[2:0] \) bits in the *Power control register 2 (PWR_CR2)*.

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the *Power status register 2 (PWR_SR2)*, to indicate if \( V_{\text{DD}} \) is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when \( V_{\text{DD}} \) drops below the PVD threshold and/or when \( V_{\text{DD}} \) rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example, the service routine could perform emergency shutdown tasks.
6.2.3 Peripheral Voltage Monitoring (PVM)

Only \( V_{DD} \) is monitored by default, as it is the only supply required for all system-related functions. The \( V_{DDA} \) can be independent from \( V_{DD} \) and can be monitored with two peripheral voltage monitoring (PVM).

Each of the PVMx (\( x=1, 2 \)) is a comparator between a fixed threshold \( VPVMx \) and the \( V_{DDA} \) power supply. \( PVMOx \) flags indicate if the independent power supply is higher or lower than the PVMx threshold: \( PVMOx \) flag is cleared when the supply voltage is above the PVMx threshold, and is set when the supply voltage is below the PVMx threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the PVMx threshold and/or when it rises above the PVMx threshold, depending on EXTI line rising/falling edge configuration.

Each PVM can remain active in Stop 0 and Stop 1 modes, and the PVM interrupt can wake up from the Stop mode.

<table>
<thead>
<tr>
<th>PVM</th>
<th>Power supply</th>
<th>PVM threshold</th>
<th>EXTI line</th>
</tr>
</thead>
<tbody>
<tr>
<td>PVM1</td>
<td>( V_{DDA} )</td>
<td>( V_{PVM1} ) (around 1.65 V)</td>
<td>40</td>
</tr>
<tr>
<td>PVM2</td>
<td>( V_{DDA} )</td>
<td>( V_{PVM2} ) (around 1.8 V)</td>
<td>41</td>
</tr>
</tbody>
</table>

The independent analog supply \( V_{DDA} \) is not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by this dedicated supply.

- If \( V_{DDA} \) is shorted externally to \( V_{DD} \), the application should assume it is available without enabling any Peripheral Voltage Monitoring.
- If \( V_{DDA} \) is independent from \( V_{DD} \), the Peripheral Voltage Monitoring (PVM) can be enabled to confirm whether the supply is present or not.
6.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power Reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features seven low-power modes:

- **Sleep mode:** CPU clock off, all peripherals including Cortex®-M4 with FPU core peripherals such as NVIC, SysTick, etc. can run and wake up the CPU when an interrupt or an event occurs. Refer to Section 6.3.4: Sleep mode.

- **Low-power run mode:** This mode is achieved when the CPU clock frequency is reduced below 2 MHz. The code is executed from the SRAM or the Flash memory. The regulator is in low-power mode to minimize the regulator's operating current. Refer to Section 6.3.2: Low-power run mode (LP run).

- **Low-power sleep mode:** This mode is entered from the Low-power run mode: Cortex®-M4 with FPU is off. Refer to Section 6.3.5: Low-power sleep mode (LP sleep).

- **Stop 0 and Stop 1 modes:** SRAM and all registers content are retained. All clocks in the VCORE domain are stopped, the PLL, the HSI16 and the HSE are disabled. The LSI and the LSE can be kept running.
  
  The RTC and TAMP can remain active (Stop mode with RTC, Stop mode without RTC).
  
  Some peripherals with the wakeup capability can enable the HSI16 RC during the Stop mode to detect their wakeup condition.

  In Stop 0 mode, the main regulator remain ON, which allows the fastest wakeup time but with higher consumption. The active peripherals and the wakeup sources are the same as in Stop 1 mode.

  The system clock, when exiting from Stop 0 or Stop 1 mode, is the HSI16 clock. If the device is configured to wake up in low-power run mode, the HPRE bits in RCC_CFGR register must be configured prior to entering Stop mode to provide a frequency not greater than 2 MHz.

  Refer to Section 6.3.6: Stop 0 mode for details on Stop 0 mode.

- **Standby mode:** VCORE domain is powered off. However, it is possible to preserve the SRAM contents:
  
  – Standby mode with SRAM2 retention when the bit RRS is set in PWR_CR3 register. In this case, SRAM2 is supplied by the low-power regulator.

  – Standby mode when the bit RRS is cleared in PWR_CR3 register. In this case the main regulator and the low-power regulator are powered off.

  All clocks in the VCORE domain are stopped, the PLL, the HSI16 and the HSE oscillator are disabled. The LSI and the LSE can be kept running.

  The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

  The system clock, when exiting Standby modes, is the HSI16 oscillator clock.

  Refer to Section 6.3.8: Standby mode.

- **Shutdown mode:** VCORE domain is powered off. All clocks in the VCORE domain are stopped, the PLL, the HSI16, the LSI and the HSE are disabled. The LSE can be kept running.

  The system clock, when exiting the Shutdown mode, is HSI16 oscillator clock.

  In this mode, the supply voltage monitoring is disabled and the product behavior is not guaranteed in case of a power voltage drop. Refer to Section 6.3.9: Shutdown mode.
In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APB and AHB peripherals when they are unused.

1. Legend: Y = Yes (Enable). O = Optional (Disable by default. Can be enabled by software). - = Not available, wakeup highlighted in gray.
2. The Flash can be configured in power-down mode. By default, it is not in power-down mode.
3. The SRAM clock can be gated on or off.
4. SRAM2 content is preserved when the bit RRS is set in PWR_CR3 register.
Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop1, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex®-M4 with FPU core is no longer clocked.

However, by setting some configuration bits in the DBGMCU_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to Section 47.16.1: Debug support for low-power modes.

6.3.1 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to Section 7.4.3: Clock configuration register (RCC_CFGR).

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers.

6.3.2 Low-power run mode (LP run)

To further reduce the consumption when the system is in Run mode, the regulator can be configured in low-power mode. In this mode, the CPU frequency should not exceed 2 MHz.

Please refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.
I/O states in Low-power run mode

In Low-power run mode, all I/O pins keep the same state as in Run mode.

**Entering the Low-power run mode**

To enter the Low-power run mode, proceed as follows:
1. Optional: Jump into the SRAM and power-down the Flash by setting the RUN_PD bit in the *Flash access control register (FLASH_ACR)*.
2. Decrease the CPU clock frequency below 2 MHz.
3. Force the regulator in low-power mode by setting the LPR bit in the PWR_CR1 register.

Refer to *Table 42: Low-power run* on how to enter the Low-power run mode.

**Exiting the Low-power run mode**

To exit the Low-power run mode, proceed as follows:
1. Force the regulator in main mode by clearing the LPR bit in the PWR_CR1 register.
2. Wait until REGLPF bit is cleared in the PWR_SR2 register.
3. Increase the CPU clock frequency.

Refer to *Table 42: Low-power run* on how to exit the Low-power run mode.

<table>
<thead>

</tr>
<tr>
<td>Wakeup latency</td>
<td>Regulator wakeup time from low-power mode</td>
</tr>
</tbody>
</table>

**6.3.3 Low power modes**

**Entering low power mode**

Low power modes are entered by the MCU by executing the WFI (Wait For Interrupt), or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M4 with FPU System Control register is set on Return from ISR.

Entering Low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

**Exiting low power mode**

From Sleep modes, and Stop modes the MCU exit low power mode depending on the way the low power mode was entered:
- If the WFI instruction or Return from ISR was used to enter the low power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low power mode, the MCU exits the low power mode as soon as an event occurs. The wakeup event can be generated either
Power control (PWR)

by:
- NVIC IRQ interrupt.

When SEVONPEND = 0 in the Cortex®-M4 with FPU System Control register. By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

Only NVIC interrupts with sufficient priority wakeup and interrupt the MCU.

- When SEVONPEND = 1 in the Cortex®-M4 with FPU System Control register.

By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts wakeup the MCU, even the disabled ones. Only enabled NVIC interrupts with sufficient priority wakeup and interrupt the MCU.

- Event

  Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set.

It may be necessary to clear the interrupt flag in the peripheral.

From Standby modes, and Shutdown modes the MCU exit low power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event occurs (see Figure 529: RTC block diagrams).

After waking up from Standby or Shutdown mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.).

6.3.4 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The Sleep mode is entered according Section : Entering low power mode, when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is clear.

Refer to Table 43: Sleep for details on how to enter the Sleep mode.

Exiting the Sleep mode

The Sleep mode is exit according Section : Exiting low power mode.

Refer to Table 43: Sleep for more details on how to exit the Sleep mode.
6.3.5 Low-power sleep mode (LP sleep)

Please refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

I/O states in Low-power sleep mode

In Low-power sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Low-power sleep mode

The Low-power sleep mode is entered from low-power run mode according Section: Entering low power mode, when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is clear.

Refer to Table 44: Low-power sleep for details on how to enter the Low-power sleep mode.

Exiting the Low-power sleep mode

The low-power Sleep mode is exit according Section: Exiting low power mode. When exiting the Low-power sleep mode by issuing an interrupt or an event, the MCU is in Low-power run mode.

Refer to Table 44: Low-power sleep for details on how to exit the Low-power sleep mode.

<tr>
<td></td>
</tr>
<tr>
<td>Wakeup latency</td>
</tr>
</tbody>
</table>
6.3.6 Stop 0 mode

The Stop 0 mode is based on the Cortex®-M4 with FPU deepsleep mode combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. In Stop 0 mode, all clocks in the V CORE domain are stopped; the PLL, the HSI16 and the HSE oscillators are disabled. Some peripherals with the wakeup capability (I2Cx (x=1,2,3,4), U(S)ARTx(x=1,2...5) and LPUART) can switch on the HSI16 to receive a frame, and switch off the HSI16 after receiving the frame if it is not a wakeup frame. In this case, the HSI16 clock is propagated only to the peripheral requesting it.

SRAM1, SRAM2, CCM SRAM and register contents are preserved.

The BOR is always available in Stop 0 mode. The consumption is increased when thresholds higher than \( V_{BOR0} \) are used.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 0 mode

The Stop 0 mode is entered according to Section : Entering low power mode, when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is set.

Table 44. Low-power sleep

<table>
<thead>
<tr>
<th>Low-power sleep-now mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode entry</td>
<td>Low-power sleep mode is entered from the Low-power run mode. WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) is pending Refer to the Cortex®-M4 with FPU System Control register.</td>
</tr>
<tr>
<td>Mode exit</td>
<td>If WFI or Return from ISR was used for entry Interrupt: refer to Table 97: STM32G4 series vector table If WFE was used for entry and SEVONPEND = 0: Wakeup event: refer to Section 15.3.2: Wake-up event management If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC: refer to Table 97: STM32G4 series vector table Wakeup event: refer to Section 15.3.2: Wake-up event management After exiting the Low-power sleep mode, the MCU is in Low-power run mode.</td>
</tr>
<tr>
<td>Wakeup latency</td>
<td>None</td>
</tr>
</tbody>
</table>

Wakeup latency: None
Refer to *Table 45: Stop 0 mode* for details on how to enter the Stop 0 mode.

If Flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started, it cannot be stopped except by a Reset. See *Section 42.3: IWDG functional description*.
- Real-time clock (RTC): this is configured by the RTCE bit in the *RTC domain control register (RCC_BDCR)*.
- Internal RC oscillator (LSI): this is configured by the LSION bit in the *Control/status register (RCC_CSR)*.
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the *RTC domain control register (RCC_BDCR)*.

Several peripherals can be used in Stop 0 mode and can add consumption if they are enabled and clocked by LSI or LSE, or when they request the HSI16 clock: LPTIM1, I2Cx (x=1,2,3,4) U(S)ARTx (x=1,2...5), LPUART.

The DACx (x=1,2,3,4), the OPAMPs and the comparators can be used in Stop 0 mode, the PVM and the PVD as well. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x=1,2,3,4,5), temperature sensor and VREFBUF buffer can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

**Exiting the Stop 0 mode**

The Stop 0 mode is exit according *Entering low power mode*.

Refer to *Table 45: Stop 0 mode* for details on how to exit Stop 0 mode.

When exiting Stop 0 mode by issuing an interrupt or a wakeup event, the HSI16 oscillator is selected as system clock. If the device is configured to wake up in Low-power run mode, the HPRE bits in RCC_CFGR register must be configured prior to entering Stop 0 mode to provide a frequency not greater than 2 MHz.

When the voltage regulator operates in low-power mode, an additional startup delay is incurred when waking up from Stop 0 mode with HSI16. By keeping the internal regulator ON during Stop 0 mode, the consumption is higher although the startup time is reduced.

When exiting the Stop 0 mode, the MCU is either in Run mode (Range 1 or Range 2 depending on VOS bit in PWR_CR1) or in Low-power run mode if the bit LPR is set in the Power control register 1 (PWR_CR1).
6.3.7 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the main regulator is OFF, and only the low-power regulator is ON. Stop 1 mode can be entered from Run mode and from Low-power run mode.

Refer to Table 46: Stop 1 mode for details on how to enter and exit Stop 1 mode.
6.3.8 Standby mode

The Standby mode allows to achieve the lowest power consumption with BOR. It is based on the Cortex®-M4 with FPU deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, the HSI16, and the HSE oscillators are also switched off.

SRAM1 and register contents are lost except for registers in the Backup domain and Standby circuitry (see Figure 12). SRAM2 content can be preserved if the bit RRS is set in the PWR.CR3 register. In this case the Low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The consumption is increased when thresholds higher than $V_{\text{BOR0}}$ are used.

</table>
I/O states in Standby mode

In the Standby mode, the I/Os can be configured either with a pull-up (refer to PWR_PUCRx registers (x=A,B,C,D,E,F,G)), or with a pull-down (refer to PWR_PDCRx registers (x=A,B,C,D,E,F,G)), or can be kept in analog state.

The RTC outputs on PC13 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. 5 wakeup pins (WKUPx, x=1,2...5) and the 3 RTC tampers are available.

Entering Standby mode

The Standby mode is entered according Section : Entering low power mode, when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is set.

Refer to Table 47: Standby mode for details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

• Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See Section 42.3: IWDG functional description in Section 42: Independent watchdog (IWDG).
• real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR)
• Internal RC oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).
• External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR)

Exiting Standby mode

The Standby mode is exit according Section : Entering low power mode. The SBF status flag in the Power control register 3 (PWR_CR3) indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for Power control register 3 (PWR_CR3).

Refer to Table 47: Standby mode for more details on how to exit Standby mode.
### Table 47. Standby mode

<table>
<thead>
<tr>
<th>Standby mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Mode entry** | WiFi (Wait for Interrupt) or WFE (Wait for Event) while:  
– SLEEPDEEP bit is set in Cortex®-M4 with FPU System Control register  
– No interrupt (for WiFi) or event (for WFE) is pending  
– LPMS = “011” in PWR_CR1  
– WUFx bits are cleared in power status register 1 (PWR_SR1)  

| **Mode exit** | On return from ISR while:  
– SLEEPDEEP bit is set in Cortex®-M4 with FPU System Control register  
– SLEEPONEXIT = 1  
– No interrupt is pending  
– LPMS = “011” in PWR_CR1 and  
– WUFx bits are cleared in power status register 1 (PWR_SR1)  
– The RTC flag corresponding to the chosen wakeup source (RTC Alarm A, RTC Alarm B, RTC wakeup, tamper or timestamp flags) is cleared  

| **Wakeup latency** | Reset phase |
6.3.9 Shutdown mode

The Shutdown mode allows to achieve the lowest power consumption. It is based on the deepsleep mode, with the voltage regulator disabled. The VCORE domain is consequently powered off. The PLL, the HSI16, the LSI and the HSE oscillators are also switched off.

SRAM1, SRAM2, CCM SRAM and register contents are lost except for registers in the Backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, the I/Os can be configured either with a pull-up (refer to PWR_PUCRx registers (x=A,B,C,D,E,F,G), or with a pull-down (refer to PWR_PDCRx registers (x=A,B,C,D,E,F,G)), or can be kept in analog state. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

The RTC outputs on PC13 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. 5 wakeup pins (WKUPx, x=1,2...5) and the 3 RTC tampers are available.

Entering Shutdown mode

The Shutdown mode is entered according to Entering low power mode, when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is set.

Refer to Table 48: Shutdown mode for details on how to enter Shutdown mode.

In Shutdown mode, the following features can be selected by programming individual control bits:

- real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR). Caution: in case of VDD power-down the RTC content is lost.
- external 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR)

Exiting Shutdown mode

The Shutdown mode is exit according to Section: Exiting low power mode. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the Backup domain) are reset after wakeup from Shutdown.

Refer to Table 48: Shutdown mode for more details on how to exit Shutdown mode.
6.3.10 Auto-wakeup from low-power mode

The RTC can be used to wakeup the MCU from low-power mode without depending on an external interrupt (Auto-wakeup mode). The RTC provides a programmable time base for waking up from Stop (0 or 1) or Standby mode at regular intervals. For this purpose, two of the three alternative RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the RTC domain control register (RCC_BDCR):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)
  This clock source provides a precise time base with very low-power consumption.
- Low-power internal RC Oscillator (LSI)
  This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC Oscillator is designed to add minimum power consumption.

To wakeup from Stop mode with an RTC alarm event, it is necessary to:

- Configure the EXTI Line 17 to be sensitive to rising edge
- Configure the RTC to generate the RTC alarm

To wakeup from Standby mode, there is no need to configure the EXTI Line 17.

To wakeup from Stop mode with an RTC wakeup event, it is necessary to:

- Configure the EXTI Line 20 to be sensitive to rising edge
- Configure the RTC to generate the RTC alarm

To wakeup from Standby mode, there is no need to configure the EXTI Line 20.
6.4 **PWR registers**

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

6.4.1 **Power control register 1 (PWR_CR1)**

Address offset: 0x00  
Reset value: 0x0000 0200  
This register is reset after wakeup from Standby mode.

Bits 31:15  Reserved, must be kept at reset value.

- **Bit 14 LPR**: Low-power run  
  When this bit is set, the regulator is switched from main mode (MR) to low-power mode (LPR).

Bits 13:11  Reserved, must be kept at reset value.

- **Bits 10:9 VOS[1:0]**: Voltage scaling range selection  
  - 00: Cannot be written (forbidden by hardware)  
  - 01: Range 1  
  - 10: Range 2  
  - 11: Cannot be written (forbidden by hardware)

- **Bit 8 DBP**: Disable backup domain write protection  
  In reset state, the RTC and backup registers are protected against parasitic write access. 
  This bit must be set to enable write access to these registers.  
  - 0: Access to RTC and Backup registers disabled  
  - 1: Access to RTC and Backup registers enabled

Bits 7:3  Reserved, must be kept at reset value.

- **Bits 2:0 LPMS[2:0]**: Low-power mode selection  
  These bits select the low-power mode entered when CPU enters the deepsleep mode.  
  - 000: Stop 0 mode  
  - 001: Stop 1 mode  
  - 010: Reserved  
  - 011: Standby mode  
  - 1xx: Shutdown mode

*Note: In Standby mode, SRAM2 can be preserved or not, depending on RRS bit configuration in PWR_CR3.*
6.4.2 Power control register 2 (PWR_CR2)

Address offset: 0x04
Reset value: 0x0000 0000

This register is reset when exiting Standby mode.

6.4.3 Power control register 3 (PWR_CR3)

Address offset: 0x08
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EIWUL**: Enable internal wakeup line
0: Internal wakeup line disable.
1: Internal wakeup line enable.

Bit 14 **UCPD1_DBDIS**: USB Type-C and Power Delivery Dead Battery disable.

- After exiting reset, the USB Type-C "dead battery" behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to hand over control to the UCPD1 (which should therefore be initialized before doing the disable).
  - 0: Enable USB Type-C dead battery pull-down behavior on UCPD1_CC1 and UCPD1_CC2 pins.
  - 1: Disable USB Type-C dead battery pull-down behavior on UCPD1_CC1 and UCPD1_CC2 pins.

Bit 13 **UCPD1_STDBY**: UCPD1_STDBY USB Type-C and Power Delivery standby mode.

- 0: Write ‘0’ immediately after standby exit when using UCPD1, (and before writing any UCPD1 registers).
- 1: Write ‘1’ just before entering standby when using UCPD1.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **APC**: Apply pull-up and pull-down configuration

- When this bit is set, the I/O pull-up and pull-down configurations defined in the PWR_PUCRx and PWR_PDCRx registers are applied. When this bit is cleared, the PWR_PUCRx and PWR_PDCRx registers are not applied to the I/Os.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RRS**: SRAM2 retention in Standby mode

- 0: SRAM2 is powered off in Standby mode (SRAM2 content is lost).
- 1: SRAM2 is powered by the low-power regulator in Standby mode (SRAM2 content is kept).

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **EWUP5**: Enable Wakeup pin WKUP5

- When this bit is set, the external wakeup pin WKUP5 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP5 bit in the PWR_CR4 register.

Bit 3 **EWUP4**: Enable Wakeup pin WKUP4

- When this bit is set, the external wakeup pin WKUP4 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP4 bit in the PWR_CR4 register.
6.4.4 Power control register 4 (PWR_CR4)

Address offset: 0x0C
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **VBR5**: V_BAT battery charging resistor selection
0: Charge V_BAT through a 5 kOhms resistor
1: Charge V_BAT through a 1.5 kOhms resistor

Bit 8 **VBE**: V_BAT battery charging enable
0: V_BAT battery charging disable
1: V_BAT battery charging enable

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **WP5**: Wakeup pin WKUP5 polarity
This bit defines the polarity used for an event detection on external wake-up pin, WKUP5
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bit 3 **WP4**: Wakeup pin WKUP4 polarity
This bit defines the polarity used for an event detection on external wake-up pin, WKUP4
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)
6.4.5 Power status register 1 (PWR_SR1)

Address offset: 0x10
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register.

Access: 2 additional APB cycles are needed to read this register vs. a standard APB read.

| Bit 31:16 Reserved, must be kept at reset value. |
|-----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Bit 15 WUI: Wakeup flag internal |
| This bit is set when a wakeup is detected on the internal wakeup line. It is cleared when all internal wakeup sources are cleared. |

| Bits 14:9 Reserved, must be kept at reset value. |
|-----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Bit 8 SBF: Standby flag |
| This bit is set by hardware when the device enters the Standby mode and is cleared by setting the CSBF bit in the PWR_SCR register, or by a power-on reset. It is not cleared by the system reset. |
| 0: The device did not enter the Standby mode |
| 1: The device entered the Standby mode |

| Bits 7:5 Reserved, must be kept at reset value. |
|-----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Bit 4 WUUF5: Wakeup flag 5 |
| This bit is set when a wakeup event is detected on wakeup pin, WKUP5. It is cleared by writing ‘1’ in the CWUUF5 bit of the PWR_SCR register. |
6.4.6 Power status register 2 (PWR_SR2)

Address offset: 0x14
Reset value: 0x0000 0000

This register is partially reset when exiting Standby/Shutdown modes.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **PVMO2**: Peripheral voltage monitoring output: VDDA vs. 1.8 V
0: VDDA voltage is above PVM2 threshold (around 1.8 V).
1: VDDA voltage is below PVM2 threshold (around 1.8 V).

*Note: PVMO2 is cleared when PVM2 is disabled (PVME2 = 0). After enabling PVM2, the PVM2 output is valid after the PVM2 wakeup time.*

Bit 14 **PVMO1**: Peripheral voltage monitoring output: VDDA vs. 1.62 V
0: VDDA voltage is above PVM1 threshold (around 1.62 V).
1: VDDA voltage is below PVM1 threshold (around 1.62 V).

*Note: PVMO1 is cleared when PVM1 is disabled (PVME1 = 0). After enabling PVM1, the PVM1 output is valid after the PVM1 wakeup time.*

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **PVDO**: Programmable voltage detector output
0: VDD is above the selected PVD threshold
1: VDD is below the selected PVD threshold
Bit 10  **VOSF**: Voltage scaling flag
A delay is required for the internal regulator to be ready after the voltage scaling has been changed. VOSF indicates that the regulator reached the voltage level defined with VOS bits of the PWR_CR1 register.
0: The regulator is ready in the selected voltage range
1: The regulator output voltage is changing to the required voltage level

Bit 9  **REGLPF**: Low-power regulator flag
This bit is set by hardware when the MCU is in Low-power run mode. When the MCU exits the Low-power run mode, this bit remains at 1 until the regulator is ready in main mode. A polling on this bit must be done before increasing the product frequency.
This bit is cleared by hardware when the regulator is ready.
0: The regulator is ready in main mode (MR)
1: The regulator is in low-power mode (LPR)

Bit 8  **REGLPS**: Low-power regulator started
This bit provides the information whether the low-power regulator is ready after a power-on reset or a Standby/Shutdown. If the Standby mode is entered while REGLPS bit is still cleared, the wakeup from Standby mode time may be increased.
0: The low-power regulator is not ready
1: The low-power regulator is ready

Bit 7  **FLASH_RDY**: Flash ready flag
This bit is set by hardware to indicate when the Flash memory is ready to be accessed after wakeup from power-down. To place the Flash memory in power-down, set either FPD_LPRUN, FPD_LPSLP or FPD_STP bits.
0: Flash memory in power-down
1: Flash memory ready to be accessed

*Note: If the system boots from SRAM, the user application must wait till FLASH_RDY bit is set, prior to jumping to Flash memory.*

Bits 6:0  Reserved, must be kept at reset value.

### 6.4.7  Power status clear register (PWR_SCR)

Address offset: 0x18
Reset value: 0x0000 0000
Access: 3 additional APB cycles are needed to write this register vs. a standard APB write.

Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **CSBF**: Clear standby flag
Setting this bit clears the SBF flag in the PWR_SR1 register.

Bits 7:5  Reserved, must be kept at reset value.
6.4.8 Power Port A pull-up control register (PWR_PUCRA)

Address offset: 0x20.

Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

6.4.9 Power Port A pull-down control register (PWR_PDCRA)

Address offset: 0x24.

Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
6.4.10 Power Port B pull-up control register (PWR_PUCRB)

Address offset: 0x28.
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PUy**: Port B pull-up bit y (y = 15 to 0)
When set, this bit activates the pull-up on PB[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PDy bit is also set.

6.4.11 Power Port B pull-down control register (PWR_PDCRB)

Address offset: 0x2C.
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **PD14**: Port A pull-down bit 14
When set, this bit activates the pull-down on PA[14] when APC bit is set in PWR_CR3 register.

Bit 13 Reserved, must be kept at reset value.

Bits 12:0 **PDy**: Port A pull-down bit y (y = 12 to 0)
When set, this bit activates the pull-down on PA[y] when APC bit is set in PWR_CR3 register.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

6.4.12 Power Port C pull-up control register (PWR_PUCRC)

Address offset: 0x30.
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

6.4.13 Power Port C pull-down control register (PWR_PDCRC)

Address offset: 0x34.
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PUy**: Port D pull-up bit y (y = 15 to 0)
When set, this bit activates the pull-up on PD[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PDy bit is also set.

### 6.4.15 Power Port D pull-down control register (PWR_PDCRD)

Address offset: 0x3C.

Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
6.4.16  Power Port E pull-up control register (PWR_PUCRE)

Address offset: 0x40.

Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  PUy: Port E pull-up bit y (y = 15 to 0)

When set, this bit activates the pull-up on PE[y] when APC bit is set in PWR_CR3 register.

6.4.17  Power Port E pull-down control register (PWR_PDCRE)

Address offset: 0x44.

Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
6.4.18 Power Port F pull-up control register (PWR_PUCRF)

Address offset: 0x48.
Reset value: 0x0000 0000

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PUy**: Port F pull-up bit y (y = 15 to 0)
When set, this bit activates the pull-up on PF[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PDy bit is also set.
Power control (PWR) RM0440

6.4.20 Power Port G pull-up control register (PWR_PUCRG)

Address offset: 0x50.
Reset value: 0x0000 0000
This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PDy**: Port F pull-down bit y (y = 15 to 0)
When set, this bit activates the pull-down on PF[y] when APC bit is set in PWR_CR3 register.

6.4.21 Power Port G pull-down control register (PWR_PDCRG)

Address offset: 0x54.
Reset value: 0x0000 0000
This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
6.4.22 Power control register (PWR_CR5)

Address offset: 0x80.

Reset value: 0x0000 0100

This register is reset only by power on reset.

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 R1MODE: Main regular range 1 mode
This bit is only valid for the main regulator in range 1 and has no effect on range 2. It is recommended to reset this bit when the system frequency is greater than 150 MHz. Refer to Table 38: Range 1 boost mode configuration.
0: Main regulator in range 1 boost mode.
1: Main regulator in range 1 normal mode.

Bits 7:0 Reserved, must be kept at reset value.

Refer to **Section 2.2 on page 81** for the register boundary addresses.
7 Reset and clock control (RCC)

7.1 Reset

There are three types of reset, defined as system reset, power reset and RTC domain reset.

7.1.1 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on reset (POR) or brown-out reset (BOR)
2. When exiting from Standby mode
3. When exiting from Shutdown mode

A brown-out reset, including power-on or power-down reset (POR/PDR), sets all registers to their reset values except the RTC domain.

When exiting Standby mode, all registers in the $V_{\text{CORE}}$ domain are set to their reset value. Registers outside the $V_{\text{CORE}}$ domain (RTC, WKUP, IWDG, and Standby/Shutdown modes control) are not impacted.

When exiting Shutdown mode, a brown-out reset is generated, resetting all registers except those in the RTC domain.

7.1.2 System reset

A system reset sets all registers to their reset values except the reset flags in the clock control/status register (RCC_CSR) and the registers in the RTC domain.

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog event (WWDG reset)
3. Independent watchdog event (IWDG reset)
4. A software reset (SW reset) (see Software reset)
5. Low-power mode security reset (see Low-power mode security reset)
6. Option byte loader reset (see Option byte loader reset)
7. A brown-out reset

The reset source can be identified by checking the reset flags in the Control/Status register, RCC_CSR (see Section 7.4.28).

NRST pin (external reset)

Through specific option bits (NRST_MODE), the NRST pin is configurable for operating as:

- Reset input/output (default at device delivery)
  Any valid reset signal on the pin is propagated to device internal logic and all internal reset sources are externally driven through a pulse generator to this pin. The GPIO functionality (PG10) is not available. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source to be output on the NRST pin. An internal reset holder option can be used, if enabled in the option bytes, to ensure that the pin is pulled low until its voltage meets VIL threshold. This function guarantee the detection of internal reset sources by external components when the line faces a
significant capacitive load. In case on an internal reset, the internal pull-up RPU is deactivated in order to save the power consumption through the pull-up resistor. This mode is always active (independently of the option bytes setting) during each device power-on-reset (until option bytes are loaded): power on the device or wake up from Shutdown mode.

- **Reset input**
  In this mode, any valid reset signal on the NRST pin is propagated to device internal logic, but resets generated internally by the device are not visible on the pin. In this configuration, GPIO functionality (PG10) is not available.

- **GPIO**
  In this mode, the pin can be used as PG10 standard GPIO. The reset function of the pin is not available. Reset is only possible from device internal reset sources and it is not propagated to the pin.

**Figure 16. Simplified diagram of the reset circuit**

---

**Software reset**

The SYSRESETREQ bit in Cortex®-M4 with FPU Application Interrupt and Reset Control Register must be set to force a software reset on the device (refer to the STM32F3xx/F4xx/L4xx Cortex®-M4 programming manual (PM0214)).

**Low-power mode security reset**

To prevent that critical applications mistakenly enter a low-power mode, two low-power mode security resets are available. If enabled in option bytes, the resets are generated in the following conditions:
1. Entering Standby mode: this type of reset is enabled by resetting nRST_STDBY bit in User option Bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.

2. Entering Stop mode: this type of reset is enabled by resetting nRST_STOP bit in User option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

3. Entering Shutdown mode: this type of reset is enabled by resetting nRST_SHDW bit in User option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the User Option Bytes, refer to Section 3.4.1: Option bytes description.

Option byte loader reset
The option byte loader reset is generated when the OBL_LAUNCH bit (bit 27) is set in the FLASH_CR register. This bit is used to launch the option byte loading by software.

7.1.3 RTC domain reset
The RTC domain has two specific resets.
A RTC domain reset is generated when one of the following events occurs:
1. Software reset, triggered by setting the BDRST bit in the RTC domain control register (RCC_BDCR).
2. $V_{DD}$ or $V_{BAT}$ power on, if both supplies have previously been powered off.
A RTC domain reset only affects the LSE oscillator, the RTC, the Backup registers and the RCC RTC domain control register.

7.2 Clocks
Three different clock sources can be used to drive the system clock (SYSCLK):
- HSI16 (high speed internal) 16 MHz RC oscillator clock
- HSE oscillator clock, from 4 to 48 MHz
- PLL clock

The HSI16 is used as system clock source after startup from Reset.

The devices have the following additional clock sources:
- 32 kHz low speed internal RC (LSI RC) which drives the independent watchdog and optionally the RTC used for Auto-wake-up from Stop and Standby modes.
- 32.768 kHz low speed external crystal (LSE crystal) which optionally drives the real-time clock (RTTCLK).
- RC 48 MHz internal clock sources (HSI48) to potentially drive the USB FS and the RNG.

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of AHB, APB1, and APB2 domains is 170 MHz.
All the peripheral clocks are derived from their bus clock (HCLK, PCLK1 or PCLK2) except:

- The 48 MHz clock, used for USB device FS, and RNG. This clock is derived (selected by software) from one of the four following sources:
  - PLL “Q” clock
  - HSI48 internal oscillator

  When available, the HSI48 48 MHz clock can be coupled to the clock recovery system allowing adequate clock connection for the USB OTG FS (Crystal less solution).

- The ADCs clock which is derived (selected by software) from one of the following sources:
  - System clock (SYSCLK)
  - PLL “P” clock

- The U(S)ARTs clocks which are derived (selected by software) from one of the following sources:
  - System clock (SYSCLK)
  - HSI16 clock
  - LSE clock
  - APB1 or APB2 clock (PCLK1 or PCLK2 depending on which APB is mapped the U(S)ART)

  The wake-up from Stop mode is supported only when the clock is HSI16 or LSE.

- The I2C clocks which are derived (selected by software) from one of the following sources:
  - System clock (SYSCLK)
  - HSI16 clock
  - APB1 clock (PCLK1)

  The wake-up from Stop mode is supported only when the clock is HSI16.

- The SAI1 clock which is derived (selected by software) from one of the following sources:
  - an external clock mapped on I2S_CKIN
  - System clock
  - PLL “Q” clock
  - HSI16 clock

- The QUADSPI kernel clock which is derived (selected by software) from one of the following sources:
  - System clock,
  - PLL “Q” clock
  - HSI16 clock

- The low-power timer (LPTIM1) clock which is derived (selected by software) from one of the following sources:
  - LSI clock
  - LSE clock
  - HSI16 clock
  - APB1 clock (PCLK1)
  - External clock mapped on LPTIMx_IN1

  The functionality in Stop mode (including wake-up) is supported only when the clock is
LSI or LSE, or in external clock mode.

- The RTC clock which is derived (selected by software) from one of the three following sources:
  - LSE clock
  - LSI clock
  - HSE clock divided by 32

  The functionality in Stop mode (including wake-up) is supported only when the clock is LSI or LSE.

- The IWDG clock which is always the LSI clock.

- The UCPD1 clock, which is derived from HSI16 clock.

- The FDCAN1 clock, which is derived (selected by software) from one of the two following sources:
  - HSE clock
  - PLL “Q” clock
  - PCLK clock

The RCC feeds the Cortex® System Timer (SysTick) external clock with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or directly with the Cortex® clock (HCLK), configurable in the SysTick Control and Status Register.

FCLK acts as Cortex®-M4 with FPU free-running clock. For more details refer to the Cortex®-M4 programming manual (PM0214).
1. For full details about the internal and external clock source characteristics, please refer to the "Electrical..."
characteristics” section in your device datasheet.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). When the programmable factor is 1, the AHB prescaler must be equal to 1.

### 7.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

#### Figure 18. HSE/ LSE clock sources

</tr>
<tr>
<td>Crystal/Ceramic resonators</td>
<td><img src="MSv31916V1" alt="Crystal/Ceramic resonators diagram" /></td>
</tr>
</tbody>
</table>
External crystal/ceramic resonator (HSE crystal)

The 4 to 48 MHz external oscillator has the advantage of producing a very accurate rate on the main clock. The associated hardware configuration is shown in Figure 18. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the Clock control register (RCC_CR) indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

The HSE Crystal can be switched on and off using the HSEON bit in the Clock control register (RCC_CR).

External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 48 MHz. You select this mode by setting the HSEBYP and HSEON bits in the Clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) has to drive the OSC_IN pin while the OSC_OUT pin can be used as GPIO. See Figure 18.

7.2.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC Oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wake-up from Stop modes (Stop 0, Stop 1). Refer to Section 7.3: Low-power modes. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 7.2.9: Clock security system (CSS).

Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at TA=25°C.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the Internal clock sources calibration register (RCC_ICSCR).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. You can trim the HSI16 frequency in the application using the HSITRIM[6:0] in the Internal clock sources calibration register (RCC_ICSCR).

For more details on how to measure the HSI16 frequency variation, refer to Section 7.2.16.

The HSIRDY flag in the Clock control register (RCC_CR) indicates if the HSI16 oscillator is stable or not. At startup, the HSI16 output clock is not released until this bit is set by hardware.

The HSI16 oscillator can be switched on and off using the HSION bit in the Clock control register (RCC_CR).

The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 7.2.9: Clock security system (CSS).
7.2.3 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG).

The internal 48 MHz RC oscillator is mainly dedicated to provide a high precision clock to the USB peripheral by means of a special Clock Recovery System (CRS) circuitry. The CRS can use the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency which is subject to manufacturing process variations.

The HSI48RDY flag in the Clock recovery RC register (RCC_CRRCRCR) indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the Clock recovery RC register (RCC_CRRCRCR).

7.2.4 PLL

The internal PLL can be used to multiply the HSI16 or HSE output clock frequency. The PLL input frequency must be within the range defined in the device datasheet. The selected clock source is divided by a programmable factor PLLM from 1 to 8 to provide a clock frequency in the requested input range. Refer to Figure 17 and PLL configuration register (RCC_PLLCFGR).

The PLL configuration (selection of the input clock and multiplication factor) must be done before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.

To modify the PLL configuration, proceed as follows:
1. Disable the PLL by setting PLLON to 0 in Clock control register (RCC_CR).
2. Wait until PLLRDY is cleared. The PLL is now fully stopped.
3. Change the desired parameter.
4. Enable the PLL again by setting PLLON to 1.
5. Enable the desired PLL outputs by configuring PLLPEN, PLLQEN, PLLREN in PLL configuration register (RCC_PLLCFGR).

An interrupt can be generated when the PLL is ready, if enabled in the Clock interrupt enable register (RCC_CIER).

The PLL output frequency must not exceed 170 MHz.

The enable bit of each PLL output clock (PLLPEN, PLLQEN, PLLREN) can be modified at any time without stopping the corresponding PLL. PLLREN cannot be cleared if PLLCLK is used as system clock.

7.2.5 LSE clock

The LSE crystal is a 32.768 kHz Low Speed External crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in RTC domain control register (RCC_BDCR). The crystal oscillator driving strength can be changed at runtime using the LSEDRV[1:0] bits in the RTC domain control register (RCC_BDCR) to obtain the best
compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive can be decreased to the lower drive capability (LSEDRV = 00) when the LSE is ON. However, once LSEDRV is selected, the drive capability can not be increased if LSEON = 1.

The LSERDY flag in the RTC domain control register (RCC_BDCR) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. You select this mode by setting the LSEBYP and LSEON bits in the AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR). The external clock signal (square, sinus or triangle) with ~50 % duty cycle has to drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO. See Figure 18.

7.2.6 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and RTC. The clock frequency is 32 kHz. For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the Control/status register (RCC_CSR).

The LSIRDY flag in the Control/status register (RCC_CSR) indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

7.2.7 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI16 oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 170 MHz. After a system reset, the HSI16 oscillator is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source which is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the Internal clock sources calibration register (RCC_ICSCR) indicate which clock(s) is (are) ready and which clock is currently used as a system clock.

To switch from low speed to high speed or from high speed to low speed system clock, it is recommended to use a transition state with medium speed clock, for at least 1 µs.

Clock source switching conditions:

- Switching from HSE or HSI16 to PLL with AHB frequency (HCLK) higher than 80 MHz
- Switching from PLL with HCLK higher than 80 MHz to HSE or HSI16
Transition state:
- Set the AHB prescaler HPRE[3:0] bits to divide the system frequency by 2
- Switch system clock to PLL
- Wait for at least 1 µs and then reconfigure AHB prescaler bits to the needed HCLK frequency

7.2.8 Clock source frequency versus voltage scaling

Table 50 gives the clock source frequencies, depending upon the product voltage range.

7.2.9 Clock security system (CSS)

Clock Security System can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled, a clock failure event is sent to the break input of the advanced-control timers (TIM1/TIM8/TIM20 and TIM15/16/17) and to the hrtim_sysflt, and an interrupt is generated to inform the software about the failure (Clock Security System Interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M4 with FPU NMI (Non-Maskable Interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSS interrupt occurs and a NMI is automatically generated. The NMI is executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, in the NMI ISR user must clear the CSS interrupt by setting the CSSC bit in the Clock interrupt clear register (RCC_CICR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock, and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the HSI16 oscillator, and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

7.2.10 Clock security system on LSE

A Clock Security System on LSE can be activated by software writing the LSECSSON bit in the Control/status register (RCC_CSR). This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE and LSI are enabled (LSEON and LSION enabled) and ready (LSERDY and LSIRDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes except VBAT. It is working also under system reset (excluding power on reset). If a failure is detected on the external 32 kHz oscillator, the LSE...
clock is no longer supplied to the RTC but no hardware action is made to the registers. If the HSI16 was in PLL-mode, this mode is disabled.

In Standby mode a wake-up is generated. In other modes an interrupt can be sent to wake up the software (see Clock interrupt enable register (RCC_CIER), Clock interrupt flag register (RCC_CIFR), Clock interrupt clear register (RCC_CICR)).

The software MUST then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

The frequency of LSE oscillator have to be higher than 30 kHz to avoid false positive CSS detection.

7.2.11 ADC clock

The ADC clock is derived from the system clock, or from the PLL “P” output. It can be divided by the following prescalers values: 1,2,4,6,8,10,12,16,32,64,128 or 256 by configuring the ADCx_CCR register. It is asynchronous to the AHB clock. Alternatively, the ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). This programmable factor is configured using the CKMODE bit fields in the ADCx_CCR.

If the programmed factor is 1, the AHB prescaler must be set to 1.

Refer to the device datasheet for the maximum ADC clock.

7.2.12 RTC clock

The RTCCLK clock source can be either the HSE/32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the RTC domain control register (RCC_BDCR). This selection cannot be modified without resetting the RTC domain. The system must always be configured so as to get a PCLK frequency greater then or equal to the RTCCLK frequency for a proper operation of the RTC.

The LSE clock is in the RTC domain, whereas the HSE and LSI clocks are not. Consequently:

- If LSE is selected as RTC clock:
  - The RTC continues to work even if the VDD supply is switched off, provided the VBAT supply is maintained.

- If LSI is selected as the RTC clock:
  - The RTC state is not guaranteed if the VDD supply is powered off.

- If the HSE clock divided by a prescaler is used as the RTC clock:
  - The RTC state is not guaranteed if the VDD supply is powered off or if the internal voltage regulator is powered off (removing power from the VCORE domain).

When the RTC clock is LSE or LSI, the RTC remains clocked and functional under system reset.

7.2.13 Timer clock

The timer clock frequencies are automatically defined by hardware. If the APB prescaler equals 1, the timer clock frequencies are set to the same frequency of the APB domain, otherwise, they are set to twice (×2) the frequency of the APB domain.
7.2.14 **Watchdog clock**

If the Independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

7.2.15 **Clock-out capability**

- **MCO**
  - The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of eight clock signals can be selected as the MCO clock.
  - LSI
  - LSE
  - SYSCLK
  - HSI16
  - HSI48
  - HSE
  - PLLCLK

  The selection is controlled by the MCOSEL[3:0] bits of the *Clock configuration register (RCC_CFGR)*. The selected clock can be divided with the MCOPRE[2:0] field of the *Clock configuration register (RCC_CFGR)*.

- **LSCO**
  - Another output (LSCO) allows a low speed clock to be output onto the external LSCO pin:
  - LSI
  - LSE

  This output remains available in Stop (Stop 0 and Stop 1) and Standby modes. The selection is controlled by the LSCOSEL, and enabled with the LSCOEN in the *RTC domain control register (RCC_BDCR)*.

The MCO clock output requires the corresponding alternate function selected on the MCO pin, the LSCO pin should be left in default POR state.

7.2.16 **Internal/external clock measurement with TIM5/TIM15/TIM16/TIM17**

It is possible to indirectly measure the frequency of all on-board clock sources by mean of the TIM5, TIM15, TIM16 or TIM17 channel 1 input capture, as represented on *Figure 19 Figure 20, Figure 21 and Figure 22.*
Figure 19. Frequency measurement with TIM15 in capture mode

The input capture channel of the Timer 15 can be a GPIO line or an internal clock of the MCU. The possibilities are the following ones:

- TIM15 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM15 Channel1 is connected to the LSE.

Figure 20. Frequency measurement with TIM16 in capture mode

The input capture channel of the Timer 16 can be a GPIO line or an internal clock of the MCU.

The possibilities are the following ones:

- TIM16 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM16 Channel1 is connected to the LSI clock.
- TIM16 Channel1 is connected to the LSE clock.
- TIM16 Channel1 is connected to the RTC wake-up interrupt signal. In this case the RTC interrupt should be enabled.
- TIM16 Channel1 is connected to the HSE/32 clock.
- TIM16 Channel1 is connected to the MCO.
The input capture channel of Timer 17 can be a GPIO line or an internal clock of the MCU. The possibilities are the following ones:

- TIM17 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM17 Channel1 is connected to the RTC wake-up interrupt. In this case the RTC interrupt should be enabled.
- TIM17 Channel1 is connected to the HSE/32 clock.
- TIM17 Channel1 is connected to the microcontroller clock output (MCO), this selection is controlled by the MCOSEL[3:0] bits of the Clock configuration register (RCC_CFGR).
- TIM17 Channel1 is connected to the LSE clock.
- TIM17 Channel1 is connected to the LSI clock.

The input capture channel of the Timer 5 can be a GPIO line or an internal clock of the MCU. The possibilities are the following ones:

- TIM5 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM5 Channel1 is connected to the LSI clock.
- TIM5 Channel1 is connected to the LSE clock.
- TIM5 Channel1 is connected to the RTC wake-up interrupt signal. In this case the RTC interrupt should be enabled.
Calibration of the HSI16

For TIM15 and TIM16, the primary purpose of connecting the LSE to the channel 1 input capture is to be able to precisely measure the HSI16 system clocks (for this, the HSI16 should be used as the system clock source). The number of HSI16 clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm’s), it is possible to determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing, process, temperature and/or voltage related frequency deviations.

The HSI16 oscillator has dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. the HSI16/LSE ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

If LSE is not available, HSE/32 is the better option in order to reach the most precise calibration possible.

Calibration of the LSI

The calibration of the LSI follows the same pattern that for the HSI16, but changing the reference clock. It is necessary to connect LSI clock to the channel 1 input capture of the TIM16. Then define the HSE as system clock source, the number of his clock counts between consecutive edges of the LSI signal provides a measure of the internal low speed clock period.

The basic concept consists in providing a relative measurement (e.g. the HSE/LSI ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

7.2.17 Peripheral clock enable register (RCC_AHBxENR, RCC_APBxENRy)

Each peripheral clock can be enabled by the xxxxEN bit of the RCC_AHBxENR, RCC_APBxENRy registers.

When the peripheral clock is not active, the peripheral registers read or write accesses are not supported.

The enable bit has a synchronization mechanism to create a glitch free clock for the peripheral. After the enable bit is set, there is a 2 clock cycles delay before the clock be active.

Caution: Just after enabling the clock for a peripheral, software must wait for a delay before accessing the peripheral registers.
7.3 Low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep and Low Power Sleep modes stop the CPU clock. The memory interface clocks (Flash and SRAM1, SRAM2 and CCM SRAM interfaces) can be stopped by software during sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop modes (Stop 0 and Stop 1) stops all the clocks in the V_{CORE} domain and disables the PLL, the HSI16, and the HSE oscillators.
  All U(S)ARTs, LPUARTs and I^2Cs have the capability to enable the HSI16 oscillator even when the MCU is in Stop mode (if HSI16 is selected as the clock source for that peripheral).
  All U(S)ARTs and LPUARTs can also be driven by the LSE oscillator when the system is in Stop mode (if LSE is selected as clock source for that peripheral) and the LSE oscillator is enabled (LSEON). In that case the LSE remains always ON in Stop mode (they do not have the capability to turn on the LSE oscillator).
- Standby and Shutdown modes stops all the clocks in the V_{CORE} domain and disables the PLL, the HSI16, and the HSE oscillators.

The CPU's deepsleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bits in the DBGMCU_CR register.

When leaving the Stop modes (Stop 0, Stop 1 or standby), the system clock is HSI16.

If a Flash memory programming operation is on going, Stop, Standby and Shutdown modes entry is delayed until the Flash memory interface access is finished. If an access to the APB domain is ongoing, Stop, Standby and Shutdown modes entry is delayed until the APB access is finished.
### 7.4 RCC registers

#### 7.4.1 Clock control register (RCC_CR)

Address offset: 0x00  
Reset value: 0x0000 0500  
HSEBYP is not affected by reset.

Access: no wait state, word, half-word and byte access

Bits 31:26 Reserved, must be kept at reset value.

- **Bit 25 PLLRDY**: Main PLL clock ready flag  
  Set by hardware to indicate that the main PLL is locked.  
  0: PLL unlocked  
  1: PLL locked

- **Bit 24 PLLON**: Main PLL enable  
  Set and cleared by software to enable the main PLL.  
  Cleared by hardware when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the PLL clock is used as the system clock.  
  0: PLL OFF  
  1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

- **Bit 19 CSSON**: Clock security system enable  
  Set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.  
  0: Clock security system OFF (clock detector OFF)  
  1: Clock security system ON (Clock detector ON if the HSE oscillator is stable, OFF if not).

- **Bit 18 HSEBYP**: HSE crystal oscillator bypass  
  Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.  
  0: HSE crystal oscillator not bypassed  
  1: HSE crystal oscillator bypassed with external clock

- **Bit 17 HSERDY**: HSE clock ready flag  
  Set by hardware to indicate that the HSE oscillator is stable.  
  0: HSE oscillator not ready  
  1: HSE oscillator ready

*Note:* Once the HSEON bit is cleared, HSERDY goes low after 6 HSE clock cycles.
Bit 16  **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE oscillator when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator OFF
1: HSE oscillator ON

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **HSIRDY**: HSI16 clock ready flag
Set by hardware to indicate that HSI16 oscillator is stable. This bit is set only when HSI16 is enabled by software by setting HSION.
0: HSI16 oscillator not ready
1: HSI16 oscillator ready

*Note: Once the HSION bit is cleared, HSIRDY goes low after 6 HSI16 clock cycles.*

Bit 9  **HSIKERON**: HSI16 always enable for peripheral kernels.
Set and cleared by software to force HSI16 ON even in Stop modes. The HSI16 can only feed USARTs and I2Cs peripherals configured with HSI16 as kernel clock. Keeping the HSI16 ON in Stop mode allows to avoid slowing down the communication speed because of the HSI16 startup time. This bit has no effect on HSION value.
0: No effect on HSI16 oscillator.
1: HSI16 oscillator is forced ON even in Stop mode.

Bit 8  **HSION**: HSI16 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby or Shutdown mode.
Set by hardware to force the HSI16 oscillator ON when STOPWUCK=1 or HSIASFS = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.
This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.
0: HSI16 oscillator OFF
1: HSI16 oscillator ON

Bits 7:0  Reserved, must be kept at reset value.

### 7.4.2  **Internal clock sources calibration register (RCC_ICSCR)**

Address offset: 0x04
Reset value: 0x40XX 00XX
where X is factory-programmed.

Access: no wait state, word, half-word and byte access

Bit 31  Reserved, must be kept at reset value.
Bits 30:24  **HSITRIM[6:0]:** HSI16 clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSI16 clock calibration. They can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI16.

The default value is 64, which, when added to the HSICAL value, trims HSI16 to 16 MHz ± 1%.

Bits 23:16  **HSICAL[7:0]:** HSI16 clock calibration

These bits are initialized at startup with the factory-programmed HSI16 calibration trim value. When HSITRIM is written, HSICAL is updated with the sum of HSITRIM and the factory trim value.

Bits 15:0  Reserved, must be kept at reset value.

### 7.4.3 Clock configuration register (RCC_CFGR)

Address offset: 0x08

Reset value: 0x0000 0005

Access: 0 ≤ wait state ≤ 2, word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during clock source switch.

From 0 to 15 wait states inserted if the access occurs when the APB or AHB prescalers values update is on going.

**Bit 31**  Reserved, must be kept at reset value.

Bits 30:28  **MCOPRE[2:0]:** Microcontroller clock output prescaler

These bits are set and cleared by software.

It is highly recommended to change this prescaler before MCO output is enabled.

- 000: MCO is divided by 1
- 001: MCO is divided by 2
- 010: MCO is divided by 4
- 011: MCO is divided by 8
- 100: MCO is divided by 16
- Others: not allowed

Bit 31  Reserved, must be kept at reset value.
Bits 27:24 **MCOSEL[3:0]:** Microcontroller clock output
Set and cleared by software.
- 0000: MCO output disabled, no clock on MCO
- 0001: SYSCLK system clock selected
- 0010: Reserved, must be kept at reset value
- 0011: HSI16 clock selected
- 0100: HSE clock selected
- 0101: Main PLL clock selected
- 0110: LSI clock selected
- 0111: LSE clock selected
- 1000: Internal HSI48 clock selected
Others: Reserved

*Note: This clock output may have some truncated cycles at startup or during MCO clock source switching.*

Bits 23:14 Reserved, must be kept at reset value.

Bits 13:11 **PPRE2[2:0]:** APB2 prescaler
Set and cleared by software to control the division factor of the APB2 clock (PCLK2).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16

Bits 10:8 **PPRE1[2:0]:** APB1 prescaler
Set and cleared by software to control the division factor of the APB1 clock (PCLK1).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16

Bits 7:4 **HPRE[3:0]:** AHB prescaler
Set and cleared by software to control the division factor of the AHB clock.

*Caution:* Depending on the device voltage range, the software must set correctly these bits to ensure that the system frequency does not exceed the maximum allowed frequency (for more details refer to *Section 6.1.5: Dynamic voltage scaling management*). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value has been taken into account.

- 0xxx: SYSCLK not divided
- 1000: SYSCLK divided by 2
- 1001: SYSCLK divided by 4
- 1010: SYSCLK divided by 8
- 1011: SYSCLK divided by 16
- 1100: SYSCLK divided by 64
- 1101: SYSCLK divided by 128
- 1110: SYSCLK divided by 256
- 1111: SYSCLK divided by 512
7.4.4 PLL configuration register (RCC_PLLCFGR)

Address offset: 0x0C
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLL clock outputs according to the formulas:

- \( f(\text{VCO clock}) = f(\text{PLL clock input}) \times (\text{PLLN} / \text{PLLM}) \)
- \( f(\text{PLL}_P) = f(\text{VCO clock}) / \text{PLLP} \)
- \( f(\text{PLL}_Q) = f(\text{VCO clock}) / \text{PLLQ} \)
- \( f(\text{PLL}_R) = f(\text{VCO clock}) / \text{PLLR} \)

</table>

Bits 3:2 **SWS[1:0]**: System clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
- 00: Reserved, must be kept at reset value
- 01: HSI16 oscillator used as system clock
- 10: HSE used as system clock
- 11: PLL used as system clock

Bits 1:0 **SW[1:0]**: System clock switch
Set and cleared by software to select system clock source (SYSCLK).
Configured by hardware to force HSI16 oscillator selection when exiting Stop and Standby modes or in case of failure of the HSE oscillator.
- 00: Reserved, must be kept at reset value
- 01: HSI16 selected as system clock
- 10: HSE selected as system clock
- 11: PLL selected as system clock

Bits 31:27 **PLLPDIV[4:0]**: Main PLLP division factor
Set and cleared by software to control the PLL “P” frequency. PLL “P” output clock frequency = VCO frequency / PLLPDIV.
- 00000: PLL “P” clock is controlled by the bit PLLP
- 00001: Reserved.
- 00010: PLL “P” clock = VCO / 2
- ...
- 11111: PLL “P” clock = VCO / 31
Bits 26:25 **PLLR[1:0]:** Main PLL division factor for PLL “R” clock (system clock)
Set and cleared by software to control the frequency of the main PLL output clock PLLCLK.
This output can be selected as system clock. These bits can be written only if PLL is disabled.
PLL “R” output clock frequency = VCO frequency / PLLR with PLLR = 2, 4, 6, or 8
00: PLLR = 2
01: PLLR = 4
10: PLLR = 6
11: PLLR = 8

**Caution:** These bits must be set so as not to exceed 170 MHz on this domain.

Bit 24 **PLLRREN:** PLL “R” clock output enable
Set and reset by software to enable the PLL “R” clock output of the PLL (used as system clock).
This bit cannot be written when PLL “R” clock output of the PLL is used as System Clock.
In order to save power, when the PLL “R” clock output of the PLL is not used, the value of PLLREN should be 0.
0: PLL “R” clock output disabled
1: PLL “R” clock output enabled

Bit 23 Reserved, must be kept at reset value.

Bits 22:21 **PLLLQ[1:0]:** Main PLL division factor for PLL “Q” clock.
Set and cleared by software to control the frequency of the main PLL output clock PLL “Q” clock. This output can be selected for USB, RNG, SAI (48 MHz clock). These bits can be written only if PLL is disabled.
PLL “Q” output clock frequency = VCO frequency / PLLQ with PLLQ = 2, 4, 6, or 8
00: PLLQ = 2
01: PLLQ = 4
10: PLLQ = 6
11: PLLQ = 8

**Caution:** These bits must be set so as not to exceed 170 MHz on this domain.

Bit 20 **PLLLQEN:** Main PLL “Q” clock output enable
Set and reset by software to enable the PLL “Q” clock output of the PLL.
In order to save power, when the PLL “Q” clock output of the PLL is not used, the value of PLLQEN should be 0.
0: PLL “Q” clock output disabled
1: PLL “Q” clock output enabled

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **PLLP:** Main PLL division factor for PLL “P” clock.
Set and cleared by software to control the frequency of the main PLL output clock PLL “P” clock. These bits can be written only if PLL is disabled.
When the PLLPDIV[4:0] is set to “00000”PLL “P” output clock frequency = VCO frequency / PLLP with PLLP = 7, or 17
0: PLLP = 7
1: PLLP = 17

**Caution:** These bits must be set so as not to exceed 170 MHz on this domain.
Bit 16 **PLLPEN**: Main PLL PLL “P” clock output enable
Set and reset by software to enable the PLL “P” clock output of the PLL.
To save power, when the PLL “P” clock output of the PLL is not used, the value of PLLPEN should be 0.
0: PLL “P” clock output disabled
1: PLL “P” clock output enabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **PLLN[6:0]**: Main PLL multiplication factor for VCO
Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLL is disabled.
VCO output frequency = VCO input frequency x PLLN with 0 ≤ PLLN ≤ 127
0000000: PLLN = 0 wrong configuration
0000001: PLLN = 1 wrong configuration
... 0000111: PLLN = 7 wrong configuration
0001000: PLLN = 8
0001001: PLLN = 9
...
1111111: PLLN = 127

**Caution:** The software must set correctly these bits to assure that the VCO output frequency is within the range defined in the datasheet.

Bits 7:4 **PLLM[3:0]**: Division factor for the main PLL input clock
Set and cleared by software to divide the PLL input clock before the VCO. These bits can be written only when all PLLs are disabled.
VCO input frequency = PLL input clock frequency / PLLM with 1 ≤ PLLM ≤ 16
0000: PLLM = 1
0001: PLLM = 2
0010: PLLM = 3
0011: PLLM = 4
0100: PLLM = 5
0101: PLLM = 6
0110: PLLM = 7
0111: PLLM = 8
1000: PLLSYSM = 9
...
1111: PLLSYSM = 16

**Caution:** The software must set these bits correctly to ensure that the VCO input frequency is within the range defined in the datasheet.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSRC[1:0]**: Main PLL entry clock source
Set and cleared by software to select PLL clock source. These bits can be written only when PLL is disabled.
In order to save power, when no PLL is used, the value of PLLSRC should be 00.
00: No clock sent to PLL
01: No clock sent to PLL
10: HSI16 clock selected as PLL clock entry
11: HSE clock selected as PLL clock entry
7.4.5 Clock interrupt enable register (RCC_CIER)

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 HSI48RDYIE: HSI48 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the internal HSI48 oscillator.
0: HSI48 ready interrupt disabled
1: HSI48 ready interrupt enabled

Bit 9 LSECSSIE: LSE clock security system interrupt enable
Set and cleared by software to enable/disable interrupt caused by the clock security system on LSE.
0: Clock security interrupt caused by LSE clock failure disabled
1: Clock security interrupt caused by LSE clock failure enabled

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 PLLRDYIE: PLL ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLL lock.
0: PLL lock interrupt disabled
1: PLL lock interrupt enabled

Bit 4 HSERDYIE: HSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled
1: HSE ready interrupt enabled

Bit 3 HSIRDYIE: HSI16 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSI16 oscillator stabilization.
0: HSI16 ready interrupt disabled
1: HSI16 ready interrupt enabled

Bit 2 Reserved, must be kept at reset value.

Bit 1 LSERDYIE: LSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled
1: LSE ready interrupt enabled
Bit 0  **LSIRDYIE**: LSI ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the LSI oscillator stabilization.  
0: LSI ready interrupt disabled  
1: LSI ready interrupt enabled

Bits 31:11 Reserved, must be kept at reset value.

Bit 10  **HSI48RDYF**: HSI48 ready interrupt flag  
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set in a response to setting the HSI48ON (refer to Clock recovery RC register (RCC_CRRCR)).  
Cleared by software setting the HSI48RDYC bit.  
0: No clock ready interrupt caused by the HSI48 oscillator  
1: Clock ready interrupt caused by the HSI48 oscillator

Bit 9  **LSECSSF**: LSE clock security system interrupt flag  
Set by hardware when a failure is detected in the LSE oscillator.  
Cleared by software setting the LSECSSC bit.  
0: No clock security interrupt caused by LSE clock failure  
1: Clock security interrupt caused by LSE clock failure

Bit 8  **CSSF**: Clock security system interrupt flag  
Set by hardware when a failure is detected in the HSE oscillator.  
Cleared by software setting the CSSC bit.  
0: No clock security interrupt caused by HSE clock failure  
1: Clock security interrupt caused by HSE clock failure

Bits 7:6 Reserved, must be kept at reset value.

Bit 5  **PLLRDYF**: PLL ready interrupt flag  
Set by hardware when the PLL locks and PLLRDYDIE is set.  
Cleared by software setting the PLLRDYC bit.  
0: No clock ready interrupt caused by PLL lock  
1: Clock ready interrupt caused by PLL lock
Bit 4 **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYDIE is set.
Cleared by software setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag
Set by hardware when the HSI16 clock becomes stable and HSIRDYDIE is set in a response to setting the HSION (refer to *Clock control register (RCC_CR)*). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYDIE is set.
Cleared by software setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYDIE is set.
Cleared by software setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator

### 7.4.7 Clock interrupt clear register (RCC_CICR)
Address offset: 0x20
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSI48RDYC**: HSI48 oscillator ready interrupt clear
This bit is set by software to clear the HSI48RDYF flag.
0: No effect
1: Clear the HSI48RDYF flag
Bit 9 LSECSSC: LSE clock security system interrupt clear
   This bit is set by software to clear the LSECSSF flag.
   0: No effect
   1: Clear LSECSSF flag

Bit 8 CSSC: Clock security system interrupt clear
   This bit is set by software to clear the CSSF flag.
   0: No effect
   1: Clear CSSF flag

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 PLLRDYC: PLL ready interrupt clear
   This bit is set by software to clear the PLLRDYF flag.
   0: No effect
   1: Clear PLLRDYF flag

Bit 4 HSERDYC: HSE ready interrupt clear
   This bit is set by software to clear the HSERDYF flag.
   0: No effect
   1: Clear HSERDYF flag

Bit 3 HSIRDYC: HSI16 ready interrupt clear
   This bit is set software to clear the HSIRDYF flag.
   0: No effect
   1: Clear HSIRDYF flag

Bit 2 Reserved, must be kept at reset value.

Bit 1 LSERDYC: LSE ready interrupt clear
   This bit is set by software to clear the LSERDYF flag.
   0: No effect
   1: LSERDYF cleared

Bit 0 LSIRDYC: LSI ready interrupt clear
   This bit is set by software to clear the LSIRDYF flag.
   0: No effect
   1: LSIRDYF cleared

7.4.8 AHB1 peripheral reset register (RCC_AHB1RSTR)

Address offset: 0x28
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

Bits 31:13 Reserved, must be kept at reset value.
Bit 12 **CRCRST**: CRC reset
Set and cleared by software.
0: No effect
1: Reset CRC

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHRST**: Flash memory interface reset
Set and cleared by software. This bit can be activated only when the Flash memory is in power down mode.
0: No effect
1: Reset Flash memory interface

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **FMACRST**: Set and cleared by software
0: No effect
1: Reset FMAC

Bit 3 **CORDICRST**: Set and cleared by software
0: No effect
1: Reset CORDIC

Bit 2 **DMAMUX1RST**: Set and cleared by software.
0: No effect
1: Reset DMAMUX1

Bit 1 **DMA2RST**: DMA2 reset
Set and cleared by software.
0: No effect
1: Reset DMA2

Bit 0 **DMA1RST**: DMA1 reset
Set and cleared by software.
0: No effect
1: Reset DMA1

### 7.4.9 AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x2C
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

Bits 31:27 Reserved, must be kept at reset value.
Bit 26  **RNGRST**: RNG reset
Set and cleared by software.
0: No effect
1: Reset RNG

Bit 25  Reserved, must be kept at reset value.

Bit 24  **AESRST**: AESRST reset
Set and cleared by software.
0: No effect
1: Reset AES

Bits 23:20  Reserved, must be kept at reset value.

Bit 19  **DAC4RST**: DAC4 reset
Set and cleared by software.
0: No effect
1: Reset DAC4

Bit 18  **DAC3RST**: DAC3 reset
Set and cleared by software.
0: No effect
1: Reset DAC3

Bit 17  **DAC2RST**: DAC2 reset
Set and cleared by software.
0: No effect
1: Reset DAC2

Bit 16  **DAC1RST**: DAC1 reset
Set and cleared by software.
0: No effect
1: Reset DAC1

Bit 15  Reserved, must be kept at reset value.

Bit 14  **ADC345RST**: ADC345 reset
Set and cleared by software.
0: No effect
1: Reset ADC345

Bit 13  **ADC12RST**: ADC12 reset
Set and cleared by software.
0: No effect
1: Reset ADC12 interface

Bits 12:7  Reserved, must be kept at reset value.

Bit 6  **GPIOGRST**: IO port G reset
Set and cleared by software.
0: No effect
1: Reset IO port G

Bit 5  **GPIOFRST**: IO port F reset
Set and cleared by software.
0: No effect
1: Reset IO port F
Bit 4 GPIOERST: IO port E reset
Set and cleared by software.
0: No effect
1: Reset IO port E

Bit 3 GPOIDRST: IO port D reset
Set and cleared by software.
0: No effect
1: Reset IO port D

Bit 2 GPOICRST: IO port C reset
Set and cleared by software.
0: No effect
1: Reset IO port C

Bit 1 GPIOBRRST: IO port B reset
Set and cleared by software.
0: No effect
1: Reset IO port B

Bit 0 GPIOARST: IO port A reset
Set and cleared by software.
0: No effect
1: Reset IO port A

7.4.10 AHB3 peripheral reset register (RCC_AHB3RSTR)

| 1: Reset SYSCFG + COMP + OPAMP + VREFBUF |

| Bit 12:1 Reserved, must be kept at reset value. |
| Bit 0 | CRCEN: CRC clock enable  
| Set and cleared by software.  
| 0: CRC clock disabled  
| 1: CRC clock enable |
| Bits 7:5 Reserved, must be kept at reset value. |

| Bit 8 | FLASHEN: Flash memory interface clock enable  
| Set and cleared by software. This bit can be disabled only when the Flash is in power down mode.  
| 0: Flash memory interface clock disabled  
| 1: Flash memory interface clock enabled |
| Bits 3:0 Reserved, must be kept at reset value. |
Bit 4 **FMACEN**: FMAC enable
Set and reset by software.
0: FMAC clock disabled
1: FMAC clock enabled

Bit 3 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC clock disabled
1: CORDIC clock enabled

Bit 2 **DMAMUX1EN**: DMAMUX1 clock enable
Set and reset by software.
0: DMAMUX1 clock disabled
1: DMAMUX1 clock enabled

Bit 1 **DMA2EN**: DMA2 clock enable
Set and cleared by software.
0: DMA2 clock disabled
1: DMA2 clock enabled

Bit 0 **DMA1EN**: DMA1 clock enable
Set and cleared by software.
0: DMA1 clock disabled
1: DMA1 clock enabled

### 7.4.15 AHB2 peripheral clock enable register (RCC_AHB2ENR)

Address offset: 0x4C
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

*Note: When the peripheral clock is not active, the peripheral registers read or write access is not supported.*

Set and cleared by software.  
0: SYSCFG + COMP + VREFBUF + OPAMP clock disabled  
1: SYSCFG + COMP + VREFBUF + OPAMP clock enabled

### 7.4.20 AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR)

Address offset: 0x68  
Reset value: 0x0000 131F  
Access: no wait state, word, half-word and byte access
Bits 31:13  Reserved, must be kept at reset value.

Bit 12  **CRCSMEN**: CRC clocks enable during Sleep and Stop modes
Set and cleared by software.
0: CRC clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: CRC clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **SRAM1SMEN**: SRAM1 interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SRAM1 interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: SRAM1 interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 8  **FLASHSMEN**: Flash memory interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: Flash memory interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: Flash memory interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **FMACSMEN**: FMACSM clock enable.
Set and cleared by software.
0: FMACSM clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: FMACSM clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 3  **CORDICSMEN**: CORDICSM clock enable.
Set and cleared by software.
0: CORDICSM clocks disabled
1: CORDICSM clocks enabled

Bit 2  **DMAMUX1SMEN**: DMAMUX1 clock enable during Sleep and Stop modes.
Set and cleared by software.
0: DMAMUX1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: DMAMUX1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 1  **DMA2SMEN**: DMA2 clocks enable during Sleep and Stop modes
Set and cleared by software during Sleep mode.
0: DMA2 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: DMA2 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 0  **DMA1SMEN**: DMA1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DMA1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
1: DMA1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.
### 7.4.21 AHB2 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB2SMENR)

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.
Bit 31 **LPTIM1SMEN**: Low power timer 1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: LPTIM1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 30 **I2C3SMEN**: I2C3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C3 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: I2C3 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 29 Reserved, must be kept at reset value.

Bit 28 **PWRSMEN**: Power interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: Power interface clocks disabled by the clock gating(1) during Sleep and Stop modes
1: Power interface clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **FDCANSMEN**: FDCAN clocks enable during Sleep and Stop modes
Set and cleared by software.
0: FDCAN clocks disabled by the clock gating(1) during Sleep and Stop modes
1: FDCAN clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 24 Reserved, must be kept at reset value.

Bit 23 **USBSMEN**: USB device clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USB device clocks disabled by the clock gating(1) during Sleep and Stop modes
1: USB device clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 22 **I2C2SMEN**: I2C2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C2 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: I2C2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 21 **I2C1SMEN**: I2C1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: I2C1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: I2C1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 20 **UART5SMEN**: UART5 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UART5 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: UART5 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 19 **UART4SMEN**: UART4 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UART4 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: UART4 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 18 **USART3SMEN**: USART3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USART3 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: USART3 clocks enabled by the clock gating(1) during Sleep and Stop modes
Bit 17 **USART2SMEN**: USART2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: USART2 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: USART2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3SMEN**: SPI3 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: SPI3 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: SPI3 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 14 **SPI2SMEN**: SPI2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: SPI2 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: SPI2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGSMEN**: Window watchdog clocks enable during Sleep and Stop modes  
Set and cleared by software. This bit is forced to 1 by hardware when the hardware WWDG option is activated.  
0: Window watchdog clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: Window watchdog clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 10 **RTCAPBSMEN**: RTC APB clock enable during Sleep and Stop modes  
Set and cleared by software.  
0: RTC APB clock disabled by the clock gating(1) during Sleep and Stop modes  
1: RTC APB clock enabled by the clock gating(1) during Sleep and Stop modes

Bit 9 Reserved, must be kept at reset value.

Bit 8 **CRSSMEN**: CRS timer clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: CRS clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: CRS clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **TIM7SMEN**: TIM7 timer clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: TIM7 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: TIM7 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 4 **TIM6SMEN**: TIM6 timer clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: TIM6 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: TIM6 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 3 **TIM5SMEN**: TIM5 timer clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: TIM5 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: TIM5 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 2 **TIM4SMEN**: TIM4 timer clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: TIM4 clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: TIM4 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 31:30 **ADC345SEL[1:0]**: ADC3/4/5 clock source selection

These bits are set and cleared by software to select the clock source used by the ADC345 interface.

- 00: No clock selected
- 01: PLL "P" clock selected as ADC345 clock
- 10: System clock selected as ADC3/4/5 clock
- 11: Reserved.
Bits 29:28  **ADC12SEL[1:0]:** ADC1/2 clock source selection
These bits are set and cleared by software to select the clock source used by the ADC interface.
- 00: No clock selected
- 01: PLL "P" clock selected as ADC1/2 clock
- 10: System clock selected as ADC1/2 clock
- 11: Reserved

Bits 27:26  **CLK48SEL[1:0]:** 48 MHz clock source selection
These bits are set and cleared by software to select the 48 MHz clock source used by USB device FS and RNG.
- 00: HSI48 clock selected as 48 MHz clock
- 01: Reserved
- 10: PLL "Q" clock (PLL48M1CLK) selected as 48 MHz clock
- 11: Reserved, must be kept at reset value

Bits 25:24  **FDCANSEL[1:0]:** clock source selection
These bits are set and cleared by software to select the FDCAN clock source.
- 00: HSE clock selected as FDCAN clock
- 01: PLL "Q" clock selected as FDCAN clock
- 10: PCLK clock selected as FDCAN clock
- 11: Reserved, must be kept at reset value.

Bits 23:22  **I2S23SEL[1:0]:** clock source selection
These bits are set and cleared by software to select the I2S23 clock source.
- 00: System clock selected as I2S23 clock
- 01: PLL "Q" clock selected as I2S23 clock
- 10: Clock provided on I2S_CKIN pin selected as I2S23 clock
- 11: HSI16 clock selected as I2S23 clock.

Bits 21:20  **SAI1SEL[1:0]:** clock source selection
These bits are set and cleared by software to select the SAI clock source.
- 00: System clock selected as SAI clock
- 01: PLL "Q" clock selected as SAI clock
- 10: Clock provided on I2S_CKIN pin selected as SAI clock
- 11: HSI16 clock selected as SAI clock

Bits 19:18  **LPTIM1SEL[1:0]:** Low power timer 1 clock source selection
These bits are set and cleared by software to select the LPTIM1 clock source.
- 00: PCLK selected as LPTIM1 clock
- 01: LSI clock selected as LPTIM1 clock
- 10: HSI16 clock selected as LPTIM1 clock
- 11: LSE clock selected as LPTIM1 clock

Bits 17:16  **I2C3SEL[1:0]:** I2C3 clock source selection
These bits are set and cleared by software to select the I2C3 clock source.
- 00: PCLK selected as I2C3 clock
- 01: System clock (SYSCLK) selected as I2C3 clock
- 10: HSI16 clock selected as I2C3 clock
- 11: Reserved
Bits 15:14 **I2C2SEL[1:0]**: I2C2 clock source selection  
These bits are set and cleared by software to select the I2C2 clock source.  
00: PCLK selected as I2C2 clock  
01: System clock (SYSCLK) selected as I2C2 clock  
10: HSI16 clock selected as I2C2 clock  
11: Reserved  

Bits 13:12 **I2C1SEL[1:0]**: I2C1 clock source selection  
These bits are set and cleared by software to select the I2C1 clock source.  
00: PCLK selected as I2C1 clock  
01: System clock (SYSCLK) selected as I2C1 clock  
10: HSI16 clock selected as I2C1 clock  
11: Reserved  

Bits 11:10 **LPUART1SEL[1:0]**: LPUART1 clock source selection  
These bits are set and cleared by software to select the LPUART1 clock source.  
00: PCLK selected as LPUART1 clock  
01: System clock (SYSCLK) selected as LPUART1 clock  
10: HSI16 clock selected as LPUART1 clock  
11: LSE clock selected as LPUART1 clock  

Bits 9:8 **UART5SEL[1:0]**: UART5 clock source selection  
These bits are set and cleared by software to select the UART5 clock source.  
00: PCLK selected as UART5 clock  
01: System clock (SYSCLK) selected as UART5 clock  
10: HSI16 clock selected as UART5 clock  
11: LSE clock selected as UART5 clock  

Bits 7:6 **UART4SEL[1:0]**: UART4 clock source selection  
This bit is set and cleared by software to select the UART4 clock source.  
00: PCLK selected as UART4 clock  
01: System clock (SYSCLK) selected as UART4 clock  
10: HSI16 clock selected as UART4 clock  
11: LSE clock selected as UART4 clock  

Bits 5:4 **USART3SEL[1:0]**: USART3 clock source selection  
This bit is set and cleared by software to select the USART3 clock source.  
00: PCLK selected as USART3 clock  
01: System clock (SYSCLK) selected as USART3 clock  
10: HSI16 clock selected as USART3 clock  
11: LSE clock selected as USART3 clock  

Bits 3:2 **USART2SEL[1:0]**: USART2 clock source selection  
This bit is set and cleared by software to select the USART2 clock source.  
00: PCLK selected as USART2 clock  
01: System clock (SYSCLK) selected as USART2 clock  
10: HSI16 clock selected as USART2 clock  
11: LSE clock selected as USART2 clock  

Bits 1:0 **USART1SEL[1:0]**: USART1 clock source selection  
This bit is set and cleared by software to select the USART1 clock source.  
00: PCLK selected as USART1 clock  
01: System clock (SYSCLK) selected as USART1 clock  
10: HSI16 clock selected as USART1 clock  
11: LSE clock selected as USART1 clock
7.4.27 RTC domain control register (RCC_BDCR)

Address offset: 0x90
Reset value: 0x0000 0000

Reset by RTC domain Reset, except LSCOSEL, LSCOEN and BDRST, which are reset only by RTC domain power-on reset.
Access: 0 ≤ wait state ≤ 3, word, half-word and byte access
Wait states are inserted in case of successive accesses to this register.

Note: The bits of this register are outside the V\textsubscript{CORE} domain. As a result, after Reset, they are write-protected and the DBP bit in the Section 6.4.1: Power control register 1 (PWR\_CR1) has to be set before these can be modified. Refer to Section 6.1.3: Battery backup domain on page 229 for further information. These bits (except LSCOSEL, LSCOEN and BDRST) are reset only after an RTC domain reset (see Section 7.1.3). Any internal or external reset does not have any effect on these bits.

<table>
<thead>
<tr>
<th>Bit 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 25</td>
<td>LSCOSEL: Low speed clock output selection</td>
</tr>
</tbody>
</table>
|           | 0: LSI clock selected  
|           | 1: LSE clock selected |
| Bit 24    | LSCOEN: Low speed clock output enable |
|           | 0: Low speed clock output (LSCO) disable  
|           | 1: Low speed clock output (LSCO) enable |
| Bit 16    | BDRST: RTC domain software reset |
|           | 0: Reset not activated  
|           | 1: Reset the entire RTC domain |
| Bit 15    | RTCEN: RTC clock enable |
|           | 0: RTC clock disabled  
|           | 1: RTC clock enabled |
| Bit 14:10 | Reserved, must be kept at reset value. |
Bits 9:8 **RTCSEL[1:0]**: RTC clock source selection

Set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the RTC domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.

- **00**: No clock
- **01**: LSE oscillator clock used as RTC clock
- **10**: LSI oscillator clock used as RTC clock
- **11**: HSE oscillator clock divided by 32 used as RTC clock

Bits 7 Reserved, must be kept at reset value.

Bit 6 **LSECSSD**: CSS on LSE failure Detection

Set by hardware to indicate when a failure has been detected by the Clock Security System on the external 32 kHz oscillator (LSE).

- **0**: No failure detected on LSE (32 kHz oscillator)
- **1**: Failure detected on LSE (32 kHz oscillator)

Bit 5 **LSECSSON**: CSS on LSE enable

Set by software to enable the Clock Security System on LSE (32 kHz oscillator). LSECSSON must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected. Once enabled this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case the software MUST disable the LSECSSON bit.

- **0**: CSS on LSE (32 kHz external oscillator) OFF
- **1**: CSS on LSE (32 kHz external oscillator) ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator drive capability

Set by software to modulate the LSE oscillator’s drive capability.

- **00**: ‘Xtal mode’ lower driving capability
- **01**: ‘Xtal mode’ medium low driving capability
- **10**: ‘Xtal mode’ medium high driving capability
- **11**: ‘Xtal mode’ higher driving capability

The oscillator is in Xtal mode when it is not in bypass mode.

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the external 32 kHz oscillator is disabled (LSEON=0 and LSERDY=0).

- **0**: LSE oscillator not bypassed
- **1**: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.

- **0**: LSE oscillator not ready
- **1**: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable

Set and cleared by software.

- **0**: LSE oscillator OFF
- **1**: LSE oscillator ON
7.4.28 Control/status register (RCC_CSR)

Address: 0x94
Reset value: 0x0C00 0000

Reset by system Reset, except reset flags by power Reset only.
Access: 0 ≤ wait state ≤ 3, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

Bit 31 LPWRRSTF: Low-power reset flag
Set by hardware when a reset occurs due to illegal Stop, Standby or Shutdown mode entry.
Cleared by writing to the RMVF bit.
0: No illegal mode reset occurred
1: Illegal mode reset occurred

Bit 30 WWDGRSTF: Window watchdog reset flag
Set by hardware when a window watchdog reset occurs.
Cleared by writing to the RMVF bit.
0: No window watchdog reset occurred
1: Window watchdog reset occurred

Bit 29 IWDGRSTF: Independent window watchdog reset flag
Set by hardware when an independent watchdog reset domain occurs.
Cleared by writing to the RMVF bit.
0: No independent watchdog reset occurred
1: Independent watchdog reset occurred

Bit 28 SFTRSTF: Software reset flag
Set by hardware when a software reset occurs.
Cleared by writing to the RMVF bit.
0: No software reset occurred
1: Software reset occurred

Bit 27 BORRSTF: BOR flag
Set by hardware when a BOR occurs.
Cleared by writing to the RMVF bit.
0: No BOR occurred
1: BOR occurred

Bit 26 PINRSTF: Pin reset flag
Set by hardware when a reset from the NRST pin occurs.
Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred
1: Reset from NRST pin occurred
Bit 25 **OBLRSTF**: Option byte loader reset flag
Set by hardware when a reset from the Option Byte loading occurs.
Cleared by writing to the RMVF bit.
0: No reset from Option Byte loading occurred
1: Reset from Option Byte loading occurred

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
Set by software to clear the reset flags.
0: No effect
1: Clear the reset flags

Bits 22:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI oscillator clock cycles. This bit can be set even if LSION = 0 if the LSI is requested by the Clock Security System on LSE, by the Independent Watchdog or by the RTC.
0: LSI oscillator not ready
1: LSI oscillator ready

Bit 0 **LSION**: LSI oscillator enable
Set and cleared by software.
0: LSI oscillator OFF
1: LSI oscillator ON

### 7.4.29 Clock recovery RC register (RCC_CRRCR)

Address: 0x98
Reset value: 0x0000 XXX0
Where X is factory-programmed.
Access: no wait state, word, half-word and byte access

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:7 **HSI48CAL[8:0]**: HSI48 clock calibration
These bits are initialized at startup with the factory-programmed HSI48 calibration trim value.
They are ready only.

Bits 6:2 Reserved, must be kept at reset value.
Bit 1 **HSI48RDY**: HSI48 clock ready flag
   Set by hardware to indicate that HSI48 oscillator is stable. This bit is set only when HSI48 is enabled by software by setting HSI48ON.
   0: HSI48 oscillator not ready
   1: HSI48 oscillator ready

Bit 0 **HSI48ON**: HSI48 clock enable
   Set and cleared by software.
   Cleared by hardware to stop the HSI48 when entering in Stop, Standby or Shutdown modes.
   0: HSI48 oscillator OFF
   1: HSI48 oscillator ON

### 7.4.30 Peripherals independent clock configuration register (RCC_CCIPR2)

Address: 0x9C
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **QSPISEL[1:0]**: QUADSPI clock source selection
   Set and reset by software.
   00: system clock selected as QUADSPI kernel clock
   01: HSI16 clock selected as QUADSPI kernel clock
   10: PLL “Q” clock selected as QUADSPI kernel clock
   11: reserved

Bits 19:2 Reserved, must be kept at reset value.

Bits 1:0 **I2C4SEL[1:0]**: I2C4 clock source selection
   These bits are set and cleared by software to select the I2C4 clock source.
   00: PCLK selected as I2C4 clock
   01: System clock (SYSCLK) selected as I2C4 clock
   10: HSI16 clock selected as I2C4 clock
   11: reserved
## 7.4.31 RCC register map

Refer to Section 2.2 on page 81 for the register boundary addresses.
8 Clock recovery system (CRS)

8.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output, or generated by user software.

8.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - LSE oscillator output
  - packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

8.3 CRS implementation

<table>

</tr>
</tbody>
</table>

Table 52. CRS features
8.4 CRS functional description

8.4.1 CRS block diagram

Figure 23. CRS block diagram

8.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFRGR register, can be the signal from the LSE clock or the USB SOF signal. For better robustness of the SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the HSI48 clock) is implemented to filter out glitches. This source signal has a configurable polarity, and can be divided by a programmable binary prescaler, to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 8.7.2.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.
8.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 24. CRS counter behavior

8.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- **TOLERANCE LIMIT**, given directly in the FELIM field of the CRS_CFGR register
- **WARNING LIMIT**, defined as 3 x FELIM value
- **OUTRANGE (error limit)**, defined as 128 x FELIM value
The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCFWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNFERR or SYNFMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

**Note:** If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

### 8.4.5 CRS initialization and configuration

**RELOAD value**

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

\[ \text{RELOAD} = \left( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) - 1 \]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

**FELIM value**

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

\[ \text{FELIM} = \left( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) \times \text{STEP[\%]} \times 100 \% \div 2 \]
The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} = 48000 \), and to a typical trimming step size of 0.14%.

*Note:* The trimming step size depends upon the product, check the datasheet for accurate setting.

*Caution:* There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

### 8.5 CRS low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>

</tr>
</tbody>
</table>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 TRIM[6:0]: HSI48 oscillator smooth trimming

The default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval.

Bit 7 SWSYNC: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action
1: A software SYNC event is generated.

Bit 6 AUTOTRIMEN: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to Section 8.4.4 for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 CEN: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled
1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 ESYNCF: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 ERRF: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled
8.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>SYNCPOL: SYNC polarity selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>30</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>29:28</td>
<td>SYNCSRC[1:0]: SYNC signal source selection</td>
</tr>
<tr>

<td>01: LSE selected as SYNC signal source</td>
</tr>
<tr>
<td></td>
<td>10: USB SOF selected as SYNC signal source (default).</td>
</tr>
<tr>
<td></td>
<td>11: Reserved</td>
</tr>
</tbody>
</table>

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs should be used as SYNC signal.

</tbody>
</table>
Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 8.4.4 for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 8.4.3 for more details about counter behavior.

### 8.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 |

**FECAP[15:0]**

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 8.4.4 for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target
1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled
1: Trimming error signaled

Bit 9 **SYNCCOMP**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled
1: SYNC missed error signaled
Bit 8  SYNCERR: SYNC error
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No SYNC error signaled
1: SYNC error signaled

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  ESYNCF: Expected SYNC flag
This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.
0: No expected SYNC signaled
1: Expected SYNC signaled

Bit 2  ERRF: Error flag
This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.
0: No synchronization or trimming error signaled
1: Synchronization or trimming error signaled

Bit 1  SYNCWARNF: SYNC warning flag
This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.
0: No SYNC warning signaled
1: SYNC warning signaled

Bit 0  SYNCOKF: SYNC event OK flag
This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCKC bit in the CRS_ICR register.
0: No SYNC event OK signaled
1: SYNC event OK signaled

9 General-purpose I/Os (GPIO)

9.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), and a 32-bit set/reset register (GPIOx_BSRR). In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

9.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

9.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. The GPIOx_BSRR registers can be used for atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.
**Figure 25** and **Figure 26** show, respectively, the basic structures of a standard and a 3- or 5-Volt tolerant I/O port bit. **Table 56** gives the possible port bit configurations.

**Figure 25. Basic structure of an I/O port bit**

**Figure 26. Basic structure of a 3- or 5-Volt tolerant I/O port bit**

1. $V_{DD\_FT}$ is a potential specific to five-volt tolerant I/Os and different from $V_{DD}$.

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.
9.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state no pull-up/pull-down

PB8/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase. See Section 9.3.15: Using PB8 as GPIO.

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

9.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:
- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:
- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:  
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
– Configure the desired I/O as an alternate function in the GPIOx_MODER register.

*Additional functions:*
– For the ADC, DAC, OPAMP and COMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, OPAMP, and COMP registers.

As indicated above, for the additional functions (such as DAC or OPAMP), the output is controlled by the corresponding peripheral. Care must be taken to select the I/O port analog function before enabling the additional function output in the peripheral control register.
– For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 9.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 9.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See [Section 9.4.5: GPIO port input data register (GPIOx_IDR) (x = A to G)](section) and [Section 9.4.6: GPIO port output data register (GPIOx_ODR) (x = A to G)](section) for the register descriptions.

### 9.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) sets the corresponding ODR(i) bit. When written to 1, bit BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.
There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

### 9.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to Section 9.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to G)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in Section 9.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to G).

### 9.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin refer to the device datasheet.

### 9.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode.

Refer to Section 15: Extended interrupts and events controller (EXTI) and to Section 15.3.2: Wake-up event management.
9.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

*Figure 27* shows the input configuration of the I/O port bit.

![Figure 27. Input floating/pull up/pull down configurations](image)

9.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

*Figure 28* shows the output configuration of the I/O port bit.
9.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

*Figure 29* shows the Alternate function configuration of the I/O port bit.
9.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up is disabled by Hardware. The weak pull-down is configurable.
- Read access to the input data register gets the value “0”

Figure 30 shows the high-impedance, analog-input configuration of the I/O port bits.

9.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the OSC_IN or OSC32_IN pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

9.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to Section 35.3: RTC functional description.
### 9.3.15 Using PB8 as GPIO

PB8 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, it switches from the input mode to the analog input mode:

- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.

**Note:** It is recommended to set PB8 in another mode than analog mode to limit consumption if the pin is left unconnected.

### 9.3.16 Using PG10 as GPIO

PG10 may be used as reset pin (NRST) or as a GPIO. Depending on the NRST_MODE bits in the user option byte, it switches to those mode:

- Reset input/output: default at power-on reset or after option bytes loading NRST_MODE = 3
- Reset input only: after option bytes loading NRST_MODE = 1
- GPIO PG10 mode: after option bytes loading NRST_MODE = 2

See description on the NRST pin in *Section 7.1.2: System reset*
9.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to Table 57.

The peripheral registers can be written in word, half word or byte mode.

9.4.1 GPIO port mode register (GPIOx_MODER) (x = A to G)

Address offset: 0x00
Reset value: 0xABFF FFFF (for port A)
Reset value: 0xFFFF FEBF (for port B)
Reset value: 0xFFFF FFFF (for ports C..G)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 OD[15:0]: Port output data I/O pin y (y = 15 to 0)  
These bits can be read and written by software.  
Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR register (x = A..F).

9.4.7 GPIO port bit set/reset register (GPIOx_BSRR)  
(x = A to G)

Address offset: 0x18
### 9.4.8 GPIO port configuration lock register (GPIOx_LCKR)

(x = A to G)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

**Note:** A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

**Address offset:** 0x1C

**Reset value:** 0x0000 0000

**Bits 31:16 BR[15:0]:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

- 0: No action on the corresponding ODx bit
- 1: Resets the corresponding ODx bit

**Note:** If both BSx and BRx are set, BSx has priority.

**Bits 15:0 BS[15:0]:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

- 0: No action on the corresponding ODx bit
- 1: Sets the corresponding ODx bit

**Address offset:** 0x1C

**Reset value:** 0x0000 0000

Refer to Section 2.2 on page 81 for the register boundary addresses.
10 System configuration controller (SYSCFG)

10.1 SYSCFG main features

The STM32G4 series devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Remapping memory areas
- Managing the external interrupt line connection to the GPIOs
- Managing robustness feature
- Setting CCM RAM write protection and software erase
- Configuring FPU interrupts
- Enabling /disabling I2C Fast-mode Plus driving capability on some I/Os and voltage booster for I/Os analog switches.

10.2 SYSCFG registers

10.2.1 SYSCFG memory remap register (SYSCFG_MEMRMP)

This register is used for specific configurations on memory remap.

Address offset: 0x00

Reset value: 0x0000 000X (X is the memory mode selected by the BOOT0 pin and BOOT1 option bit)

<tr>
<td>0</td>
<td>MEM_MODE: Memory mode selection</td>
</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 FB_MODE: Flash Bank mode selection
- 0: Flash Bank 1 mapped at 0x0800 0000 and Flash Bank 2 mapped at 0x0804 0000
- 1: Flash Bank 2 mapped at 0x0800 0000 and Flash Bank 1 mapped at 0x0804 0000

Bits 7:3 Reserved, must be kept at reset value.
Bits 2:0 **MEM_MODE**: Memory mapping selection

These bits control the memory internal mapping at address 0x0000 0000. These bits are used to select the physical remap by software and so, bypass the BOOT pin and the option bit setting. After reset these bits take the value selected by BOOT0 pin (or option bit nBOOT0) and BOOT1 option bit.

- 000: Main Flash memory mapped at 0x00000000(1).
- 001: System Flash memory mapped at 0x00000000.
- 010: FSMC memory.
- 011: SRAM1 mapped at 0x00000000.
- 100: QUADSPI memory mapped at 0x0000 0000
- 101: Reserved
- 111: Reserved

1. When BFB2 bit is set, the system memory remains aliased at @0x0000 0000

**Note**: When the FSMC is remapped at address 0x0000 0000, only the first two regions of Bank 1 memory controller (Bank1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.

### 10.2.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

**Bits 31:26** **FPU_IE[5..0]**: Floating Point Unit interrupts enable bits

- FPU_IE[5]: Inexact interrupt enable
- FPU_IE[4]: Input denormal interrupt enable
- FPU_IE[3]: Overflow interrupt enable
- FPU_IE[2]: Underflow interrupt enable
- FPU_IE[1]: Divide-by-zero interrupt enable
- FPU_IE[0]: Invalid operation interrupt enable

**Bits 25:24** Reserved, must be kept at reset value.

**Bit 23** **I2C4_FMP**: Fast-mode Plus driving capability activation

This bit enables the Fm+ driving mode on I2C4 pins selected through AF selection bits.

- 0: Fm+ mode is not enabled on I2C4 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C4 pins selected through AF selection bits.
Table 58 describes when the bit 9 (ANASWVDD) and the bit 8 (BOOSTEN) should be set or reset depending on the voltage settings.

Note: When FM+ mode is activated on GPIO pin, the speed configuration of the GPIO (in GPIOx_OSEPEEDR register) is ignored. Program this register only after the AF selection through the GPIOx_AFRH or GPIOx_AFRL register.

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **CCMBSY:** CCM SRAM busy by erase operation  
0: No CCM SRAM erase operation is on going.  
1: CCM SRAM erase operation is on going.

Bit 0 **CCMER:** CCM SRAM Erase  
Setting this bit starts a hardware CCM SRAM erase operation. This bit is automatically cleared at the end of the CCM SRAM erase operation.  
*Note: This bit is write-protected: setting this bit is possible only after the correct key sequence is written in the SYSCFG_SKR register.*
10.2.8 SYSCFG configuration register 2 (SYSCFG_CFRG2)

Address offset: 0x1C
System reset value: 0x0000 0000

</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value

Bit 8 SPF: SRAM1 and CCM SRAM parity error flag
This bit is set by hardware when an SRAM1 or CCM SRAM parity error is detected. It is cleared by software by writing '1'.
0: No parity error detected
1: Parity error detected

Bits 7:4 Reserved, must be kept at reset value

Bit 3 ECCL: ECC Lock
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Flash ECC error connection to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
0: ECC error disconnected from TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
1: ECC error connected to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.

Bit 2 PVDL: PVD lock enable bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1, as well as the PVDE and PLS[2:0] in the PWR_CR2 register.
0: PVD interrupt disconnected from TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1. PVDE and PLS[2:0] bits can be programmed by the application.
1: PVD interrupt connected to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1, PVDE and PLS[2:0] bits are read only.

Bit 1 SPL: SRAM1 and CCM SRAM parity lock bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM1 or CCM SRAM parity error signal connection to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
0: CCM SRAM parity error signal disconnected from TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
1: CCM SRAM parity error signal connected to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
Bit 0 **CLL:** Cortex®-M4 LOCKUP (Hardfault) output enable bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex®-M4 with FPU LOCKUP (Hardfault) output to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
0: Cortex®-M4 LOCKUP output disconnected from TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.
1: Cortex®-M4 LOCKUP output connected to TIM1/8/15/16/17/20 break input and hrtim_sys_flt input of HRTIM1.

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **KEY[7:0]:** CCM SRAM write protection key for software erase
The following steps are required to unlock the write protection of the CCMER bit in the SYSCFG_SCSR register.
1. Write "0xCA" into Key[7:0]
2. Write "0x53" into Key[7:0]
Writing a wrong key reactivates the write protection.
### 10.2.11 SYSCFG register map

The following table gives the SYSCFG register map and the reset values.

| Offset | Register     | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | SYSCFG_MEMRMP| 0x00 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|        | Reset value  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x04   | SYSCFG_CFRG1 | FPU_IE[5..0] | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|        | Reset value  | 0 1 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 | | | | | | | | | | | | | | | | | | | | | | |
| 0x08   | SYSCFG_EXTCR1|  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|        | Reset value  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x0C   | SYSCFG_EXTCR2|  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|        | Reset value  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0x10   | SYSCFG_EXTCR3|  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|        | Reset value  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

|        | Reset value  | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Refer to Section 2.2 on page 81 for the register boundary addresses.
11 Peripherals interconnect matrix

11.1 Introduction

Several peripherals have direct connections between them.

This allows autonomous communication and or synchronization between peripherals, saving CPU resources thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, Low-power run and sleep, Stop 0 and Stop 1 modes.

The HRTIM burst operation can be triggered by on chip event coming from other general purpose timer.
The burst mode controller counter can be clocked by general purpose timers as well as shown in the Table 62.

Some of the TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in Master Mode, it can reset, start, stop or clock the counter of another timer configured in Slave Mode.

A description of the feature is provided in: Section 28.3.30: Timer synchronization.

The modes of synchronization are detailed in:
- Section 28.3.30: Timer synchronization for advanced-control timers (TIM1/TIM8/TIM20)
- Section 29.4.23: Timer synchronization for general-purpose timers (TIM2/TIM3/TIM4/TIM5)
- Section 30.4.26: Timer synchronization (TIM15 only) for general-purpose timer (TIM15)
Triggering signals
The output (from Master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/TIM8/TIM20) following a configurable timer event.

The input (to slave) is on signals TIMx_ITRx

The input and output signals for TIM1/TIM8/TIM20 are shown in Figure 269: Advanced-control timer block diagram.

The possible master/slave connections are given in:
- Table 252: Internal trigger connection

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

11.3.2 From timer (TIMx, HRTIM) and EXTI to ADC (ADCx)

</table>
Timers (TIMx, HRTIM) can be used to generate an ADC triggering event.

TIMx synchronization is described in: Section 28.3.31: ADC triggers (TIM1/TIM8).

ADC synchronization is described in: Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN).

### Triggering signals

The output (from timer) is on signal TIMx_TRGO, TIMx_TRGO2 or TIMx_CCx event.

The input (to ADC) is on signal EXT[15:0], JEXT[15:0].

The connection between timers and ADC is provided in:
- Table 163: ADC1/2 - External triggers for regular channels
- Table 164: ADC1/2 - External trigger for injected channels

### Active power mode

Run, Sleep, Low-power run, Low-power sleep.
11.3.3 From ADC (ADCx) to timer (TIMx, HRTIM)

See please Table 73: Interconnect 2 and Table 81.: Interconnect 10

ADCs Analog watchdogs are connected to TIM1/8/20 for digital power applications (cycle-
by-cycle current regulation with ADC).

A description of the ADC analog watchdog setting is provided in: Section 21.4.28: Analog
window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH,
AWD_HTx, AWD_LTx, AWDx).

Trigger settings on the timer are provided in: Section 28.3.6: External trigger input.

11.3.4 From timer (TIMx, HRTIM) and EXTI to DAC (DACx)

</tr>
</tbody>
</table>
Timers (TIMx, HRTIM) and EXTI can be used as triggering event to start a DAC conversion.

**Triggering signals**

The output (from timer) is on signal TIMx_TRGO directly connected to corresponding DAC inputs.

Selection of input triggers on DAC is provided in Section 22.4.7: DAC trigger selection (single and dual mode).

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

### 11.3.5 From HSE, LSE, LSI, HSI16, MCO, RTC to timer (TIMx)

See please Table 75: Interconnect 4 and Table 73: Interconnect 2

External clocks (HSE, LSE), internal clocks (LSI, HSI16), microcontroller output clock (MCO), GPIO and RTC wakeup interrupt can be used as input to timer (TIMx).

This allows to calibrate the HSI16 and precisely measure the LSI oscillator frequency.

When Low Speed External (LSE) oscillator is used, no additional hardware connections are required.

This feature is described in Section 7.2.16: Internal/external clock measurement with TIM5/TIM15/TIM16/TIM17.

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

---

</tbody>
</table>

RTC alarm A/B, RTC_TAMP1/2/3 input detection, COMPx_OUT can be used as trigger to start LPTIM counters (LPTIM1).

Triggering signals

This trigger feature is described in Section 32.4.6: Trigger multiplexer (and following sections).

The input selection is described in Table 312: LPTIM1 external trigger connection.

Active power mode

Run, Sleep, Low-power run, Low-power sleep, Stop 0, Stop 1.
11.3.7 From timer (TIMx) to comparators (COMPx)

Timers (TIMx) can be used as blanking window to COMPx (x = 1...7)

The blanking function is described in Section 24.3.6: COMP output blanking.

The blanking sources are given in comparators control and status register (COMP_CxCSR) bits BLANKSEL[2:0].

**Triggering signals**

Timer output signal TIMx_Ocx are the inputs to blanking source of COMPx.

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

11.3.8 From internal analog source to ADC (ADCx), comparator (COMPx) and OPAMP (OPAMPx)

*Table 69* provides the ADC channels mapping on GPIOs or internal connections to temperature sensor (VTS), internal reference voltage VREFINT, VBAT/3 or opampxint_vout.

11.3.9 From comparators (COMPx) to timers (TIMx, HRTIM)

Comparators (COMPx) output values can be connected to:
- Timers (TIMx) input captures or TIMx_ETR signals or TIMx_OCREFCLR signals.
- hrtim_eevx[4:1] and hrtim_in_fltx[4:1]

Comparators (COMPx) output values can also generate break input signals for timers (TIMx) see Section 30.3.17: Bidirectional break inputs.

11.3.10 From system errors to timers (TIMx) and HRTIM

TIMx (TIM1/TIM8/TIM20/TIM15/TIM16/TIM17) break inputs and HRTIM system fault input gather MCU internal fault events coming from:
- the clock failure event generated by the clock security system (CSS),
- the PVD output,
- the SRAM parity error signal,
- the Cortex-M4 LOCKUP (Hardfault) output
- Flash ECC double error detection

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

The functionality is described in:
- Section 28.3.18: Using the break function (TIM1/TIM8/TIM20)
- Section 30.4.15: Using the break function (TIM15/TIM16/TIM17/TIM20)

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

General-purpose timer (TIM16/TIM17) output channel TIMx_OC1 are used to generate the waveform of infrared signal output.

The functionality is described in Section 33: Infrared interface (IRTIM).

Active power mode
Run, Sleep, Low-power run, Low-power sleep.
12 Direct memory access controller (DMA)

12.1 Introduction

The direct memory access (DMA) controller is a bus master and system peripheral.

The DMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories, upon the control of an off-loaded CPU.

The DMA controller features a single AHB master architecture.

There are two instances of DMA, DMA1 and DMA2 (See Table 85: DMA1 and DMA2 implementation for number of supported channels).

Each channel is dedicated to managing memory access requests from one or more peripherals. Each DMA includes an arbiter for handling the priority between DMA requests.

12.2 DMA main features

- Single AHB master
- Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Access, as source and destination, to on-chip memory-mapped devices such as flash memory, SRAM, and AHB and APB peripherals
- All DMA channels independently configurable:
  - Each channel is associated either with a DMA request signal coming from a peripheral, or with a software trigger in memory-to-memory transfers. This configuration is done by software.
  - Priority between the requests is programmable by software (four levels per channel: very high, high, medium, low) and by hardware in case of equality (such as request to channel 1 has priority over request to channel 2).
  - Transfer size of source and destination are independent (byte, half-word, word), emulating packing and unpacking. Source and destination addresses must be aligned on the data size.
  - Support of transfers from/to peripherals to/from memory with circular buffer management
  - Programmable number of data to be transferred: 0 to $2^{16} - 1$
- Generation of an interrupt request per channel. Each interrupt request is caused from any of the three DMA events: transfer complete, half transfer, or transfer error.
12.3 DMA implementation

12.3.1 DMA1 and DMA2

DMA1 and DMA2 are implemented with the hardware configuration parameters shown in the table below.

Table 85. DMA1 and DMA2 implementation

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. See Table 1: STM32G4 series memory density.

12.3.2 DMA request mapping

The DMA controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX peripheral.

For the mapping of the different requests, refer to the DMAMUX section.
12.4 DMA functional description

12.4.1 DMA block diagram

The DMA block diagram is shown in the figure below.

Figure 31. DMA block diagram
Note: See Figure 31: DMA block diagram for feature implementation.

The DMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and DMA target the same destination (memory or peripheral).

According to its configuration through the AHB slave interface, the DMA controller arbitrates between the DMA channels and their associated received requests. The DMA controller also schedules the DMA data transfers over the single AHB port master.

The DMA controller generates an interrupt per channel to the interrupt controller.

12.4.2 DMA pins and internal signals

<table>

<td>Output</td>
<td>DMA channel x interrupt</td>
</tr>
</tbody>
</table>

12.4.3 DMA transfers

The software configures the DMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB bus transfers.

A DMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.

After an event, the following steps of a single DMA transfer occur:
1. The peripheral sends a single DMA request signal to the DMA controller.
2. The DMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the DMA controller grants the peripheral, an acknowledge is sent to the peripheral by the DMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller.
5. Once the request is de-asserted by the peripheral, the DMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single DMA transfer.

The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the DMA controller. The DMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel x, a DMA block transfer consists of a repeated sequence of:
- a single DMA transfer, encapsulating two AHB transfers of a single data, over the DMA AHB bus master:
  - a single data read (byte, half-word, or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory
address register.
The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.

- a single data write (byte, half-word, or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register.

The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.

- post-decrementing of the programmed DMA_CNDTRx register

This register contains the remaining number of data items to transfer (number of AHB 'read followed by write' transfers).

This sequence is repeated until DMA_CNDTRx is null.

Note: The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.

12.4.4 DMA arbitration

The DMA arbiter manages the priority between the different channels.

When an active channel x is granted by the arbiter (hardware requested or software triggered), a single DMA transfer is issued (such as a AHB 'read followed by write' transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.

The priorities are managed in two stages:

- software: priority of each channel is configured in the DMA_CCRx register, to one of the four different levels:
  - very high
  - high
  - medium
  - low

- hardware: if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel x is programmed for a block transfer in memory-to-memory mode, re arbitration is considered between each single DMA transfer of this channel x. Whenever there is another concurrent active requested channel, the DMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.

12.4.5 DMA channels

Each channel may handle a DMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

A DMA channel is programmed at block transfer level.
Programmable data sizes

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the DMA_CCRx register.

Pointer incrementation

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the DMA_CCRx register.

If the incremented mode is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the DMA_CPARx or DMA_CMARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in non-circular mode, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the DMA_CNDTRx register.

Note: If the channel x is disabled, the DMA registers are not reset. The DMA channel registers (DMA_CCRx, DMA_CPARx and DMA_CMARx) retain the initial values programmed during the channel configuration phase.

In circular mode, after the last data transfer, the DMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA_CPARx and DMA_CMARx registers.

Channel configuration procedure

The following sequence is needed to configure a DMA channel x:

1. Set the peripheral register address in the DMA_CPARx register.
   The data is moved from/to this address to/from the memory after the peripheral event, or after the channel is enabled in memory-to-memory mode.
2. Set the memory address in the DMA_CMARx register.
   The data is written to/read from the memory after the peripheral event or after the channel is enabled in memory-to-memory mode.
3. Configure the total number of data to transfer in the DMA_CNDTRx register.
   After each data transfer, this value is decremented.
4. Configure the parameters listed below in the DMA_CCRx register:
   – the channel priority
   – the data transfer direction
   – the circular mode
   – the peripheral and memory incremented mode
   – the peripheral and memory data size
   – the interrupt enable at half and/or full transfer and/or transfer error
5. Activate the channel by setting the EN bit in the DMA_CCRx register.

A channel, as soon as enabled, may serve any DMA request from the peripheral connected to this channel, or may start a memory-to-memory block transfer.
Note: The two last steps of the channel configuration procedure may be merged into a single access to the DMA_CCRx register, to configure and enable the channel.

Channel state and disabling a channel

A channel x in the active state is an enabled channel (read DMA_CCRx.EN = 1). An active channel x is a channel that must have been enabled by the software (DMA_CCRx.EN set to 1) and afterwards with no occurred transfer error (DMA_ISR.TEIFx = 0). In case there is a transfer error, the channel is automatically disabled by hardware (DMA_CCRx.EN = 0).

The three following use cases may happen:

- Suspend and resume a channel
  This corresponds to the two following actions:
  - An active channel is disabled by software (writing DMA_CCRx.EN = 0 whereas DMA_CCRx.EN = 1).
  - The software enables the channel again (DMA_CCRx.EN set to 1) without reconfiguring the other channel registers (such as DMA_CNDTRx, DMA_CPARx and DMA_CMARx).

  This case is not supported by the DMA hardware, that does not guarantee that the remaining data transfers are performed correctly.

- Stop and abort a channel
  If the application does not need any more the channel, this active channel can be disabled by software. The channel is stopped and aborted but the DMA_CNDTRx register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/registry.

- Abort and restart a channel
  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.

  This is supported by the hardware if the following conditions are met:
  - The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.
  - The software must operate separated write accesses to the same DMA_CCRx register: First disable the channel. Second reconfigure the channel for a next block transfer including the DMA_CCRx if a configuration change is needed. There are read-only DMA_CCRx register fields when DMA_CCRx.EN=1. Finally enable again the channel.

  When a channel transfer error occurs, the EN bit of the DMA_CCRx register is cleared by hardware. This EN bit cannot be set again by software to reactivate the channel x, until the TEIFx bit of the DMA_ISR register is set.

Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the CIRC bit in the DMA_CCRx register.

Note: The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (CIRC = 1), the software must clear the MEM2MEM bit of the DMA_CCRx register. When the circular mode is activated, the amount of data to transfer is
automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel. The software must explicitly program the DMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.

**Memory-to-memory mode**

The DMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the DMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the DMA_CNDTRx register reaches zero.

**Note:** The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the DMA_CCRx register.

**Peripheral-to-peripheral mode**

Any DMA channel can operate in peripheral-to-peripheral mode:

- when the hardware request from a peripheral is selected to trigger the DMA channel
  This peripheral is the DMA initiator and paces the data transfer from/to this peripheral to/from a register belonging to another memory-mapped peripheral (this one being not configured in DMA mode).
- when no peripheral request is selected and connected to the DMA channel
  The software configures a register-to-register transfer by setting the MEM2MEM bit of the DMA_CCRx register.

**Programming transfer direction, assigning source/destination**

The value of the DIR bit of the DMA_CCRx register sets the direction of the transfer, and consequently, it identifies the source and the destination, regardless the source/destination type (peripheral or memory):

- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The **source** attributes are defined by the DMA_MARx register, the MSIZE[1:0] field, and MINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘memory’ register, field, and bit are used to define the source peripheral in peripheral-to-peripheral mode.
  - The **destination** attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and the PINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field, and bit are used to define the destination memory in memory-to-memory mode.

- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The **source** attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and the PINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field, and bit are used to define the source memory in memory-to-memory mode.
  - The **destination** attributes are defined by the DMA_MARx register, the MSIZE[1:0] field and the MINC bit of the DMA_CCRx register.
Regardless of their usual naming, these 'memory' register, field and bit are used to define the destination peripheral in peripheral-to-peripheral mode.

### 12.4.6 DMA data width, alignment, and endianness

When PSIZE[1:0] and MSIZE[1:0] are not equal, the DMA controller performs some data alignments as described in the table below.

<table>
<thead>
<tr>
<th>Source port width (MSIZE if DIR = 1, else PSIZE)</th>
<th>Destination port width (PSIZE if DIR = 1, else MSIZE)</th>

</table>
Addressing AHB peripherals not supporting byte/half-word write transfers

When the DMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word write transfers and does not generate any error, the DMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the DMA controller sets the HWDATA bus to 0xABCDABCD with a half-word data size (HSIZE = HalfWord in the AHB master bus).
- To write the byte 0xAB, the DMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).

Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2, or 0x3 addresses, is converted to an APB word write transfer of 0xB0B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

12.4.7 DMA error management

A DMA transfer error is generated when reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding DMA_CCRx register.

The TEIFx bit of the DMA_ISR register is set. An interrupt is then generated if the TEIE bit of the DMA_CCRx register is set.

The EN bit of the DMA_CCRx register cannot be set again by software (channel x reactivated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).

When the software is notified with a transfer error over a channel, which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both DMA and the peripheral in DMA mode for a new transfer.
12.5 DMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x. Separate interrupt enable bits are available for flexibility.

12.6 DMA registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The DMA registers have to be accessed by words (32-bit).

*Note:* See Figure 31: DMA block diagram for feature implementation.

12.6.1 DMA interrupt status register (DMA_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIxF, in the DMA_IFCR register.

Bit 18 **HTIF5**: Half transfer (HT) flag for channel 5
0: No HT event
1: An HT event occurred.

Bit 17 **TCIF5**: Transfer complete (TC) flag for channel 5
0: No TC event
1: A TC event occurred.

Bit 16 **GIF5**: Global interrupt flag for channel 5
0: No TE, HT, or TC event
1: A TE, HT, or TC event occurred.

Bit 15 **TEIF4**: Transfer error (TE) flag for channel 4
0: No TE event
1: A TE event occurred.

Bit 14 **HTIF4**: Half transfer (HT) flag for channel 4
0: No HT event
1: An HT event occurred.

Bit 13 **TCIF4**: Transfer complete (TC) flag for channel 4
0: No TC event
1: A TC event occurred.
Bit 12 **GIF4**: global interrupt flag for channel 4
0: No TE, HT, or TC event
1: A TE, HT, or TC event occurred.

Bit 11 **TEIF3**: Transfer error (TE) flag for channel 3
0: No TE event
1: A TE event occurred.

Bit 10 **HTIF3**: Half transfer (HT) flag for channel 3
0: No HT event
1: An HT event occurred.

Bit 9 **TCIF3**: Transfer complete (TC) flag for channel 3
0: No TC event
1: A TC event occurred.

Bit 8 **GIF3**: Global interrupt flag for channel 3
0: No TE, HT, or TC event
1: A TE, HT, or TC event occurred.

Bit 7 **TEIF2**: Transfer error (TE) flag for channel 2
0: No TE event
1: A TE event occurred.

Bit 6 **HTIF2**: Half transfer (HT) flag for channel 2
0: No HT event
1: An HT event occurred.

Bit 5 **TCIF2**: Transfer complete (TC) flag for channel 2
0: No TC event
1: A TC event occurred.

Bit 4 **GIF2**: Global interrupt flag for channel 2
0: No TE, HT, or TC event
1: A TE, HT, or TC event occurred.

Bit 3 **TEIF1**: Transfer error (TE) flag for channel 1
0: No TE event
1: A TE event occurred.

Bit 2 **HTIF1**: Half transfer (HT) flag for channel 1
0: No HT event
1: An HT event occurred.

Bit 1 **TCIF1**: Transfer complete (TC) flag for channel 1
0: No TC event
1: A TC event occurred.

Bit 0 **GIF1**: Global interrupt flag for channel 1
0: No TE, HT, or TC event
1: A TE, HT, or TC event occurred.
### 12.6.2 DMA interrupt flag clear register (DMA_IFCR)

Address offset: 0x04

Reset value: 0x0000 0000

Setting the global clear bit CGIFx of the channel x in this DMA_IFCR register, causes the DMA hardware to clear the corresponding GIFx bit and any individual flag among TEIFx, HTIFx, TCIFx, in the DMA_ISR register.

Setting any individual clear bit among CTEIFx, CHTIFx, CTCIFx in this DMA_IFCR register, causes the DMA hardware to clear the corresponding individual flag and the global flag GIFx in the DMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

Bit 0 **CGIF1**: Global interrupt flag clear for channel 1

### 12.6.3 DMA channel x configuration register (DMA_CCRx)

Address offset: 0x08 + 0x14 * (x - 1), (x = 1 to 8)  
Reset value: 0x0000 0000

The register fields/bits MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.

The states of MEM2MEM and CIRC bits must not be both high at the same time.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **MEM2MEM**: Memory-to-memory mode  
0: Disabled  
1: Enabled  

*Note: This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).*

Bits 13:12 **PL[1:0]**: Priority level  
00: Low  
01: Medium  
10: High  
11: Very high  

*Note: This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).*
Bits 11:10 **MSIZE[1:0]**: Memory size

Defines the data size of each DMA transfer to the identified memory.

In memory-to-memory mode, this bitfield identifies the memory source if DIR = 1 and the memory destination if DIR = 0.

In peripheral-to-peripheral mode, this bitfield identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.

00: 8 bits
01: 16 bits
10: 32 bits
11: Reserved

*Note:* This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

Bits 9:8 **PSIZE[1:0]**: Peripheral size

Defines the data size of each DMA transfer to the identified peripheral.

In memory-to-memory mode, this bitfield identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this bitfield identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

00: 8 bits
01: 16 bits
10: 32 bits
11: Reserved

*Note:* This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

Bit 7 **MINC**: Memory increment mode

Defines the increment mode for each DMA transfer to the identified memory.

In memory-to-memory mode, this bit identifies the memory source if DIR = 1 and the memory destination if DIR = 0.

In peripheral-to-peripheral mode, this bit identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.

0: Disabled
1: Enabled

*Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

Bit 6 **PINC**: Peripheral increment mode

Defines the increment mode for each DMA transfer to the identified peripheral.

In memory-to-memory mode, this bit identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this bit identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

0: Disabled
1: Enabled

*Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

Bit 5 **CIRC**: Circular mode

0: Disabled
1: Enabled

*Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is not read-only when the channel is enabled (EN = 1).
Bit 4  **DIR**: Data transfer direction
   This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.
   0: Read from peripheral
      – Source attributes are defined by PSIZE and PINC, plus the DMA_CPARx register.
         This is still valid in a memory-to-memory mode.
      – Destination attributes are defined by MSIZE and MINC, plus the DMA_CMARx register.
         This is still valid in a peripheral-to-peripheral mode.
   1: Read from memory
      – Destination attributes are defined by PSIZE and PINC, plus the DMA_CPARx register.
         This is still valid in a memory-to-memory mode.
      – Source attributes are defined by MSIZE and MINC, plus the DMA_CMARx register.
         This is still valid in a peripheral-to-peripheral mode.
   *Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

Bit 3  **TEIE**: Transfer error interrupt enable
   0: Disabled
   1: Enabled
   *Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is not read-only when the channel is enabled (EN = 1).

Bit 2  **HTIE**: Half transfer interrupt enable
   0: Disabled
   1: Enabled
   *Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is not read-only when the channel is enabled (EN = 1).

Bit 1  **TCIE**: Transfer complete interrupt enable
   0: Disabled
   1: Enabled
   *Note:* This bit is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is not read-only when the channel is enabled (EN = 1).

Bit 0  **EN**: Channel enable
   When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).
   0: Disabled
   1: Enabled
   *Note:* This bit is set and cleared by software.
### 12.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx)

Address offset: 0x0C + 0x14 * (x - 1), (x = 1 to 8)  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 15:0</td>
<td><strong>NDT[15:0]</strong>: Number of data to transfer (0 to $2^{16} - 1$)</td>
</tr>
</tbody>
</table>

This bitfield is updated by hardware when the channel is enabled:
- It is decremented after each single DMA ‘read followed by write’ transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the DMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this bitfield is zero, no transfer can be served whatever the channel status (enabled or not).

**Note:** This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).

### 12.6.5 DMA channel x peripheral address register (DMA_CPARx)

Address offset: 0x10 + 0x14 * (x - 1), (x = 1 to 8)  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>

</tr>
</thead>
<tbody>
<tr>
<td>Bits 15:0</td>
<td>PA[15:0]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Reserved, must be kept at reset value.</th>
<th>PA[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NDT[15:0]</strong>: Number of data to transfer (0 to $2^{16} - 1$)</td>
<td>PA[15:0]</td>
</tr>
</tbody>
</table>

This bitfield is updated by hardware when the channel is enabled:
- It is decremented after each single DMA ‘read followed by write’ transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the DMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this bitfield is zero, no transfer can be served whatever the channel status (enabled or not).

**Note:** This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is read-only when the channel is enabled (EN = 1).
12.6.6 DMA channel x memory address register (DMA_CMARx)

Address offset: 0x14 + 0x14 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

Bits 31:0  PA[31:0]: Peripheral address

It contains the base address of the peripheral data register from/to which the data is read/written.

When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address.
When PSIZE[1:0] = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this bitfield identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0.
In peripheral-to-peripheral mode, this bitfield identifies the peripheral destination address if DIR = 1 and the peripheral source address if DIR = 0.

Note: This bitfield is set and cleared by software. It must not be written when the channel is enabled (EN = 1). It is not read-only when the channel is enabled (EN = 1).

Refer to Section 2.2 for the register boundary addresses.
13 DMA request multiplexer (DMAMUX)

13.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is deasserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in Section 13.3.1.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend upon product implementation. They are detailed in Section 13.3.2.
13.2 DMAMUX main features

- Up to 16-channel programmable DMA request line multiplexer output
- 4-channel DMA request generator
- 21 trigger inputs to DMA request generator
- 21 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - 115 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining

13.3 DMAMUX implementation

13.3.1 DMAMUX instantiation

DMAMUX is instantiated with the hardware configuration parameters listed in the following table.

Table 90. DMAMUX instantiation

<table>
<thead>
<tr>
<th>Feature</th>

</table>

1. See Table 1: STM32G4 series memory density

13.3.2 DMAMUX mapping

The mapping of resources to DMAMUX is hardwired.

DMAMUX is used with DMA1 and DMA2:

For category 3 and category 4 devices:

- DMAMUX channels 0 to 7 are connected to DMA1 channels 1 to 8
- DMAMUX channels 8 to 15 are connected to DMA2 channels 1 to 8
For category 2 devices:

- DMAMUX channels 0 to 5 are connected to DMA1 channels 1 to 6
- DMAMUX channels 6 to 11 are connected to DMA2 channels 1 to 6

13.4 DMAMUX functional description

13.4.1 DMAMUX block diagram

*Figure 32* shows the DMAMUX block diagram.

**Figure 32. DMAMUX block diagram**

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)
13.4.2 DMAMUX signals

Table 94 lists the DMAMUX signals.

13.4.3 DMAMUX channels

A DMAMUX channel is a request multiplexer channel that can include, depending upon the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to a single channel of DMA controller(s).

Channel configuration procedure

Follow the sequence below to configure a DMAMUX x channel and the related DMA channel y:
1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

13.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals, or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAREQ_ID field in the DMAMUX_CxCR register.

Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected.
**Caution:** A same non-null DMAREQ_ID cannot be programmed to different x and y DMAMUX request multiplexer channels (via DMAMUX_CxCR and DMAMUX_CyCR), except when the application guarantees that the two connected DMA channels are not simultaneously active.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

### Synchronization mode and channel event generation

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once a programmable rising/falling edge is detected on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, internally to the DMAMUX request multiplexer, there is a programmable DMA request counter, which can be used for the channel request output generation, and for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in Figure 34, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output.

**Note:** If a synchronization event occurs while there is no pending selected input DMA request line, it is discarded. The following asserted input request lines is not connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is deasserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in the NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in the NBREQ field, plus one.

**Note:** The NBREQ field value can be written by software only when both synchronization enable bit (SE) and event generation enable bit (EGE) of the corresponding multiplexer channel x are disabled.
If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in Figure 33 and Figure 34.
Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

Synchronization overrun and interrupt

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR register.

Note: The request multiplexer channel x synchronization must be disabled (DMAMUX_CxCR.SE = 0) when the use of the related channel of the DMA controller is completed. Else, upon a new detected synchronization event, there is a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

13.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is deasserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter is automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.
Note: The GNBREQ field value can be written by software only when the enable GE bit of the corresponding generator channel x is disabled.

There is no hardware write protection.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

Trigger overrun and interrupt

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the DMAMUX_RGSR register.

Note: The request generator channel x must be disabled (DMAMUX_RGxCR.GE = 0) when the usage of the related channel of the DMA controller is completed. Else, upon a new detected trigger event, there is a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

13.5 DMAMUX interrupts

An interrupt can be generated upon:

- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel individual interrupt enable, status, and clear flag register bits are available.

13.6 DMAMUX registers

Refer to the table containing register boundary addresses for the DMAMUX base address.

DMAMUX registers may be accessed per byte (8-bit), half-word (16-bit), or word (32-bit). The address must be aligned with the data size.

13.6.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR)

Address offset: 0x0000 + 0x04 * x (x = 0 to 15)

Reset value: 0x0000 0000

Refer to *Section 2.2 on page 81* for the register boundary addresses.
14 Nested vectored interrupt controller (NVIC)

14.1 NVIC main features

- 102 maskable interrupt channels (not including the sixteen Cortex®-M4 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to the PM0214 programming manual for Cortex™-M4 products.

14.2 SysTick calibration value register

The SysTick calibration value is set to 0x3E8, which gives a reference time base of 1 ms with the SysTick clock set to 125 KHz (1 MHz / 8).
### 14.3 Interrupt and exception vectors

The gray rows in Table 97 describe the vectors without specific position.

15 Extended interrupts and events controller (EXTI)

15.1 Introduction

The EXTI main features are:
- Generation of up to 42 event/interrupt requests
  - 29 configurable lines
  - 13 direct lines
- Independent mask on each event/interrupt line
- Configurable rising or falling edge (configurable lines only)
- Dedicated status bit (configurable lines only)
- Emulation of event/interrupt requests (configurable lines only)

15.2 EXTI main features

The extended interrupts and events controller (EXTI) manages the external and internal asynchronous events/interrupts and generates the event request to the CPU/Interrupt Controller and a wake-up request to the Power Controller.

The EXTI allows the management of up to 42 event lines which can wake up from the Stop mode.

The lines are either configurable or direct:
- The lines are configurable: the active edge can be chosen independently, and a status flag indicates the source of the interrupt. The configurable lines are used by the I/Os external interrupts, and by few peripherals.
- The lines are direct: they are used by some peripherals to generate a wake-up from Stop event or interrupt. The status flag is provided by the peripheral.

Each line can be masked independently for an interrupt or an event generation.

This controller also allows to emulate events or interrupts by software, multiplexed with the corresponding hardware event line, by writing to a dedicated register.

15.3 EXTI functional description

For the configurable interrupt lines, the interrupt line should be configured and enabled in order to generate an interrupt. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing 1 to the corresponding bit in the interrupt mask register. When the selected edge occurs on the interrupt line, an interrupt request is generated. The pending bit corresponding to the interrupt line is also set. This request is cleared by writing 1 in the pending register.

For the direct interrupt lines, the interrupt is enabled by default in the interrupt mask register and there is no corresponding pending bit in the pending register.

To generate an event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing 1 to the corresponding bit in the event mask register. When the
selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

For the configurable lines, an interrupt/event request can also be generated by software by writing 1 in the software interrupt/event register.

Note: The interrupts or events associated to the direct lines are triggered only when the system is in Stop mode. If the system is still running, no interrupt/event is generated by the EXTI.

15.3.1 EXTI block diagram

The extended interrupt/event block diagram is shown on Figure 35.

**Figure 35. Configurable interrupt/event block diagram**

15.3.2 Wake-up event management

The devices handle external or internal events to wake up the core (WFE). The wake-up event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex™-M4 System Control register. When the MCU resumes from WFE, the EXTI peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared
- or by configuring an EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.
15.3.3 Peripherals asynchronous Interrupts

Some peripherals are able to generate events when the system is in run mode and also when the system is in Stop mode, allowing to wake up the system from Stop mode.

To accomplish this, the peripheral generates both a synchronized (to the system clock, e.g. APB clock) and an asynchronous version of the event. This asynchronous event is connected to an EXTI direct line.

*Note:* Few peripherals with wake-up from Stop capability are connected to an EXTI configurable line. In this case, the EXTI configuration is necessary to allow the wake-up from Stop mode.

15.3.4 Hardware interrupt selection

To configure a line as an interrupt source, use the following procedure:

1. Configure the corresponding mask bit in the EXTI_IMR register.
2. Configure the Trigger Selection bits of the Interrupt line (EXTI_RTSR and EXTI_FTSR).
3. Configure the enable and mask bits that control the NVIC IRQ channel mapped to the EXTI so that an interrupt coming from one of the EXTI lines can be correctly acknowledged.

*Note:* The direct lines do not require any EXTI configuration.

15.3.5 Hardware event selection

To configure a line as an event source, use the following procedure:

1. Configure the corresponding mask bit in the EXTI_EMR register.
2. Configure the Trigger Selection bits of the Event line (EXTI_RTSR and EXTI_FTSR).

15.3.6 Software interrupt/event selection

Any of the configurable lines can be configured as a software interrupt/event line. The procedure to generate a software interrupt is as follows:

1. Configure the corresponding mask bit (EXTI_IMR, EXTI_EMR).
2. Set the required bit of the software interrupt register (EXTI_SWIER).

15.4 EXTI interrupt/event line mapping

In the STM32G4 series, 42 interrupt/event lines are available. The GPIOs are connected to 16 configurable interrupt/event lines (see Figure 36).
The EXTI lines are connected as shown in Table 98: EXTI lines connections.

Bits 31:0 **EMx**: Event mask on line x (x = 31 to 0)

0: Event request from line x is masked
1: Event request from line x is not masked

### 15.5.3 Rising trigger selection register 1 (EXTI_RTSR1)

Address offset: 0x08

Reset value: 0x0000 0000
### 15.5.4 Falling trigger selection register 1 (EXTI_FTSR1)

Address offset: 0x0C

<table>
<thead>
<tr>
<th>Bits</th>
<th>Configuration</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:29</td>
<td>RTx: Rising trigger event configuration bit of line x (x = 31 to 29)</td>
<td>0: Rising trigger disabled (for Event and Interrupt) for input line 1: Rising trigger enabled (for Event and Interrupt) for input line</td>
</tr>
<tr>
<td>28:23</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>
<td>22:19</td>
<td>FTx: Falling trigger event configuration bit of line x (x = 22 to 19)</td>
<td>0: Falling trigger disabled (for Event and Interrupt) for input line 1: Falling trigger enabled (for Event and Interrupt) for input line</td>
</tr>
<tr>
<td>18</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>
<td>17:0</td>
<td>FTx: Falling trigger event configuration bit of line x (x = 17 to 0)</td>
<td>0: Falling trigger disabled (for Event and Interrupt) for input line 1: Falling trigger enabled (for Event and Interrupt) for input line</td>
</tr>
</tbody>
</table>

Note: The configurable wake-up lines are edge-triggered. No glitch must be generated on these lines. If a rising edge on a configurable interrupt line occurs during a write operation in the EXTI_RTSR register, the pending bit is not set. Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.
Bits 17:0 **FTx**: Falling trigger event configuration bit of line x (x = 17 to 0)
0: Falling trigger disabled (for Event and Interrupt) for input line
1: Falling trigger enabled (for Event and Interrupt) for input line

**Note:** The configurable wake-up lines are edge-triggered. No glitch must be generated on these lines. If a falling edge on a configurable interrupt line occurs during a write operation to the EXTI_FTSR register, the pending bit is not set.
Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.

Bits 31:29 **SWIx**: Software interrupt on line x (x = 31 o 29)
If the interrupt is enabled on this line in the EXTI_IMR, writing a '1' to this bit when it is at '0' sets the corresponding pending bit in EXTI_PR resulting in an interrupt request generation.
This bit is cleared by clearing the corresponding bit in the EXTI_PR register (by writing 1 into the bit).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:19 **SWIx**: Software interrupt on line x (x = 22 o 19)
If the interrupt is enabled on this line in the EXTI_IMR, writing a '1' to this bit when it is at '0' sets the corresponding pending bit in EXTI_PR resulting in an interrupt request generation.
This bit is cleared by clearing the corresponding bit in the EXTI_PR register (by writing 1 into the bit).

Bit 18 Reserved, must be kept at reset value.

Bits 17:0 **SWIx**: Software interrupt on line x (x = 17 to 0)
If the interrupt is enabled on this line in the EXTI_IMR, writing a '1' to this bit when it is at '0' sets the corresponding pending bit in EXTI_PR resulting in an interrupt request generation.
This bit is cleared by clearing the corresponding bit of EXTI_PR (by writing 1 into the bit).

**Bits 31:29 PIFx**: Pending interrupt flag on line x (x = 31 to 29)

0: No trigger request occurred  
1: Selected trigger request occurred  
This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing 1 to the bit.

**Bits 28:23** Reserved, must be kept at reset value.

**Bits 22:19 PIFx**: Pending interrupt flag on line x (x = 22 to 19)

0: No trigger request occurred  
1: Selected trigger request occurred  
This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing 1 to the bit.

**Bit 18** Reserved, must be kept at reset value.

**Bits 17:0 PIFx**: Pending interrupt flag on line x (x = 17 to 0)

0: No trigger request occurred  
1: Selected trigger request occurred  
This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing 1 to the bit.

### 15.5.7 Interrupt mask register 2 (EXTI_IMR2)

Address offset: 0x20  
Reset value: Direct lines are set to 1, others lines are set to 0. See Table 98.

Extended interrupts and events controller (EXTI) RM0440

Bits 31:10  Reserved, must be kept at reset value.

Bits 9:8  \textbf{RT}x: Rising trigger event configuration bit of line x (x = 40 to 41)
0: Rising trigger disabled (for Event and Interrupt) for input line
1: Rising trigger enabled (for Event and Interrupt) for input line

Bits 7:2  Reserved, must be kept at reset value.

Bits 1:0  \textbf{RT}x: Rising trigger event configuration bit of line x (x = 32 to 33)
0: Rising trigger disabled (for Event and Interrupt) for input line
1: Rising trigger enabled (for Event and Interrupt) for input line

Note:  The configurable wake-up lines are edge-triggered. No glitch must be generated on these lines. If a rising edge on a configurable interrupt line occurs during a write operation to the EXTI_RTSR register, the pending bit is not set.
Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.
15.5.10 **Falling trigger selection register 2 (EXTI_FTSR2)**

Address offset: 0x2C  
Reset value: 0x0000 0000

| Bits 31:10 | Reserved, must be kept at reset value. |
| Bits 9:8  | FTx: Falling trigger event configuration bit of line x (x = 40 to 41) |
| 0: Falling trigger disabled (for Event and Interrupt) for input line |
| 1: Falling trigger enabled (for Event and Interrupt) for input line |
| Bits 7:2  | Reserved, must be kept at reset value. |
| Bits 1:0  | FTx: Falling trigger event configuration bit of line x (x = 32 to 33) |
| 0: Falling trigger disabled (for Event and Interrupt) for input line |
| 1: Falling trigger enabled (for Event and Interrupt) for input line |

**Note:** The configurable wake-up lines are edge-triggered. No glitch must be generated on these lines. If a falling edge on a configurable interrupt line occurs during a write operation to the EXTI_FTSR register, the pending bit is not set.  
Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 **PIFx**: Pending interrupt flag on line x (x = 40 to 41)
- 0: No trigger request occurred
- 1: Selected trigger request occurred
  This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing 1 into the bit.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **PIFx**: Pending interrupt flag on line x (x = 32 to 33)
- 0: No trigger request occurred
- 1: Selected trigger request occurred
  This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing 1 into the bit.

Bits 9:8 **SWIx**: Software interrupt on line x (x = 40 to 41)
- If the interrupt is enabled on this line in EXTI_IMR, writing a ‘1’ to this bit when it is at ‘0’ sets the corresponding pending bit of EXTI_PR resulting in an interrupt request generation.
- This bit is cleared by clearing the corresponding bit of EXTI_PR (by writing 1 to the bit).

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **SWIx**: Software interrupt on line x (x = 32 to 33)
- If the interrupt is enabled on this line in EXTI_IMR, writing a ‘1’ to this bit when it is at ‘0’ sets the corresponding pending bit of EXTI_PR resulting in an interrupt request generation.
- This bit is cleared by clearing the corresponding bit of EXTI_PR (by writing 1 to the bit).
15.5.13 EXTI register map

Table 99 gives the EXTI register map and the reset values.

Refer to Section 2.2 on page 81 for the register boundary addresses.
16  Cyclic redundancy check calculation unit (CRC)

16.1  Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

16.2  CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1\]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes
16.3 CRC functional description

16.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.
The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register. The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

*Note:* The type of an even polynomial is \(X+X^2+..+X^n\), while the type of an odd polynomial is \(1+X+X^2+..+X^n\).

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size cannot be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
16.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

Refer to Section 2.2 on page 81 for the register boundary addresses.
17  CORDIC coprocessor (CORDIC)

17.1  CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

17.2  CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

17.3  CORDIC functional description

17.3.1  General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle $\theta$ are determined by rotating the unit vector $[1, 0]$ through decreasing angles until the cumulative sum of the rotation angles equals the input angle $\theta$. The $x$ and $y$ cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of $\theta$. Inversely, the angle of a vector $[x, y]$ corresponding to arctangent ($y / x$), is determined by rotating $[x, y]$ through successively decreasing angles to obtain the unit vector $[1, 0]$. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

17.3.2  CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.
Table 102 lists the functions supported by the CORDIC coprocessor.

### Table 102. CORDIC functions

</tr>
</tbody>
</table>

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: $\sin \theta$ also generates $\cos \theta$, $\cos \theta$ also generates $\sin \theta$. Similarly, for rectangular-to-polar conversion ($\text{phase}(x,y)$, $\text{modulus}(x,y)$) and for hyperbolic functions ($\cosh \theta$, $\sinh \theta$).

**Note:** The exponential function, $\exp x$, can be obtained as the sum of $\sinh x$ and $\cosh x$. Furthermore, base $N$ logarithms, $\log_N x$, can be derived by multiplying $\ln x$ by a constant $K$, where $K = 1/\ln N$.

For certain functions (atan, log, sqrt) a scaling factor (see Section 17.3.4) can be applied to extend the range of the function beyond the maximum $[-1, 1]$ supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

### Cosine

**Table 103. Cosine parameters**

<table>
<thead>
<tr>

<tr>
<td>SCALE</td>
<td>Not applicable</td>
<td>0</td>
</tr>
</tbody>
</table>

This function calculates the cosine of an angle in the range $-\pi$ to $\pi$. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle $\theta$ in radians. It must be divided by $\pi$ before programming ARG1.

The secondary argument is the modulus $m$. If $m$ is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 104. Sine parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

<tr>
<td>RES2</td>
<td>$m \cdot \cos \theta$</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>SCALE</td>
<td>Not applicable</td>
<td>0</td>
</tr>
</tbody>
</table>

This function calculates the sine of an angle in the range $-\pi$ to $\pi$. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle $\theta$ in radians. It must be divided by $\pi$ before programming ARG1.

The secondary argument is the modulus $m$. If $m$ is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 105. Phase parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARG1</td>
<td>x coordinate</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>ARG2</td>
<td>y coordinate</td>
<td>[-1, 1]</td>
</tr>
<tr>
<td>RES1</td>
<td>Phase angle $\theta$ in radians, divided by $\pi$</td>
<td>[-1, 1]</td>
</tr>
</tbody>
</table>
This function calculates the phase angle in the range $-\pi$ to $\pi$ of a vector $v = [x \ y]$ (also known as $\text{atan2}(y,x)$). It can also be used to perform rectangular to polar conversion.

The primary argument is the $x$ coordinate, that is, the magnitude of the vector in the direction of the $x$ axis. If $|x| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of argv1.

The secondary argument is the $y$ coordinate, that is, the magnitude of the vector in the direction of the $y$ axis. If $|y| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of argv2.

The primary result, argv1, is the phase angle $\theta$ of the vector $v$. argv1 must be multiplied by $\pi$ to obtain the angle in radians. Note that values close to $\pi$ may sometimes wrap to $-\pi$ due to the circular nature of the phase angle.

The secondary result, argv2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If $|v| > 1$ the result in argv2 is saturated to 1.

**Modulus**

This function calculates the magnitude, or modulus, of a vector $v = [x \ y]$. It can also be used to perform rectangular to polar conversion.

The primary argument is the $x$ coordinate, that is, the magnitude of the vector in the direction of the $x$ axis. If $|x| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of argv1.

The secondary argument is the $y$ coordinate, that is, the magnitude of the vector in the direction of the $y$ axis. If $|y| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of argv2.

The primary result, argv1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If $|v| > 1$ the result in argv1 is saturated to 1.

The secondary result, argv2, is the phase angle $\theta$ of the vector $v$. argv2 must be multiplied by $\pi$ to obtain the angle in radians. Note that values close to $\pi$ may sometimes wrap to $-\pi$ due to the circular nature of the phase angle.
Arctangent

This function calculates the arctangent, or inverse tangent, of the input argument \( x \).

The primary argument, ARG1, is the input value, \( x = \tan \theta \). If \( |x| > 1 \), a scaling factor of \( 2^{-n} \) must be applied in software such that \(-1 < x \cdot 2^{-n} < 1\). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the scale factor \( n \) must be programmed in the SCALE parameter.

Note that the maximum input value allowed is \( \tan \theta = 128 \), which corresponds to an angle \( \theta = 89.55 \) degrees. For \( |x| > 128 \), a software method must be used to find \( \tan^{-1} x \).

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle \( \theta = \tan^{-1} x \). RES1 must be multiplied by \( 2^n \cdot \pi \) to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

This function calculates the hyperbolic cosine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \) and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \(-1.118\) to \(+1.118\) are supported. Since the minimum value of \( \cosh x \) is \( 1 \), which is beyond the range of the q1.31 format, a scaling factor of \( 2^n \) must be applied in software. The factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, \( \cosh x \). RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, \( \sinh x \). RES2 must be multiplied by 2 to obtain the correct result.

### Hyperbolic sine

This function calculates the hyperbolic sine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \) and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \(-1.118 \) to \(+1.118 \) are supported. For all input values, a scaling factor of \( 2^{-n} \) must be applied in software, where \( n = 1 \). The scaled value \( x \cdot 0.5 \) is programmed in ARG1 and the factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, \( \sinh x \). RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, \( \cosh x \). RES2 must be multiplied by 2 to obtain the correct result.

</tr>
<tr>
<td>SCALE</td>
<td>( n )</td>
<td>([1 \ 4])</td>
</tr>
</tbody>
</table>

This function calculates the natural logarithm of the input argument \( x \).

The primary argument is the input value \( x \). Only values of \( x \) in the range 0.107 to 9.35 are supported. The value \( x \) must be scaled by a factor \( 2^{-n} \), such that \( x \cdot 2^{-n} < 1-2^{-n} \). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the factor \( n \) must be programmed in the SCALE parameter.

*Table 112* lists the valid scaling factors, \( n \), and the corresponding ranges of \( x \) and ARG1.

**Table 112. Natural log scaling factors and corresponding ranges**

<table>
<thead>
<tr>

<td>( 3 \leq x &lt; 7 )</td>
<td>( 0.375 \leq \text{ARG1} &lt; 0.875 )</td>
</tr>
<tr>
<td>4</td>
<td>( 7 \leq x \leq 9.35 )</td>
<td>( 0.4375 \leq \text{ARG1} &lt; 0.584 )</td>
</tr>
</tbody>
</table>

The secondary argument is not used.

The primary result is the natural logarithm, \( \ln x \). RES1 must be multiplied by \( 2^{(n+1)} \) to obtain the correct value.

The secondary result is not used.

</tbody>
</table>

This function calculates the square root of the input argument $x$.

The primary argument is the input value $x$. Only values of $x$ in the range 0.027 to 2.34 are supported. The value $x$ must be scaled by a factor $2^n$, such that $x \cdot 2^n < (1 - 2^{(n-2)})$.

The scaled value $x \cdot 2^n$ is programmed in ARG1 and the factor $n$ must be programmed in the SCALE parameter.

Table 114 lists the valid scaling factors, $n$, and the corresponding ranges of $x$ and ARG1.

Table 114. Square root scaling factors and corresponding ranges

<table>
<thead>
<tr>

<td>$0.4375 \leq ARG1 \leq 0.585$</td>
</tr>
</tbody>
</table>

The secondary argument is not used.

The primary result is the square root of $x$. RES1 must be multiplied by $2^n$ to obtain the correct value.

The secondary result is not used.

17.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to 1 - $2^{31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to 1 - $2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

17.3.4 Scaling factor

Several of the functions listed in Section 17.3.2 specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is...
required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

17.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see Figure 38.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see Figure 39). The square root function converges at roughly twice the speed of the hyperbolic functions (see Figure 40).

Figure 38. CORDIC convergence for trigonometric functions
Figure 39. CORDIC convergence for hyperbolic functions
The convergence rate decreases as the quantization error starts to become significant. The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in Table 115, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

### Table 115. Precision vs. number of iterations

</tr>
</tbody>
</table>

Note: The convergence rate decreases as the quantization error starts to become significant.
17.3.6 **Zero-overhead mode**

The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

**Note:**

ARG2 is set to +1 (0x7FFFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.
Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus
wait-states until the calculation is completed, before returning the result. It is then possible
for the software to write the input and immediately read the result without polling to see if it is
valid. Alternatively, the processor can wait for the appropriate number of clock cycles before
reading the result. This time can be used to program the CORDIC_CSR register for the next
calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be
reprogrammed while a calculation is in progress, without affecting the result of the ongoing
calculation. In the same way, the CORDIC_WDATA register can be updated with the next
argument(s) once the previous ones have been taken into account. The next arguments and
settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register.
If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is
read out first, followed by the secondary result (RES2). If only one 32-bit result is expected
(NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both
results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper
half-word. In this case, it is recommended to program NRES = 0. If NRES = 1, a second
read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation.
The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided
the expected number of arguments has been written. This means that at any time, there can
be a calculation in progress, or waiting for the results to be read, and an operation pending.
Any further access to CORDIC_WDATA while an operation is pending cancels it and
overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:
1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This
   launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next
calculation.
6. Go to step 3.

17.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the
CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading
the CORDIC_RDATA register (once or twice, depending on the NRES field of the
CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register
directly, since the result is not read as soon as it is available. The processor and bus
interface are not stalled while reading the CORDIC_CSR register, so this mode may be of
interest if stalling the processor is not acceptable (for example, if low latency interrupts must
be serviced).
17.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

17.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.
Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

17.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format

17.4.1 CORDIC control/status register (CORDIC_CSR)

</table>

Bit 31 RRDY: Result ready flag
0: No new data in output register
1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 ARGSIZE: Width of input data
0: 32-bit
1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.
If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format.
The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 RESIZE: Width of output data
0: 32-bit
1: 16-bit

RESIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.
If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.
Bit 20  **NARGS**: Number of arguments expected by the CORDIC_WDATA register
   0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
   1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
   Reads return the current state of the bit.

Bit 19  **NRES**: Number of results in the CORDIC_RDATA register
   0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
   1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
   Reads return the current state of the bit.

Bit 18  **DMAWEN**: Enable DMA write channel
   0: Disabled. No DMA write requests are generated.
   1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending.
   This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17  **DMAREN**: Enable DMA read channel
   0: Disabled. No DMA read requests are generated.
   1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
   This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16  **IEN**: Enable interrupt.
   0: Disabled. No interrupt requests are generated.
   1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
   This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11  Reserved, must be kept at reset value.

Bits 10:8  **SCALE[2:0]**: Scaling factor
   The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor $2^n$, and/or the results need to be multiplied by $2^n$. Refer to Section 17.3.2 for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4  **PRECISION[3:0]**: Precision required (number of iterations)
   0: reserved
   1 to 15: (Number of iterations)/4
   To determine the number of iterations needed for a given accuracy refer to Table 115.
   Note that for most functions, the recommended range for this field is 3 to 6.

**Bits 31:0 ARG[31:0]: Function input arguments**

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

- If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).
- If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).
- If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to Section 17.3.2 for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrites the argument data.
17.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08
Reset value: 0x0000 0000

<table>
<thead>

</tbody>
</table>

Bits 31:0 RES[31:0]: Function result
If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed. A read from this register resets the RRDY flag in the CORDIC_CSR register.

17.4.4 CORDIC register map

Refer to Section 2.2 for the register boundary addresses.
18  Filter math accelerator (FMAC)

18.1  FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

18.2  FMAC main features

- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels
18.3 FMAC functional description

18.3.1 General description

The FMAC is shown in Figure 41.

The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in Section 18.3.6: Filter functions.
18.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (Section 18.3.5: Initialization functions) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in Section 18.3.6: Filter functions. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.

There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level must be chosen according to the application performance requirements. For maximum throughput, the input buffer must never go empty, so d must be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

18.3.3 Input buffers

The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.
The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.
The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) must generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. *Figure 43* illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.

The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.

![Figure 43. Circular input buffer](image)
**Note:** If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in **Figure 44**. This example shows an 8-tap FIR filter with a watermark set to four.

**Figure 44. Circular input buffer operation**

18.3.4 **Output buffer**

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.
The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, \(y[n-M]\) to \(y[n-1]\), used for calculating the next output sample \(y[n]\). Each time a new sample is added to the set, the least recent sample \(y[n-M]\) drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in Figure 46. This example shows a 7-tap IIR filter with a watermark set to four.
18.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.
Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters
- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters
- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

18.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

\[ Y = B^\ast X \]

\[ y_n = 2^R \sum_{k=0}^{N} b_k x_{n-k} \]

This function performs a convolution of a vector \( B \) of length N+1 and a vector \( X \) of indefinite length. The elements of \( Y \) for incrementing values of n are calculated as the dot product,
\[ y_n = \mathbf{B} \mathbf{X}_n, \] where \( \mathbf{X}_n = [x_{n-N}, ..., x_n] \) is composed of the \( N+1 \) elements of \( \mathbf{X} \) at indexes \( n - N \) to \( n \).

This function corresponds to a finite impulse response (FIR) filter, where vector \( \mathbf{B} \) contains the filter coefficients and vector \( \mathbf{X} \) the sampled data.

The structure of the filter (direct form) is shown in Figure 47.

**Figure 47. FIR filter structure**

Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector \( \mathbf{B} \).

**Input:**
- X1 buffer contains the elements of vector \( \mathbf{X} \). It is a circular buffer of length \( N + 1 + d \).
- X2 buffer contains the elements of vector \( \mathbf{B} \). It is a fixed buffer of length \( N + 1 \).

**Output:**
- Y buffer contains the output values, \( y_n \). It is a circular buffer of length \( d \).
Parameters:

- The parameter P contains the length, N+1, of the coefficient vector \( B \) in the range \([2:127]\).
- The parameter R contains the gain to be applied to the accumulator output. The value output to the \( Y \) buffer is multiplied by \( 2^R \), where \( R \) is in the range \([0:7]\).
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.

**IIR filter**

\[
Y = B \cdot X + A \cdot Y'
\]

\[
y_n = 2^R \cdot \left( \sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right)
\]

This function implements an infinite impulse response (IIR) filter. The filter output vector \( Y \) is the convolution of a coefficient vector \( B \) of length N+1 and a vector \( X \) of indefinite length, plus the convolution of the delayed output vector \( Y' \) with a second coefficient vector \( A \) of length M. The elements of \( Y \) for incrementing values of \( n \) are calculated as \( y_n = B \cdot X_n + A \cdot Y_{n-1} \), where \( X_n = [x_{n-N}, \ldots, x_n] \) comprises the N+1 elements of \( X \) at indexes \( n - N \) to \( n \), while \( Y_{n-1} = [y_{n-M}, \ldots, y_{n-1}] \) comprises the M elements of \( Y \) at indexes \( n - M \) to \( n - 1 \). The structure of the filter (direct form 1) is shown in Figure 48.
Input:
- X1 buffer contains the elements of vector $\mathbf{X}$. It is a circular buffer of length $N + 1 + d$.
- X2 buffer contains the elements of coefficient vectors $\mathbf{B}$ and $\mathbf{A}$ concatenated ($b_0, b_1, b_2, ..., b_N, a_1, a_2, ..., a_M$). It is a fixed buffer of length $M+N+1$.

Output:
- Y buffer contains the output values, $y_n$. It is a circular buffer of length $M + d$.

Parameters
- The parameter $P$ contains the length, $N + 1$, of the coefficient vector $\mathbf{B}$ in the range $[2:64]$.
- The parameter $Q$ contains the length, $M$, of the coefficient vector $\mathbf{A}$ in the range $[1:63]$.
- The parameter $R$ contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by $2^R$, where $R$ is in the range $[0:7]$.
The function completes when the START bit in the FMAC_PARAM register is reset by software.

18.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2⁻¹⁵ (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2⁻¹⁵ or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

18.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration is:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1
However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- $X2\_BASE = 0$
- $X1\_BASE = N$
- $Y\_BASE = N$

In this case, $Y\_BUF\_SIZE = X1\_BUF\_SIZE = N + d1$, so that the buffers remain in sync.

**Note:** The $FULL\_WM$ bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $\log_2(d1)$, otherwise the buffer is flagged full before $N$ input samples have been written, and no more samples are requested. Similarly, the $EMPTY\_WM$ bitfield of the Y buffer configuration register must be less than or equal to $\log_2(d2)$.

The filter coefficients **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of $N$. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register must be programmed according to the method used for writing and reading data to and from the FMAC memory. There are three methods supported:

- **Polling:** No DMA request or Interrupt request is generated. Software must check that the $X1\_FULL$ flag is low before writing to $WDATA$, or that the $Y\_EMPTY$ flag is low before reading from $RDATA$.
- **Interrupt:** The interrupt request is asserted while the $X1\_FULL$ flag is low, for writes, or when the $Y\_EMPTY$ flag is low, for reads.
- **DMA:** DMA requests are asserted on the DMA write channel while the $X1\_FULL$ flag is low, and on the read channel while the $Y\_EMPTY$ flag is low.

Different methods can be used for read and for write. However, it is not recommended to use both interrupts and DMA requests for the same operation\(^a\). The valid combinations are listed in Table 117.

</tbody>
</table>

\(^a\) If both interrupts and DMA requests are enabled then only DMA must perform the transfer.
The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- **FUNC** = 8 (FIR filter);
- **P** = N (number of coefficients);
- **Q** = “Don’t care”;
- **R** = Gain;
- **START** = 1;

If less than \( N + d - 2^{\text{FULL} \_\text{WM}} \) values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write \( 2^{\text{FULL} \_\text{WM}} \) additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every \( 2^{\text{FULL} \_\text{WM}} \) writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When \( 2^{\text{EMPTY} \_\text{WM}} \) output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read \( 2^{\text{EMPTY} \_\text{WM}} \) samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every \( 2^{\text{EMPTY} \_\text{WM}} \) reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

### 18.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length N, where N is the number of feed-forward taps or coefficients. The number of feedback coefficients, M, can be any value from 1 to N-1. Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with N feed-forward coefficients and M feed-back coefficients is \( 2N + 2M \):

- N + M coefficients
- N input samples
- M output samples

If \( M = N-1 \), then the maximum filter length that can be implemented is \( N = 64 \).

As for the FIR, for maximum throughput, a small amount of additional space, \( d1 \) and \( d2 \), is allowed in the input and output buffer size respectively, making the total memory requirement \( 2M + 2N + d1 + d2 \).

The buffers must be configured as follows:

- \( \text{X1\_BUF\_SIZE} = N + d1 \);
- \( \text{X2\_BUF\_SIZE} = N + M \);
- \( \text{Y\_BUF\_SIZE} = M + d2 \);
The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- X2_BASE = 0;
- X1_BASE = N + M;
- Y_BASE = 2N + M + d1;

**Note:** The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to \( \log_2(d1) \), otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to \( \log_2(d2) \).

The filter coefficients (N feed-forward followed by M feedback) must be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. The Y buffer can optionally be pre-loaded with any number of values up to a maximum of M. This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC_CR register must be programmed in the same way as for the FIR filter (see Section 18.3.8: Implementing FIR filters with the FMAC).

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 9 (IIR filter);
- P = N (number of feed-forward coefficients);
- Q = M (number of feed-back coefficients);
- R = Gain;
- START = 1;

If less than \( N + d - 2^{\text{FULL_WM}} \) values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write \( 2^{\text{FULL_WM}} \) additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every \( 2^{\text{FULL_WM}} \) writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first N samples in the X1 buffer, and the first M samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at Y_BASE + M.

When \( 2^{\text{EMPTY_WM}} \) new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read \( 2^{\text{EMPTY_WM}} \) samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every \( 2^{\text{EMPTY_WM}} \) reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.
18.3.10 Examples of filter initialization

The example in Figure 49 illustrates an X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.
18.3.11 Examples of filter operation

The example in Figure 50 illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in Figure 49. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.

In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

**Note:** In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the
filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size would not help.

Figure 51. Filtering example 2

The example in Figure 51 illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in Figure 49. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.
18.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms must be converted to direct form 1.

2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.

3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients’ absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is “undone” before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.

4. The IIR filter has feed-forward (numerator) coefficients \([b_0, b_1, ..., b_{N-1}]\), and feed-back (denominator) coefficients \([1, a_1, ..., a_M]\). Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor \(2^R\), such that \(2^{-R} \cdot [1, a_1, ..., a_M]\) are all less than 1, such filters can be implemented. However an inverse gain of \(2^R\) must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.
18.4 **FMAC registers**

18.4.1 **FMAC X1 buffer configuration register (FMAC_X1BUFCFG)**

Address offset: 0x00  
Reset value: 0x0000 0000  
Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

### FULL_WM[1:0]

  - Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than \(2^{\text{FULL_WM}}\).
  - 0: Threshold = 1
  - 1: Threshold = 2
  - 2: Threshold = 4
  - 3: Threshold = 8

Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt. Threshold must be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register).

### X1_BUF_SIZE[7:0]  
### X1_BASE[7:0]

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words

The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1).

Bits 7:0 **X1_BASE[7:0]**: Base address of X1 buffer

18.4.2 **FMAC X2 buffer configuration register (FMAC_X2BUFCFG)**

Address offset: 0x04  
Reset value: 0x0000 0000  
Access: word access

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16** **RESET**: Reset FMAC unit  
This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.  
0: Reset inactive  
1: Reset active

**Bit 15** **CLIPEN**: Enable clipping  
0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.  
1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

Bits 14:10 Reserved, must be kept at reset value.

**Bit 9** **DMAWEN**: Enable DMA write channel requests  
0: Disable. No DMA requests are generated  
1: Enable. DMA requests are generated while the X1 buffer is not full.  
This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

**Bit 8** **DMAREN**: Enable DMA read channel requests  
0: Disable. No DMA requests are generated  
1: Enable. DMA requests are generated while the Y buffer is not empty.  
This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bits 7:5 Reserved, must be kept at reset value.

**Bit 4** **SATIEN**: Enable saturation error interrupts  
0: Disabled. No interrupts are generated upon saturation detection.  
1: Enabled. An interrupt request is generated if the SAT flag is set  
This bit is set and cleared by software. A read returns the current state of the bit.

**Bit 3** **UNFLIEN**: Enable underflow error interrupts  
0: Disabled. No interrupts are generated upon underflow detection.  
1: Enabled. An interrupt request is generated if the UNFL flag is set  
This bit is set and cleared by software. A read returns the current state of the bit.
Bit 2 **OVFLIEN**: Enable overflow error interrupts  
0: Disabled. No interrupts are generated upon overflow detection. 
1: Enabled. An interrupt request is generated if the OVFL flag is set 
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt  
0: Disabled. No write interrupt requests are generated. 
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set. 
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt  
0: Disabled. No read interrupt requests are generated. 
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set. 
This bit is set and cleared by software. A read returns the current state of the bit.

</tbody>
</table>

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag  
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.  
0: No saturation detected  
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated. 
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag  
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.  
0: No underflow detected  
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated. 
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag  
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.  
0: No overflow detected  
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated. 
This flag is cleared by a reset of the unit.

Bits 7:2 Reserved, must be kept at reset value.
Bit 1  X1FULL: X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.
1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

Note: after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0  YEMPTY: Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.
1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

Note: after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

18.4.7  FMAC write data register (FMAC_WDATA)

19 Flexible static memory controller (FSMC)

19.1 Introduction
The flexible static memory controller (FSMC) includes two memory controllers:
- The NOR/PSRAM memory controller
- The NAND memory controller
This memory controller is also named flexible memory controller (FMC).

19.2 FMC main features
The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND flash memory. Its main purposes are:
- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices
All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:
- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth
The Write FIFO is common to all memory controllers and consists of:
- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM). In this case, the AHB burst is broken into two FIFO entries.
At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, the settings can be changed at any time.

### 19.3 FMC block diagram

The FMC consists of the following main blocks:
- The AHB interface (including the FMC configuration registers)
- The NOR flash/PSRAM/SRAM controller

The block diagram is shown in the figure below.

#### Figure 52. FMC block diagram

![FMC block diagram](MS34473V3)

### 19.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:
- When reading or writing to a FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.
The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex®-M4 with FPU CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

19.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal
  There is no issue in this case.
- AHB transaction size is greater than the memory size:
  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.
- AHB transaction size is smaller than the memory size:
  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)
    In this case, the FMC allows read/write transactions and accesses to the right data through its byte lanes NBL[1:0].
    Bytes to be written are addressed by NBL[1:0].
    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND flash memories)
    This situation occurs when a byte access is requested to a 16-bit wide flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR flash/PSRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

Configuration registers

The FMC can be configured through a set of registers. Refer to Section 19.6.6, for a detailed description of the NOR flash/PSRAM controller registers. Refer to Section 19.7.7, for a detailed description of the NAND flash registers.
19.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 53):

- Bank 1 used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 3 used to address NAND flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 53. FMC memory banks

<table>
<thead>
<tr>
<th>Bank</th>
<th>Supported memory type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bank 1</td>
<td>NOR/PSRAM/SRAM</td>
</tr>
<tr>
<td>Bank 3</td>
<td>NAND flash memory</td>
</tr>
</tbody>
</table>

19.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in Table 119.

<table>
<thead>
<tr>
<th>HADDR[27:26][1)</th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
</tbody>
</table>
The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

### Table 119. NOR/PSRAM bank selection (continued)

<table>
<thead>
<tr>
<th>HADDR[27:26][1)</th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. HADDR are internal AHB address lines that are translated to external memory.

### Table 120. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>HADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbits</td>
</tr>
<tr>
<td>16-bit</td>
<td>HADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbits</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0]. Whatever the external memory width, FMC_A[0] must be connected to external memory address A[0].

#### 19.5.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 121.

### Table 121. NAND memory mapping and timing registers

<table>
<thead>
<tr>
<th>Start address</th>
<th>End address</th>
<th>FMC bank</th>
<th>Memory space</th>
<th>Timing register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8800 0000</td>
<td>0x8BFF FFFF</td>
<td>Bank 3 - NAND flash</td>
<td>Attribute</td>
<td>FMC_PATT (0x8C)</td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>0x83FF FFFF</td>
<td>Bank 1 - NAND flash</td>
<td>Common</td>
<td>FMC_PMEM (0x88)</td>
</tr>
</tbody>
</table>

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 122 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common/attribute memory space)
- Address section (next 128 Kbytes in the common/attribute memory space)

### Table 122. NAND bank selection

<table>
<thead>
<tr>
<th>Section name</th>
<th>HADDR[17:16]</th>
<th>Address range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address section</td>
<td>1X</td>
<td>0x000000-0x03FFFF</td>
</tr>
<tr>
<td>Command section</td>
<td>01</td>
<td>0x010000-0x01FFFF</td>
</tr>
<tr>
<td>Data section</td>
<td>00</td>
<td>0x000000-0x0FFFF</td>
</tr>
</tbody>
</table>
The application software uses the 3 sections to access the NAND flash memory:

- **To sending a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

### 19.6 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
- **PSRAM (CellularRAM™)**
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- **NOR flash memory**
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must
be configured in Synchronous mode (see Section 19.6.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to Section 19.6.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 19.6.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 123) and support for wait management (for PSRAM and NOR flash accessed in Burst mode).

19.6.3 **General timing rules**

**Signals synchronization**

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

19.6.4 **NOR flash/PSRAM controller asynchronous transactions**

**Asynchronous static memories (NOR flash, PSRAM, SRAM, FRAM)**

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).
Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

**Figure 54. Mode 1 read access waveforms**

**Figure 55. Mode 1 write access waveforms**
The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCHWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.
The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   \[
   \text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time}
   \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   \[
   \text{if} \quad \text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}
   \]
   then:
   \[
   \text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})
   \]
   otherwise
   \[
   \text{DATAST} \geq 4 \times \text{HCLK}
   \]

where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

*Figure 67* and *Figure 68* show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 67. Asynchronous wait during a read access waveforms**

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not enable maintaining the chip select signal (NE) low for longer than the t_{CEM} timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses.

19.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:
- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration.
Flexible static memory controller (FSMC)  

register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) CLK clock cycles
- or NOR flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed. Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller is used to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state
The FMC supports both NOR flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

19.6.6 NOR/PSRAM controller registers

SRAM/NOR-flash chip-select control register for bank x
(FMC_BCRx) (x = 1 to 4)

Address offset: 0x00 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 30DB, 0x0000 30D2, 0x0000 30D2, 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR flash memories.

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **NBLSET[1:0]:** Byte lane (NBL) setup

These bits configure the NBL setup timing from NBLx low to chip select NEx low.

- 00: NBL setup time is 0 AHB clock cycle
- 01: NBL setup time is 1 AHB clock cycle
- 10: NBL setup time is 2 AHB clock cycles
- 11: NBL setup time is 3 AHB clock cycles

Bit 21 **WFDIS:** Write FIFO disable

This bit disables the Write FIFO used by the FMC controller.

- 0: Write FIFO enabled (Default after reset)
- 1: Write FIFO disabled

**Note:** The WFDIS bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous clock enable

This bit enables the FMC_CLK clock output to external memory devices.

- 0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
- 1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

**Note:** The CCLKEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

**Note:** If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don’t care.

**Note:** If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)
Bit 19 **CBURSTRW**: Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode.
1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size

These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)
001: 128 bytes
010: 256 bytes
011: 512 bytes
100: 1024 bytes
Others: Reserved, must not be used

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken into account when running an asynchronous protocol (default after reset).
1: NWAIT signal is taken into account when running an asynchronous protocol.

Bit 14 **EXTMOD**: Extended mode enable

This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)
1: values inside FMC_BWTR register are taken into account

**Note**: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:

- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).

Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period).
1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC.

0: Write operations are disabled in the bank by the FMC, an AHB error is reported.
1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state.

0: NWAIT signal is active one data cycle before wait state (default after reset).
1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.
Bit 9 **WAITPOL**: Wait signal polarity bit
- Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.
  - 0: NWAiT active low (default after reset)
  - 1: NWAiT active high

Bit 8 **BURSTEN**: Burst enable bit
- This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.
  - 0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
  - 1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable
- Enables NOR flash memory access operations.
  - 0: Corresponding NOR flash memory access is disabled.
  - 1: Corresponding NOR flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]**: Memory data bus width
- Defines the external memory device width, valid for all type of memories.
  - 00: 8 bits
  - 01: 16 bits (default after reset)
  - 10: reserved
  - 11: reserved

Bits 3:2 **MTYP[1:0]**: Memory type
- Defines the type of external memory attached to the corresponding memory bank.
  - 00: SRAM/FRAM (default after reset for Bank 2...4)
  - 01: PSRAM (CRAM) / FRAM
  - 10: NOR flash/OneNAND flash (default after reset for Bank 1)
  - 11: reserved

Bit 1 **MUXEN**: Address/data multiplexing enable bit
- When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
  - 0: Address/data non multiplexed
  - 1: Address/data multiplexed on databus (default after reset)

Bit 0 **MBKEN**: Memory bank enable bit
- Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.
  - 0: Corresponding memory bank is disabled.
  - 1: Corresponding memory bank is enabled.

**SRAM/NOR-flash chip-select timing register for bank x (FMC_BTRx)**

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0xFFFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to
configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

Bits 31:30 **DATAHLD[1:0]**: Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 54 to Figure 66), used in asynchronous accesses:

For read accesses
- 00: DATAHLD phase duration = 0 × HCLK clock cycle (default)
- 01: DATAHLD phase duration = 1 × HCLK clock cycle
- 10: DATAHLD phase duration = 2 × HCLK clock cycle
- 11: DATAHLD phase duration = 3 × HCLK clock cycle

For write accesses
- 00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
- 01: DATAHLD phase duration = 2 × HCLK clock cycle
- 10: DATAHLD phase duration = 3 × HCLK clock cycle
- 11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28 **ACCMOD[1:0]**: Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

- 00: Access mode A
- 01: Access mode B
- 10: Access mode C
- 11: Access mode D

Bits 27:24 **DATLAT[3:0]**: (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

- 0000: Data latency of 2 CLK clock cycles for first burst access
- 1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC_CLK signal)

Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:

- 0000: FMC_CLK period = 1x HCLK period
- 0001: FMC_CLK period = 2 × HCLK periods
- 0010: FMC_CLK period = 3 × HCLK periods
- 1111: FMC_CLK period = 16 × HCLK periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don't care.

Note: Refer to Section 19.6.5: Synchronous transactions for FMC_CLK divider ratio formula)
Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank. This delay is used to match the minimum time between consecutive transactions ($t_{EHEL}$ from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access ($t_{EHQZ}$, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.

$$(BUSTURN + 1) \times \text{HCLK period} \geq \max(t_{EHEL} \text{ min}, t_{EHQZ} \text{ max})$$

For FRAM memories, the bus turnaround delay must be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.

$$0000: \text{BUSTURN phase duration} = 1 \times \text{HCLK clock cycle added}$$

$$1111: \text{BUSTURN phase duration} = 16 \times \text{HCLK clock cycles added (default value after reset)}$$

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to Figure 54 to Figure 66), used in asynchronous accesses:

$$0000 0000: \text{Reserved}$$
$$0000 0001: \text{DATAST phase duration} = 1 \times \text{HCLK clock cycles}$$
$$0000 0010: \text{DATAST phase duration} = 2 \times \text{HCLK clock cycles}$$

$$1111 1111: \text{DATAST phase duration} = 255 \times \text{HCLK clock cycles (default value after reset)}$$

For each memory type and access mode data-phase duration, refer to the respective figure (Figure 54 to Figure 66).

Example: Mode 1, write access, DATAST=1: Data-phase duration = DATAST+1 = 2 HCLK clock cycles.

*Note: In synchronous accesses, this value is don’t care.*

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the address hold phase (refer to Figure 54 to Figure 66), used in mode D or multiplexed accesses:

$$0000: \text{Reserved}$$
$$0001: \text{ADDHLD phase duration} = 1 \times \text{HCLK clock cycle}$$
$$0010: \text{ADDHLD phase duration} = 2 \times \text{HCLK clock cycle}$$

$$1111: \text{ADDHLD phase duration} = 15 \times \text{HCLK clock cycles (default value after reset)}$$

For each access mode address-hold phase duration, refer to the respective figure (Figure 54 to Figure 66).

*Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.*
Bits 3:0 ADDSET[3:0]: Address setup phase duration
These bits are written by software to define the duration of the address setup phase (refer to Figure 54 to Figure 66), used in SRAMs, ROMs, asynchronous NOR flash and PSRAM:

- 0000: ADDSET phase duration = 0 × HCLK clock cycle
- ... 1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure (Figure 54 to Figure 66).

Note: In synchronous accesses, this value is don’t care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.
With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers x (FMC_BWTRx)
Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)
Reset value: 0x0FFF FFFF
This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

Bits 31:30 DATAHLD[1:0]: Data hold phase duration
These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 54 to Figure 66), used in asynchronous write accesses:

- 00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
- 01: DATAHLD phase duration = 2 × HCLK clock cycle
- 10: DATAHLD phase duration = 3 × HCLK clock cycle
- 11: DATAHLD phase duration = 4 × HCLK clock cycle
Flexible static memory controller (FSMC) RM0440

Bits 29:28 ACCMOD[1:0]: Access mode.
   Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
   00: Access mode A
   01: Access mode B
   10: Access mode C
   11: Access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 BUSTURN[3:0]: Bus turnaround phase duration
   These bits are written by software to add a delay at the end of current write transaction to next transaction on the same bank.
   For FRAM memories, the bus turnaround delay must be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses.
   (BUSTURN + 1)HCLK period ≥ tPC min
   0000: BUSTURN phase duration = 1 HCLK clock cycle added
   1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)

Bits 15:8 DATAST[7:0]: Data-phase duration.
   These bits are written by software to define the duration of the data phase (refer to Figure 54 to Figure 66), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:
   0000 0000: Reserved
   0000 0001: DATAST phase duration = 1 x HCLK clock cycles
   0000 0010: DATAST phase duration = 2 x HCLK clock cycles
   ...
   1111 1111: DATAST phase duration = 255 x HCLK clock cycles (default value after reset)

Bits 7:4 ADDHLD[3:0]: Address-hold phase duration.
   These bits are written by software to define the duration of the address hold phase (refer to Figure 63 to Figure 66), used in asynchronous multiplexed accesses:
   0000: Reserved
   0001: ADDHLD phase duration = 1 x HCLK clock cycle
   0010: ADDHLD phase duration = 2 x HCLK clock cycle
   ...
   1111: ADDHLD phase duration = 15 x HCLK clock cycles (default value after reset)
   Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 ADDSET[3:0]: Address setup phase duration.
   These bits are written by software to define the duration of the address setup phase in HCLK cycles (refer to Figure 54 to Figure 66), used in asynchronous accesses:
   0000: ADDSET phase duration = 0 x HCLK clock cycle
   ...
   1111: ADDSET phase duration = 15 x HCLK clock cycles (default value after reset)
   Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.
PSRAM chip select counter register (FMC_PCSCNTR)

Address offset: 0x20
Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width (tCEM) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.

CSCOUNT[15:0]

Bits 31:20  Reserved, must be kept at reset value.

Bit 19  CNTB4EN: Counter Bank 4 enable
This bit enables the chip select counter for PSRAM/NOR Bank 4.
0: Counter disabled for Bank 4
1: Counter enabled for Bank 4

Bit 18  CNTB3EN: Counter Bank 3 enable
This bit enables the chip select counter for PSRAM/NOR Bank 3.
0: Counter disabled for Bank 3.
1: Counter enabled for Bank 3

Bit 17  CNTB2EN: Counter Bank 2 enable
This bit enables the chip select counter for PSRAM/NOR Bank 2.
0: Counter disabled for Bank 2.
1: Counter enabled for Bank 2

Bit 16  CNTB1EN: Counter Bank 1 enable
This bit enables the chip select counter for PSRAM/NOR Bank 1.
0: Counter disabled for Bank 1.
1: Counter enabled for Bank 1

Bits 15:0  CSCOUNT[15:0]: Chip select counter.
This bitfield is used to define the maximum duration of the chip select low, which is obtained by the formula:

CSCOUNT[15:0] * T_{AHB}, where T_{AHB} is the AHB clock period.

For refresh considerations, the PSRAM chip select must not stay low for more than t_{CEM} ~ 4 μs.
CSCOUNT[15:0] applies both to asynchronous and synchronous modes.
When CSCOUNT[15:0] = 0x0000, the feature is disabled.
19.7 NAND flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND flash memories

The NAND bank is configured through dedicated registers (Section 19.7.7). The programmable memory parameters include access timings (shown in Table 149) and ECC configuration.

19.7.3 Timing diagrams for NAND flash memory

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. Figure 72 shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 72. NAND flash controller waveforms for common memory access

1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write access, the hold phase delay is (MEMHOLD) HCLK cycles and for read access is (MEMHOLD + 2) HCLK cycles.

19.7.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 19.7.5: NAND flash prewait functionality) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash, PTYP = 1, PWAITEN = 0
or 1 as needed, see Section 19.5.2: NAND flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to implement the prewait functionality needed by some NAND flash memories (see details in Section 19.7.5: NAND flash prewait functionality).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.

6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND flash device by restarting at step 2

19.7.5 NAND flash prewait functionality

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 73).
1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don’t care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the tWB timing. However any CPU read access to the NAND flash memory has a hold delay of (MEMHOLD + 2) HCLK cycles and CPU write access has a hold delay of (MEMHOLD) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the tWB timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

19.7.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.
These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1024, 2048, 4096 or 8192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:
- When accessing NAND flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read-written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they must be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

To perform an ECC computation:
1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 19.7.7 NAND flash controller registers

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]**: ECC page size
- Defines the page size for the extended ECC:
  - 000: 256 bytes
  - 001: 512 bytes
  - 010: 1024 bytes
  - 011: 2048 bytes
  - 100: 4096 bytes
  - 101: 8192 bytes

Bits 16:13 **TAR[3:0]**: ALE to RE delay
- Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
  - Time is: \( t_{\text{ar}} = (\text{TAR} + \text{SET} + 2) \times \text{THCLK} \) where THCLK is the HCLK clock period
  - 0000: 1 HCLK cycle (default)
  - 1111: 16 HCLK cycles

  *Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR[3:0]**: CLE to RE delay
- Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
  - Time is \( t_{\text{clr}} = (\text{TCLR} + \text{SET} + 2) \times \text{THCLK} \) where THCLK is the HCLK clock period
  - 0000: 1 HCLK cycle (default)
  - 1111: 16 HCLK cycles

  *Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit
- 0: ECC logic is disabled and reset (default after reset),
- 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width
- Defines the external memory device width.
  - 00: 8 bits
  - 01: 16 bits (default after reset).
  - 10: reserved.
  - 11: reserved.

Bit 3 **PTYP**: Memory type
- Defines the type of device attached to the corresponding memory bank:
  - 0: Reserved, must be kept at reset value
  - 1: NAND flash (default after reset)

Bit 2 **PBKEN**: NAND flash memory bank enable bit
- Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
  - 0: Corresponding memory bank is disabled (default after reset)
  - 1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit
- Enables the Wait feature for the NAND flash memory bank:
  - 0: disabled
  - 1: enabled

Bit 0 Reserved, must be kept at reset value.
FIFO status and interrupt register (FMC_SR)

Address offset: 0x84
Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT**: FIFO empty
Read-only bit that provides the status of the FIFO
0: FIFO not empty
1: FIFO empty

Bit 5 **IFEN**: Interrupt falling edge detection enable bit
0: Interrupt falling edge detection request disabled
1: Interrupt falling edge detection request enabled

Bit 4 **ILEN**: Interrupt high-level detection enable bit
0: Interrupt high-level detection request disabled
1: Interrupt high-level detection request enabled

Bit 3 **IREN**: Interrupt rising edge detection enable bit
0: Interrupt rising edge detection request disabled
1: Interrupt rising edge detection request enabled

Bit 2 **IFS**: Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred

*Note: If this bit is written by software to 1 it is set.*

Bit 1 **ILS**: Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred
Flexible static memory controller (FSMC) RM0440

Bit 0  IRS: Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred

Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)
Address offset: 0x88
Reset value: 0xF0FC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

Bits 31:24  MEMHIZ[7:0]: Common memory x data bus Hi-Z time
Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space on socket. This is only valid for write transactions:
0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

Bits 23:16  MEMHOLD[7:0]: Common memory hold time
Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space on socket x:
0000 0000: reserved.
0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
1111 1111: reserved.

Bits 15:8  MEMWAIT[7:0]: Common memory wait time
Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:
0000 0000: reserved
0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1111: reserved.
**Attribute memory space timing register (FMC_PATT)**

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to Section 19.7.5: NAND flash prewait functionality).

Bits 31:24 **ATTIZ[7:0]:** Attribute memory data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for write transaction:

0000 0000: 0 HCLK cycle  
1111 1110: 255 HCLK cycles  
1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space on socket:

0000 0000: reserved  
0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access  
1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access  
1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved  
0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)  
1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)  
1111 1111: reserved.
Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space on socket:

0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

**ECC result registers (FMC_ECCR)**

Address offset: 0x94
Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND flash memory page at the correct address (refer to *Section 19.7.6: Computation of the error correction code (ECC) in NAND flash memory*), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register must be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

Refer to Section 2.2 on page 81 for the register boundary addresses.
20 Quad-SPI interface (QUADSPI)

20.1 Introduction

The QUADSPI is a specialized communication interface targeting single, dual- or quad-SPI flash memories. It can operate in any of the three following modes:

- **indirect mode:** all the operations are performed using the QUADSPI registers.
- **automatic status-polling mode:** the external flash memory status register is periodically read and an interrupt can be generated in case of flag setting.
- **memory-mapped mode:** the external flash memory is mapped to the device address space and is seen by the system as if it was an internal memory.

Both throughput and capacity can be increased two-fold using dual-flash mode, where two Quad-SPI flash memories are accessed simultaneously.

20.2 QUADSPI main features

- Three functional modes: indirect, automatic status-polling, and memory-mapped
- Dual-flash mode, where 8 bits can be sent/received simultaneously by accessing two flash memories in parallel
- SDR and DDR support
- Fully programmable opcode for both indirect and memory-mapped modes
- Fully programmable frame format for both indirect and memory-mapped modes
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

20.3 QUADSPI functional description

20.3.1 QUADSPI block diagram

Figure 74. QUADSPI block diagram when dual-flash mode is disabled
20.3.2 QUADSPI pins

The table below lists the QUADSPI pins, six for interfacing with a single flash memory, or 10 to 11 for interfacing with two flash memories (FLASH 1 and FLASH 2) in dual-flash mode.

</table>

20.3.3 QUADSPI command sequence

The QUADSPI communicates with the flash memory using commands. Each command can include five phases: instruction, address, alternate byte, dummy, data. Any of these phases
can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phase must be present.

NCS falls before the start of each command and rises again after each command finishes.

**Figure 76. Example of read command in quad-SPI mode**

### Instruction phase

During this phase, an 8-bit instruction, configured in INSTRUCTION bitfield of QUADSPI_CCR[7:0] register, is sent to the flash memory, specifying the type of operation to be performed.

Most flash memories can receive instructions only one bit at a time from the IO0/SO signal (single-SPI mode), the instruction phase can optionally send 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the IMODE[1:0] bitfield of QUADSPI_CCR[9:8] register.

When IMODE = 00, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

### Address phase

In the address phase, 1-4 bytes are sent to the flash memory to indicate the address of the operation. The number of address bytes to be sent is configured in the ADSIZE[1:0] bitfield of QUADSPI_CCR[13:12] register. In indirect and automatic status-polling modes, address bytes to be sent are specified in the ADDRESS[31:0] bitfield of QUADSPI_AR register, while in memory-mapped mode, the address is given directly via the AHB (from the Cortex or from a DMA).

The address phase can send 1 bit at a time (over SO in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ADMODE[1:0] bitfield of QUADSPI_CCR[11:10] register.

When ADMODE = 00, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

### Alternate-byte phase

In the alternate-byte phase, 1-4 bytes are sent to the flash memory, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the [1:0] bitfield of QUADSPI_CCR[17:16] register. The bytes to be sent are specified in the QUADSPI_ABR register.
The alternate-bytes phase can send 1 bit at a time (over SO in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ABMODE[1:0] bitfield of QUADSPI_CCR[15:14] register.

When ABMODE = 00, the alternate-byte phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-mode is used and only two cycles are used for the alternate bytes. In this case, the firmware can use quad-mode (ABMODE = 11) and send a byte with bits 7 and 3 of ALTERNATE set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low). In this case, the upper two bits of the nibble to be sent are placed in bits 4:3 of ALTERNATE, while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE must be set to 0x8A (1000_1010).

**Dummy-cycle phase**

In the dummy-cycle phase, 1-31 cycles are given without any data being sent or received, in order to give time to the flash memory to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in the DCYC[4:0] bitfield of QUADSPI_CCR[22:18] register. In both SDR and DDR modes, the duration is specified as a number of full CLK cycles.

When DCYC is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

The operating mode of the dummy-cycles phase is determined by DMODE.

In order to assure enough “turn-around” time for changing data signals from output mode to input mode, there must be at least one dummy cycle when using dual or quad mode to receive data from the flash memory.

**Data phase**

During the data phase, any number of bytes can be sent to, or received from the flash memory.

In indirect and automatic status-polling modes, the number of bytes to be sent/received is specified in the QUADSPI_DLR register.

In indirect-write mode the data to be sent to the flash memory must be written to the QUADSPI_DR register. In indirect-read mode the data received from the flash memory is obtained by reading the QUADSPI_DR register.

In memory-mapped mode, the data which is read is sent back directly over the AHB to the Cortex or to a DMA.

The data phase can send/receive 1 bit at a time (over SO/SI in single-SPI mode), 2 bits at a time (over IO0/IO1 in dual-SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad-SPI mode). This can be configured using the ABMODE[1:0] bitfield of QUADSPI_CCR[15:14] register.

When DMODE = 00, the data phase is skipped, and the command sequence finishes immediately by raising NCS. This configuration must only be used in only indirect write mode.
20.3.4 QUADSPI signal interface protocol modes

Single-SPI mode

This legacy SPI mode allows just one single bit to be sent/received serially. In this mode, data are sent to the flash memory over the SO signal (whose I/O shared with IO0). Data received from the flash memory arrive via SI (whose I/O shared with IO1).

The different phases can each be configured separately to use this mode by setting the IMODE/ADMODE/ABMODE/DMODE fields (in QUADSPI_CCR) to 01.

In each phase which is configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).

This is the case even for the dummy phase if DMODE = 01.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 10.

In each phase which is configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.

In the dummy phase when DMODE = 01, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use quad-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 11.

In each phase which is configured in this mode, IO0/IO1/IO2/IO3 are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE = 11, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in quad-SPI mode. If none of the phases are configured to use quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the QUADSPI is active.

SDR mode

By default, the DDRM bit (QUADSPI_CCR[31]) is 0 and the QUADSPI operates in single-data rate (SDR) mode.
In SDR mode, when the QUADSPI drives IO0/SO, IO1, IO2, IO3 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the QUADSPI assumes that flash memories also send the data using CLK falling edge. By default (when SSHIFT = 0), the signals are sampled using the following (rising) edge of CLK.

**DDR mode**

When the DDRM bit (QUADSPI\_CCR[31]) is set to 1, the QUADSPI operates in double-data rate (DDR) mode.

In DDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals in the address/alternate-byte/data phases, a bit is sent on each of CLK falling and rising edges.

The instruction phase is not affected by DDRM. The instruction is always sent using CLK falling edge.

When receiving data in DDR mode, the QUADSPI assumes that flash memories also send the data using both CLK rising and falling edges. When DDRM = 1, the firmware must clear SSHIFT (bit 4 of QUADSPI\_CR). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

**Dual-flash mode**

When the DFM bit (bit 6 of QUADSPI\_CR) is 1, the QUADSPI is in dual-flash mode, where two external quad-SPI flash memories (FLASH 1 and FLASH 2) are used in order to send/receive 8 bits (or 16 bits in DDR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the flash memories uses the same CLK and optionally the same NCS signals, but each have separate IO0, IO1, IO2, and IO3 signals.

The dual-flash mode can be used in conjunction with single-, dual-, and quad-SPI modes, as well as with either SDR or DDR mode.

The flash memory size, as specified in FSIZE[4:0] (QUADSPI\_DCR[20:16]), must reflect the total flash memory capacity, which is double the size of one individual component.

If address X is even, then the byte which the QUADSPI gives for address X is the byte at the address X/2 of FLASH 1, and the byte which the QUADSPI gives for address X+1 is the byte at the address X/2 of FLASH 2. In other words, bytes at even addresses are all stored in FLASH 1 and bytes at odd addresses are all stored in FLASH 2.
When reading the flash memories status registers in dual-flash mode, twice as many bytes must be read compared to doing the same read in single-flash mode. This means that if each flash memory gives 8 valid bits after the instruction for fetching the status register, then the QUADSPI must be configured with a data length of 2 bytes (16 bits), and the QUADSPI receives one byte from each flash memory. If each flash memory gives a status of 16 bits, then the QUADSPI must be configured to read 4 bytes to get all the status bits of both flash memories in dual-flash mode. The least-significant byte of the result (in the data register) is the least-significant byte of FLASH 1 status register, while the next byte is the least-significant byte of FLASH 2 status register. Then, the third byte of the data register is FLASH 1 second byte, while the forth byte is FLASH 2 second byte (in the case that the flash memories have 16-bit status registers).

An even number of bytes must always be accessed in dual-flash mode. For this reason, bit 0 of the data length bitfield (QUADSPI_DLR[0]) is stuck at 1 when DFM = 1.

In dual-flash mode, the behavior of FLASH 1 interface signals are basically the same as in normal mode. FLASH 2 interface signals have exactly the same waveforms as FLASH 1 during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each flash memory always receives the same instruction and the same address. Then, during the data phase, the BK1_IOx and BK2_IOx buses are both transferring data in parallel, but the data that are sent to (or received from) FLASH 1 are distinct from those of FLASH 2.

### 20.3.5 QUADSPI indirect mode

When in indirect mode, commands are started by writing to QUADSPI registers, and data are transferred by writing or reading the data register, in the same way as for other communication peripherals.

When FMODE = 00 (QUADSPI_CCR[27:26]), the QUADSPI is in indirect-write mode, where bytes are sent to the flash memory during the data phase. Data are provided by writing to the data register (QUADSPI_DR).

When FMODE = 01, the QUADSPI is in indirect-read mode, where bytes are received from the flash memory during the data phase. Data are recovered by reading QUADSPI_DR.

The number of bytes to be read/written is specified in the data length register (QUADSPI_DLR). If QUADSPI_DLR = 0xFFFF_FFFF (all 1s), then the data length is considered undefined and the QUADSPI simply continues to transfer data until the end of flash memory (as defined by FSIZE) is reached. If no bytes are to be transferred, DMODE (QUADSPI_CCR[25:24]) must be set to 00.

If QUADSPI_DLR = 0xFFFF_FFFF and FSIZE = 0x1F (max value indicating a 4-Gbyte flash memory), then in this special case, transfers continue indefinitely, stopping only after an abort request or after the QUADSPI is disabled. After the last memory address is read (at address 0xFFFF_FFFF), reading continues with address = 0x0000_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE = 1. In the case of undefined number of data, the TCF is set when the limit of the external SPI memory is reached according to the flash memory size defined in QUADSPI_CR.
Triggering the start of a command

Essentially, a command starts as soon as firmware gives the last information that is necessary for this command. Depending on the QUADSPI configuration, there are three different ways to trigger the start of a command in indirect mode. The commands starts immediately:

- after a write is performed to INSTRUCTION[7:0] (QUADSPI_CCR), if no address is necessary (when ADMODE = 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
- after a write is performed to ADDRESS[31:0] (QUADSPI_AR), if an address is necessary (when ADMODE ≠ 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
- after a write is performed to DATA[31:0] (QUADSPI_DR), if data needs to be provided by the firmware (when FMODE = 00 and DMODE != 00)

Writes to the alternate byte register (QUADSPI_ABR) never trigger the communication start. If alternate bytes are required, they must be programmed before.

As soon as a command is started, BUSY (bit 5 of QUADSPI_SR) is automatically set.

FIFO and data management

In indirect mode, data go through a 16-byte FIFO which is internal to the QUADSPI. FLEVEL[4:0] (QUADSPI_SR[12:8]) indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE = 00), the firmware adds data to the FIFO when it writes QUADSPI_DR. Word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If the firmware adds too many bytes to the FIFO (more than is indicated by DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

Byte/halfword accesses to QUADSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[3:0] is used to define a FIFO threshold. When the threshold is reached, FTF (FIFO threshold flag) is set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there are data in the FIFO after the last byte is read from the flash memory, regardless of the FTHRES setting. In indirect-write mode, FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when FTF is set. If DMAEN = 1, a DMA transfer is initiated when FTF is set. FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data is transferred by the CPU or DMA).

20.3.6 QUADSPI automatic status-polling mode

In automatic status-polling mode, the QUADSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

Accesses to the flash memory begin in the same way as in indirect-read mode: if no address is required (AMODE = 00), accesses begin as soon as the QUADSPI_CCR is written.
Otherwise, if an address is required, the first access begins when QUADSPI_AR is written. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (QUADSPI_PSMAR) are used to mask the data from the flash memory in automatic status-polling mode. If MASK[n] = 0, then bit n of the result is masked and not considered. If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] (QUADSPI_PSMAR), then there is a match for bit n.

If the polling match mode bit (PMM, bit 23 of QUADSPI_CR) is 0, then “AND” match mode is activated. This means status match flag (SMF) is set only when there is a match on all of the unmasked bits.

If PMM = 1, then “OR” match mode is activated. This means SMF is set if there is a match on any of the unmasked bits.

An interrupt is called when SMF is set if SMIE = 1.

If the automatic status-polling mode stop (APMS) bit is set, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1, and the periodic accesses continue until there is an abort or the QUADSPI is disabled (EN = 0).

The data register (QUADSPI DR) contains the latest received status bytes (the FIFO is deactivated). The content of the data register is not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and FTF is cleared as soon as the data is read.

### 20.3.7 QUADSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

It is forbidden to access the quad-SPI flash bank area before having properly configured and enabled the QUADSPI peripheral.

No more than 256 Mbytes can addressed even if the flash memory capacity is larger.

If an access is made to an address outside of the range defined by FSIZE but still within the 256-Mbyte range, then a bus error is given. The effect of this error depends on the bus master that attempted the access:

- If it is the Cortex CPU, bus fault exception is generated when enabled (or an HardFault exception when bus fault is disabled).
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, halfword, and word access types are all supported.

Support for execute in place (XIP) operation is implemented, where the QUADSPI anticipates the next access and load in advance the byte at the following address. If the subsequent access is indeed made at a continuous address, the access is completed faster since the value is already prefetched.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with NCS maintained low, even if no access to the flash memory occurs for a long time. Since flash memories tend to consume more when NCS is held low, the application may want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI CR) so that NCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without any access since when the FIFO becomes full with prefetch data.
BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

20.3.8 QUADSPI flash memory configuration

The device configuration register (QUADSPI_DCR) can be used to specify the characteristics of the external SPI flash memory.

The FSIZE[4:0] bitfield defines the size of external memory using the following formula:

\[
\text{Number of bytes in flash memory} = 2^{[\text{FSIZE}+1]}
\]

FSIZE+1 is effectively the number of address bits required to address the flash memory. The flash memory capacity can be up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

If DFM = 1, FSIZE indicates the total capacity of the two flash memories together.

When the QUADSPI executes two commands, one immediately after the other, it raises NCS high between the two commands for only one CLK cycle by default. If the flash memory requires more time between commands, the CSHT bitfield can be used to specify the minimum number of CLK cycles (up to 8) that NCS must remain high.

The clock mode (CKMODE) bit indicates the CLK signal logic level in between commands (when NCS = 1).

20.3.9 QUADSPI delayed data sampling

By default, the QUADSPI samples the data driven by the flash memory one half of a CLK cycle after the flash memory drives the signal. In case of external signal delays, it may be beneficial to sample the data later. Using SSHIFT (bit 4 of QUADSPI_CR), the sampling of the data can be shifted by half of a CLK cycle.

Clock shifting is not supported in DDR mode: SSHIFT must be clear when DDRM bit is set.

20.3.10 QUADSPI configuration

The QUADSPI configuration is done in two phases:

1. QUADSPI peripheral configuration
2. QUADSPI flash memory configuration

Once configured and enabled, the QUADSPI can be used in one of its three operating modes: indirect, automatic status-polling, or memory-mapped mode.

QUADSPI configuration

The QUADSPI is configured using QUADSPI_CR. The user must configure the clock prescaler division factor and the sample shifting settings for the incoming data.

The DDR mode can be set through the DDRM bit. When setting the quad-SPI interface in DDR mode, the internal divider of kernel clock must be set with a division ratio of two or more. Once enabled, the address and the alternate bytes are sent on both clock edges, and the data are sent/received on both clock edges. Regardless of the DDRM bit setting, instructions are always sent in SDR mode.
DMA requests are enabled setting the DMAEN bit. In case of interrupt usage, their respective enable bit can be also set during this phase.

The FIFO level for either DMA request generation or interrupt generation is programmed in the FTHRES bits.

If a timeout counter is needed, the TCEN bit can be set and the timeout value programmed in the QUADSPI_LPTR register.

The dual-flash mode can be activated by setting DFM to 1.

**QUADSPI flash memory configuration**

The parameters related to the targeted external flash memory are configured through the QUADSPI_DCR register. The user must program the flash memory size in the FSIZE bits, the chip-select minimum high time in CSHT bits, and the functional mode (Mode 0 or Mode 3) in the MODE bit.

20.3.11 **QUADSPI use**

The operating mode is selected using FMODE[1:0] (QUADSPI_CCR[27:26]).

**Indirect mode**

When FMODE is programmed to 00, the indirect-write mode is selected and data can be sent to the flash memory. With FMODE = 01, the indirect-read mode is selected where data can be read from the flash memory.

When the QUADSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in QUADSPI_DLR.
2. Specify the frame format, mode and instruction code in QUADSPI_CCR.
3. Specify optional alternate byte to be sent right after the address phase in QUADSPI_ABR.
4. Specify the operating mode in QUADSPI_CR. If FMODE = 00 (indirect-write mode) and DMAEN = 1, then QUADSPI_AR must be specified before QUADSPI_CR. Otherwise QUADSPI_DR can be written by the DMA before QUADSPI_AR is updated (if the DMA controller has already been enabled).
5. Specify the targeted address in QUADSPI_AR.
6. Read/write the data from/to the FIFO through QUADSPI_DR.

When writing QUADSPI_CR, the user specifies the following settings:

- enable bit (EN) set to 1
- DMA enable bit (DMAEN) for transferring data to/from RAM
- timeout counter enable bit (TCEN)
- sample shift setting (SSSHIFT)
- FIFO threshold level (FTRHES) to indicate when the FTF flag must be set
- interrupt enables
- automatic status-polling mode parameters: match mode and stop mode (valid when FMODE = 11)
- clock prescaler
When writing QUADSPI_CCR, the user specifies the following parameters:

- instruction byte through INSTRUCTION bits
- the way the instruction has to be sent through the IMODE bits (1/2/4 lines)
- the way the address has to be sent through the ADMODE bits (None/1/2/4 lines)
- address size (8/16/24/32-bit) through ADSIZE bits
- the way the alternate bytes have to be sent through the ABMODE (None/1/2/4 lines)
- alternate bytes number (1/2/3/4) through the ABSIZE bits
- presence or not of dummy bytes through the DBMODE bit
- number of dummy bytes through the DCYC bits
- the way data have to be sent/received (none/1/2/4 lines) through DMODE bits

If neither QUADSPI_AR nor QUADSPI_DR need to be updated for a particular command, then the command sequence starts as soon as QUADSPI_CCR is written. This is the case when both ADMODE and DMODE are 00, or if just ADMODE = 00 when in indirect read mode (FMODE = 01).

When an address is required (ADMODE is not 00) and the data register does not need to be written (when FMODE = 01 or DMODE = 00), the command sequence starts as soon as the address is updated with a write to QUADSPI_AR.

In case of data transmission (FMODE = 00 and DMODE! = 00), the communication start is triggered by a write in the FIFO through QUADSPI_DR.

**Automatic status-polling mode**

This mode is enabled setting the FMODE bitfield (QUADSPI_CCR[27:26]) to 10. In this mode, the programmed frame is sent and the data retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in QUADSPI_DLR, it is ignored and only 4 bytes are read.

The periodicity is specified in the QUADSPI_PISR register.

Once the status data is retrieved, it can internally be processed:

- to set the status match flag and generate an interrupt if enabled
- to stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in QUADSPI_PSMKR and ORed or ANDed with the value stored in QUADSPI_PSMAR.

In case of match, the status match flag is set and an interrupt is generated if enabled, and the QUADSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in QUADSPI_DR.

**Memory-mapped mode**

In memory-mapped mode, the external flash memory is seen as an internal memory but with some latency during accesses. Only read operations are allowed to the external flash memory in this mode.

The memory-mapped mode is entered by setting FMODE to 11 in QUADSPI_CCR.

The programmed instruction and frame is sent when a master is accessing the memory-mapped space.
The FIFO is used as a prefetch buffer to anticipate linear reads. Any access to QUADSPI_DR in this mode returns zero.

QUADSPI_DLR has no meaning in memory-mapped mode.

20.3.12 Sending the instruction only once

Some flash memories (for example: Winbound) provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. One can take advantage of such a feature using the SIOO bit (QUADSPI_CCR[28]).

SIOO is valid for all functional modes (indirect, automatic status-polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to QUADSPI_CCR. Subsequent command sequences skip the instruction phase, until there is a write to QUADSPI_CCR.

SIOO has no effect when IMODE = 00 (no instruction).

20.3.13 QUADSPI error management

An error can be generated in the following case:

- In indirect mode or automatic status-polling mode when a wrong address is programmed in QUADSPI_AR (according to the flash memory size defined by FSIZE[4:0] in the QUADSPI_DCR), TEF is set and an interrupt is generated if enabled. Also in indirect mode, if the address plus the data length exceeds the flash memory size, TEF is set as soon as the access is triggered.

- In memory-mapped mode, when an out-of-range access is done by a master or when the QUADSPI is disabled, a bus error is generated as a response to the faulty bus master request.

20.3.14 QUADSPI busy bit and abort functionality

Once the QUADSPI starts an operation with the flash memory, the BUSY bit is automatically set in QUADSPI_SR.

In indirect mode, BUSY is reset once the QUADSPI has completed the requested command sequence, and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

Any operation can be aborted by setting the ABORT bit in QUADSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Note: Some flash memories may misbehave if a write operation to a status registers is aborted.
20.3.15 NCS behavior

By default, NCS is high, deselecting the external flash memory. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 ("mode0", where CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge, as shown in the figure below.

![Figure 78. NCS when CKMODE = 0 (T = CLK period)](image)

When CKMODE=1 ("mode3", where CLK goes high when no operation is in progress) and DDRM=0 (SDR mode), NCS still falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge, as shown in the figure below.

![Figure 79. NCS when CKMODE = 1 in SDR mode (T = CLK period)](image)

When CKMODE = 1 ("mode3") and DDRM = 1 (DDR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge, as shown in the figure below. Because DDR operations must
finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 80. NCS when CKMODE = 1 in DDR mode (T = CLK period)**

When the FIFO stays full in a read operation or if the FIFO stays empty in a write operation, the operation stalls and CLK stays low until firmware services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later, as shown in **Figure 81**.

**Figure 81. NCS when CKMODE = 1 with an abort (T = CLK period)**

When not in dual-flash mode (DFM = 0) and FSEL = 0 (default value), only FLASH 1 is accessed. Thus BK2_NCS stays high, if FSEL = 1, only FLASH 2 is accessed and BK1_NCS stays high. In dual-flash mode, BK2_NCS behaves exactly the same as BK1_NCS. Thus, if there is a FLASH 2 and if the application is dual-flash mode only, then BK1_NCS signal can be used for FLASH 2 as well, and the pin devoted to BK2_NCS can be used for other functions.
20.4 **QUADSPI interrupts**

An interrupt can be produced on the following events:
- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Bits 31:24 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating CLK based on the clock (value+1).
0: $F_{CLK} = F$, clock used directly as QUADSPI CLK (prescaler bypassed)
1: $F_{CLK} = F/2$
2: $F_{CLK} = F/3$
...
255: $F_{CLK} = F/256$

For odd clock division factors, CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

When setting quad-SPI interface in DDR mode, the prescaler must be set with a division ratio of two or more.

*Note: This bitfield can be modified only when BUSY = 0.*
Bit 23  **PMM**: Polling match mode
This bit indicates which method must be used for determining a “match” during automatic status-polling mode.
- 0: AND match mode. SMF is set if all the unmasked bits received from the flash memory match the corresponding bits in the match register.
- 1: OR match mode. SMF is set if any one of the unmasked bits received from the flash memory matches its corresponding bit in the match register.

*Note: This bit can be modified only when BUSY = 0.*

Bit 22  **APMS**: Automatic status-polling mode stop
This bit determines if automatic status-polling is stopped after a match.
- 0: Automatic status-polling mode is stopped only by abort or by disabling the QUADSPI.
- 1: Automatic status-polling mode stops as soon as there is a match.

*Note: This bit can be modified only when BUSY = 0.*

Bit 21  Reserved, must be kept at reset value.

Bit 20  **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 19  **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 18  **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 17  **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 16  **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bits 15:12  Reserved, must be kept at reset value.
Bits 11:8  \textbf{FTHRES[3:0]}: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag (bit FTF in register QUADSPI_SR) to be set.

- 0: In indirect-write mode (FMODE = 00), FTF is set if there are one or more free bytes location left in the FIFO, or indirect-read mode (FMODE = 01), FTF is set if there are 1 or more valid bytes that can be read from the FIFO.
- 1: In indirect-write mode (FMODE = 00), FTF is set if there are two or more free bytes location left in the FIFO, or indirect read mode (FMODE = 01), FTF is set if there are two or more valid bytes that can be read from the FIFO.
- ... 15: In indirect-write mode (FMODE = 00), FTF is set if there are 16 free bytes location left in the FIFO, or indirect read mode (FMODE = 01), FTF is set if there are 16 valid bytes that can be read from the FIFO.

If DMAEN = 1, then the DMA controller for the corresponding channel must be disabled before changing the FTHRES value.

Bit 7  \textbf{FSEL}: Flash memory selection

This bit selects the flash memory to be addressed in single-flash mode (when DFM = 0).

- 0: FLASH 1 selected
- 1: FLASH 2 selected

\textit{Note: This bit can be modified only when BUSY = 0. This bit is ignored when DFM = 1.}

Bit 6  \textbf{DFM}: Dual-flash mode

This bit activates dual-flash mode, where two external flash memories are used simultaneously to double throughput and capacity.

- 0: Dual-flash mode disabled
- 1: Dual-flash mode enabled

\textit{Note: This bit can be modified only when BUSY = 0.}

Bit 5  Reserved, must be kept at reset value.

Bit 4  \textbf{SSHIFT}: Sample shift

By default, the QUADSPI samples data 1/2 of a CLK cycle after the data is driven by the flash memory. This bit allows the data to be sampled later in order to account for external signal delays.

- 0: No shift
- 1: 1/2 cycle shift

The firmware must assure that SSHIFT = 0 when in DDR mode (when DDRM = 1).

\textit{Note: This bitfield can be modified only when BUSY = 0.}

Bit 3  \textbf{TCEN}: Timeout counter enable

This bit is valid only when memory-mapped mode (FMODE = 11) is selected. Activating this bit causes the NCS to be released (and thus reduces consumption) if there has not been an access after a certain amount of time, where this time is defined by TIMEOUT[15:0] (QUADSPI_LPTR). This bit enables the timeout counter.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with NCS maintained low, even if no access to the flash memory occurs for a long time. Since flash memories tend to consume more when NCS is held low, the application may want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI_CR) so that NCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without an access since when the FIFO becomes full with prefetch data.

- 0: Timeout counter is disabled, and thus the NCS remains active indefinitely after an access in memory-mapped mode.
- 1: Timeout counter is enabled, and thus the NCS is released in memory-mapped mode after TIMEOUT[15:0] cycles of flash memory inactivity.

\textit{Note: This bit can be modified only when BUSY = 0.}
### QUADSPI device configuration register (QUADSPI_DCR)

**Bits 31:21**  Reserved, must be kept at reset value.  

**Bits 20:16**  **FSIZE[4:0]: Flash memory size**  
This bitfield defines the size of external memory using the following formula:  
Number of bytes in flash memory = 2[^FSIZE+1]  
FSIZE+1 is effectively the number of address bits required to address the flash memory.  
The flash memory capacity can be up to 4 Gbytes (addressed using 32 bits) in indirect mode,  
but the addressable space in memory-mapped mode is limited to 256 Mbytes.  
If DFM = 1, FSIZE indicates the total capacity of the two flash memories together.  
**Note:** This bitfield can be modified only when BUSY = 0.  

**Bits 15:11**  Reserved, must be kept at reset value.  

**Bits 10:8**  **CSHT[2:0]: Chip select high time**  
CSHT+1 defines the minimum number of CLK cycles which the chip select (NCS) must remain high between commands issued to the flash memory.  
0: NCS stays high for at least 1 cycle between flash memory commands  
1: NCS stays high for at least 2 cycles between flash memory commands  
...  
7: NCS stays high for at least 8 cycles between flash memory commands  
**Note:** This bitfield can be modified only when BUSY = 0.  

**Bits 7:1**  Reserved, must be kept at reset value.
Bit 0 **CKMODE**: Mode 0/mode 3 
This bit indicates the level that CLK takes between commands (when NCS = 1).
0: CLK must stay low while NCS is high (chip select released). This is referred to as mode 0.
1: CLK must stay high while NCS is high (chip select released). This is referred to as mode 3.
*Note: This bitfield can be modified only when BUSY = 0.*

### 20.5.3 QUADSPI status register (QUADSPI_SR)

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:8 **FLEVEL[4:0]**: FIFO level
This bitfield gives the number of valid bytes which are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 16 when it is full. In memory-mapped mode and in automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy
This bit is set when an operation is on going. This bit clears automatically when the operation with the flash memory is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag
This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (QUADSPI_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag
In indirect mode, this bit is set when the FIFO threshold is reached, or if there is any data left in the FIFO after reads from the flash memory are complete. It is cleared automatically as soon as threshold condition is no longer true.
In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag
This bit is set in indirect mode when the programmed number of data is transferred or in any mode when the transfer is aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

Bits 31:5 Reserved, must be kept at reset value.

- Bit 4 **CTOF**: Clear timeout flag
  Writing 1 clears the TOF flag in QUADSPI_SR.

- Bit 3 **CSMF**: Clear status match flag
  Writing 1 clears the SMF flag in QUADSPI_SR.

- Bit 2 Reserved, must be kept at reset value.

- Bit 1 **CTCF**: Clear transfer complete flag
  Writing 1 clears the TCF flag in QUADSPI_SR.

- Bit 0 **CTEF**: Clear transfer error flag
  Writing 1 clears the TEF flag in QUADSPI_SR.

</tbody>
</table>

**DL[15:0]**
Bits 31:0  DL[31:0]: Data length
Number of data to be retrieved (value+1) in indirect and automatic status-polling modes.
A value no greater than 3 (indicating 4 bytes) must be used for automatic status-polling
mode.
All 1s in indirect mode means undefined length, where the QUADSPI continues until the end
of memory, as defined by FSIZE.
0x0000_0000: 1 byte is to be transferred
0x0000_0001: 2 bytes are to be transferred
0x0000_0002: 3 bytes are to be transferred
0x0000_0003: 4 bytes are to be transferred
...
0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred
0xFFFF_FFFF: undefined length -- all bytes until the end of flash memory (as defined by
FSIZE) are to be transferred. Continue reading indefinitely if FSIZE = 0x1F.
DL[0] is stuck at 1 in dual-flash mode (DFM = 1) even when 0 is written to this bit, thus
assuring that each access transfers an even number of bytes.
This bitfield has no effect when in memory-mapped mode (FMODE = 10).
Note: This bitfield can be written only when BUSY = 0.

20.5.6  QUADSPI communication configuration register (QUADSPI_CCR)

Bit 31  DDRM: Double data rate mode
This bit sets the DDR mode for the address, alternate byte and data phase:
0: DDR mode disabled
1: DDR mode enabled
Note: This bit can be written only when BUSY = 0.

Bit 30  DHHC: DDR hold
This bit delays the data output by 1/4 of the QUADSPI output clock cycle in DDR mode:
0: Data output delayed using analog delay
1: Data output delayed by 1/4 of a QUADSPI output clock cycle
This feature is only active in DDR mode.
Note: This bit can be written only when BUSY = 0.
PRESCALER > 0 is mandatory when DHHC = 1.

Bit 29  Reserved, must be kept at reset value.
Bit 28 **SIOO**: Send instruction only once mode
- This bit has no effect when IMODE = 00. See Section 20.3.12 for more details.
  
  0: Instruction sent on every transaction
  1: Instruction sent only for the first command

*Note:* *This bit can be written only when BUSY = 0.*

Bits 27:26 **FMODE[1:0]**: Functional mode
- This bitfield defines the QUADSPI functional mode of operation.
  
  00: Indirect-write mode
  01: Indirect-read mode
  10: Automatic status-polling mode
  11: Memory-mapped mode

  If DMAEN = 1 already, the DMA controller for the corresponding channel must be disabled before changing the FMODE value.

*Note:* *This bitfield can be written only when BUSY = 0.*

Bits 25:24 **DMODE[1:0]**: Data mode
- This bitfield defines the data phase mode of operation:
  
  00: No data
  01: Data on a single line
  10: Data on two lines
  11: Data on four lines

  This bitfield also determines the dummy phase mode of operation.

*Note:* *This bitfield can be written only when BUSY = 0.*

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **DCYC[4:0]**: Number of dummy cycles
- This bitfield defines the duration of the dummy phase. In both SDR and DDR modes, it specifies a number of CLK cycles (0-31).

*Note:* *This bitfield can be written only when BUSY = 0.*

Bits 17:16 **ABSIZE[1:0]**: Alternate-byte size
- This bit defines the size of alternate bytes.
  
  00: 8-bit alternate byte
  01: 16-bit alternate bytes
  10: 24-bit alternate bytes
  11: 32-bit alternate bytes

*Note:* *This bitfield can be written only when BUSY = 0.*

Bits 15:14 **ABMODE[1:0]**: Alternate byte mode
- This bitfield defines the alternate-byte phase mode of operation.
  
  00: No alternate bytes
  01: Alternate bytes on a single line
  10: Alternate bytes on two lines
  11: Alternate bytes on four lines

*Note:* *This bitfield can be written only when BUSY = 0.*

Bits 13:12 **ADSIZE[1:0]**: Address size
- This bit defines address size:
  
  00: 8-bit address
  01: 16-bit address
  10: 24-bit address
  11: 32-bit address

*Note:* *This bitfield can be written only when BUSY = 0.*
Bits 11:10  **ADMODE[1:0]: Address mode**
This bitfield defines the address phase mode of operation.
- 00: No address
- 01: Address on a single line
- 10: Address on two lines
- 11: Address on four lines

*Note: This bitfield can be written only when BUSY = 0.*

Bits 9:8  **IMODE[1:0]: Instruction mode**
This bitfield defines the instruction phase mode of operation.
- 00: No instruction
- 01: Instruction on a single line
- 10: Instruction on two lines
- 11: Instruction on four lines

*Note: This bitfield can be written only when BUSY = 0.*

Bits 7:0  **INSTRUCTION[7:0]: Instruction**
Instruction to be sent to the external SPI device.

*Note: This bitfield can be written only when BUSY = 0.*

</tbody>
</table>
20.5.11 QUADSPI polling status match register (QUADSPI_PSMAR)

Address offset: 0x028

Reset value: 0x0000 0000

Bits 31:0  **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match.

Note: This bitfield can be written only when BUSY = 0.

Bits 31:0  **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match.

Note: This bitfield can be written only when BUSY = 0.

20.5.12 QUADSPI polling interval register (QUADSPI_PIR)

Address offset: 0x02C

Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **INTERVAL[15:0]**: Polling interval

Number of CLK cycles between two read during automatic status-polling phases.

Note: This bitfield can be written only when BUSY = 0.

**Bits 31:16** Reserved, must be kept at reset value.

**Bits 15:0** `TIMEOUT[15:0]`: Timeout period

After each access in memory-mapped mode, the QUADSPI prefetches the subsequent bytes and holds these bytes in the FIFO. This bitfield indicates how many CLK cycles the QUADSPI waits after the FIFO becomes full until it raises NCS, putting the flash memory in a lower-consumption state.

*Note: This bitfield can be written only when BUSY = 0.*

21 Analog-to-digital converters (ADC)

21.1 Introduction

This section describes the implementation of up to 5 ADCs:
- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 and ADC4 are tightly coupled and can operate in dual mode (ADC3 is master).
- ADC5 is controlled independently.

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performance while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
21.2 ADC main features

- High-performance features
  - Up to 5 ADCs, out of which four of them (in pairs) can operate in dual mode:
    ADC1 is connected to 14 external channels + 4 internal channels
    ADC2 is connected to 16 external channels + 2 internal channels
    ADC3 is connected to 15 external channels + 3 internal channels
    ADC4 is connected to 16 external channels + 2 internal channels
    ADC5 is connected to 13 external channels + 5 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - 4 dedicated data registers for the injected channels

- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256
  - Programmable data shift up to 8-bit

- Data preconditioning
  - Gain compensation
  - Offset compensation

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency
application (auto-delayed mode)

- Number of external analog input channels per ADC
  - Up to 5 fast channels from GPIO pads
  - Up to 13 slow channels from GPIO pads

- In addition, there are several internal dedicated channels
  - The internal reference voltage ($V_{\text{REFINT}}$), connected to ADC1, 3, 4 and 5
  - The internal temperature sensor ($V_{\text{TS}}$), connected to ADC1 and 5
  - The $V_{\text{BAT}}$ monitoring channel ($V_{\text{BAT}}/3$), connected to ADC1, 3 (for category 3 devices only) and 5
  - The OPAMP1 internal output connected to ADC1
  - The OPAMP2 and OPAMP3 internal outputs connected to ADC2
  - The OPAMP3 internal output connected to ADC3
  - The OPAMP6 internal output connected to ADC4 (for category 3 devices) or ADC3 (for category 4 devices)
  - The OPAMP4 and OPAMP5 internal outputs connected to ADC5

- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode

- Dual ADC mode for ADC1, ADC2, ADC3 and ADC4

- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events

- 3 analog watchdogs per ADC
  - Watchdog can perform filtering to ignore out-of-range data

- ADC input range: $V_{\text{REF-}} \leq V_{\text{IN}} \leq V_{\text{REF+}}$

*Figure 82* shows the block diagram of one ADC.

Refer to the OPAMP electrical characteristics section of the product datasheet for the ADC sampling time value to be applied when converting the OPAMP output voltage.

21.4.3 ADC clocks

**Dual clock domain architecture**

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see Figure 83: ADC clock scheme):

1. The ADC clock can be a specific clock source, derived from the following clock sources:
   - The system clock
   - PLL “P” clock
   Refer to RCC Section for more information on how to generate ADC dedicated clock. To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).
   To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be different from 00.

*Note:* For option 2), a prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set (HPRE[3:0] = 0xxx in RCC_CFGR register).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains).
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{\text{adc_hclk}} \geq F_{\text{ADC}} / 4$ if the resolution of all channels are 12-bit or 10-bit
- $F_{\text{adc_hclk}} \geq F_{\text{ADC}} / 3$ if there are some channels with resolutions equal to 8-bit (and none with lower resolution)
- $F_{\text{adc_hclk}} \geq F_{\text{ADC}} / 2$ if there are some channels with resolutions equal to 6-bit
21.4.4 ADC1/2/3/4/5 connectivity

ADC1, ADC2, ADC3, ADC4 and ADC5 are tightly coupled and share some external channels as described in the below figures.

ADCy_INPx correspond to ADCy_INx pins defined in the product datasheet.

21.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, follow the sequence below:
1. Exit Deep-power-down mode by clearing DEEPPWD bit.
2. Enable the ADC voltage regulator by setting ADVREGEN.
3. Wait for the startup time to configure the ADC (refer to the device datasheet for the value of the startup time).

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

*Note:* Writing DEEPPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

*When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.*

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to *Section 21.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)*).
21.4.7 **Single-ended and differential input channels**

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage equal to VINP[i] (positive input) and VREF (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage positive input equal to VINP[i], and the ADCy_INNx negative input equal to VINN[i].

The input voltage in differential mode ranges from VREF- to VREF+, which makes a full scale range of 2xVREF+. When VINP[i] equals VREF−, VINN[i] equals VREF, and the maximum negative input differential voltage (VREF−) corresponds to 0x000 ADC output. When VINP[i] equals VREF+, VINN[i] equals VREF, and the maximum positive input differential voltage (VREF+) corresponds to 0xFFF ADC output. When VINP[i] and VINN[i] are connected together, the zero input differential voltage corresponds to 0x800 ADC output.

The ADC sensitivity in differential mode is twice smaller than in single-ended mode.

When ADC is configured as differential mode, both inputs should be biased at (VREF+) / 2 voltage. Refer to the device datasheet for the allowed common mode input voltage VCMIN.

Internal channels (such as VTS and VREFINT) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to Section 21.4.4: ADC1/2/3/4/5 connectivity.

**Caution:** When configuring the channel “i” in differential input mode, its negative input voltage VINN[i] is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted.

Some channels are shared between ADC1/ADC2/ADC3/ADC4/ADC5: this can make the channel on the other ADC unusable. The only exception is when ADC master and the slave operate in interleaved mode.

21.4.8 **Calibration (ADCAL, ADCALDIF, ADC_CALFACT)**

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration to be applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration to be applied for differential input conversions.
The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration).

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

**Figure 89. ADC calibration**
Software procedure to re-inject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.
21.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN))

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately, as shown in Figure 92. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART = 1 (refer to Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART = 1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing 1 (optional).

Caution: ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).
Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

![Figure 92. Enabling / disabling the ADC](image)

21.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_Try, ADC_SQRy, ADC_JDRy, ADC_OFRx, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_Try registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 21.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx) for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).
The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1) and JADSTART is cleared. The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set (injected conversions are ongoing) only when the context queue is enabled (JQDIS = 0 in the ADC_CFGR register). Refer to Section 21.7.16: ADC injected sequence register (ADC_JSQR) for additional details.

**Note:** There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN as well as all the bits of ADC_CR register).

### 21.4.11 Channel selection (SQRx, JSQRx)

There are up to 19 multiplexed channels per ADC:
- Up to 13 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6:18])
  - Depending on the products, not all of them are available on GPIO pads.
- The ADCs are connected to the following internal analog inputs:
  - The internal reference voltage (VREFINT) is connected to ADC1_INP18, ADC3_INP18, ADC4_INP18 and ADC5_INP18.
  - The internal temperature sensor (VTS) is connected to ADC1_INP16 and ADC5_INP4.
  - The VBAT monitoring channel (VBAT/3) is connected to ADC1_INP17, ADC3_INP17 and ADC5_INP17.

**Note:** To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATSEL or VSENSESEL in the ADCx_CCR registers.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to Section 21.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFGR register). Refer to Section 21.4.21: Queue of context for injected conversions.
21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + 12.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{adc, ker, ck}} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{\text{CONV}} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The Bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The Bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

</tr>
</tbody>
</table>

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion. The EXTEN[1:0] bits must be set to 01. Hardware triggers with not defined rising and falling edges (one pulse event) cannot be used in Bulb mode.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion. EXTEN[1:0] bits must be set to 00.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the VDDA voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low VDDA voltage by enabling an internal voltage booster through the BOOSTEN bit of the SYSCFG_CFRG1 register.

SMPPPLUS control bit

When a sampling time of 2.5 ADC clock cycles is selected, the total conversion time becomes 15 cycles in 12-bit mode. If the dual interleaved mode is used (see Section: Interleaved mode with independent injected), the sampling interval cannot be equal to the value specified since an even number of cycles is required for the conversion. The SMPPPLUS bit can be used to change the sampling time 2.5 ADC clock cycles into 3.5 ADC clock cycles. In this way, the total conversion time becomes 16 clock cycles, thus making possible to interleave every 8 cycles.
21.4.13 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

*Note:* To convert a single channel, program a sequence with a length of 1.

21.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversion of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.
Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is
forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected
channel is configured to be converted automatically after regular channels in continuous
mode (using JAUTO bit), refer to Auto-injection mode section.

21.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN[1:0] is not
equal to 00

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN[1:0] is not
equal to 00

Note: In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions
followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is
currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and
JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of
    subgroup processing if DISCEN = 1
- In all cases (CONT=x, EXTSEL=x)
  - After execution of the ADSTP procedure asserted by the software.

Note: In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of
EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTSEL≠0x00),
ADSTART is not cleared by hardware with the assertion of EOS to help the software which
does not need to reset ADSTART again for the next hardware trigger event. This ensures
that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of
    subgroup processing if JDISCEN = 1
- In all cases (JEXTSEL=x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still
high.
21.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[ T_{CONV} = T_{SMPL} + T_{SAR} = [2.5 \mu\text{min} + 12.5 \mu\text{12bit}] \times T_{ADC\_CLK} \]

\[ T_{CONV} = 83.33 \text{ ns} \mu\text{min} + 416.67 \text{ ns} \mu\text{12bit} = 500.0 \text{ ns} \text{ (for F}_{ADC\_CLK} = 30 \text{ MHz)} \]

**Figure 94. Analog-to-digital conversion time**

1. \( t_{SMPL} \) depends on SMP[2:0].
2. \( t_{SAR} \) depends on RES[2:0].

21.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the
software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

**Note:** In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

21.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 161 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

### Table 161. Configuring the trigger polarity for regular external triggers

<th>Source</th>
</tr>
</thead>
</table>
| 00          | - If JQDIS = 1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled  
            | - If JQDIS = 0 (Queue enabled), Hardware and software trigger detection disabled |
| 01          | Hardware Trigger with detection on the rising edge |
| 10          | Hardware Trigger with detection on the falling edge |
| 11          | Hardware Trigger with detection on both the rising and falling edges |

> Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 21.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
**Note:** The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 21.4.21: Queue of context for injected conversions on page 624.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 97.

**Figure 97. Triggers sharing between ADC master and ADC slave**

Table 163 to Table 166 give all the possible external triggers of the three ADCs for regular and injected conversions.

### 21.4.19 Injected channel management

#### Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC\_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC\_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC\_CR register is set during the conversion of a regular group of channels, the current conversion is
reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 98 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.
21.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions (\( n \leq 8 \)) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- **DISCEN = 1, n = 3**, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - first trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - second trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - third trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...

- **DISCEN = 0**, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - first trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.
Analog-to-digital converters (ADC) RM0440

624/2138 RM0440 Rev 8

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN = 1, channels to be converted = 1, 2, 3
  - first trigger: channel 1 converted (a JEOC event is generated)
  - second trigger: channel 2 converted (a JEOC event is generated)
  - third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

21.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFRG:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue. The first trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1\textsuperscript{st} trigger, discontinuous. Sequence 1: context 1 consumed, 1\textsuperscript{st} conversion carried out
- 2\textsuperscript{nd} trigger, discontinuous. Sequence 1: 2\textsuperscript{nd} conversion.
- 3\textsuperscript{rd} trigger, discontinuous. Sequence 1: 3\textsuperscript{rd} conversion.
- 4\textsuperscript{th} trigger, discontinuous. Sequence 2: context 2 consumed, 1\textsuperscript{st} conversion carried out.
- 5\textsuperscript{th} trigger, discontinuous. Sequence 2: 2\textsuperscript{nd} conversion.
- 6\textsuperscript{th} trigger, discontinuous. Sequence 2: 3\textsuperscript{rd} conversion.
Behavior when changing the trigger or sequence context

The Figure 99 and Figure 100 show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 99. Example of JSQR queue of context (sequence change)**

1. Parameters:
   - P1: sequence of 3 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 4 conversions, hardware trigger 1

**Figure 100. Example of JSQR queue of context (trigger change)**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 101 and Figure 102 show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 101. Example of JSQR queue of context with overflow before conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1

Figure 102. Example of JSQR queue of context with overflow during conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 103* and *Figure 104* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

**Figure 103. Example of JSQR queue of context with empty queue (case JQM = 0)**

1. Parameters:
   
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
Figure 104. Example of JSQR queue of context with empty queue (case JQM = 1)

Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 105. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0)
Case when JADSTP occurs during an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 106. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0)
Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 107. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0)
Case when JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 108. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 1)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 109. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 0)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN[1:0] not equal to 00 (otherwise triggering a software conversion).
6. Set JADSTART.
7. Set JADSTP.
8. Wait until JADSTART is reset.
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

21.4.22 Programmable resolution (RES) - Fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 115, Figure 116, Figure 117 and Figure 118 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 167.
21.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

21.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

21.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 115, Figure 116, Figure 117 and Figure 118.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 117 and Figure 118.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by setting the bit OFFSETy_EN = 1 into ADC_OFRy register. The channel to which the offset is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 168 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

<table>

</tbody>
</table>

The user must configure OFFSET[1:0] to 00.
When reading data from ADC_DR (regular channel) or from ADC_JDRy (injected channel, y = 1,2,3,4) corresponding to the channel “i”:

- If one of the offsets is enabled (bit OFFSETy_EN = 1) for the corresponding channel, the read data is signed.
- If none of the four offsets is enabled for this channel, the read data is not signed.

*Figure 115, Figure 116, Figure 117 and Figure 118* show alignments for signed and unsigned data.

Gain compensation

When GCOMP bit is set in ADC_CFGR2 register, the gain compensation is activated on all the converted data. After each conversion, data is calculated with the following formula.

\[
\text{DATA} = \text{DATA(adc result)} \times \left(\frac{\text{GCOMPCOEFF}}{4096}\right)
\]

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATA or JDATAx registers, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used for the oversampling mode, the gain calculation is performed after the accumulation and right-shift operations to minimize the power consumption (the gain calculation is done only once instead of at each conversion).

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed on unsigned values, after offset and gain compensation. For correct watchdog operation, the data after offset compensation must be in unsigned format (SATEN bit set in ADC_OFRy register).
ADC overrun (OVR, OVRMOD)

The overrun flag (OSR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before new converted data became available.

The OVR flag is set if the EOC flag is still 1 at the time when a new conversion completes. An interrupt can be generated if bit OVRIE = 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting bit ADSTP = 1.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0: The overrun event preserves the data register from being overrun: the old data is maintained and the new conversion is discarded and lost. If OVR remains at 1, any further conversions occur but the result data is also discarded.
- OVRMOD = 1: The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, any further conversions operate normally and the ADC_DR register always contains the latest converted data.

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events as an error.
Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set in the ADC_CFGR register in single ADC mode or MDMA different from 00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- **DMA one shot mode (DMACFG = 0).**
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- **DMA circular mode (DMACFG = 1)**
  This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMACFG = 0)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.
DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

21.4.27 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 120).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 121).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 121).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 123).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 124).
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:

1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS.
3. Set ADSTP.
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

21.4.28 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 125. Analog watchdog guarded area**

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels\(^{(1)}\) remain within a configured voltage range (window).

**Table 169** shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 170 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

1. Refer to Section : Gain compensation for additional details on analog watchdog comparison.

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in Scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set an the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x=2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x=2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. Table 171 describes how the comparison is performed for all the possible resolutions.
ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y=ADC number, x=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

**Note:** AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in new analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt or AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

Analog watchdog with gain and offset compensation

When gain and offset compensation are enabled, the analog watchdog compares the threshold after the compensated data.

Note: When the offset compensation is enabled (OFFSETy_EN set in ADC_OFRy register), data overflow or underflow can result in a wrong watchdog result. When the saturation is enabled (SATEN set in ADC_OFRy), the watchdog provides a correct result. However this prevents from using the signed data format.

21.4.29 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times 2^{16} \times \sum_{n=0}^{n-N-1} \text{Conversion}(t_n)$$

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.

</table>

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N
conversions, with an equivalent delay equal to \( N \times T_{\text{CONV}} = N \times (t_{\text{SMPL}} + t_{\text{SAR}}) \). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every \( N \) conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after \( N \times \) sequence length conversions total)

**ADC operating modes supported when oversampling (single ADC mode)**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per \( \text{RES}[1:0] \) bits in \( \text{ADC\_CFGR1} \) register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The \( \text{ALIGN} \) bit in \( \text{ADC\_CFGR1} \) is ignored and the data are always provided right-aligned.

**Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy\_EN bit in ADC\_OFRy register is ignored (considered as reset).**

**Analog watchdog**

The analog watchdog functionality is maintained, with the following difference:

- The \( \text{RES}[1:0] \) bits are ignored, comparison is always done using the full 12-bit values \( \text{HT}[11:0] \) and \( \text{LT}[11:0] \)
- the comparison is performed on the most significant 12-bit of the 16-bit oversampled results \( \text{ADC\_DR}[15:4] \)

**Note:** Care must be taken when using high shifting values, since this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between \( \text{ADC\_DR}[11:4] \) and \( \text{HT}[0:7] / \text{LT}[0:7] \), and \( \text{HT}[11:8] / \text{LT}[11:8] \) must be kept reset.

**Triggered mode**

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with \( \text{TROVS} \) bit in \( \text{ADC\_CFGR2} \), to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

*Figure 132* below shows how conversions are started in response to triggers during discontinuous mode.

If the \( \text{TROVS} \) bit is set, the content of the \( \text{DISCEN} \) bit is ignored and considered as 1.
Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequencer is blocked.

*Figure 133* gives examples for a 4x oversampling ratio.
Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 134 below.

**Figure 134. Regular and injected oversampling modes used simultaneously**
Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 135 below.

Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 136 below shows how the conversions are sequenced.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).
Combined modes summary

The Table 173 below summarizes all combinations, including modes not supported.

21.4.30 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see Figure 137).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:
- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:
- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN[1:0], EXTSEL, JEXTEN[1:0], JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).
In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

**Note:** *Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).*

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 138), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 138. Injected simultaneous mode on 4 channels: dual ADC mode**

If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the
ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.

**Regular simultaneous mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

*Note:* Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

*In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.

- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.

- If the duration of the master regular sequence is equal to the duration of the slave one (like in *Figure 139*), it is possible for the software to enable only one of the two EOC interrupts (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.

- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0] = 10 or 11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CDR register.
  - Both EOC flags are cleared when the DMA reads the ADCx_CDR register.

*Note:* In MDMA mode (MDMA[1:0] = 10 or 11), the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions does not generate a DMA request.
If DISCEN = 1 then each "n" simultaneous conversions of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits MDMA must be set to 10 or 11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master's sequence is equal to the number of conversions in the slave's.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

### Interleaved mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a
conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.

- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure MDMA[1:0] = 10 or 11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

Figure 140. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode
If DISCEN = 1, each "n" simultaneous conversions ("n" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 142 below).

**Figure 142. Interleaved conversion with injection**

Alternate trigger mode

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 00.

Injected discontinuous mode disabled (JDISCEN = 0 for both ADC)
1. When the first trigger occurs, all injected master ADC channels in the group are converted.
2. When the second trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

**Figure 143. Alternate trigger: injected group of each ADC**

Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

**Injected discontinuous mode enabled (JDISCEN = 1 for both ADC)**
If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the first trigger occurs, the first injected channel of the master ADC is converted.
- When the second trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 144. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

**Combined regular/injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Combined regular simultaneous + alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 145** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Figure 145. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. Figure 146 shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 146. Case of trigger occurring during injected conversion

Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0] = 00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. Figure 147, Figure 148 and Figure 149 show the behavior using an example.

Caution: In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 147. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 148. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 149. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 150: DMA Requests in regular simultaneous mode when MDMA = 00).

Figure 150. DMA Requests in regular simultaneous mode when MDMA = 00

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADCx_CCR register:

- **MDMA = 10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.
  
  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

  **Example:**

  Interleaved dual mode: a DMA request is generated each time 2 data items are available:

  first DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
  second DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
Figure 151. DMA requests in regular simultaneous mode when MDMA = 10

Figure 152. DMA requests in interleaved mode when MDMA = 10
Note: When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- MDMA = 11: This mode is similar to the MDMA = 10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.
  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

Example:
Interleaved dual mode: a DMA request is generated each time 2 data items are available:
first DMA request: ADCx_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]
second DMA request: ADCx_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Overrun detection
In dual ADC mode (when DUAL[4:0] is not equal to 00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

DMA one shot mode/ DMA circular mode when MDMA mode is selected
When MDMA mode is selected (10 or 11), bit DMACFG of the ADCx_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section Section : Managing conversions using the DMA (bits DMACFG of master and slave ADC_CFGR are not relevant).

Stopping the conversions in dual ADC modes
The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

21.4.31 Temperature sensor
The temperature sensor can be used to measure the junction temperature (Tj) of the device. The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value. When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

Figure 153 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).
The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

*Figure 153* shows the block diagram of the temperature sensor.

**Figure 153. Temperature sensor channel block diagram**

---

**Reading the temperature**

To use the sensor:
1. Select the ADC input channels that is connected to $V_{TS}$.
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the VSENSESEL bit in the ADCx_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting $V_{TS}$ data in the ADC data register.
6. Calculate the actual temperature using the following formula:

\[
\text{Temperature (in °C)} = \frac{(TS\_CAL2 \_ TEMP - TS\_CAL1 \_ TEMP)}{TS\_CAL2 - TS\_CAL1} \times (TS\_DATA - TS\_CAL1) + TS\_CAL1 \_ TEMP
\]
Where:
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output $V_{TS}$ at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and VSENSESEL bits should be set at the same time.

The above formula is given for TS_DATA measurement done with the same $V_{REF+}$ voltage as TS_CAL1/TS_CAL2 values. If $V_{REF+}$ is different, the formula must be adapted. For example if $V_{REF+} = 3.3$ V and TS_CAL data are acquired at $V_{REF+} = 3.0$ V, TS_DATA must be replaced by $TS_{DATA} \times (3.3/3.0)$.

### 21.4.32 V\(_{BAT}\) supply monitoring

The VBATSEL bit in the ADCx_CCR register is used to switch to the battery voltage. As the $V_{BAT}$ voltage could be higher than $V_{DDA}$, to ensure the correct operation of the ADC, the VBAT pin is internally connected to a bridge divider by 3. This bridge is automatically enabled when VBATSEL is set, to connect $V_{BAT}/3$ to the ADC input channels. As a consequence, the converted digital value is one third of the $V_{BAT}$ voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/3$ voltage.

The figure below shows the block diagram of the $V_{BAT}$ sensing feature.

**Figure 154. V\(_{BAT}\) channel block diagram**

![Block Diagram](MSv46151V1)

1. The VBATSEL bit must be set to enable the conversion of internal channel for $V_{BAT}/3$. 

---

**ST**

RM0440 Rev 8 673/2138
21.4.33 Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference \(V_{\text{REFINT}}\) to have a reference point for evaluating the ADC \(V_{\text{REF+}}\) voltage level.

The internal reference voltage \(V_{\text{REFINT}}\) is internally connected to ADC1\_INP18, ADC3\_INP18, ADC4\_INP18 and ADC5\_INP18.

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage. Figure 155 shows the block diagram of the \(V_{\text{REFINT}}\) sensing feature.

**Figure 155. \(V_{\text{REFINT}}\) channel block diagram**

1. The VREFEN bit into ADCx\_CCR register must be set to enable the conversion of internal channels \(V_{\text{REFINT}}\).

**Calculating the actual \(V_{\text{REF+}}\) voltage using the internal reference voltage**

The power supply voltage applied to the device may be subject to variations or not precisely known. When \(V_{\text{DDA}}\) is connected to \(V_{\text{REF+}}\), it is possible to compute the actual \(V_{\text{DDA}}\) voltage using the embedded internal reference voltage \(V_{\text{REFINT}}\). \(V_{\text{REFINT}}\) and its calibration data, acquired by the ADC during the manufacturing process at \(V_{\text{DDA}\_\text{Charac}}\), can be used to evaluate the actual \(V_{\text{DDA}}\) voltage level.

The following formula gives the actual \(V_{\text{REF+}}\) voltage supplying the device:

\[
V_{\text{REF+}} = V_{\text{REF+_Charac}} \times \frac{V_{\text{REFINT\_CAL}}}{V_{\text{REFINT\_DATA}}}
\]

Where:
- \(V_{\text{REF+_Charac}}\) is the value of \(V_{\text{REF+}}\) voltage characterized at \(V_{\text{REFINT}}\) during the manufacturing process. It is specified in the device datasheet.
- \(V_{\text{REFINT\_CAL}}\) is the \(V_{\text{REFINT}}\) calibration value
- \(V_{\text{REFINT\_DATA}}\) is the actual \(V_{\text{REFINT}}\) output value converted by ADC

**Converting a supply-relative ADC measurement to an absolute voltage value**

The ADC is designed to deliver a digital value corresponding to the ratio between \(V_{\text{REF+}}\) and the voltage applied on the converted channel.

For most applications \(V_{\text{DDA}}\) value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from \(V_{\text{DDA}}\):
V_{\text{CHANNEL}x} = \frac{V_{\text{REF}+}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}

By replacing $V_{\text{REF}+}$ by the formula provided above, the absolute voltage value is given by the following formula:

$$V_{\text{CHANNEL}x} = \frac{V_{\text{REF}+\_Charac} \times V_{\text{REFINT\_CAL}} \times \text{ADC\_DATA}}{V_{\text{REFINT\_DATA}} \times \text{FULL\_SCALE}}$$

For applications where $V_{\text{REF}+}$ is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{\text{CHANNEL}x} = \frac{V_{\text{REF}+}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}$$

Where:
- $V_{\text{REF}+\_Charac}$ is the value of $V_{\text{REF}+}$ voltage characterized at $V_{\text{REFINT}}$ during the manufacturing process.
- $V_{\text{REFINT\_CAL}}$ is the $V_{\text{REFINT}}$ calibration value
- $\text{ADC\_DATA}$ is the value measured by the ADC on channel $x$ (right-aligned)
- $V_{\text{REFINT\_DATA}}$ is the actual $V_{\text{REFINT}}$ output value converted by the ADC
- $\text{FULL\_SCALE}$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it is $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

### 21.5 ADC in low-power mode

21.6 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

21.7 ADC registers (for each ADC)

Refer to Section 1.2 on page 73 for a list of abbreviations used in register descriptions.

21.7.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00
Reset value: 0x0000 0000

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 JQOVF: Injected context queue overflow
This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 21.4.21: Queue of context for injected conversions for more information.
0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
1: Injected context queue overflow has occurred

Bit 9 AWD3: Analog watchdog 3 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.
0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 3 event occurred

Bit 8 AWD2: Analog watchdog 2 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.
0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 2 event occurred

Bit 7 AWD1: Analog watchdog 1 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.
0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 1 event occurred

Bit 6 JEOS: Injected channel end of sequence flag
This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Injected conversions complete
Bit 5  **JEOC**: Injected channel end of conversion flag
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.
- 0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Injected channel conversion complete

Bit 4  **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
- 0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
- 1: Overrun has occurred

Bit 3  **EOS**: End of regular sequence flag
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
- 0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular Conversions sequence complete

Bit 2  **EOC**: End of conversion flag
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
- 0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular channel conversion complete

Bit 1  **EOSMP**: End of sampling flag
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
- 0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
- 1: End of sampling phase reached

Bit 0  **ADRDY**: ADC ready
This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
- 0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
- 1: ADC is ready to start conversion

Bit 5  **JEOCIE**: End of injected conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 4  **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE**: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled.
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 0  **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled.
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
21.7.3 ADC control register (ADC_CR)

Address offset: 0x08
Reset value: 0x2000 0000

Bit 31 ADCAL: ADC calibration
This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.
It is cleared by hardware after calibration is complete.
0: Calibration complete
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.
Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.
The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing)

Bit 30 ADCALDIF: Differential mode for calibration
This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.
0: Writing ADCAL launches a calibration in single-ended inputs mode.
1: Writing ADCAL launches a calibration in differential inputs mode.
Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 29 DEEPPWD: Deep-power-down enable
This bit is set and cleared by software to put the ADC in Deep-power-down mode.
0: ADC not in Deep-power down
1: ADC in Deep-power-down (default reset state)
Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 28 ADVREGEN: ADC voltage regulator enable
This bits is set by software to enable the ADC voltage regulator.
Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.
0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.
For more details about the ADC voltage regulator enable and disable sequences, refer to Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).
The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
Bits 27:6  Reserved, must be kept at reset value.

Bit 5  **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configure. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note:* The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4  **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configure. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note:* The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.

Bit 3  **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

*Note:* The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in single conversion mode when software trigger is selected (EXTSEL = 0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)*

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note: The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)*
21.7.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C
Reset value: 0x8000 0000

**Bit 31 JQDIS:** Injected Queue disable
These bits are set and cleared by software to disable the Injected Queue mechanism:
0: Injected Queue enabled
1: Injected Queue disabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

**Bits 30:26 AWD1CH[4:0]:** Analog watchdog 1 channel selection
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel 0 monitored by AWD1 (available on ADC1 only)
00001: ADC analog input channel 1 monitored by AWD1
......
10010: ADC analog input channel 18 monitored by AWD1
others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.
The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

**Bit 25 JAUTO:** Automatic injected group conversion
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.
Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels.
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21 **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to **Section 21.4.21: Queue of context for injected conversions** for more information.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

*When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.*

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

*It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

*When dual mode is enabled (bits DUAL of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.*
Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count
- These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
  - 000: 1 channel
  - 001: 2 channels
  - ...
  - 111: 8 channels

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels
- This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.
  - 0: Discontinuous mode for regular channels disabled
  - 1: Discontinuous mode for regular channels enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 **ALIGN**: Data alignment
- This bit is set and cleared by software to select right or left alignment. Refer to Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN).
  - 0: Right alignment
  - 1: Left alignment

*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **AUTDLY**: Delayed conversion mode
- This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.
  - 0: Auto-delayed conversion mode off
  - 1: Auto-delayed conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.
Bit 13  **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode
1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12  **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

*Note:* The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10  **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5  **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: Event 0
00001: Event 1
00010: Event 2
00011: Event 3
00100: Event 4
00101: Event 5
00110: Event 6
00111: Event 7
... 11111: Event 31

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 4:3  **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
21.7.5 ADC configuration register 2 (ADC_CFG2)

Address offset: 0x10
Reset value: 0x0000 0000

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMACFG**: Direct memory access configuration
- This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
  - 0: DMA One Shot mode selected
  - 1: DMA Circular mode selected
- For more details, refer to Section : Managing conversions using the DMA
- Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
- In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADCx_CCR register.

Bit 0 **DMAEN**: Direct memory access enable
- This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to Section : Managing conversions using the DMA.
  - 0: DMA disabled
  - 1: DMA enabled
- Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
- In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADCx_CCR register.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **SMPTRIG**: Sampling time control trigger mode
- This bit is set and cleared by software to enable the sampling time control trigger mode.
  - 0: Sampling time control trigger mode disabled
  - 1: Sampling time control trigger mode enabled
- The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.
- **EXTEN[1:0]** bits should be set to 01. BULB bit must not be set when the SMPTRIG bit is set.
- When **EXTEN[1:0]** bits are set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.
  
  *Note:* The software is allowed to write this bit only when **ADSTART** = 0 (which ensures that no conversion is ongoing).

Bit 26  **BULB**: Bulb sampling mode
- This bit is set and cleared by software to enable the bulb sampling mode.
  - 0: Bulb sampling mode disabled
  - 1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.
- **SAMPTRIG** bit must not be set when the BULB bit is set.
- The very first ADC conversion is performed with the sampling time specified in SMPx bits.
  
  *Note:* The software is allowed to write this bit only when **ADSTART** = 0 (which ensures that no conversion is ongoing).

Bit 25  **SWTRIG**: Software trigger bit for sampling time control trigger mode
- This bit is set and cleared by software to enable the bulb sampling mode.
  - 0: Software trigger starts the conversion for sampling time control trigger mode
  - 1: Software trigger starts the sampling for sampling time control trigger mode
  
  *Note:* The software is allowed to write this bit only when **ADSTART** = 0 (which ensures that no conversion is ongoing).

Bits 24:17  Reserved, must be kept at reset value.

Bit 16  **GCOMP**: Gain compensation mode
- This bit is set and cleared by software to enable the gain compensation mode.
  - 0: Regular ADC operating mode
  - 1: Gain compensation enabled and applied on all channels
  
  *Note:* The software is allowed to write this bit only when **ADSTART** = 0 (which ensures that no conversion is ongoing).

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **ROVSM**: Regular Oversampling mode
- This bit is set and cleared by software to select the regular oversampling mode.
  - 0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
  - 1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)
  
  *Note:* The software is allowed to write this bit only when **ADSTART** = 0 (which ensures that no conversion is ongoing).
Bit 9  **TROVS**: Triggered Regular Oversampling
- This bit is set and cleared by software to enable triggered oversampling
  - 0: All oversampled conversions for a channel are done consecutively following a trigger
  - 1: Each oversampled conversion for a channel needs a new trigger

  *Note:* The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5  **OVSS[3:0]**: Oversampling shift
- This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
  - 0000: No shift
  - 0001: Shift 1-bit
  - 0010: Shift 2-bits
  - 0011: Shift 3-bits
  - 0100: Shift 4-bits
  - 0101: Shift 5-bits
  - 0110: Shift 6-bits
  - 0111: Shift 7-bits
  - 1000: Shift 8-bits
  - Other codes reserved

  *Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2  **OVSR[2:0]**: Oversampling ratio
- This bitfield is set and cleared by software to define the oversampling ratio.
  - 000: 2x
  - 001: 4x
  - 010: 8x
  - 011: 16x
  - 100: 32x
  - 101: 64x
  - 110: 128x
  - 111: 256x

  *Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 1  **JOVSE**: Injected Oversampling Enable
- This bit is set and cleared by software to enable injected oversampling.
  - 0: Injected Oversampling disabled
  - 1: Injected Oversampling enabled

  *Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0  **ROVSE**: Regular Oversampling Enable
- This bit is set and cleared by software to enable regular oversampling.
  - 0: Regular Oversampling disabled
  - 1: Regular Oversampling enabled

  *Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)
### 21.7.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16  **HT1[11:0]**: Analog watchdog 1 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 1.
Refer to Section 21.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx).

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **AWDFILT**: Analog watchdog filtering parameter
This bit is set and cleared by software.
000: No filtering
001: two consecutive detection generates an AWDx flag or an interrupt
...
111: Eight consecutive detection generates an AWDx flag or an interrupt

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 11:0 **LT1[11:0]**: Analog watchdog 1 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 1.
Refer to Section 21.4.28: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** fourth conversion in regular sequence  
These bits are written by software with the channel number (0 to 18) assigned as the fourth in the regular conversion sequence.

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 23 Reserved, must be kept at reset value.
Bits 22:18 SQ3[4:0]: third conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the third in
the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 SQ2[4:0]: second conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the second
in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 SQ1[4:0]: first conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the first in
the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 L[3:0]: Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular
channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures
that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

</tr>
</tbody>
</table>
Bits 31:27  **JSQ4[4:0]**: fourth conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the fourth in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing), unless the context queue is enabled (JQDIS = 0 in the ADC_CFGR register).

Bit 26  Reserved, must be kept at reset value.

Bits 25:21  **JSQ3[4:0]**: third conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the third in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing), unless the context queue is enabled (JQDIS = 0 in the ADC_CFGR register).

Bit 20  Reserved, must be kept at reset value.

Bits 19:15  **JSQ2[4:0]**: second conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the second in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing), unless the context queue is enabled (JQDIS = 0 in the ADC_CFGR register).

Bit 14  Reserved, must be kept at reset value.

Bits 13:9  **JSQ1[4:0]**: first conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the first in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing), unless the context queue is enabled (JQDIS = 0 in the ADC_CFGR register).

Bits 8:7  **JEXTEN[1:0]**: External Trigger Enable and Polarity Selection for injected channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS = 0 (queue enabled), Hardware and software trigger detection disabled
00: If JQDIS = 1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

If JQM = 1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 21.4.21: Queue of context for injected conversions)
21.7.17 ADC offset y register (ADC_OFRy)

</tr>
</tbody>
</table>

Bit 31 **OFFSET_EN**: Offset y enable

This bit is written by software to enable or disable the offset programmed into bits OFFSETy[11:0].

Note: *The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
Bits 30:26 **OFFSET_CH[4:0]**: Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[11:0] applies.

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the data offset y.

Bit 25 **SATEN**: Saturation enable

This bit is set and cleared by software to enable the saturation at 0x000 and 0xFFF for the offset function.

0: No saturation control, offset result can be signed
1: Saturation enabled, offset result unsigned and saturated at 0x000 and 0xFFF

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **OFFSETPOS**: Positive offset

This bit is set and cleared by software to enable the positive offset.

0: Negative offset
1: Positive offset

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **OFFSET[11:0]**: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[11:0] which is subtracted when converting channel 4.

### 21.7.18 ADC injected channel y data register (ADC_JDRy)

</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 DIFSEL[18:0]: Differential mode for channels 18 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel i is configured in single ended mode
DIFSEL[i] = 1: ADC analog input channel i is configured in differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0

| Bits 31:14: Reserved, must be kept at reset value. |
| Bits 13:0 GCOMPCOEFF[13:0]: Gain compensation coefficient |
| These bits are set and cleared by software to program the gain compensation coefficient. |
| 00 0000 0000 0000: gain factor of 0.5 |
| 01 0000 0000 0000: gain factor of 1 |
| 10 0000 0000 0000: gain factor of 2 |
| 11 0000 0000 0000: gain factor of 3 |
| The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.999756. |

Note: This gain compensation is only applied when GCOMP bit of ADC_CFG2 register is 1.
21.8 **ADC common registers**

These registers define the control and status registers common to master and slave ADCs:

21.8.1 **ADCx common status register (ADCx_CSR) (x = 12 or 345)**

Address offset: 0x300
Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

One interface controls ADC1 and ADC2, while the other interface controls ADC3, ADC4 and ADC5.

Bit 24 **VBATSEL**: VBAT selection
This bit is set and cleared by software to control VBAT.
0: VBAT channel disabled.
1: VBAT channel enabled

Bit 23 **VSENSESEL**: VTS selection
This bit is set and cleared by software to control VTS.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled

Bit 22 **VREFEN**: VREFINT enable
This bit is set and cleared by software to enable/disable the VREFINT channel.
0: VREFINT channel disabled
1: VREFINT channel enabled

Bits 21:18 **PRESC[3:0]**: ADC prescaler
These bits are set and cleared by software to select the frequency of the clock to the ADC.
The clock is common for all the ADCs.
0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
other: reserved

*Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0). The ADC prescaler value is applied only when CKMODE[1:0] = 00.*

Bits 17:16 **CKMODE[1:0]**: ADC clock mode
These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):
00: adc_ker_ck (x = 123) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
01: adc_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set (HPRE[3:0] = 0xxx in RCC_CFGR register) and if the system clock has a 50% duty cycle.
10: adc_hclk/2 (Synchronous clock mode)
11: adc_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*
Bits 15:14 MDMA[1:0]: Direct memory access mode for dual ADC mode

This bitfield is set and cleared by software. Refer to the DMA controller section for more details.
00: MDMA mode disabled
01: Reserved
10: MDMA mode enabled for 12 and 10-bit resolution
11: MDMA mode enabled for 8 and 6-bit resolution

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 13 DMACFG: DMA configuration (for dual ADC mode)

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
0: DMA One Shot mode selected
1: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 DELAY: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 176 for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DUAL[4:0]: Dual ADC mode selection

These bits are written by software to select the operating mode.
All the ADCs independent:
00000: Independent mode

00001 to 01001: Dual mode, master and slave ADCs working together
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined Interleaved mode + injected simultaneous mode
00100: Reserved
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
All other combinations are reserved and must not be programmed

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

21.8.3 ADCx common regular data register for dual mode (ADCx_CDR)  
(x = 12 or 345)

Address offset: 0x30C  
Reset value: 0x0000 0000

One interface controls ADC1 and ADC2, while the other interface controls ADC3, ADC4 and ADC5.

| Bits 31:16 | RDATA_SLV[15:0]| Regular data of the slave ADC  
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 21.4.30: Dual ADC modes.  
The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN))

| Bits 15:0 | RDATA_MST[15:0]| Regular data of the master ADC.  
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 21.4.30: Dual ADC modes.  
The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN))

In MDMA = 11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

21.9 ADC register map

The following table summarizes the ADC registers.

| Table 177. ADC global register map |
| Offset                  | Register                        |
| 0x000 - 0x0FC           | Master ADC1/ADC3                |
| 0x100 - 0x1FC           | Slave ADC2/ADC4                 |
| 0x200 - 0x2FC           | Reserved/single ADC5            |
| 0x300 - 0x30C           | Master and slave ADCs common registers |

Refer to Section 2.2 on page 81 for the register boundary addresses.
22 Digital-to-analog converter (DAC)

22.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features up to two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer (VREFBUF) section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

22.2 DAC main features

The DAC main features are the following (see Figure 156: Dual-channel DAC block diagram)

- Up to four DAC interfaces, maximum two output channels each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Sawtooth wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from VREF+ pin or internal VREFBUF reference

Figure 156 shows the block diagram of a DAC channel and Table 181 gives the pin description.
## 22.3 DAC implementation

22.4 DAC functional description

22.4.1 DAC block diagram

Figure 156. Dual-channel DAC block diagram
1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.
2. Refer to Section 22.3: DAC implementation for channel2 availability.
3. DAC channel2 is available only on DAC1, DAC3 and DAC4.

### 22.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

</table>
22.4.3 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time. DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

22.4.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:
  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

![Figure 157. Data registers in single DAC channel mode](image-url)
Dual DAC channels (when available)

There are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
- 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
- 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12LDx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.

22.4.5 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time \( t_{SETTLING} \) that depends on the power supply voltage and the analog output load.

HFSEL bits of DAC_MCR must be set when dac_hclk clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table HFSEL description below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

The above timing is only related to the limitation of the DAC interface. Refer also to the \( t_{SETTLING} \) parameter value in the product datasheet.

1. Refer to the device datasheet for the value of the maximum AHB frequency.
22.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and $V_{REF+}$. The analog output voltages on each DAC channel pin are determined by the following equation:

$$DAC_{output} = V_{REF} \times \frac{DOR}{4096}$$

22.4.7 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 22.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

The reset trigger selection and the increment trigger selection of the sawtooth generation are performed through STRSTTRIGSELx and STINCTRIGSELx control bits, respectively. STRSTTRIGSELx mapping is similar to TSELx. Refer to the Section 22.4.2: DAC pins and internal signals for TSELx, STRSTTRIGSELx, and STINCTRIGSELx mappings.

Note: 

TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.
22.4.8 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

DMA Double data mode

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.

2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.
The following conditions must be met to change from Double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

### 22.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.

![Figure 160. DAC LFSR register calculation algorithm](image)

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

![Figure 161. DAC conversion (SW trigger enabled) with LFSR wave generation](image)
Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

22.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 162. DAC triangle wave generation

Figure 163. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
22.4.11 DAC sawtooth wave generation

The DAC can generate a sawtooth waveform. Specific register settings for the initial value, increment value and direction control are required:

- DAC sawtooth wave generation is selected by setting WAVEx[1:0] to 11 in the DAC_CR register.
- The sawtooth counter initial value (reset value) is configured through STRSTDATAx[11:0] bits in the DAC_STRx register.
- The increment value is defined by the STINCDATAx[15:0] bits in the DAC_STRx register.
- The sawtooth direction is defined by STDIRx bit in the DAC_STRx register.

The sawtooth counter starts from STRSTDATAx[11:0] (bits 12 to 15 are set to 0000), each increment trigger then increments (or decrements) STINCDATAx[15:0] value.

The DAC output is used from 12 MSB of those counter value. When the counter reaches 0x0000 or 0xFFFF, the value is saturated. The sawtooth reset trigger signal initializes the counter value to the STRSTDATAx[11:0] (bits 12 to 15 are set to 0000) value.

The increment trigger and reset trigger must be selected through the STINCTRIGSELx[3:0] and the STRSTTRIGSELx[3:0] bits.

Figure 164. DAC sawtooth wave generation (STDIRx = 0)

![Figure 164. DAC sawtooth wave generation (STDIRx = 0)](image1)

Figure 165. DAC sawtooth wave generation (STDIRx = 1)

![Figure 165. DAC sawtooth wave generation (STDIRx = 1)](image2)
The STRSTTRIG signal has higher priority than STINCTRIG. The trigger signal cannot be faster than the DAC_DORx update rate defined in Table HFSEL description. If STINCTRIG is asserted faster than the allowed data update rate, the STINCTRIG trigger is ignored. If the STRSTTRIG signal is applied after the STINCTRIG and before DAC_DORx update rate constraints, STRSTTRIG is put on hold. Then, immediately after the data increment, the reset trigger is applied.

**Figure 166. DAC sawtooth STINCTRIG and STRSTTRIG priority (STDIR = 0)**

### 22.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

**Normal mode**

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODE[x][2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODE[x][2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals
Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation.

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register.

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register.

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
- 62 cycles are required for hold phase: THOLDx[9:0] = 62,
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 189. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>( t_SAMP) (^{(1)(2)})</th>
<th>( t_REFRESH) (^{(2)(3)})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>( 7 \mu s + (10R_BON_C_SH) )</td>
<td>( 7 \mu s + (R_BON_C_SH)\ln(2^{N_LSB}) )</td>
</tr>
<tr>
<td>Disable</td>
<td>( 3 \mu s + (10R_BOFF_C_SH) )</td>
<td>( 3 \mu s + (R_BOFF_C_SH)\ln(2^{N_LSB}) )</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with \( \frac{1}{2} \) LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. \( C\_SH \) is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with \( \frac{1}{2} \) LSB error accuracy requires \( \ln(2^{N\_LSB}) \) constant time of the DAC.
Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

- $C_{SH} = 100 \text{ nF}$
- $V_{DDA} = 3.0 \text{ V}$

**Sampling phase:**

$$t_{SAMP} = 7 \mu s + (10 \times 2000 \times 100 \times 10^{-9}) = 2.007 \text{ ms}$$

(where $R_{BON} = 2 \text{ k}\Omega$)

**Refresh phase:**

$$t_{REFRESH} = 7 \mu s + (2000 \times 100 \times 10^{-9}) \times \ln(2\times10) = 606.1 \mu s$$

(where $N_{LSB} = 10$ (10 LSB drop during the hold phase))

**Hold phase:**

$$D_v = \frac{i_{\text{leak}} \times t_{\text{hold}}}{C_{SH}} = 0.0073 \text{ V}$$

(10 LSB of 12bit at 3 V)

- $i_{\text{leak}} = 150 \text{ nA}$ (worst case on the IO leakage on all the temperature range)
- $t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \text{ ms}$

*Figure 167. DAC Sample and hold mode phase diagram*

Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals
To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{L_{int}} holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Note: The sawtooth wave generation is not supported in Sample and hold mode operation.

### 22.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[
V_{out} = \left(\frac{D}{2^N}\times G \times V_{ref}\right) + V_{OS}
\]

Where \( V_{OUT} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{ref} \) is the nominal full-scale voltage, and \( V_{os} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{os} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{os} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). If applied in other modes when the buffer is off, it has no effect. During the calibration:
- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to VREF+/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_\_FLAGx bit).
Two calibration techniques are provided:

- Factory trimming (default setting)
  
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming
  
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when VDDA voltage, temperature, VREF+ values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when VDD is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   
   b) Wait for tTRIM delay.
   
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

Note: A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.
22.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).
When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.
When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is
transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Independent trigger with single sawtooth generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure different trigger sources by setting different values in STRSTTRIGSEL1[3:0], STRSTTRIGSEL2[3:0], STINCTRIGSEL2[3:0] and STINCTRIGSEL1[3:0] bits.
2. Configure the two DAC channel WAVEx[1:0] bits to 11 and set the same STRSTDATAx[11:0], STINCDATAx[15:0] and STDIRx values for each register.

When a DAC channel1 trigger arrives, the DAC channel1 sawtooth counter updates the DHR1 register and transfers it into DAC_DOR1 (three AHB clock cycles later).

When a DAC channel2 trigger arrives, the DAC channel2 sawtooth counter updates the DHR1 register and transfers it into DAC_DOR1 (three AHB clock cycles later).

**Independent trigger with different sawtooth wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure different trigger sources by setting different values in the STRSTTRIGSEL1[23:0], STRSTTRIGSEL2[23:0], STINCTRIGSEL2[3:0] and STINCTRIGSEL1[3:0] bits.
2. Configure the two DAC channel WAVEx[1:0] bits as 11 and set different STRSTDATAx[11:0], STINCDATAx[15:0] and STDIRx value for each register.

When a DAC channel1 trigger arrives, the DAC channel1 sawtooth counter updates the DHR1 register and loads it into DAC_DOR1 (three AHB clock cycles later).

When a DAC channel2 trigger arrives, the DAC channel2 sawtooth counter updates the DHR2 register and loads it into DAC_DOR1 (three AHB clock cycles later).

**Simultaneous software start**

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

**Simultaneous trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.
At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

**Simultaneous trigger with single sawtooth wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure the same trigger source for both DAC channels by setting the same value in STRSTTRIGSEL1[3:0], STRSTTRIGSEL2[3:0], STINCTRIGSEL2[3:0] and STINCTRIGSEL1[3:0] bits.
2. Configure the two DAC channel WAVEx[1:0] bits to 11 and set the same STRSTDATAx[11:0], STINCDATAx[15:0] and STDIRx value for each register.

When a trigger arrives, the DAC channel1/2 sawtooth counter updates DHR1 and DHR2 registers and loads them into DAC_DOR1/2 (three AHB clock cycles later).

**Simultaneous trigger with different sawtooth wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure the same trigger source for both DAC channels by setting the same value in STRSTTRIGSEL1[3:0], STRSTTRIGSEL2[3:0], STINCTRIGSEL2[3:0] and STINCTRIGSEL1[3:0] bits.
2. Configure the two DAC channel WAVEx[1:0] bits to 11 and set different STRSTDATAx[11:0], STINCDATAx[15:0], STDIRx values for each register.

When a trigger arrives, DAC channel1/2 sawtooth counter updates the DHR1 and DHR2 registers and loads them independently into DAC_DOR1/2 (three AHB clock cycles later).

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
- 0000: Unmask bit 0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable
These bits are set/reset by software.
- 00: wave generation disabled
- 01: Noise wave generation enabled
- 10: Triangle wave generation enabled
- 11: Sawtooth wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection
These bits select the external event used to trigger DAC channel2
- 0000: SWTRIG2
- 0001: dac_ch2_trg1
- 0010: dac_ch2_trg2
- ...
- 1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable
This bit is set and cleared by software to enable/disable DAC channel2 trigger
- 0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
- 1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.
These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bit 16 **EN2**: DAC channel2 enable
This bit is set and cleared by software to enable/disable DAC channel2.
0: DAC channel2 disabled
1: DAC channel2 enabled

*Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel1 in Normal operating mode
1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
0: DAC channel1 DMA Underrun Interrupt disabled
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
10: Triangle wave generation enabled
11: Sawtooth wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2 **TSEL[3:0]:** DAC channel1 trigger selection
   These bits select the external event used to trigger DAC channel1
   0000: SWTRIG1
   0001: dac_ch1_trg1
   0010: dac_ch1_trg2
   ...
   1111: dac_ch1_trg15
   Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.
   **Note:** Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1:** DAC channel1 trigger enable
   This bit is set and cleared by software to enable/disable DAC channel1 trigger.
   0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
   1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register
   **Note:** When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_hclk clock cycle.

Bit 0 **EN1:** DAC channel1 enable
   This bit is set and cleared by software to enable/disable DAC channel1.
   0: DAC channel1 disabled
   1: DAC channel1 enabled

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SWTRIGB2:** DAC channel2 software trigger B
   This bit is set by software to trigger the DAC in software trigger mode (sawtooth generation)
   It is cleared by hardware.
   0: No trigger
   1: Trigger for sawtooth increment
   **Note:** This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 16 **SWTRIGB1:** DAC channel1 software trigger B
   This bit is set by software to trigger the DAC in software trigger mode (sawtooth generation)
   It is cleared by hardware.
   0: No trigger
   1: Trigger for sawtooth increment
Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note*: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register. This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note*: This bit is cleared by hardware (one dac_hclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

### 22.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08
Reset value: 0x0000 0000

Bit 31 **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI/LSE periods of synchronization).

0: There is no write operation of DAC_SHSR2 ongoing; DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing; DAC_SHSR2 cannot be written

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 28 **DORSTAT2**: DAC channel2 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.

0: DOR[11:0] is used actual DAC output
1: DORB[11:0] is used actual DAC output

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 27 **DAC2RDY**: DAC channel2 ready status bit

This bit is set and cleared by hardware.

0: DAC channel2 is not yet ready to accept the trigger nor output data
1: DAC channel2 is ready to accept the trigger or output data

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*
Bits 26:16  Reserved, must be kept at reset value.

Bit 15  **BWST1**: DAC channel1 busy writing sample time flag
This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).
0: There is no write operation of DAC_SHSR1 ongoing; DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing; DAC_SHSR1 cannot be written

Bit 14  **CAL_FLAG1**: DAC channel1 calibration offset status
This bit is set and cleared by hardware
0: calibration trimming value is lower than the offset correction value
1: calibration trimming value is equal or greater than the offset correction value

Bit 13  **DMAUDR1**: DAC channel1 DMA underrun flag
This bit is set by hardware and cleared by software (by writing it to 1).
0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12  **DORSTAT1**: DAC channel1 output register status bit
This bit is set and cleared by hardware. It is applicable only when the DAC operates in Double data mode.
0: DOR[11:0] is used actual DAC output
1: DORB[11:0] is used actual DAC output

Bit 11  **DAC1RDY**: DAC channel1 ready status bit
This bit is set and cleared by hardware.
0: DAC channel1 is not yet ready to accept the trigger nor output data
1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0  Reserved, must be kept at reset value.

</thead>
<tbody>
<tr>
<td>Bits 31:26</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
| Bit 25 | **SINFORMAT2**: Enable signed format for DAC channel2  
This bit is set and cleared by software.  
0: Input data is in unsigned format  
1: Input data is in signed format (2’s complement). The MSB bit represents the sign.  
*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.* |
| Bit 24 | **DMADOUBLE2**: DAC channel2 DMA double data mode  
This bit is set and cleared by software.  
0: DMA Normal mode selected  
1: DMA Double data mode selected  
*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.* |
| Bits 23:19 | Reserved, must be kept at reset value. |
| Bits 18:16 | **MODE2[2:0]**: DAC channel2 mode  
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.  
They can be set and cleared by software to select the DAC channel2 mode:  
– DAC channel2 in Normal mode  
000: DAC channel2 is connected to external pin with Buffer enabled  
001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled  
010: DAC channel2 is connected to external pin with buffer disabled  
011: DAC channel2 is connected to on chip peripherals with Buffer disabled  
– DAC channel2 in Sample and hold mode  
100: DAC channel2 is connected to external pin with Buffer enabled  
101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled  
110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled  
111: DAC channel2 is connected to on chip peripherals with Buffer disabled  
*Note: This register can be modified only when EN2 = 0.  
Refer to Section 22.3: DAC implementation for the availability of DAC channel2.* |
Bits 15:14  **HFSEL[1:0]**: High frequency interface mode selection
- 00: High frequency interface mode disabled
- 01: High frequency interface mode enabled for AHB clock frequency > 80 MHz
- 10: High frequency interface mode enabled for AHB clock frequency > 160 MHz
- 11: Reserved

Bits 13:10  Reserved, must be kept at reset value.

Bit 9  **SINFORMAT1**: Enable signed format for DAC channel1
- This bit is set and cleared by software.
- 0: Input data is in unsigned format
- 1: Input data is in signed format (2’s complement). The MSB bit represents the sign.

Bit 8  **DMADouble1**: DAC channel1 DMA double data mode
- This bit is set and cleared by software.
- 0: DMA Normal mode selected
- 1: DMA Double data mode selected

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  **MODE1[2:0]**: DAC channel1 mode
- These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
- They can be set and cleared by software to select the DAC channel1 mode:
  - DAC channel1 in Normal mode
    - 000: DAC channel1 is connected to external pin with Buffer enabled
    - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
    - 010: DAC channel1 is connected to external pin with Buffer disabled
    - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled
  - DAC channel1 in sample & hold mode
    - 100: DAC channel1 is connected to external pin with Buffer enabled
    - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
    - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
    - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

**Note:** This register can be modified only when EN1 = 0.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 STINCTRIGSEL2[3:0]: DAC channel2 sawtooth increment trigger selection
Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.
0000: SWTRIGB2
0001: dac_inc_ch2_trg1
....
1111: dac_inc_ch2_trg15

*Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 STRSTTRIGSEL2[3:0]: DAC channel2 sawtooth reset trigger selection
Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.
0000: SWTRIGB2
0001: dac_ch2_trg1
....
1111: dac_ch2_trg15
The mapping is the same as for TSEL2[3:0].

*Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bits 15:12 Reserved, must be kept at reset value.
Bits 11:8 **STINCTRIGSEL[3:0]**: DAC channel1 sawtooth increment trigger selection
Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.
0000: SWTRIGB1
0001: dac_inc_ch1_trg1
....
1111: dac_inc_ch1_trg15

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **STRSTTRIGSEL[3:0]**: DAC channel1 sawtooth reset trigger selection
Refer to the trigger selection tables in Section 22.4.2: DAC pins and internal signals for details on trigger configuration and mapping.
0000: SWTRIGB1
0001: dac_ch1_trg1
....
1111: dac_ch1_trg15
The mapping is the same as for TSEL1[3:0].

Refer to Section 2.2 on page 81 for the register boundary addresses.
23 Voltage reference buffer (VREFBUF)

23.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin. When the VREF+ pin is double-bonded with VDDA pin in a package, the voltage reference buffer is not available and must be kept disabled (refer to datasheet for packages pinout description).

23.2 VREFBUF functional description

The internal voltage reference buffer supports three voltages\(^a\), which are configured with VRS bits in the VREFBUF_CSR register:

- \(VRS = 00\): around 2.048 V.
- \(VRS = 01\): around 2.5 V.
- \(VRS = 10\): around 2.90 V.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(- V_{REF+} ) pin pulled-down to (V_{SSA})</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(- V_{REF+} ) pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(- V_{REF+} ) pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(- V_{REF+} ) is enable without output buffer, (V_{REF+}) pin voltage is hold with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(- V_{RR}) detection disabled and (V_{RR}) bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

\(^a\) The minimum \(V_{DDA}\) voltage depends on VRS setting, refer to the product datasheet.
23.3 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

23.4 VREFBUF registers

</tbody>
</table>

Bits 31:6  Reserved, must be kept at reset value.

Bits 5:4  **VRS[1:0]**: Voltage reference scale
These bits select the value generated by the voltage reference buffer.
- 00: Voltage reference set to 2.048 V
- 01: Voltage reference set to 2.5 V
- 10: Voltage reference set to 2.90 V
- 11: Reserved

*Note:* The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3  **VRR**: Voltage reference buffer ready
- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **HIZ**: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to **Table 194: VREF buffer modes** for the mode descriptions depending on ENVR bit configuration.

Bit 0  **ENVR**: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
23.4.2 VREFBUF calibration control register (VREFBUF_CCR)

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 TRIM[5:0]: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset: TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

VRS change: TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

Write in TRIM[5:0]: User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

23.4.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Refer to Section 2.2 for the register boundary addresses.
24 Comparator (COMP)

24.1 COMP introduction

The device embeds up to seven ultra-fast analog comparators.

The comparators can be used for a variety of functions including:
- Wake-up from low-power mode triggered by an analog signal,
- Analog signal conditioning,
- Cycle-by-cycle current control loop when combined with a PWM output from a timer.

24.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - DAC channels
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by a scaler (buffered voltage divider)
- Programmable hysteresis
- Output redirection to I/Os or to timer inputs for triggering break events for fast PWM shutdowns
- Output blanking for immunity to switching noise
- Per-channel interrupt generation with wake-up from Sleep and Stop modes

24.3 COMP functional description

24.3.1 COMP block diagram

The block diagram of one comparator channel front-end is shown in Figure 168: Comparator block diagram.

![Comparator block diagram](image-url)
24.3.2 COMP pins and internal signals

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down of PWM signals, using BKin and BKin2 inputs
- Cycle-by-cycle current control, using OCREF_CLR inputs
- Input capture for timing measures

It is possible to have the comparator output simultaneously redirected internally and externally.

24.3.3 COMP reset and clocks

The COMP clock provided by the clock controller is synchronous with the APB2 clock.

There is no COMP-dedicated clock enable control bit in the RCC controller. Reset and clock enable bits are common for COMP and SYSCFG.

Note: Important: The polarity selection logic and the output redirection to the port works independently of APB clock. This allows the comparator to work even in Stop mode.
24.3.4 COMP LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, it is necessary to insure that the comparator programming cannot be altered in case of spurious register access or program counter corruption.

For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPx LOCK bit can be set. This causes the whole register to become read-only, including the COMPx LOCK bit.

The write protection can only be removed by an MCU reset.

24.3.5 COMP hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions with noisy input signals. It is non-symmetrical and only acting to falling edge of the comparator output. The internal hysteresis function can be disabled so as to set the amount of hysteresis with external components, which can be useful for example when exiting a low-power mode.

![Figure 169. Comparator hysteresis](image)

24.3.6 COMP output blanking

The purpose of the blanking function is to prevent the current regulation from tripping upon short current spikes at the beginning of PWM period (typically the recovery current in power switch anti-parallel diodes). This goes through setting a dead window defined with a timer output compare signal. The blanking source is selected individually per comparator channel by software through BLANKSEL[2:0] bitfield of corresponding COMP_CxCSR register, as shown in Table 198: Blanking sources. The inverted blanking signal is logical AND-ed with the comparator stage output to produce the comparator channel x output. See the example provided in the following figure.

</tr>
<tr>
<td>Standby, Shutdown</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby or Shutdown mode.</td>
</tr>
</tbody>
</table>

24.5 COMP interrupts

The comparator outputs are internally connected to the Extended interrupts and events controller. Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit Sleep and Stop low-power modes.

Refer to Interrupt and events section for more details.

To enable the COMPx interrupt, it is required to follow this sequence:
1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select sensitivity to rising edge, falling edge or to both edges
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines
3. Enable COMPx

Interrupt events are flagged through flags in EXTI_PR1/EXTI_PR2 registers.

24.6 COMP registers

24.6.1 Comparator x control and status register (COMP_CxCSR)

For x = 1 through 7, the COMP_CxCSR register contains all bits and flags related to the comparator x.

Address offset: 4(x-1), where x = 1 to 7

System reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low-power sleep</td>
<td>No effect. COMP interrupts cause the device to exit the Low-power sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby, Shutdown</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby or Shutdown mode.</td>
</tr>
</tbody>
</table>
Bit 31 **LOCK**: COMP_CxCSR register lock
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the comparator x control register COMP_CxCSR[31:0]. When locked, all control bits and flags can be read only but not written. When unlocked, the control bits can also be written by software.
0: Unlock
1: Lock

Bit 30 **VALUE**: Comparator x output status
This read-only flag reflects the level of the comparator x output before the polarity selector and blanking, as indicated in Figure 168.

Bits 29:24 Reserved, must be kept at reset value

Bit 23 **SCALEN**: \(V_{\text{REFINT}}\) scaler enable
This bit controlled by software enables the operation of \(V_{\text{REFINT}}\) scaler at the inverting input of all comparator. To disable the \(V_{\text{REFINT}}\) scaler, SCALEN bits of all COMP_CxCSR registers must be set to Disable state. When the \(V_{\text{REFINT}}\) scaler is disabled, the 1/4 \(V_{\text{REFINT}}\), 1/2 \(V_{\text{REFINT}}\), 3/4 \(V_{\text{REFINT}}\) and \(V_{\text{REFINT}}\) inputs of the multiplexer should not be selected.
0: Disable
1: Enable

Bit 22 **BRGEN**: \(V_{\text{REFINT}}\) scaler resistor bridge enable
This bit controlled by software enables the operation of resistor bridge in the \(V_{\text{REFINT}}\) scaler. To disable the resistor bridge, BRGEN bits of all COMP_CxCSR registers must be set to Disable state. When the resistor bridge is disabled, the 1/4 \(V_{\text{REFINT}}\), 1/2 \(V_{\text{REFINT}}\), and 3/4 \(V_{\text{REFINT}}\) inputs of the input selector receive \(V_{\text{REFINT}}\) voltage.
0: Disable
1: Enable

Bits 21:19 **BLANKSEL[2:0]**: Comparator x blanking signal select
This bitfield controlled by software selects the blanking signal for comparator channel x, as shown in Table 198: Blanking sources.

Bits 18:16 **HYST[2:0]**: Comparator x hysteresis
This bitfield controlled by software selects the hysteresis of the comparator x:
000: No hysteresis
001: 10mV hysteresis
010: 20mV hysteresis
011: 30mV hysteresis
100: 40mV hysteresis
101: 50mV hysteresis
110: 60mV hysteresis
111: 70mV hysteresis

Bit 15 **POL**: Comparator x polarity
This bit controlled by software selects the comparator x output polarity:
0: Non-inverted
1: Inverted

Bits 14:9 Reserved, must be kept at reset value

Bit 8 **INPSEL**: Comparator x signal select for non-inverting input
This bitfield controlled by software selects the signal for the non-inverting input COMPx_INP of the comparator x, as shown in Table 196: COMPx non-inverting input assignment.

Bit 7 Reserved, must be kept at reset value
The following table summarizes the comparator registers.

The comparator registers share SYSCFG peripheral register base addresses.

Refer to *Section 2.2.2: Memory map and register boundary addresses* for the register boundary addresses.
25 Operational amplifiers (OPAMP)

25.1 Introduction

The devices embed six operational amplifiers, each with two inputs and one output. The three I/Os can be connected to the external pins, enabling any type of external interconnection. The operational amplifiers can be configured internally as a follower, as an amplifier with a non-inverting gain ranging from 2 to 64, or with inverting gain ranging from -1 to -63.

The positive input can be connected to the internal DAC.

The output can be connected to the internal ADC.

25.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current
- Low input offset voltage
- High frequency gain bandwidth
- High-speed mode to achieve a better slew rate

*Note:* Refer to the product datasheet for detailed OPAMP characteristics.

25.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

In functional mode the inputs and output of the OPAMP are connected as described in Section 25.3.4.

25.3.1 OPAMP output redirection to internal ADC channels

Operational amplifier output can be redirected internally to an ADC channel by setting OPAINTOEN bit in OPAMPx_CSR register. In this case, the GPIO on which is mapped given OPAMPx_VOUT output is free and can be used for another purpose. ADC can measure OPAMPx_VOUT voltage internally. See Figure 201 for assignment between OPAMPx internal outputs and ADC channels.

25.3.2 OPAMP reset and clocks

The OPAMP clock provided by the clock controller is synchronized with the PCLK2 (APB2 clock). There is no clock enable control bit provided in the RCC controller. To use a clock source for the OPAMP, the SYSCFG clock enable control bit must be set in the RCC controller.
The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations must be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.

25.3.3 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three input/outputs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values for its offset calibration. The trimming values can be adjusted, see Section 25.3.7: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the standard performance. The bit OPAHSM can be set in order to switch the operational amplifier to high-speed mode for a better slew rate. Both normal and high-speed mode characteristics are defined in the datasheet.

As soon as the OPAEN bit in OPAMPx_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 25.3.4: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

25.3.4 Signal routing

The routing for the operational amplifier pins is determined by OPAMPx_CSR and OPAMPx_TCMR registers.

The connections of the six operational amplifiers (OPAMPx, x = 1...6) are described in the table below.

1. This ADC channel is connected internally to the OPAMPx_VOUT when OPINTOEn bit is set. In this case, the I/O on which the OPAMPx_VOUT is available, can be used for another purpose.
2. For category 3 devices only.
3. For category 4 devices only.
4. OPAMP4/5 are supported in category 3 devices only.
5. OPAMP6 is supported only in category 3 and category 4 devices.
25.3.5 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

**Note:** The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

**Standalone mode (external gain setting mode)**

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMPx_CSR, and the default state of GPIOx_MODER, as soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPAHSM can be set to "operational amplifier high-speed" mode in order to have high slew rate.
- USERTRIM can be set to modify the trimming values for input offsets.

---

**Figure 171. Standalone mode: external gain setting mode**

1. opamp_out can be redirected internally to an ADC channel by setting OPAINTOEN bit.
   In this case, the I/O on which is mapped the OPAMPx_VOUT is free and can be used for another purpose. In standalone mode, VOUT pin is disconnected from the OPAMP output and the gain cannot be set by an external resistors (in this case OPAMP can be used only as comparator).
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure VM_SEL bits as “opamp_out connected to OPAMPx_VINM input”, 11
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00
- As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is buffered to pin OPAMPx_VOUT.

Note: The pin corresponding to OPAMPx_VINM is free for another usage.

The signal on the OPAMP output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Figure 172. Follower configuration
Programmable gain amplifier mode

The procedure to use the OPAMP as programmable gain amplifier is presented hereafter.

- configure VM_SEL bits as "Feedback resistor is connected to OPAMPx_VINM input", 10
- configure PGA_GAIN bits as "internal Gain 2, 4, 8, 16, 32, or 64", 00000 to 00101
- configure VP_SEL bits as "GPIO connected to OPAMPx_VINP", 00

As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is amplified by the selected gain and visible on pin OPAMPx_VOUT.

Note: To avoid saturation, the input voltage must stay below $V_{DDA}$ divided by the selected gain.

Figure 173. PGA mode, internal gain setting (x2/x4/x8/x16/x32/x64), inverting input not used

1. opamp_out can be redirected internally to an ADC channel by setting OPAINTOEN bit. In this case, the I/O on which is mapped the OPAMPx_VOUT is free and can be used for another purpose.
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8, 16, 32 or 64 with filtering on VINM0”, 10000 to 10101
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on VINM can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 174. PGA mode, internal gain setting (x2/x4/x8/x16/x32/x64), inverting input used for filtering

1. opamp_out can be redirected internally to an ADC channel by setting OPAINTOEN bit. In this case, the I/O on which is mapped the OPAMPx_VOUT is free and can be used for another purpose.

1. The gain depends on the cut-off frequency.
Programmable gain amplifier, non-inverting with external bias or inverting mode

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “Inverting gain = -1, -3, -7, -15, -31, -63 / Non-inverting gain = 2, 4, 8, 16, 32, 64 with VINM0”, 01000 to 01101
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Figure 175. PGA mode, non-inverting gain setting (x2/x4/x8/x16/x32/x64) or inverting gain setting (x-1/x-3/x-7/x-15/x-31/x-63)

Programmable gain amplifier, non-inverting with external bias or inverting mode with filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode with filtering

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “Inverting gain = -1, -3, -7, -15, -31, -63 / Non-inverting gain = 2, 4, 8, 16, 32, 64 with VINM0, VINM1 pin for filtering”, 11000 to 11101
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on VINM1 can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and VINM1 for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).
25.3.6 **OPAMP PGA gain**

When the OPAMP is configured in PGA mode, the gain can be programmed to x2, x4, x8, x16, x32, x64 in non-inverting configuration and x-1, x-3, x-7, x-15, x-31, x-63 for inverting configuration.

When the OPAMP is configured in non-inverting mode, the gain solely depends on internal resistive divider. When it is configured as inverting mode, Gain factor is defined not only the on-chip feedback resistor but also the signal source output impedance. If signal source output impedance is not negligible compared to the input feedback resistance of PGA, it creates the gain error.
25.3.7 Calibration

The OPAMP offset value is minimized using a trimming circuitry. At startup, the trimming values are initialized with the preset ‘factory’ trimming value. Each operational amplifier can also be trimmed by the user if the OPAMP is used in conditions different from the factory trimming conditions.

Each operational amplifier can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for high-speed mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the input offset voltage to less than +/-3 mV within stable voltage and temperature conditions.

For each operational amplifier and two trimming values (TRIMOFFSETP and TRIMOFFSETN in OPAMPx_CSR register) need to be trimmed, one for N differential pair and one for P differential pair.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMPx_CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP option registers.

The offset trimming TRIMOFFSETP and TRIMOFFSETN bits are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the I/Os.

- Setting CALSEL to 01 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 11 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT reflects the influence of the trimming value selected by CALSEL and OPAHSM. The software must increment the TRIMOFFSETN bits in the OPAMP control register from 0x00 to the first value that causes the CALOUT bit to change from 1 to 0 in the OPAMP register. If the CALOUT bit is reset, the offset is calibrated correctly and the corresponding trimming value must be stored. The CALOUT flag needs up to 2 ms after the trimming value is changed to become steady (see tOFFTRIMmax delay specification in the electrical characteristics section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 2 ms in any case).

Table 202. Operating modes and calibration
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set the OPAEN bit in OPAMPx_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMPx_CSR register to 1.
3. Choose a calibration mode (refer to Table 202: Operating modes and calibration). The steps 3 to 4 have to be repeated four times. For the first iteration select Normal mode and N differential pair. This calibration mode correspond to OPAHSM = 0 and CALSEL = 11 in the OPAMPx_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 0b00000 until CALOUT changes to 0 in OPAMPx_CSR.

Note: Between the write to the TRIMOFFSETP and TRIMOFFSETN bits and the read of the CALOUT value, make sure to wait for the $t_{OFFTRIM}^{max}$ delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the is correctly compensated and that the corresponding trim code must be saved in the TRIMOFFSETP and TRIMOFFSETN bits.

Repeat steps 3 to 4 for:
- Normal mode and P differential pair, CALSEL = 01
- High-speed mode and N differential pair
- High-speed mode and P differential pair

If a mode is not used, it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 µA.

If the OPAMP output is internally connected to an ADC channel and disconnected from the output pin (OPAINTOEN = 1 in the OPAMPx_CSR register), the offset trimming procedure differs from the case where the OPAMP output is connected to the output pin (OPAINTOEN = 0). The calibration procedure is the similar as above but the CALOUT bit change detection cannot be used as indicated in step 4. Instead, the ADC output data must be used as indicator to detect the OPAMP output change: a change of CALOUT from 1 to 0 corresponds to the change of ADC output data from values close to the maximum ADC output to values close to the minimum ADC output (the ADC works as a comparator connected to the OPAMP output). Another solution is to perform the calibration with OPAINTOEN = 0, and then change OPAINTOEN to 1. In this case, the OPAMP output GPIO toggles during the calibration and care must be taken that there is no conflict on this GPIO.

25.3.8 Timer controlled Multiplexer mode

The selection of the OPAMP inverting and non inverting inputs can be done automatically. In this case, the switch from one input to another is done automatically. This automatic switch is triggered by the TIM1 CC6 or TIM8 CC6 or TIM20 CC6 output arriving on the OPAMP input multiplexers.

This is useful for dual motor control with a need to measure the currents on the 3 phases simultaneously on a first motor and then on the second motor.

The automatic switch is enabled by setting the TxCMEN bit, $x = 1,8,20$, in the OPAMP switch control register. The inverting and non inverting inputs selection is performed using
the VPS_SEL and VMS_SEL bit fields in the OPAMP timer controlled mode register. If the TxCMEN bit is cleared, the selection is done using the VP_SEL and VM_SEL bit fields in the OPAMP control/status register.

Bits 10:9 Reserved, must be kept at reset value.
Bit 8 **OPAINTOEN**: Operational amplifier internal output enable.
   - 0: The OPAMP output is connected to the output pin
   - 1: The OPAMP output is connected internally to an ADC channel and disconnected from the output pin

Bit 7 **OPAHSM**: Operational amplifier high-speed mode
   The operational amplifier must be disable to change this configuration.
   - 0: Operational amplifier in normal mode
   - 1: Operational amplifier in high-speed mode

Bits 6:5 **VM_SEL[1:0]**: Inverting input selection
   - 00: VINM0 pin connected to OPAMP VINM input
   - 01: VINM1 pin connected to OPAMP VINM input
   - 10: Feedback resistor is connected to OPAMP VINM input (PGA mode), Inverting input selection depends on the PGA_GAIN setting
   - 11: opamp_out connected to OPAMP VINM input (Follower mode)

Bit 4 **USERTRIM**: User trimming enable
   This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
   This bit is active for both mode normal and high-power.
   - 0: ‘factory’ trim code used
   - 1: ‘user’ trim code used

Bits 3:2 **VP_SEL[1:0]**: Non-inverted input selection
   - 00: VINP0 pin connected to OPAMP1 VINP input
   - 01: VINP1 pin connected to OPAMP1 VINP input
   - 10: VINP2 pin connected to OPAMP1 VINP input
   - 11: DAC3_CH1 connected to OPAMP1 VINP input

Bit 1 **FORCE_VP**: Force internal reference on OPAMP VINP input (reserved for test)
   - 0: Normal operating mode. Non-inverting input connected to inputs.
   - 1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
   - 0: Operational amplifier disabled
   - 1: Operational amplifier enabled

**Bit 31: LOCK**
- This bit is write-once. It is set by software. It can only be cleared by a system reset.

**Bit 30: CALOUT**
- This bit is used to configure the OPAMP2_CSR register as read-only.

**Bits 28:24: TRIMOFFSETN[4:0]**
- Trim for NMOS differential pairs

**Bits 23:19: TRIMOFFSETP[4:0]**
- Trim for PMOS differential pairs
Bits 18:14 **PGA_GAIN[4:0]**: Operational amplifier Programmable amplifier gain value

- **00000**: Non inverting internal gain = 2
- **00001**: Non inverting internal gain = 4
- **00010**: Non inverting internal gain = 8
- **00011**: Non inverting internal gain = 16
- **00100**: Non inverting internal gain = 32
- **00101**: Non inverting internal gain = 64
- **00110**: Not used
- **00111**: Not used
- **01000**: Inverting gain = -1 / non inverting gain = 2 with VINM0 pin for input or bias
- **01001**: Inverting gain = -3 / non inverting gain = 4 with VINM0 pin for input or bias
- **01010**: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias
- **01011**: Inverting gain = -15 / non inverting gain = 16 with VINM0 pin for input or bias
- **01100**: Inverting gain = -31 / non inverting gain = 32 with VINM0 pin for input or bias
- **01101**: Inverting gain = -63 / non inverting gain = 64 with VINM0 pin for input or bias
- **01110**: Not used
- **01111**: Not used
- **10000**: Non inverting gain = 2 with filtering on VINM0 pin
- **10001**: Non inverting gain = 4 with filtering on VINM0 pin
- **10010**: Non inverting gain = 8 with filtering on VINM0 pin
- **10011**: Non inverting gain = 16 with filtering on VINM0 pin
- **10100**: Non inverting gain = 32 with filtering on VINM0 pin
- **10101**: Non inverting gain = 64 with filtering on VINM0 pin
- **10110**: Not used
- **10111**: Not used
- **11000**: Inverting gain = -1 / non inverting gain = 2 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11001**: Inverting gain = -3 / non inverting gain = 4 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11010**: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11011**: Inverting gain = -15 / non inverting gain = 16 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11100**: Inverting gain = -31 / non inverting gain = 32 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11101**: Inverting gain = -63 / non inverting gain = 64 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11110**: Not used
- **11111**: Not used

Bits 13:12 **CALSEL[1:0]**: Calibration selection

It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.

- **00**: 0.033*VDDA applied on OPAMP inputs
- **01**: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
- **10**: 0.5*VDDA applied on OPAMP inputs
- **11**: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON**: Calibration mode enabled

- **0**: Normal mode
- **1**: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.
Bit 8 **OPAINTOEN**: Operational amplifier internal output enable.
0: The OPAMP output is connected to the output pin
1: The OPAMP output is connected internally to an ADC channel and disconnected from the output pin

Bit 7 **OPAHSM**: Operational amplifier high-speed mode
The operational amplifier must be disable to change this configuration.
0: Operational amplifier in normal mode
1: Operational amplifier in high-speed mode

Bits 6:5 **VM_SEL[1:0]**: Inverting input selection
00: VINM0 pin connected to OPAMP VINM input
01: VINM1 pin connected to OPAMP VINM input
10: Feedback resistor is connected to OPAMP VINM input (PGA mode), Inverting input selection is depends on the PGA_GAIN setting
11: opamp_out connected to OPAMP VINM input (Follower mode)

Bit 4 **USERTRIM**: User trimming enable
This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
This bit is active for both mode normal and high-power.
0: ‘factory’ trim code used
1: ‘user’ trim code used

Bits 3:2 **VP_SEL[1:0]**: Non inverted input selection
00: VINP0 pin connected to OPAMP2 VINP input
01: VINP1 pin connected to OPAMP2 VINP input
10: VINP2 pin connected to OPAMP2 VINP input
11: VINP3 pin connected to OPAMP2 VINP input

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
0: Normal operating mode. Non-inverting input connected to inputs.
1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
0: Operational amplifier disabled
1: Operational amplifier enabled
25.5.3 OPAMP3 control/status register (OPAMP3_CSR)

Address offset: 0x08
Reset value: 0x0000 0000

### Bit 31 LOCK: OPAMP3_CSR lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
0: OPAMP3_CSR is read-write
1: OPAMP3_CSR is read-only

### Bit 30 CALOUT: Operational amplifier calibration output
This bit shows the digital value of OPAMP output and is the calibration output status during calibration offset mode (Calibration is successful when CALOUT switches from 1 to 0.)

### Bit 29 Reserved, must be kept at reset value.

### Bits 28:24 TRIMOFFSETN[4:0]: Trim for NMOS differential pairs

### Bits 23:19 TRIMOFFSETP[4:0]: Trim for PMOS differential pairs
At reset these bits are loaded by the factory trimming value. They can be modified only when USER_TRIM =1
Bits 18:14  \textbf{PGA\_GAIN[4:0]}: Operational amplifier Programmable amplifier gain value

- 00000: Non inverting internal gain = 2
- 00001: Non inverting internal gain = 4
- 00010: Non inverting internal gain = 8
- 00011: Non inverting internal gain = 16
- 00100: Non inverting internal gain = 32
- 00101: Non inverting internal gain = 64
- 00110: Not used
- 00111: Not used
- 01000: Inverting gain = -1 / non inverting gain = 2 with VINM0 pin for input or bias
- 01001: Inverting gain = -3 / non inverting gain = 4 with VINM0 pin for input or bias
- 01010: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias
- 01011: Inverting gain = -15/ non inverting gain = 16 VINM0 pin for input or bias
- 01100: Inverting gain = -31/ non inverting gain = 32 VINM0 pin for input or bias
- 01101: Inverting gain = -63/ non inverting gain = 64 VINM0 pin for input or bias
- 01110: Not used
- 01111: Not used
- 10000: Non inverting gain = 2 with filtering on VINM0 pin
- 10001: Non inverting gain = 4 with filtering on VINM0 pin
- 10010: Non inverting gain = 8 with filtering on VINM0 pin
- 10011: Non inverting gain = 16 with filtering on VINM0 pin
- 10100: Non inverting gain = 32 with filtering on VINM0 pin
- 10101: Non inverting gain = 64 with filtering on VINM0 pin
- 10110: Not used
- 10111: Not used
- 11000: Inverting gain = -1 / non inverting gain = 2 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11001: Inverting gain = -3 / non inverting gain = 4 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11010: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11011: Inverting gain = -15/ non inverting gain = 16 VINM0 pin for input or bias, VINM1 pin for filtering
- 11100: Inverting gain = -31/ non inverting gain = 32 VINM0 pin for input or bias, VINM1 pin for filtering
- 11101: Inverting gain = -63/ non inverting gain = 64 VINM0 pin for input or bias, VINM1 pin for filtering
- 11110: Not used
- 11111: Not used

Bits 13:12  \textbf{CALSEL[1:0]}: Calibration selection

It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE\_VP= 1.

- 00: 0.033\*VDDA applied on OPAMP inputs
- 01: 0.1\*VDDA applied on OPAMP inputs (for PMOS calibration)
- 10: 0.5\*VDDA applied on OPAMP inputs
- 11: 0.9\*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11  \textbf{CALON}: Calibration mode enabled

- 0: Normal mode
- 1: Calibration mode (all switches opened by HW)

Bits 10:9  Reserved, must be kept at reset value.
Bit 8  **OPAINTOEN**: Operational amplifier internal output enable.
   0: The OPAMP output is connected to the output pin
   1: The OPAMP output is connected internally to an ADC channel and disconnected from the output pin

Bit 7  **OPAHSM**: Operational amplifier high-speed mode
   The operational amplifier must be disable to change this configuration.
   0: Operational amplifier in normal mode
   1: Operational amplifier in high-speed mode

Bits 6:5  **VM_SEL[1:0]**: Inverting input selection
   00: VINM0 pin connected to OPAMP VINM input
   01: VINM1 pin connected to OPAMP VINM input
   10: Feedback resistor is connected to OPAMP VINM input (PGA mode), Inverting input selection is depends on the PGA_GAIN setting
   11: opamp_out connected to OPAMP VINM input (Follower mode)

Bit 4  **USERTRIM**: User trimming enable
   This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
   0: ‘factory’ trim code used
   1: ‘user’ trim code used

Bits 3:2  **VP_SEL[1:0]**: Non inverted input selection
   00: VINP0 pin connected to OPAMP3 VINP input
   01: VINP1 pin connected to OPAMP3 VINP input
   10: VINP2 pin connected to OPAMP3 VINP input
   11: DAC3_CH2 connected to OPAMP3 VINP input

Bit 1  **FORCE_VP**: Force internal reference on VP (reserved for test)
   0: Normal operating mode. Non-inverting input connected to inputs.
   1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0  **OPAEN**: Operational amplifier Enable
   0: Operational amplifier disabled
   1: Operational amplifier enabled

- 11010: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11011: Inverting gain = -15 / non inverting gain = 16 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11100: Inverting gain = -31 / non inverting gain = 32 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11101: Inverting gain = -63 / non inverting gain = 64 with VINM0 pin for input or bias, VINM1 pin for filtering
- 11110: Not used
- 11111: Not used

Bits 13:12 CALSEL[1:0]: Calibration selection
It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.
- 00: 0.033VDDA applied on OPAMP inputs
- 01: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
- 10: 0.5*VDDA applied on OPAMP inputs
- 11: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 CALON: Calibration mode enabled
- 0: Normal mode
- 1: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.
Bit 8 **OPAINTOEN**: Operational amplifier internal output enable.
- 0: The OPAMP output is connected to the output pin
- 1: The OPAMP output is connected internally to an ADC channel and disconnected from the output pin

Bit 7 **OPAHSM**: Operational amplifier high-speed mode
- The operational amplifier must be disable to change this configuration.
- 0: Operational amplifier in normal mode
- 1: Operational amplifier in high-speed mode

Bits 6:5 **VM_SEL[1:0]**: Inverting input selection
- 00: VINM0 pin connected to OPAMP VINM input
- 01: VINM1 pin connected to OPAMP VINM input
- 10: Feedback resistor is connected to OPAMP VINM input (PGA mode). Inverting input selection is depends on the PGA_GAIN setting
- 11: opamp_out connected to OPAMP VINM input (Follower mode)

Bit 4 **USERTRIM**: User trimming enable
- This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
- This bit is active for both mode normal and high-power.
- 0: ‘factory’ trim code used
- 1: ‘user’ trim code used

Bits 3:2 **VP_SEL[1:0]**: Non inverted input selection
- 00: VINP0 pin connected to OPAMP4 VINP input
- 01: VINP1 pin connected to OPAMP4 VINP input
- 10: VINP2 pin connected to OPAMP4 VINP input
- 11: DAC4_CH1 connected to OPAMP4 VINP input

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
- 0: Normal operating mode. Non-inverting input connected to inputs.
- 1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
- 0: Operational amplifier disabled
- 1: Operational amplifier enabled
### OPAMP5 control/status register (OPAMP5_CSR)

Address offset: 0x10  
Reset value: 0x0000 0000

| Bit 31  | LOCK: OPAMP5_CSR lock | This bit is write-once. It is set by software. It can only be cleared by a system reset. This bit is used to configure the OPAMP5_CSR register as read-only.  
| Bit 30  | CALOUT: Operational amplifier calibration output | This bit shows the digital value of OPAMP output and is the calibration output status during calibration offset mode (Calibration is successful when CALOUT switches from 1 to 0.) |
| Bit 29  | Reserved, must be kept at reset value. |
| Bits 28:24 | TRIMOFFSETN[4:0]: Trim for NMOS differential pairs |
| Bits 23:19 | TRIMOFFSETP[4:0]: Trim for PMOS differential pairs |

At reset these bits are loaded by the factory trimming value. They can be modified only when USER_TRIM = 1

- **11010**: Inverting gain = -7 / non inverting gain = 8 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11011**: Inverting gain = -15 / non inverting gain = 16 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11100**: Inverting gain = -31 / non inverting gain = 32 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11101**: Inverting gain = -63 / non inverting gain = 64 with VINM0 pin for input or bias, VINM1 pin for filtering
- **11110**: Not used
- **11111**: Not used

Bits 13:12 **CALSEL[1:0]**: Calibration selection

It is used to select the offset calibration bus used to generate the internal reference voltage when **CALON** = 1 or **FORCE_VP** = 1.

- **00**: 0.033 VDDA applied on OPAMP inputs
- **01**: 0.1 VDDA applied on OPAMP inputs (for PMOS calibration)
- **10**: 0.5 VDDA applied on OPAMP inputs
- **11**: 0.9 VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON**: Calibration mode enabled

- **0**: Normal mode
- **1**: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.
Bit 8 **OPAINTOEN**: Operational amplifier internal output enable.
0: The OPAMP output is connected to the output pin
1: The OPAMP output is connected internally to an ADC channel and disconnected from the output pin

Bit 7 **OPAHSM**: Operational amplifier high-speed mode
The operational amplifier must be disable to change this configuration.
0: Operational amplifier in normal mode
1: Operational amplifier in high-speed mode

Bits 6:5 **VM_SEL[1:0]**: Inverting input selection
00: VINM0 pin connected to OPAMP VINM input
01: VINM1 pin connected to OPAMP VINM input
10: Feedback resistor is connected to OPAMP VINM input (PGA mode), Inverting input selection is depends on the PGA_GAIN setting
11: opamp_out connected to OPAMP VINM input (Follower mode)

Bit 4 **USERTRIM**: User trimming enable
This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
This bit is active for both mode normal and high-power.
0: ‘factory’ trim code used
1: ‘user’ trim code used

Bits 3:2 **VP_SEL[1:0]**: Non inverted input selection
00: VINP0 pin connected to OPAMP5 VINP input
01: VINP1 pin connected to OPAMP5 VINP input
10: VINP2 pin connected to OPAMP5 VINP input
11: DAC4_CH2 connected to OPAMP5 VINP input

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
0: Normal operating mode. Non-inverting input connected to inputs.
1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
0: Operational amplifier disabled
1: Operational amplifier enabled

Bit 31  **LOCK**: OPAMP1_TCMR lock
- This bit is write-once. It is set by software. It can only be cleared by a system reset.
- This bit is used to configure the OPAMP1_TCMR register as read-only.
  - 0: OPAMP1_TCMR is read-write
  - 1: OPAMP1_TCMR is read-only

Bits 30:6 Reserved, must be kept at reset value.

Bit 5  **T20CM_EN**: TIM20 controlled mux mode enable
- This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non-inverting inputs. This automatic switch is triggered by the TIM20 CC6 output arriving on the OPAMPx input multiplexers.
  - 0: Automatic switch is disabled.
  - 1: Automatic switch is enabled.

Bit 4  **T8CM_EN**: TIM8 controlled mux mode enable
- This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non-inverting inputs. This automatic switch is triggered by the TIM8 CC6 output arriving on the OPAMPx input multiplexers.
  - 0: Automatic switch is disabled.
  - 1: Automatic switch is enabled.
Bit 3  **T1CM_EN**: TIM1 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM1 CC6 output arriving on the OPAMPx input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bits 2:1  **VPS_SEL[1:0]**: OPAMP1 Non inverting input secondary selection.
These bits are set and cleared by software. They are used to select the OPAMPx non inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)
00: VINP0 pin connected to OPAMP1 VINP input
01: VINP1 pin connected to OPAMP1 VINP input
10: VINP2 pin connected to OPAMP1 VINP input
11: DAC3_CH1 connected to OPAMP1 VINP input

Bit 0  **VMS_SEL**: OPAMP1 inverting input secondary selection
This bit is set and cleared by software. It is used to select the OPAMPx inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)
When standalone mode is used (i.e. VM_SEL = "00" or "01"):
0: Input from VINM0
1: Input from VINM1
When PGA (VM_SEL = "10") or Follower mode (VM_SEL = "11") is used:
0: Resistor feedback output selected (PGA mode)
1: $V_{OUT}$ selected as input minus (follower mode)
25.5.8  OPAMP2 timer controlled mode register (OPAMPx_TCMR) (x = 1...6)

Address offset: 0x1C
Reset value: 0x0000 0000

Bit 31  **LOCK**: OPAMP2_TCMR lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit is used to configure the OPAMP2_TCMR register as read-only.
0: OPAMP2_TCMR is read-write
1: OPAMP2_TCMR is read-only

Bits 30:6  Reserved, must be kept at reset value.

Bit 5  **T20CM_EN**: TIM20 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM20 CC6 output arriving on the OPAMP2 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bit 4  **T8CM_EN**: TIM8 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM8 CC6 output arriving on the OPAMP2 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.
Bit 3  **T1CM_EN**: TIM1 controlled mux mode enable

This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM1 CC6 output arriving on the OPAMP2 input multiplexers.

0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bits 2:1  **VPS_SEL[1:0]**: OPAMP2 Non inverting input secondary selection.

These bits are set and cleared by software. They are used to select the OPAMP2 non inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)

00: VINP0 pin connected to OPAMP2 VINP input
01: VINP1 pin connected to OPAMP2 VINP input
10: VINP2 pin connected to OPAMP2 VINP input
11: VINP3 pin connected to OPAMP2 VINP input

Bit 0  **VMS_SEL**: OPAMP2 inverting input secondary selection

This bit is set and cleared by software. It is used to select the OPAMPx inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)

When standalone mode is used (i.e. VM_SEL = “00” or “01”):

0: Input from VINM0
1: Input from VINM1

When PGA (VM_SEL = “10”) or Follower mode (VM_SEL = “11”) is used:

0: Resistor feedback output selected (PGA mode)
1: VOUT selected as input minus (follower mode)
25.5.9 OPAMP3 timer controlled mode register (OPAMPx_TCMR) (x = 1...6)

Bit 31  **LOCK**: OPAMP4_TCMR lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit is used to configure the OPAMP4_TCMR register as read-only.
0: OPAMP4_TCMR is read-write
1: OPAMP4_TCMR is read-only

Bits 30:6  Reserved, must be kept at reset value.

Bit 5  **T20CM_EN**: TIM20 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM20 CC6 output arriving on the OPAMP4 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bit 4  **T8CM_EN**: TIM8 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM8 CC6 output arriving on the OPAMP4 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.
Bit 3  **T1CM_EN**: TIM1 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM1 CC6 output arriving on the OPAMP4 input multiplexers.

0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bits 2:1  **VPS_SEL[1:0]**: OPAMP4 Non inverting input secondary selection.
These bits are set and cleared by software. They are used to select the OPAMP4 non inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)
00: VINP0 pin connected to OPAMP4 VINP input
01: VINP1 pin connected to OPAMP4 VINP input
10: VINP2 pin connected to OPAMP4 VINP input
11: DAC4_CH1 connected to OPAMP4 VINP input

Bit 0  **VMS_SEL**: OPAMP4 inverting input secondary selection
This bit is set and cleared by software. It is used to select the OPAMP4 inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1).
When standalone mode is used (i.e. VM_SEL = “00” or “01”):
0: Input from VINM0
1: Input from VINM1
When PGA (VM_SEL = “10”) or Follower mode (VM_SEL = “11”) is used:
0: Resistor feedback output selected (PGA mode)
1: VOUT selected as input minus (follower mode)
25.5.11 OPAMP5 timer controlled mode register (OPAMPx_TCMR) (x = 1...6)

Bit 31 **LOCK**: OPAMP5_TCMR lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit is used to configure the OPAMP5_TCMR register as read-only.
0: OPAMP5_TCMR is read-write
1: OPAMP5_TCMR is read-only

Bits 30:6 Reserved, must be kept at reset value.

Bit 5 **T20CM_EN**: TIM20 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM20 CC6 output arriving on the OPAMP5 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bit 4 **T8CM_EN**: TIM8 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the TIM8 CC6 output arriving on the OPAMP5 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.
Bit 3  **T1CM_EN**: TIM1 controlled mux mode enable
This bit is set and cleared by software. It is used to control automatically the switch between the
default selection (VP_SEL and VM_SEL) and the secondary selection (VPS_SEL and
VMS_SEL) of the inverting and non inverting inputs. This automatic switch is triggered by the
TIM1 CC6 output arriving on the OPAMP5 input multiplexers.
0: Automatic switch is disabled.
1: Automatic switch is enabled.

Bits 2:1  **VPS_SEL[1:0]**: OPAMP5 Non inverting input secondary selection.
These bits are set and cleared by software. They are used to select the OPAMP5 non
inverting input when the controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or
T20CM_EN = 1)
00: VINP0 pin connected to OPAMP5 VINP input
01: VINP1 pin connected to OPAMP5 VINP input
10: VINP2 pin connected to OPAMP5 VINP input
11: DAC4_CH2 connected to OPAMP5 VINP input

Bit 0  **VMS_SEL**: OPAMP5 inverting input secondary selection
This bit is set and cleared by software. It is used to select the OPAMP5 inverting input when the
controlled mux mode is enabled (T1CM_EN = 1 or T8CM_EN = 1 or T20CM_EN = 1)
When standalone mode is used (i.e. VM_SEL = “00” or “01”):
0: Input from VINM0
1: Input from VINM1
When PGA (VM_SEL = “10”) or Follower mode (VM_SEL = “11”) is used:
0: Resistor feedback output selected (PGA mode)
1: VOUT selected as input minus (follower mode)

26 True random number generator (RNG)

26.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG can be used to construct a NIST compliant deterministic random bit generator (DRBG), acting as a live entropy source.

The RNG true random number generator has been tested using the German BSI statistical tests of AIS-31 (T0 to T8).

26.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source processed by a high quality conditioning stage.
- In the NIST configuration, it produces four 32-bit random samples every $16 \times \frac{f_{AHB}}{f_{RNG}}$ AHB clock cycles, if value is higher than 213 cycles (213 cycles otherwise).
- It allows embedded continuous basic health tests with associated error management – Includes too low sampling clock detection and repetition count tests.
- It can be disabled to reduce power consumption.
- It has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
26.3 RNG functional description

26.3.1 RNG block diagram

*Figure 179* shows the RNG block diagram.

**Figure 179. RNG block diagram**

26.3.2 RNG internal signals

*Table 205* describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

26.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals. Within its boundary the RNG implements the entropy source model pictured on Figure 180.

It includes an analog noise source, a digitization stage with post-processing, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

Figure 180. Entropy source model

The components pictured above are detailed hereafter.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. It is composed of:

- Two analog noise sources, each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 26.3.8: RNG low-power use.
- A sampling stage of these outputs clocked by a dedicated clock input (rng_clk), delivering a 2-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk).

Note: In Section 26.6: RNG entropy source validation the recommended RNG clock frequencies are given.
Post processing

The sample values obtained from a true random noise source consist of 2-bit bitstrings. Because this noise source output is biased, the RNG implements a post-processing component that reduces that bias to a tolerable level.

More specifically, for each of the two noise source bits the RNG takes half of the bits from the sampled noise source, and half of the bits from the inverted sampled noise source. Thus, if the source generates more ‘1’ than ‘0’ (or the opposite), it is filtered.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit).

Also note that post-processing computations are triggered when at least 32 bits of raw datum is received and when output FIFO needs a refill. Thus, the RNG output entropy is maximum when the RNG 128-bit FIFO is emptied by application after 64 RNG clock cycles.

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 26.5: RNG processing time.

The conditioning component is clocked by the faster AHB clock.

Output buffer

A data output buffer can store up to four 32-bit words, which have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register 213 AHB clock cycles later.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features.

1. Continuous health tests, running indefinitely on the output of the noise source
   - Repetition count test, flagging an error when:
     a) One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bits patterns ("01" or "10")
     b) Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bits patterns ("01" or "10")

2. Vendor specific continuous test
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle is smaller than AHB clock cycle divided by 32.

The CECS and SECS status bits in the RNG_Short register indicate when an error condition is detected, as detailed in Section 26.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

26.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 181.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and logic immediately starts sampling the analog output, filling the 128-bit conditioning shift register.
2. The conditioning logic is enabled and the post-processing context is initialized using two 128 noise source bits.
3. The conditioning stage internal input data buffer is filled again with 128-bit and one conditioning round is performed. The output buffer is then filled with the post processing result.
4. The output buffer is refilled automatically according to the RNG usage.
26.3.5 RNG operation

Normal operations

To run the RNG using interrupts, the following steps are recommended:

1. Enable the interrupts by setting the IE bit in the RNG_CR register. At the same time, enable the RNG by setting the bit RNGEN=1.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 26.3.7 must be used.
To run the RNG in polling mode following steps are recommended:

1. Enable the random number generation by setting the RNGEN bit to “1” in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in Section 26.3.7 must be used.

**Note:** When data is not ready (DRDY = 0) RNG_DR returns zero. It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

### Low-power operations
If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 26.3.8: RNG low-power use.

### Software post-processing
If a NIST approved DRBG with 128 bits of security strength is required an approved random generator software must be built around the RNG true random number generator. Built-in health check functions are described in Section 26.3.3: Random number generation.

#### 26.3.6 RNG clocking
The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock is used for noise source sampling. Recommended clock configurations are detailed in Section 26.6: RNG entropy source validation.

**Note:** When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency the must be higher than the AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 26.3.1: RNG block diagram for details (AHB and RNG clock domains).

#### 26.3.7 Error management
In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

##### Clock error detection
When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see
Section 26.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

Note: The clock error has no impact on generated random numbers that is the application can still read the RNG_DR register.

CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy. If the error was detected during the initialization phase the whole initialization sequence is automatically restarted by the RNG.

The following sequence must be used to fully recover from a seed error after the RNG initialization:
1. Clear the SEIS bit by writing it to “0”.
2. Read out 12 words from the RNG_DR register, and discard each of them in order to clean the pipeline.
3. Confirm that SEIS is still cleared. Random number generation is back to normal.

26.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to the software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case the RNG must be re-enabled by the application until at least 32 new bits are collected from the noise source and a complete conditioning round is done. It corresponds to 16 RNG clock cycles to sample new bits, and 216 AHB clock cycles to run a conditioning round.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1.
26.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 26.3.7: Error management
- Clock error, see Section 26.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 206.

Table 206. RNG interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG</td>
<td>Data ready flag</td>

<td>IE</td>
<td>Write 0 to SEIS</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

26.5 RNG processing time

The conditioning stage can produce four 32-bit random numbers every \(16 \times \frac{f_{\text{AHB}}}{f_{\text{RNG}}}\) clock cycles, if the value is higher than 213 cycles (213 cycles otherwise). More time is needed for the first set of random numbers after the device exits reset (see Section 26.3.4: RNG initialization). Indeed, after enabling the RNG for the first time, random data is first available after either:

- 128 RNG clock cycles + 426 AHB cycles, if \(f_{\text{AHB}} < f_{\text{threshold}}\)
- 192 RNG clock cycles + 213 AHB cycles, if \(f_{\text{AHB}} \geq f_{\text{threshold}}\)

With \(f_{\text{threshold}} = \frac{213 \times f_{\text{RNG}}}{64}\)

26.6 RNG entropy source validation

26.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using the German BSI AIS-31 statistical tests (T0 to T8). The results can be provided on demand or the customer can reproduce the tests.

26.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk= 48 MHz (CED bit = ‘0’ in RNG_CR register) and rng_clk = 400 kHz (CED bit = ‘1’ in RNG_CR register).
26.6.3 Data collection

In order to run statistical tests, it is required to collect samples from the entropy source at the raw data level as well as at the output of the entropy source. Contact STMicroelectronics if the above samples need to be retrieved for the product.

26.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

26.7.1 RNG control register (RNG_CR)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 CED: Clock error detection
0: Clock error detection enabled
1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Bit 4 Reserved, must be kept at reset value.

Bit 3 IE: Interrupt enable
0: RNG interrupt is disabled
1: RNG interrupt is enabled. An interrupt is pending as soon as the DRDY, SEIS, or CEIS is set in the RNG_SR register.

Bit 2 RNGEN: True random number generator enable
0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.
### 26.7.2 RNG status register (RNG_SRs)

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 SEIS: Seed error interrupt status**

This bit is set at the same time as SECS. It is cleared by writing 0. Writing 1 has no effect.

- 0: No faulty sequence detected
- 1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

**Bit 5 CEIS: Clock error interrupt status**

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

- 0: The RNG clock is correct (fRNGCLK > fHCLK/32)
- 1: The RNG is detected too slow (fRNGCLK < fHCLK/32)

An interrupt is pending if IE = 1 in the RNG_CR register.

**Bits 4:3 Reserved, must be kept at reset value.**

**Bit 2 SECS: Seed error current status**

- 0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.
- 1: At least one of the following faulty sequences has been detected:
  - One of the noise sources has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bit patterns ("01" or "10")
  - Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bit patterns ("01" or "10")

**Bit 1 CECS: Clock error current status**

- 0: The RNG clock is correct (fRNGCLK > fHCLK/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.
- 1: The RNG clock is too slow (fRNGCLK < fHCLK/32).

*Note: CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.*

**Bit 0 DRDY: Data ready**

- 0: The RNG_DR register is not yet valid, no random data is available.
- 1: The RNG_DR register contains valid random data.

Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.

*Note: The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).*

If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.
26.7.3 RNG data register (RNG_DR)

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. After being read, this register delivers a new random value after 216 periods of AHB clock if the output FIFO is empty.

The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

RNDATA[15:0]

Bits 31:0 RNDATA[31:0]: Random data
32-bit random data, which are valid when DRDY = 1. When DRDY = 0, the RNDATA value is zero.

When DRDY is set, it is recommended to always verify that RNG_DR is different from zero. The zero value means that a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

26.7.4 RNG register map

Table 207. RNG register map and reset map

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.2: Memory organization for the register boundary addresses.
27  High-resolution timer (HRTIM)

27.1  Introduction

The high-resolution timer can generate up to 12 digital signals with highly accurate timings. It is primarily intended to drive power conversion systems such as switch mode power supplies or lighting systems, but can be of general purpose usage, whenever a very fine timing resolution is expected.

Its modular architecture allows to generate either independent or coupled waveforms. The wave-shape is defined by self-contained timings (using counters and compare units) and a broad range of external events, such as analog or digital feedbacks and synchronization signals. This allows to produce a large variety of control signal (PWM, phase-shifted, constant Ton, ...) and address most of conversion topologies.

For control and monitoring purposes, the timer has also timing measure capabilities and links to built-in ADC and DAC converters. Last, it features light-load management mode and is able to handle various fault schemes for safe shut-down purposes.
27.2 Main features

- High-resolution timing units
  - 184 ps resolution, compensated against voltage and temperature variations
  - Duty cycle, frequency, phase shift and pulse width (triggered one-pulse mode) can be adjusted with full resolution, on all outputs
  - 6 16-bit timing units (each one with an independent counter and 4 compare units)
  - 12 outputs that can be controlled by any timing unit, up to 32 set/reset sources per channel
  - Modular architecture to address either multiple independent converters with 1 or 2 switches or few large multi-switch topologies
- Up to 10 external events, available for any timing unit
  - suitable for peak current control, zero voltage and zero current detection (ZVS and ZCS operation) and counter reset (variable frequency operation)
  - 4 sources per external events (digital inputs, built-in comparators outputs, ADC's analog watchdogs and general purpose timer's trigger outputs)
  - Programmable polarity and edge sensitivity
  - 5 events with a fast asynchronous mode
  - 5 events with a programmable digital filter
  - Spurious events filtering with blanking and windowing modes
- Direct connections to built-in analog peripherals
  - 10 triggers to ADC converters
  - 9 triggers for DAC converters, among which 6 with slope compensation capabilities
  - Comparator outputs (including filtering and blanking features)
- Versatile protection scheme
  - suitable for over-current, short-circuit and over-voltage / under-voltage protection
  - 6 fault inputs can be combined and associated to any timing unit
  - 3 sources per fault channel (digital inputs, built-in comparators outputs and external events)
  - Programmable polarity, edge sensitivity, and programmable digital filter
  - Dedicated delayed protections for resonant converters
- Multiple HRTIM instances can be synchronized with external synchronization inputs/outputs
- Versatile output stage
  - High-resolution deadtime insertion (down to 735 ps)
  - Programmable output polarity
  - Chopper mode
- Burst mode controller to handle light-load operation synchronously on multiple converters
- 8 interrupt vectors, each one with up to 14 sources
- 7 DMA requests with up to 14 sources, with a burst mode for multiple registers update
27.3 Functional description

27.3.1 General description

The HRTIM can be partitioned into several sub entities:

- The master timer
- The timing units (timer A to timer F)
- The output stage
- The burst mode controller
- An external event and fault signal conditioning logic that is shared by all timers
- The system interface

The master timer is based on a 16-bit up counter. It can set/reset any of the 12 outputs via 4 compare units and it provides synchronization signals to the 6 timer units. Its main purpose is to have the timer units controlled by a unique source. An interleaved buck converter is a typical application example where the master timer manages the phase-shifts between the multiple units.

The timer units are working either independently or coupled with the other timers including the master timer. Each timer contains the controls for two outputs. The outputs set/reset events are triggered either by the timing units compare registers or by events coming from the master timer, from the other timers or from external events.

The output stage has several duties

- Addition of deadtime when the 2 outputs are configured in complementary PWM mode
- Addition of a carrier frequency on top of the modulating signal
- Management of fault events, by asynchronously asserting the outputs to a predefined safe level

The burst mode controller can take over the control of one or multiple timers in case of light-load operation. The burst length and period can be programmed, as well as the idle state of the outputs.

The external event and fault signal conditioning logic includes:

- The input selection MUXes (for instance for selecting a digital input or an on-chip source for a given external event channel)
- Polarity and edge-sensitivity programming
- Digital filtering (for 5 channels out of 12)

The system interface allows the HRTIM to interact with the rest of the MCU:

- Interrupt requests to the CPU
- DMA controller for automatic accesses to/from the memories, including an HRTIM specific burst mode
- Triggers for the ADC and DAC converters

The HRTIM registers are split into 8 groups:

- Master timer registers
- Timer A to timer F registers
- Common registers for features shared by all timer units
Note: As a writing convention, references to the 6 timing units in the text and in registers are generalized using the “x” letter, where x can be any value from A to F.

The block diagram of the timer is shown in Figure 182.

Figure 182. High-resolution timer overview
### 27.3.2 HRTIM pins and internal signals

The tables in this section summarize the HRTIM inputs and outputs, both on-chip and off-chip.

27.3.3 Clocks

The HRTIM must be supplied by the \( f_{\text{HRTIM}} \) APB2 clock to offer a full resolution. The \( f_{\text{HRTIM}} \) clock period is evenly divided into up to 32 intermediate steps using an edge positioning logic. All clocks present in the HRTIM are derived from this reference clock.

Definition of terms

- \( f_{\text{HRTIM}} \): main HRTIM clock (\text{hrtim\_ker\_ck}). All subsequent clocks are derived and synchronous with this source.
- \( f_{\text{HRCK}} \): high-resolution equivalent clock. Considering the \( f_{\text{HRTIM}} \) clock period division by 32, it is equivalent to a frequency of \( 32 \times f_{\text{HRTIM}} \).
- \( f_{\text{DTG}} \): deadtime generator clock. For convenience, only the \( t_{\text{DTG}} \) period (\( t_{\text{DTG}} = 1/f_{\text{DTG}} \)) is used in this document.
- \( f_{\text{CHPFRQ}} \): chopper stage clock source.
- \( f_{\text{1STPW}} \): clock source defining the length of the initial pulse in chopper mode. For convenience, only the \( t_{\text{1STPW}} \) period (\( t_{\text{1STPW}} = 1/f_{\text{1STPW}} \)) is used in this document.
- \( f_{\text{BRST}} \): burst mode controller counter clock.
- \( f_{\text{SAMPLING}} \): clock needed to sample the fault or the external events inputs.
- \( f_{\text{FLTS}} \): clock derived from \( f_{\text{HRTIM}} \) which is used as a source for \( f_{\text{SAMPLING}} \) to filter fault events.
- \( f_{\text{EEVS}} \): clock derived from \( f_{\text{HRTIM}} \) which is used as a source for \( f_{\text{SAMPLING}} \) to filter external events.

Timer clock and prescaler

Each timer in the HRTIM has its own individual clock prescaler, which allows you to adjust the timer resolution (see Table 216).

<table>

<td>23.53 ns</td>
<td>0.65 kHz</td>
</tr>
</tbody>
</table>

The high-resolution is available for edge positioning, PWM period adjustment and externally triggered pulse duration.
The high-resolution is not available for the following features

- Timer counter read and write accesses
- Capture unit

For clock prescaling ratios below 32 (CKPSC[2:0] < 5), the least significant bits of the counter and capture registers are not significant. The least significant bits cannot be written (counter register only) and return 0 when read.

For instance, if CKPSC[2:0] = 2 (prescaling by 4), writing 0xFFFF into the counter register yields an effective value of 0xFFF8. Conversely, any counter value between 0xFFFF and 0xFFF8 is read as 0xFFF8.

<tr>
<td></td>
<td></td>
<td>32</td>
</tr>
</tbody>
</table>

*Significant bit: read returns effective value
*Not significant bit: read returns 0

**Initialization**

At start-up, it is mandatory to initialize first the prescaler bitfields before writing the compare and period registers. Once the timer is enabled (MCEN or TxCEN bit set in the HRTIM_MCR register), the prescaler cannot be modified.

When multiple timers are enabled, the prescalers are synchronized with the prescaler of the timer that was started first.

**Warning:** It is possible to have different prescaling ratios in the master and TIMA..E timers only if the counter and output behavior does not depend on other timers’ information and signals. It is mandatory to configure identical prescaling ratios in these timers when one of the following events is propagated from one timing unit (or master timer) to another: output set/reset event, counter reset event, update event, external event filter or capture triggers. Prescaler factors not equal yield to unpredictable results.

**Deadtime generator clock**

The deadtime prescaler is supplied by \( f_{\text{HRTIM}} \times 8 \) / \( 2^{\text{DTPRSC}[2:0]} \), programmed with DTPRSC[2:0] bits in the HRTIM_DTxR register.
t\textsubscript{DTG} ranges from 735 ps to 94.1 ns for f\textsubscript{HRTIM} = 170 MHz.

**Chopper stage clock**

The chopper stage clock source f\textsubscript{CHPFRO} is derived from f\textsubscript{HRTIM} with a division factor ranging from 16 to 256, so that 664 kHz ≤ f\textsubscript{CHPFRO} ≤ 10.625 MHz for f\textsubscript{HRTIM} = 170 MHz.

f\textsubscript{1STPW} is the length of the initial pulse in chopper mode, programmed with the STRPW[3:0] bits in the HRTIM\_CHPXR register, as follows:

\[ t_{1\text{STPW}} = (\text{STRPW}[3:0]+1) \times 16 \times t_{\text{HRTIM}}. \]

It uses \( f_{\text{HRTIM}} / 16 \) as clock source (10.625 MHz for \( f_{\text{HRTIM}} = 170 \) MHz).

**Burst mode prescaler**

The burst mode controller counter clock \( f_{\text{BRST}} \) can be supplied by several sources, among which one is derived from \( f_{\text{HRTIM}} \).

In this case, \( f_{\text{BRST}} \) ranges from \( f_{\text{HRTIM}} \) to \( f_{\text{HRTIM}} / 32768 \) (5.19 kHz for \( f_{\text{HRTIM}} = 170 \) MHz).

**Fault input sampling clock**

The fault input noise rejection filter has a time constant defined with \( f_{\text{SAMPLING}} \) which can be either \( f_{\text{HRTIM}} \) or \( f_{\text{FLTS}} \).

\( f_{\text{FLTS}} \) is derived from \( f_{\text{HRTIM}} \) and ranges from 170 MHz to 21.25 MHz for \( f_{\text{HRTIM}} = 170 \) MHz.

**External event input sampling clock**

The fault input noise rejection filter has a time constant defined with \( f_{\text{SAMPLING}} \) which can be either \( f_{\text{HRTIM}} \) or \( f_{\text{EEVS}} \).

\( f_{\text{EEVS}} \) is derived from \( f_{\text{HRTIM}} \) and ranges from 170 MHz to 21.25 MHz for \( f_{\text{HRTIM}} = 170 \) MHz.
27.3.4 Timer A..F timing units

The HRTIM embeds 6 identical timing units made of a 16-bit up-counter with an auto-reload mechanism to define the counting period, 4 compare and 2 capture units, as per Figure 184. Each unit includes all control features for 2 outputs, so that it operates as a standalone timer.

Figure 184. Timer A..F overview

The period and compare values must be within a lower and an upper limit related to the high-resolution implementation and listed in Table 217:

- The minimum value must be greater than or equal to 3 periods of the $f_{HRTIM}$ clock. The value 0x0000 can be written in CMP1 and CMP3 registers only, to skip a PWM pulse. See Section : Null duty cycle exception case for details
- The maximum value must be less than or equal to 0xFFFF - 1 periods of the $f_{HRTIM}$ clock.
Note: A compare value greater than the period register value does not generate a compare match event.

Counter operating mode

Timer A..F operate in continuous (free-running) mode or in single-shot manner where counting is started by a reset event, using the CONT bit in the HRTIM_TIMxCR control register. An additional RETRIG bit allows you to select whether the single-shot operation is retriggerable or non-retriggerable. Details of operation are summarized on Table 218 and on Figure 185 and Figure 186.

Table 217. Period and compare registers min and max values

</tr>
</tbody>
</table>

The TxEN bit can be cleared at any time to disable the timer and stop the counting.
Figure 185. Continuous timer operation

Figure 186. Single-shot timer operation

* Legend: Reset active  Reset ignored
Roll-over event

A counter roll-over event is generated when the counter goes back to 0 after having reached the period value set in the HRTIM_PERxR register in continuous mode.

This event is used for multiple purposes in the HRTIM:

- To set/reset the outputs
- To trigger the register content update (transfer from preload to active)
- To trigger an IRQ or a DMA request
- To serve as a burst mode clock source or a burst start trigger
- As an ADC trigger
- To decrement the repetition counter

If the initial counter value is above the period value when the timer is started, or if a new period is set while the counter is already above this value, the counter is not reset: it overflows at the maximum period value and the repetition counter does not decrement.

Timer reset

The reset of the timing unit counter can be triggered by up to 30 events that can be selected simultaneously in the HRTIM_RSTxR register, among the following sources:

- The timing unit: compare 2, compare 4 and update (3 events)
- The master timer: reset and compare 1..4 (5 events)
- The external events EXTEVNT1..10 (10 events)
- All other timing units (e.g. timer B..F for timer A): compare 1, 2 and 4 (12 events)

Several events can be selected simultaneously to handle multiple reset sources. In this case, the multiple reset requests are ORed. When 2 counter reset events are generated within the same \( f_{\text{HRTIM}} \) clock cycle, the last counter reset is taken into account.

Additionally, it is possible to do a software reset of the counter using the TxRST bits in the HRTIM_CR2 register. These control bits are grouped into a single register to allow the simultaneous reset of several counters.

The reset requests are taken into account only once the related counters are enabled (TxCEN bit set).

When the \( f_{\text{HRTIM}} \) clock prescaling ratio is above 32 (counting period above \( f_{\text{HRTIM}} \)), the counter reset event is delayed to the next active edge of the prescaled clock. This allows to maintain a jitterless waveform generation when an output transition is synchronized to the reset event (typically a constant \( T_{\text{on}} \) time converter).

*Figure 187* shows how the reset is handled for a clock prescaling ratio of 128 (\( f_{\text{HRTIM}} \) divided by 4).
Repetition counter

A common software practice is to have an interrupt generated when the period value is reached, so that the maximum amount of time is left for processing before the next period begins. The main purpose of the repetition counter is to adjust the period interrupt rate and off-load the CPU by decoupling the switching frequency and the interrupt frequency.

The timing units have a repetition counter. This counter cannot be read, but solely programmed with an auto-reload value in the HRTIM_REPxR register.

The repetition counter is initialized with the content of the HRTIM_REPxR register when the timer is enabled (TXCEN bit set). Once the timer has been enabled, any time the counter is cleared, either due to a reset event or due to a counter roll-over, the repetition counter is decreased. When it reaches zero, a REP interrupt or a DMA request is issued if enabled (REPIE and REPDE bits in the HRTIM_DIER register).

If the HRTIM_REPxR register is set to 0, an interrupt is generated for each and every period. For any value above 0, a REP interrupt is generated after (HRTIM_REPxR + 1) periods. Figure 188 presents the repetition counter operation for various values, in continuous mode.
The repetition counter can also be used when the counter is reset before reaching the period value (variable frequency operation) either in continuous or in single-shot mode (Figure 189 here-below). The reset causes the repetition counter to be decremented, at the exception of the very first start following counter enable (TxCEN bit set).

A reset or start event from the HRTIM_SCIN[3:1] source causes the repetition to be decremented as any other reset. However, in SYNCIN-started single-shot mode (SYNCSTRTx bit set in the HRTIM_TIMxCR register), the repetition counter is decremented only on the 1st reset event following the period. Any subsequent reset does not alter the repetition counter until the counter is re-started by a new request on HRTIM_SCIN[3:1] inputs.
Set / reset crossbar

A “set” event corresponds to a transition to the output active state, while a “reset” event corresponds to a transition to the output inactive state.

The polarity of the waveform is defined in the output stage to accommodate positive or negative logic external components: an active level corresponds to a logic level 1 for a positive polarity (POLx = 0), and to a logic level 0 for a negative polarity (POLx = 1).

Each of the timing units handles the set/reset crossbar for two outputs. These 2 outputs can be set, reset or toggled by up to 32 events that can be selected among the following sources:

- The timing unit: period, compare 1..4, register update (6 events)
- The master timer: period, compare 1..4, HRTIM synchronization (6 events)
- All other timing units (e.g. timer B..F for timer A): TIMEVNT1..9 (9 events described in Table 219)
- The external events EXTEVNT1..10 (10 events)
- A software forcing (1 event)

**Note:** In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

The event sources are ORed and multiple events can be simultaneously selected.

Each output is controlled by two 32-bit registers, one coding for the set (HRTIM_SETxyR) and another one for the reset (HRTIM_RSTxyR), where x stands for the timing unit: A..F and y stands for the output 1 or 2 (e.g. HRTIM_SETA1R, HRTIM_RSTC2R, ...).

If the same event is selected for both set and reset, it toggles the output. It is not possible to toggle the output state more than once per t\(_{\text{HRTIM}}\) period: in case of two consecutive toggling events within the same cycle, only the first one is considered.

The set and reset requests are taken into account only once the counter is enabled (TxCEN bit set), except if the software is forcing a request to allow the prepositioning of the outputs at timer start-up.

*Table 219* summarizes the events from other timing units that can be used to set and reset the outputs. The number corresponds to the timer events (such as TIMEVNTx) listed in the register, and empty locations are indicating non-available events.

For instance, timer A outputs can be set or reset by the following events: timer B compare 1 and 2, timer C compare 2 and 3,... and timer E compare 3 is listed as TIMEVNT7 in HRTIM_SETA1R.
Figure 190 represents how a PWM signal is generated using two compare events.

**Set / reset on update events**

A set or reset event on update is done at low resolution. When CKPSC[2:0] < 5, the high-resolution delay is set to its maximum value so that a set/reset event on update always lags as compared to other compare set/reset events, with a jitter varying between 0 and 31/32 of a \( f_{HRTIM} \) clock period.

**Half mode**

This mode aims at generating square signal with fixed 50% duty cycle and variable frequency (typically for converters using resonant topologies). It allows to have the duty cycle automatically forced to half of the period value when a new period is programmed.
This mode is enabled by writing HALF bit to 1 in the HRTIM_TIMxCR register. When the HRTIM_PERxR register is written, it causes an automatic update of the compare 1 value with HRTIM_PERxR/2 value.

The output on which a square wave is generated must be programmed to have one transition on CMP1 event, and one transition on the period event, as follows:

- HRTIM_SETxyR = 0x0000 0008, HRTIM_RSTxyR = 0x0000 0004, or
- HRTIM_SETxyR = 0x0000 0004, HRTIM_RSTxyR = 0x0000 0008

The HALF mode overrides the content of the HRTIM_CMP1xR register. The access to the HRTIM_PERxR register only causes compare 1 internal register to be updated. The user-accessible HRTIM_CMP1xR register is not updated with the HRTIM_PERxR / 2 value.

When the preload is enabled (PREEN = 1, MUDIS, TxUDIS), compare 1 active register is refreshed on the update event. If the preload is disabled (PREEN= 0), compare 1 active register is updated as soon as HRTIM_PERxR is written.

The period must be greater than or equal to 6 periods of the f_HRTIM clock (0xC0 if CKPSC[2:0] = 0, 0x60 if CKPSC[2:0] = 1, 0x30 if CKPSC[2:0] = 2,...) when the HALF mode is enabled.

**Interleaved mode**

This mode complements the Half mode and helps the implementation of interleaved topologies.

It allows to re-compute automatically the content of compare registers when the HRTIM_PERxR value is updated.

The selection is done using the HALF bit and the IL[1:0] bits in HRTIM_MCR and HRTIM_TIMxCR registers, as shown on the Table 220 below.

*Table 221* gives the compare values for the 3 available modes. The content of the compare registers is overridden. The corresponding compare events can be used to trigger an output set / reset or to reset a slave timer.
Null duty cycle exception case

The high-resolution behavior is not supported for pulses narrower than 3 \( t_{\text{HRTIM}} \) periods (see Section 27.3.7: Set / reset events priorities and narrow pulses management) and any value strictly below 3 periods of the \( f_{\text{HRTIM}} \) clock (that is 0x60 if \( \text{CKPSC}[2:0] = 0 \), 0x30 if \( \text{CKPSC}[2:0] = 1 \), 0x18 if \( \text{CKPSC}[2:0] = 2 \),...) in the HRTIM\_TIMxCMPy register is forbidden (see 27.5.19: HRTIM timer x compare 1 register (HRTIM\_CMP1xR) (x = A to F)). However, it is possible to skip an output pulse and have a null duty cycle by simply writing a null value in the following two registers: HRTIM\_TIMxCMP1 and HRTIM\_TIMxCMP3, if and only if the following conditions are met:

- the output SET event is generated by the PERIOD event
- the output RESET if generated by the compare 1 (respectively compare 3) event
- the compare 1 (compare 3) event is active within the timer unit itself, and not used for other timing units

For any other use case, this can be done by programming the SET and RESET events with the very same compare values, above 3 periods of the \( f_{\text{HRTIM}} \) clock. In this case, the output is reset forced (following the set/reset priority scheme defined in the Section 27.3.7: Set / reset events priorities and narrow pulses management).

Swap mode

This mode allows to swap the two outputs with a single bit access: the output 1 signal is connected to the output 2 pin and the output 2 signal is connected to output 1 pin. The output swap is triggered with the SWPx bits in the HRTIM\_CR2 register and is effective on the next update event.

The outputs are swapped prior to the set/reset crossbar unit, as following:

- if SWPx = 0, HRTIM\_SETx1R and HRTIM\_RSTx1R are coding for the output 1, HRTIM\_SETx2R and HRTIM\_RSTx2R are coding for the output 2
- if SWPx = 1, HRTIM\_SETx1R and HRTIM\_RSTx1R are coding for the output 2, HRTIM\_SETx2R and HRTIM\_RSTx2R are coding for the output 1

The swap mode is only affecting the preload register, and not the active registers.

Note: The preload mode must be enabled when using the swap mode.
Consequently, it does not modify the auxiliary outputs in parallel with the regular outputs going to the output stage (see Section 27.3.18 for details). They provide the following internal status, events and signals:
- O1CPY, O2CPY, SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset (TA2, TB2, TC2, TD2, TE2, TF2)
- External event filters generated with a Tx2 output copy

For instance the SETx1 flag is related to the output 1 when SWP = 0 and is related to the output 2 when SWPx = 1.

Similarly, the swap mode does not change the attribution of control bits in the HRTIM_OUTxR register (DIDLx, CHPx, FAULTx[1:0], IDLESx, POLx bits). For instance, the POL1 bit controls the output 1 polarity whatever the SWP bit value.

**Note:** The SWPx bits are ignored in push-pull mode (PSHPLL = 1 in the HRTIM_TIMxCR register).

**Capture**

The timing unit has the capability to capture the counter value, triggered by internal and external events. The purpose is to:
- measure events arrival timings or occurrence intervals
- update compare 2 and compare 4 values in auto-delayed mode (see Section : Auto-delayed mode).

The capture is done with $f_{HRTIM}$ resolution: for a clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the register are not significant (read as 0).

The timer has 2 capture registers: HRTIM_CPT1xR and HRTIM_CPT2xR. The capture triggers are programmed in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers.

The capture of the timing unit counter can be triggered by up to 28 events that can be selected simultaneously in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers, among the following sources:
- The external events, EXTEVNT1..10 (10 events)
- All other timing units (e.g. timer B..F for timer A): compare 1, 2 and output 1 set/reset events (16 events)
- The timing unit: update (1 event)
- A software capture (1 event)

Several events can be selected simultaneously to handle multiple capture triggers. In this case, the concurrent trigger requests are ORed. The capture can generate an interrupt or a DMA request when CPTxIE and CPTxDE bits are set in the HRTIM_TIMxDIER register.

Over-capture is not prevented by the circuitry: a new capture is triggered even if the previous value was not read, or if the capture flag was not cleared.
Auto-delayed mode

This mode allows to have compare events generated relatively to capture events, so that for instance an output change can happen with a programmed timing following a capture. In this case, the compare match occurs independently from the timer counter value. It enables the generation of waveforms with timings synchronized to external events without the need of software computation and interrupt servicing.

As long as no capture is triggered, the content of the HRTIM_CMPxR register is ignored (no compare event is generated when the counter value matches the compare value. Once the capture is triggered, the compare value programmed in HRTIM_CMPxR is summed with the captured counter value in HRTIM_CPTxyR, and it updates the internal auto-delayed compare register, as seen on Figure 192. The auto-delayed compare register is internal to the timing unit and cannot be read. The HRTIM_CMPxR preload register is not modified after the calculation.

This feature is available only for compare 2 and compare 4 registers. compare 2 is associated with capture 1, while compare 4 is associated with capture 2. HRTIM_CMP2xR and HRTIM_CMP4xR comparers cannot be programmed with a value below 3 f_{HRTIM} clock periods, as in the regular mode.
The auto-delayed compare is only valid from the capture up to the period event: once the counter has reached the period value, the system is re-armed with compare disabled until a capture occurs.

DELCMP2[1:0] and DELCMP4[1:0] bits in HRTIM_TIMxCR register allow to configure the auto-delayed mode as follows:

- **00**
  Regular compare mode: HRTIM_CMP2xR and HRTIM_CMP4xR register contents are directly compared with the counter value.

- **01**
  Auto-delayed mode: compare 2 and compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event.

- **10** or **11**
  Auto-delayed mode with timeout: compare 2 and compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event or after a compare 1
match (DELCMPx[1:0] = 10) or a compare 3 match (DELCMPx[1:0] = 11) to have a timeout function if capture 1/2 event is missing.

When the capture occurs, the comparison is done with the (HRTIM_CMP2/4xR + HRTIM_CPT1/2xR) value. If no capture is triggered within the period, the behavior depends on the DELCMPx[1:0] value:

- DELCMPx[1:0] = 01: the compare event is not generated
- DELCMPx[1:0] = 10 or 11: the comparison is done with the sum of the 2 compares (for instance HRTIM_CMP2xR + HRTIM_CMP1xR). The captures are not taken into account if they are triggered after CMPx + CMP1 (resp. CMPx + CMP3).

The captures are enabled again at the beginning of the next PWM period.

If the result of the auto-delayed summation is above 0xFFFF (overflow), the value is ignored and no compare event is generated until a new period is started.

**Note:** DELCMPx[1:0] must be reset when reprogrammed from one value to the other to reinitialize properly the auto-delayed mechanism, for instance:

- DELCMPx[1:0] = 10
- DELCMPx[1:0] = 00
- DELCMPx[1:0] = 11

As an example, Figure 193 shows how the following signal is generated:

- Output set when the counter is equal to compare 1 value
- Output reset 5 cycles after a falling edge on a given external event

**Note:** To simplify the figure, the high-resolution is not used in this example (CKPSC[2:0] = 101), thus the counter is incremented at the \( f_{HRTIM} \) rate. Similarly, the external event signal is shown without any resynchronization delay: practically, there is a delay of 1 to 2 \( f_{HRTIM} \) clock periods between the falling edge and the capture event due to an internal resynchronization stage which is necessary to process external input signals.

**Figure 193. Auto-delayed compare**

A regular compare channel (e.g. compare 1) is used for the output set: as soon as the counter matches the content of the compare register, the output goes to its active state.
A delayed compare is used for the output reset: the compare event can be generated only if a capture event has occurred. No event is generated when the counter matches the delayed compare value (counter = 4). Once the capture event has been triggered by the external event, the content of the capture register is summed to the delayed compare value to have the new compare value. In the example, the auto-delayed value 4 is summed to the capture equal to 7 to give a value of 12 in the auto-delayed compare register. From this time on, the compare event can be generated and happens when the counter is equal to 12, causing the output to be reset.

**Overcapture management in auto-delayed mode**

Overcapture is prevented when the auto-delayed mode is enabled (DELCMPx[1:0] = 01, 10, 11).

When multiple capture requests occur within the same counting period, only the first capture is taken into account to compute the auto-delayed compare value. A new capture is possible only:

- Once the auto-delayed compare has matched the counter value (compare event)
- Once the counter has rolled over (period)
- Once the timer has been reset

**Changing auto-delayed compare values**

When the auto-delayed compare value is preloaded (PREEN bit set), the new compare value is taken into account on the next coming update event (for instance on the period event), regardless of when the compare register was written and if the capture occurred (see Figure 193, where the delay is changed when the counter rolls over).

When the preload is disabled (PREEN bit reset), the new compare value is taken into account immediately, even if it is modified after the capture event has occurred, as per the example below:

1. At t1, DELCMP2 = 1.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, a capture event occurs capturing the value CPTR1 = 0x20. => comparison enabled, compare value = 0x60
4. At t4, CMP2_act = 0x100 (before the counter reached value CPTR1 + 0x40) => comparison still enabled, new compare value = 0x120
5. At t5, the counter reaches the period value => comparison disabled, cmp2_act = 0x100

Similarly, if the CMP1(CMP3) value changes while DELCMPx = 10 or 11, and preload is disabled:

1. At t1, DELCMP2 = 2.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, CMP3 event occurs - CMP3_act = 0x50 before capture 1 event occurs => comparison enabled, compare value = 0x90
4. At t4, CMP3_act = 0x100 (before the counter reached value 0x90) => comparison still enabled, compare 2 event occurs at = 0x140

**Triggered-half mode**

The purpose of this mode is to allow the synchronization of 2 interleaved converters that have variable frequency operation and require a 180° phase-shift. The basic principle is to
have a master-slave system. The slave converter synchronization is continuously adjusted based on the previous switching period of the master converter.

This is done using the capture unit. The switching period of the master converter is captured, divided by 2 and then stored in the compare 2 register by hardware. The compare 2 register contains a value equal to half of the captured period, which is the master converter switching period. The compare 2 event can then be used to trigger a second timing unit that manages the slave converter.

This mode is enabled by setting the TRGHLF bit in the HRTIM_TIMxCR2 register. This bit cannot be changed once the timer is operating (TxEN bit set).

The triggered-half mode must not be used simultaneously with other modes using CMP2 (dual channel dac trigger, interleaved and balanced idle modes).

The initial value CMP2 can be written by the user, but is ignored once the first capture is triggered. The preload mechanism is disabled for CMP2 when the TRGHLF bit is reset.

</tbody>
</table>
**Note:** In triggered half mode, the compare2 register is controlled by hardware and writing it has no effect. However the written value is stored in the preload register and becomes active on the update event following the exit of this mode.

**Push-pull mode**

This mode primarily aims at driving converters using push-pull topologies. It also needs to be enabled when the delayed idle protection is required, typically for resonant converters (refer to Section 27.3.10: Delayed protection).

The push-pull mode is enabled by setting PSHPLL bit in the HRTIM_TIMxCR register.

It applies the signals generated by the crossbar to output 1 and output 2 alternatively, on the period basis, maintaining the other output to its inactive state. The redirection rate (push-pull frequency) is defined by the timer’s period event, as shown on **Figure 195**. The push-pull period is twice the timer counting period.

**Figure 195. Push-pull mode block diagram**

![Push-pull mode block diagram](MS3268V1)

The push-pull mode is available when the timer operates in continuous mode and in single-shot mode. It is necessary to disable the timer to stop a push-pull operation and to reset the counter before re-enabling it.

To get a correct behavior, the event selected as source of the counter reset must be also selected for setting (or resetting) the output. It must set the output if the output is set on period, else it must reset it. If it is not done, the output switching from its inactive period to its active period may be incorrect (may unexpectedly rise or may unexpectedly stay low).

The signal shape is defined using HRTIM_SETxyR and HRTIM_RSTxyR for both outputs. It is necessary to have HRTIM_SETx1R = HRTIM_SETx2R and HRTIM_RSTx1R = HRTIM_RSTx2R to have both outputs with identical waveforms and to achieve a balanced operation. Still, it is possible to have different programming on both outputs for other uses.

The CPPSAT status bit in HRTIM_TIMxISR indicates on which output the signal is currently active. CPPSTAT is reset when the push-pull mode is disabled.

In the example given on **Figure 196**, the timer internal waveform is defined as follows:

- Output set on period event
- Output reset on compare 1 match event
Figure 196. Push-pull mode example

Figure 197 shows how the deadtime is inserted in push-pull mode, for both positive and negative deadtimes. In this case, the outputs are not complemented any more, and the deadtime is applied on each output individually (both output 1 and output 2 of the crossbar are used).
Deadtime

A deadtime insertion unit allows to generate a couple of complementary signals from a single reference waveform, with programmable delays between active state transitions. This is commonly used for topologies using half-bridges or full bridges. It simplifies the software: only 1 waveform is programmed and controlled to drive two outputs.

The Dead time insertion is enabled by setting DTEN bit in HRTIM_OUTxR register. The complementary signals are built based on the reference waveform defined for output 1, using HRTIM_SETx1R and HRTIM_RSTx1R registers: HRTIM_SETx2R and HRTIM_RSTx2R registers are not significant when DTEN bit is set.

Two deadtimes can be defined in relationship with the rising edge and the falling edge of the reference waveform, as in Figure 198.
Negative deadtime values can be defined when some control overlap is required. This is done using the deadtime sign bits (SDTFx and SDTRx bits in HRTIM_DTxR register).

*Figure 199* shows complementary signal waveforms depending on respective signs.

The deadtime values are defined with DTFx[8:0] and DTRx[8:0] bitfields and based on a specific clock prescaled according to DTPRSC[2:0] bits, as follows:

\[ t_{\text{DTx}} = +/- \text{DTx}[8:0] \times t_{\text{DTG}} \]

where \( x \) is either R or F and \( t_{\text{DTG}} = (2^{\text{DTPRSC}[2:0]}) \times (t_{\text{HRTIM}} / 8) \).
Table 222 gives the resolution and maximum absolute values depending on the prescaler value.

Figure 200 to Figure 203 present how the deadtime generator behaves for reference waveforms with pulsewidth below the deadtime values, for all deadtime configurations.

Figure 200. Complementary outputs for low pulsewidth (SDTRx = SDTFx = 0)

Figure 201. Complementary outputs for low pulsewidth (SDTRx = SDTFx = 1)
For safety purposes, it is possible to prevent any spurious write into the deadtime registers by locking the sign and/or the value of the deadtime using DTFLKx, DTRLKx, DTFSLKx and DTRSLKx. Once these bits are set, the related bits and bitfields are becoming read only until the next system reset.

Caution: DTEN bit must not be changed in the following cases:
- When the timer is enabled (TxEN bit set)
- When the timer outputs are set/reset by another timer (while TxEN is reset)
Otherwise, an unpredictable behavior would result. It is therefore necessary to disable the timer (TxCEN bit reset) and have the corresponding outputs disabled.

For the particular case where DTEN must be set while the burst mode is enabled with a deadtime upon entry (BME = 1, DIDL = 1, IDLEM = 1), it is necessary to force the two outputs in their IDLES state by software commands (SST, RST bits) before setting DTEN bit. This is to avoid any side effect resulting from a burst mode entry that would happen immediately before a deadtime enable.

27.3.5 Master timer

The main purpose of the master timer is to provide common signals to the 6 timing units, either for synchronization purpose or to set/reset outputs. It does not have direct control over any outputs, but still can be used indirectly by the set/reset crossbars.
Figure 204 provides an overview of the master timer.

The master timer is based on the very same architecture as the timing units, with the following differences:

- It does not have outputs associated with, nor output related control
- It does not have its own crossbar unit, nor push-pull or deadtime mode
- It can only be reset by the external synchronization circuitry
- It does not have a capture unit, nor the auto-delayed mode
- It does not include external event blanking and windowing circuitry
- It has a limited set of interrupt / DMA requests: compare 1..4, repetition, register update and external synchronization event.

The master timer control register includes all the timer enable bits, for the master and timer A..F timing units. This allows to have all timer synchronously started with a single write access.

It also handles the external synchronization for the whole HRTIM timer (see Section 27.3.19: Synchronizing the HRTIM with other timers or HRTIM instances), with both MCU internal and external (inputs/outputs) resources.

Master timer control registers are mapped with the same offset as the timing units’ registers.
27.3.6 Up-down counting mode

The HRTIM is natively designed with up-counters. It offers however an operating mode with up-down counters, also called center-aligned mode.

This mode is enabled using the UDM bit in the HRTIM_TIMxCR2 register. This bit must not be changed once the timer is operating (TxEN bit set). It is only available for the TIMA..F.

The master timer only works in up-counting mode.

Not all HRTIM features are supported in up-down counting. This section details the functional differences versus up-counting mode.

The period in HRTIM_PERxR must be preloaded (or static) in up-down mode. It can be updated only on period event or on counter reset.

The set/reset crossbar programming differs as follows:

The events coming from the timing units are setting/resetting the outputs depending on the counter up/down direction:

- If the event is enabled in the HRTIM_SETxyR register, it sets the output during up-counting and reset it during down-counting.
- If the event is enabled in the HRTIM_RSTxyR register, it resets the output during up-counting and set it during down-counting.
- If the events are enabled both in HRTIM_SETxyR and HRTIM_RSTxyR registers, the output toggles.

This applies to:
- The timing unit: period, compare 1..4, register update (6 events)
- The master timer: period, compare 1..4, HRTIM synchronization (6 events)
- All other timing units (e.g. timer B..F for timer A): TIMEVNT1..9 (9 events described in Table 219)

The Figure 205 below shows how to generate basic waveforms.

Figure 205. Basic symmetric waveform in up-down counting mode
The Figure 206 below shows how to generate some more complex waveforms, using the 4 available compare units and the toggle mode.

**Figure 206. Complex symmetric waveform in up-down counting mode**

![Complex symmetric waveform in up-down counting mode](image1)

The Figure 207 shows how to generate an asymmetric waveform. In this case, it must be noticed that it is necessary to have compare 2 value greater than compare 1 value for the waveform to be asymmetric.

**Figure 207. Asymmetric waveform in up-down counting mode**

![Asymmetric waveform in up-down counting mode](image2)

*Note:* For asymmetric operation, it is required that CMP2 > CMP1.
The behavior of the software forcing bits and external events EXTEVNT1..10 is identical for up-only and up-down counting mode. The Figure 208 below shows how a pulse can be shorten in response to external events.

Figure 208. External event management in up-down counting mode

The up-down counting mode is available for both continuous and single-shot (retriggerable and non-retriggerable) operating modes. A reset causes the counter to re-start from 0. The Figure 209 below shows the counter behavior in single-shot retriggerable mode, for TimB.
Note: In up-down counting mode, the compare values must be 3 periods of the \(f_{\text{HRTIM}}\) clock below the period value (\(\text{TIMx\_PER} - 0xC0 \text{ if } \text{CKPSC}[2:0] = 0 \), \(\text{TIMx\_PER} - 0x60 \text{ if } \text{CKPSC}[2:0] = 1 \), \(\text{TIMx\_PER} - 0x30 \text{ if } \text{CKPSC}[2:0] = 2 \),...). This applies for the compare events generated inside the timing unit. For compare events generated in other timing units, it is mandatory to avoid any event occurring within less than 1 period of the \(f_{\text{HRTIM}}\) clock of a counter direction change (counter at 0, period event or counter reset).

The following features are supported in up-down counting mode:
- Half mode
- Deadtime insertion
- Push-pull mode, alternance push-pull done on when counter = 0 (see Figure 211).
- Delayed Idle
- Burst mode
- PWM mode with “greater than” comparison (see Figure 212).
Figure 212. Up-down mode with “greater than” comparison

Caution: The following features are not supported in up-down counting mode:
- Auto-delayed mode
- Balanced Idle
- Triggered-half mode

The capture function is supported with the following differences:
- the capture value is referred to counting start, when up-counting
- the capture value is referred to the PER event when down counting
- the bit 16 of the capture register holds the counting direction status

The counter roll-over event is defined differently in up-down counting mode to support various operating condition. It can be either generated:
- when the counter is equal to 0 (“valley” mode)
- when the counter reaches the period value set in the HRTIM_PERxR (“crest” mode)
- when both conditions are met (either 0 or HRTIM_PERxR value)

This event is used for multiple purposes in the HRTIM. The generation mode (valley, crest or both) can be programmed individually depending on the destination. Table 223 summarizes the use cases and associated roll-over mode (xxROM[1:0]) programming bits in the HRTIM_TIMxCR2 register.

<table>
<thead>
<tr>

<tr>
<td>Fault and event counter</td>
<td>FEROM[1:0]</td>
</tr>
</tbody>
</table>
Note: For events where both reset and roll-over are considered (IRQ/DMA and TxRSTU), the ROM[1:0] only influences the roll-over generation. The reset event is always taken into account whatever the ROM[1:0] value.

The roll-over event generation is defined as per following xxROM[1:0] bitfield setting:
- xxROM[1:0] = 00: event generated when both conditions are met (either 0 or HRTIM_PERxR value)
- xxROM[1:0] = 01: event generated when the counter is equal to 0 ("valley" mode) or when the counter is reset
- xxROM[1:0] = 10: event generated when the counter reaches the period value set in the HRTIM_PERxR ("crest" mode)

*Figure 213* here-below shows a push-pull up-down mode with set on period event and OUTROM[1:0] =10.

*Figure 213. Up-down mode with output set on period event, for OUTROM[1:0]=10*
Figure 214 below shows how the repetition counter is decremented in up-down counting mode.

The dual channel DAC triggers are working as for the up-counting mode.

The event blanking and windowing differs so as to have the blanking or windowing done within the output pulse, at a programmable time. The ExFLTR[3:0] codes are depending on the UDM bit setting, as per the Table 224 below. Whenever the roll-over event is used for blanking or windowing, the ROM[1:0] programming applies for defining when it is generated.

Figure 214. Repetition counter behavior in up-down counting mode
27.3.7 Set / reset events priorities and narrow pulses management

This section describes how the output waveform is generated when several set and/or reset requests are occurring within 3 consecutive $t_{HRTIM}$ periods.

Case 1: clock prescaler CKPSC[2:0] < 5

An arbitration is performed during each $t_{HRTIM}$ period, in 3 steps:

1. For each active event, the desired output transition is determined (set, reset or toggle).
2. A predefined arbitration is performed among the active events (from highest to lowest priority CMP4 → CMP3 → CMP2 → CMP1 → PER, see Section : Concurrent set requests/ Concurrent reset requests).
3. A high-resolution delay-based arbitration is performed with reset having the highest priority, among the low-resolution events and events having won the predefined arbitration.

When set and reset requests from two different sources are simultaneous, the reset action has the highest priority. If the interval between set and reset requests is below 2 $f_{HRTIM}$ period, the behavior depends on the time interval and on the alignment with the $f_{HRTIM}$ clock, as shown on Figure 215.

Note: If the set and reset requests are simultaneous and coming from the same timing unit, the CMPx priority applies, as shown in step 2 here-above. For instance, taking CMP2 = CMP4:
- If CMP2 does a set and CMP4 a reset, the output is reset.
- If CMP2 does a reset and CMP4 a set, the output is set.
If the set and reset events are generated within the same $t_{HRTIM}$ period, the reset event has the highest priority and the set event is ignored.

If the set and reset events are generated with an interval below $t_{HRTIM}$ period, across 2 periods, a pulse of 1 $t_{HRTIM}$ period is generated.

If the set and reset events are generated with an interval below 2 $t_{HRTIM}$ periods, a pulse of 2 $t_{HRTIM}$ periods is generated.

If the set and reset events are generated with an interval between 2 and 3 $t_{HRTIM}$ periods, the high-resolution is available if the interval is over 2 complete $t_{HRTIM}$ periods.
If the set and reset events are generated with an interval above 3 \( t_{\text{HRTIM}} \) periods, the high-resolution is always available.

**Concurrent set requests/ Concurrent reset requests**

When multiple sources are selected for a set event, an arbitration is performed when the set requests occur within the same \( f_{\text{HRTIM}} \) clock period.

In case of multiple requests from adjacent timers (TIMEVNT1..9), the request which occurs first is taken into account. The arbitration is done in 2 steps, depending on:

1. the source (CMP4 \( \rightarrow \) CMP3 \( \rightarrow \) CMP2 \( \rightarrow \) CMP1),
2. the delay.

If multiple requests from the master timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and a single request is taken into account, whatever the effective high-resolution setting (from the highest to the lowest priority):

\[ \text{MSTCMP4} \rightarrow \text{MSTCMP3} \rightarrow \text{MSTCMP2} \rightarrow \text{MSTCMP1} \rightarrow \text{MSTCMPER} \]

**Note:** It is advised to avoid generating multiple set (reset) requests from the master timer to a given timer with an interval below 3x \( t_{\text{HRTIM}} \) to maintain the high-resolution.

When multiple requests internal to the timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and the requests are taken with the following priority, whatever the effective timing (from highest to lowest):

\[ \text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \rightarrow \text{PER} \]

**Note:** Practically, this is of a primary importance when multiple compare events can be simultaneously generated or when using auto-delayed compare 2 and compare 4 simultaneously (i.e. when the effective set/reset cannot be determined a priori because it is related to an external event). In this case, the highest priority signal must be affected to the CMP4 event.

Last, the highest priority is given to low-resolution events: EXTEVNT1..10, RESYNC (coming from SYNC event if SYNRSTx or SYNSRTx is set or from a software reset), update and software set (SST). The update event is considered as having the largest delay (0x1F if PSC = 0).

As a summary, in case of a close vicinity (events occurring within the same \( f_{\text{HRTIM}} \) clock period), the effective set (reset) event is arbitrated between:

- Any TIMEVNT1..9 event
- A single source from the master (as per the fixed arbitration given above)
- A single source from the timer
- The “low-resolution events”.

The same arbitration principle applies for concurrent reset requests. In this case, the reset request has the highest priority.

**Case 2: clock prescaler CKPSC[2:0] \( \geq 5 \)**

The narrow pulse management is simplified when the high-resolution is not effective.

A set or reset event occurring within the prescaler clock cycle is delayed to the next active edge of the prescaled clock (as for a counter reset), even if the arbitration is still performed every \( t_{\text{HRTIM}} \) cycle.
If a reset event is followed by a set event within the same prescaler clock cycle, the latest event is considered.

27.3.8 External events global conditioning

The HRTIM timer can handle events not generated within the timer, referred to as “external event”. These external events come from multiple sources, either on-chip or off-chip:

- built-in comparators,
- digital input pins (typically connected to off-chip comparators and zero-crossing detectors),
- on-chip events for other peripheral (ADC’s analog watchdogs and general purpose timer trigger outputs).

The external events conditioning circuitry allows to select the signal source for a given channel (with a 4:1 multiplexer) and to convert it into an information that can be processed by the crossbar unit (for instance, to have an output reset triggered by a falling edge detection on an external event channel).

Up to 10 external event channels can be conditioned and are available simultaneously for any of the 6 timers. This conditioning is common to all timers, since this is usually dictated by external components (such as a zero-crossing detector) and environmental conditions (typically the filter set-up is related to the applications noise level and signature). Figure 216 presents an overview of the conditioning logic for a single channel.
The 10 external events are initialized using the HRTIM_EECR1 and HRTIM_EECR2 registers:

- to select up to 4 sources with the EExSRC[1:0] bits,
- to select the sensitivity with EExSNS[1:0] bits, to be either level-sensitive or edge-sensitive (rising, falling or both),
- to select the polarity, in case of a level sensitivity, with EExPOL bit,
- to have a low latency mode, with EExFAST bits (see Section: Latency to external events), for external events 1 to 5.

Note: The external events used as triggers for reset, capture, burst mode, ADC triggers and delayed protection are edge-sensitive even if EESNS bit is reset (level-sensitive selection): if POL = 0 the trigger is active on external event rising edge, while if POL = 1 the trigger is active on external event falling edge.

The external events are discarded as long as the counters are disabled (TxCEN bit reset) to prevent any output state change and counter reset, except if they are used as ADC triggers.

Additionally, it is possible to enable digital noise filters, for external events 6 to 10, using EExF[3:0] bits in the HRTIM_EECR3 register.

A digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and
transmitted as a correct external event. Consequently, the digital filter adds a latency to the
events being filtered, depending on the sampling clock and on the filter length
(number of valid samples expected).

The sampling clock is either the $f_{\text{HRTIM}}$ clock or a specific prescaled clock $f_{\text{EEVS}}$ derived
from $f_{\text{HRTIM}}$, defined with EEVSD[1:0] bits in HRTIM_EECR3 register.

Table 225 summarizes the available features associated with each of the 10 external events
channels. The features and sources are summarized in Table 209.

Latency to external events

The external event conditioning gives the possibility to adjust the external event processing
time (and associated latency) depending on performance expectations:

- A regular operating mode, in which the external event is resampled with the clock
  before acting on the output crossbar. This adds some latency but gives access to all
crossbar functionalities. It enables the generation of an externally triggered high-
resolution pulse.
- A fast operating mode, in which the latency between the external event and the action
  on the output is minimized. This mode is convenient for ultra-fast over-current
  protections, for instance.

EExFAST bits in the HRTIM_EECR1 register allow to define the operating for channels 1 to 5. This influences the latency and the jitter present on the output pulses, as summarized in the table below.
The EExFAST mode is only available with level-sensitive programming (EExSNS[1:0] = 00); the edge-sensitivity cannot be programmed.

It is possible to apply event filtering to external events (both blanking and windowing with EExFLTR[3:0] != 0000, see Section 27.3.9). In this case, EExLTCHx bit must be reset: the postponed mode is not supported, neither the windowing timeout feature.

**Note:** The external event configuration (source and polarity) must not be modified once the related EExFAST bit is set.

A fast external event cannot be used to toggle an output: if must be enabled either in HRTIM_SETxyR or HRTIM_RSTxyR registers, not in both.

When a set and a reset event - from 2 independent fast external events - occur simultaneously, the reset has the highest priority in the crossbar and the output becomes inactive.

When EExFAST bit is set, the output cannot be changed during the 11 f_HRTIM clock periods following the external event.

*Figure 217* and *Figure 218* give practical examples of the reaction time to external events, for output set/reset and counter reset.
27.3.9 External event filtering in timing units

Once conditioned, the 10 external events are available for all timing units. They can be used directly and are active as soon as the timing unit counter is enabled (TxCEN bit set).

They can also be filtered to have an action limited in time, usually related to the counting period. Two operations can be performed:

- blanking, to mask external events during a defined time period,
- windowing, to enable external events only during a defined time period.
These modes are enabled using HRTIM_EExFLTR[3:0] bits in the HRTIM_EEFxR1 and HRTIM_EEFxR2 registers. Each of the 6 timer A..F timing units has its own programmable filter settings for the 10 external events.

**Blanking mode**

In event blanking mode (see *Figure 219*), the external event is ignored if it happens during a given blanking period. This is convenient, for instance, to avoid a current limit to trip on switching noise at the beginning of a PWM period. This mode is active for EExFLTR[3:0] bitfield values ranging from 0001 to 1100.

*Figure 219. Event blanking mode*

In event postpone mode, the external event is not taken into account immediately but is memorized (latched) and generated as soon as the blanking period is completed, as shown on *Figure 220*. This mode is enabled by setting EExLTCH bit in HRTIM_EEFxR1 and HRTIM_EEFxR2 registers.

*Figure 220. Event postpone mode*

The blanking signal comes from several sources:

- the timer itself: the blanking lasts from the counter reset to the compare match (EExFLTR[3:0] = 0001 to 0100 for compare 1 to compare 4). In up/down mode (UDM bit set to 1), the counter reset event is defined as per the ROM[1:0] bit setting.
- from other timing units (EExFLTR[3:0] = 0101 to 1100): the blanking lasts from the selected timing unit counter reset to one of its compare match, or can be fully programmed as a waveform on Tx2 output. In this case, events are masked as long as the Tx2 signal is inactive (it is not necessary to have the output enabled, the signal is taken prior to the output stage).

The EExFLTR[3:0] configurations from 0101 to 1100 are referred to as TIMFLTR1 to TIMFLTR8 in the bit description, and differ from one timing unit to the other. *Table 227* gives the 8 available options per timer: CMPx refers to blanking from counter reset to compare match, Tx2 refers to the timing unit TIMx output 2 waveform defined with HRTIM_SETx2 and HRTIM_RSTx2 registers. For instance, timer B (TIMFLTR6) is timer C output 2 waveform.

EExLTCH = 1

EExSNS[1:0] = 01  EExSNS[1:0] = 10  EExSNS[1:0] = 11

Internal event generated after blanking
Windowing mode

In event windowing mode, the event is taken into account only if it occurs within a given time window, otherwise it is ignored. This mode is active for EExFLTR[3:0] ranging from 1101 to 1111.

EExLTCH bit in EEFxR1 and EEFxR2 registers allows to latch the signal, if set to 1: in this case, an event is accepted if it occurs during the window but is delayed at the end of it.

- If EExLTCH bit is reset and the signal occurs during the window, it is passed through directly.
- If EExLTCH bit is reset and no signal occurs, a timeout event is generated at the end of the window.

A use case of the windowing mode is to filter synchronization signals. The timeout generation allows to force a default synchronization event, when the expected synchronization event is lacking (for instance during a converter start-up).
There are 3 sources for each external event windowing, coded as follows:

- 1101 and 1110: the windowing lasts from the counter reset to the compare match (respectively compare 2 and compare 3). In up/down mode (UDM bit set to 1), the counter reset event is defined as per the ROM[1:0] bit setting.
- 1111: the windowing is related to another timing unit and lasts from its counter reset to its compare 2 match. The source is described as TIMWIN in the bit description and is given in Table 228. As an example, the external events in timer B can be filtered by a window starting from timer A counter reset to timer A compare 2.

Table 228. Windowing signals mapping per timer (EEFLTR[3:0] = 1111)

<td>Timer C CMP2</td>
<td>Timer F CMP2</td>
<td>Timer E CMP2</td>
</tr>
</tbody>
</table>

Note: The timeout event generation is not supported if the external event is programmed in fast mode.

Figure 224 and Figure 225 present how the events are generated for the various edge and level sensitivities, as well as depending on EExLTCH bit setting. Timeout events are specifically mentioned for clarity reasons.
External event counter

Each timing unit also features an external event counter following the filtering unit, typically for valley skipping implementation.

The circuitry allows to filter any of the 10 external events filtered, as shown on Figure 226.

The counter is enabled using the EEVACE bit in the HRTIM_EEFxR3 register. This mode is only valid for edge-sensitive external events (EEASNS[1:0] bit = 01, 10 or 11).

The external event is propagated to the timer only if the number of active edges is greater or equal to the value programmed in (EEVACNT[5:0]+1).
Two operating modes are available:

- when the EEVARSTM bit is reset, the external event counter is reset on each reset/rollover event: the external event is active only if it appears several times within a given PWM period.
- when the EEVARSTM/ bit is set, the external event counter is reset only if the event did not occur during the last PWM period. This a cumulative mode, where the event must occur at least once during multiple PWM period, as shown on Figure 227 below.

The external event counter must be enabled after having programmed the counter value (the EEVACE bit must be set after having written the EEVACNT[5:0] bits).

Once the counter is enabled, the EEVACNT[5:0] bits can then be changed on-the-fly at any time. The new value is taken into account on the following reset/rollover event as per the EEVARSTM bit programming, or after a software reset (EEVACRES bit set).

The EEVASEL[3:0] bits must not be modified once the EEVACE bit is set.

**Figure 227. External event counter cumulative mode (EEVxRSTM = 1, EEVxCNT = 2)**

---

### 27.3.10 Delayed protection

The HRTIM features specific protection schemes, typically for resonant converters when it is necessary to shut down the PWM outputs in a delayed manner, either once the active pulse is completed or once a push-pull period is completed. These features are enabled with DLYPRTEN bit in the HRTIM_OUTxR register, and are using specific external event channels.

**Delayed idle**

In this mode, the active pulse is completed before the protection is activated. The selected external event causes the output to enter in idle mode at the end of the active pulse (defined by an output reset event in HRTIM_RSTx1R or HRTIM_RSTx2R).

Once the protection is triggered, the idle mode is permanently maintained but the counter continues to run, until the output is re-enabled. Tx1OEN and Tx2OEN bits are not affected.
by the delayed idle entry. To exit from delayed idle and resume operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1. The output state changes on the first transition to an active state following the output enable command.

Note: The delayed idle mode cannot be exited immediately after having been entered, before the active pulse is completed: it is mandatory to make sure that the outputs are in idle state before resuming the run mode. This can be done by waiting up to the next period, for instance, or by polling the O1CPY and/or O2CPY status bits in the TIMxISR register.

The delayed idle mode can be applied to a single output (DLYPRT[2:0] = x00 or x01) or to both outputs (DLYPRT[2:0] = x10).

An interrupt or a DMA request can be generated in response to a Delayed Idle mode entry. The DLYPRT flag in HRTIM_TIMxISR is set as soon as the external event arrives, independently from the end of the active pulse on output.

When the Delayed Idle mode is triggered, the output states can be determined using O1STAT and O2STAT in HRTIM_TIMxISR. Both status bits are updated even if the delayed idle is applied to a single output. When the push-pull mode is enabled, the IPPSTAT flag in HRTIM_TIMxISR indicates during which period the delayed protection request occurred.

This mode is available whatever the timer operating mode (regular, push-pull, deadtime). It is available with 2 external events only:
- hrtim_eev6 and hrtim_eev7 for timer A, B and C
- hrtim_eev8 and hrtim_eev9 for timer D, E and F

The delayed protection mode can be triggered only when the counter is enabled (TxCEN bit set). It remains active even if the TxEN bit is reset, until the TxyOEN bits are set.
The delayed idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the delayed idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode is resumed normally and the output is maintained in the idle state until the burst mode exits. Figure 229 gives an overview of these different scenarios.
The same priorities are applied when the delayed burst mode entry is enabled (DIDL bit set), as shown on Figure 230 below.
Balanced idle

Only available in push-pull mode, the balanced idle allows to have a balanced pulsewidth on the two outputs when one of the active pulse is shortened due to a protection. The pulsewidth, terminated earlier than programmed, is copied on the alternate output, then the two outputs are put in idle state, until the normal operation is resumed by software. This mode is enabled by writing x11 in DLYPRT[2:0] bitfield in HRTIM_OUTxR.

This mode is available with only 2 external events:
- hrtim_eev6 and hrtim_eev7 for timer A, B and C
- hrtim_eev8 and hrtim_eev9 for timer D, E and F
When the balanced Idle mode is enabled, the selected external event triggers a capture of the counter value into the compare 4 active register (this value is not user-accessible). The push-pull is maintained for one additional period so that the shorten pulse can be repeated: a new output reset event is generated while the regular output set event is maintained.

The Idle mode is then entered and the output takes the level defined by IDLESx bits in the HRTIM_OUTxR register. The balanced idle mode entry is indicated by the DLYPRT flag.
while the IPPSTAT flag indicates during which period the external event occurred, to
determine the sequence of shorten pulses (A1 then A2 or vice versa).

The timer operation is not interrupted (the counter continues to run).

To enable the balanced idle mode, it is necessary to have the following initialization:
- timer operating in continuous mode (CONT = 1)
- Push-pull mode enabled
- HRTIM_CMP4xR must be set to 0 and the content transferred into the active
  register (for instance by forcing a software update)
- DELCMP4[1:0] bit field must be set to 00 (auto-delayed mode disabled)
- DLYPRT[2:0] = x11 (delayed protection enable)

Note: The HRTIM_CMP4xR register must not be written during a balanced idle operation. The
CMP4 event is reserved and cannot be used for another purpose.

In balanced idle mode, it is recommended to avoid multiple external events or software-based
reset events causing an output reset. If such an event arrives before a balanced idle
request within the same period, it causes the output pulses to be unbalanced (1st pulse
length defined by the external event or software reset, while the 2nd pulse is defined by the
balanced idle mode entry).

The minimum pulsewidth that can be handled in balanced idle mode is 4 fHRTIM clock
periods (0x80 if CKPSC[2:0] = 0, 0x40 if CKPSC[2:0] = 1, 0x20 if CKPSC[2:0] = 2,...).

If the capture occurs before the counter has reached this minimum value, the current pulse
is extended up to 4 fHRTIM clock periods before being copied into the secondary output. In
any case, the pulsewidths are always balanced.

Tx1OEN and Tx2OEN bits are not affected by the balanced idle entry. To exit from balanced
idle and resume the operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1
simultaneously. The output state changes on the first active transition following the output
enable.

It is possible to resume operation similarly to the delayed idle entry. For instance, if the
external event arrives while output 1 is active (delayed idle effective after output 2 pulse),
the re-start sequence can be initiated for output 1 first. To do so, it is necessary to poll
CPPSTAT bit in the HRTIM_TIMxISR register. Using the above example (IPPSTAT flag
equal to 0), the operation is resumed when CPPSTAT bit is 0.

In order to have a specific re-start sequence, it is possible to poll the CPPSTAT to know
which output is active first. This allows, for instance, to re-start with the same sequence as
the idle entry sequence: if the external event arrives during output 1 active, the re-start
sequence is initiated when the output 1 is active (CPPSTAT = 0).

Note: The balanced idle mode must not be disabled while a pulse balancing sequence is on-going. It is necessary to wait until the CMP4 flag is set, thus indicating that the sequence is completed, to reset the DLYPRTEN bit.

The balanced idle protection mode can be triggered only when the counter is enabled
(TxCEN bit set). It remains active even if the TxCEN bit is reset, until TxyOEN bits are set.

Balanced idle can be used together with the burst mode under the following conditions:
- TxBM bit must be reset (counter clock maintained during the burst, see
  Section 27.3.15),
- No balanced idle protection must be triggered while the outputs are in a burst idle state.
The balanced idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the balanced idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode is resumed normally.

Note: Although the output state is frozen in idle mode, a number of events are still generated on the auxiliary outputs (see Section 27.3.18) during the idle period following the delayed protection:
- Output set/reset interrupt or DMA requests
- External event filtering based on output signal
- Capture events triggered by set/reset

Balanced idle automatic resuming

The balanced Idle mode can be configured to have an automatic resuming of operation after a trigger.

Once the shorten pulse has been copied to the alternate output, the pulse width is reset to its original value and the timer resumes operation: the two outputs keep on being in RUN mode.

This is enabled by setting the BIAR bit in the HRTIM_OUTxR register.

This mode must be used only when the period in HRTIM_PERxR is greater than 6 periods of the \( f_{\text{HRTIM}} \) clock (0xC0 if CKPSC[2:0] = 0, 0x60 if CKPSC[2:0] = 1, 0x30 if CKPSC[2:0] = 2, ...).

Note: This bit is only significant if DLYPRT[2 :0] = 011 or 111, it is ignored otherwise.

Note: In balanced idle automatic resuming mode, it is mandatory to set the IDLES state to inactive.

27.3.11 Register preload and update management

Most of HRTIM registers are buffered and can be preloaded if needed. Typically, this allows to prevent the waveforms from being altered by a register update not synchronized with the active events (set/reset).

When the preload mode is enabled, accessed registers are shadow registers. Their content is transferred into the active register after an update request, either software or synchronized with an event.

By default, PREEN bits in HRTIM_MCR and HRTIM_TIMxCR registers are reset and the registers are not preloaded: any write directly updates the active registers. If PREEN bit is reset while the timer is running and preload was enabled, the content of the preload registers is directly transferred into the active registers.

Each timing unit and the master timer have their own PREEN bit. If PRREN is set, the preload registers are enabled and transferred to the active register only upon an update event.

There are two options to initialize the timer when the preload feature is needed:
- Enable PREEN bit at the very end of the timer initialization to have the preload registers transferred into the active registers before the timer is enabled (by setting MCEN and TxCEN bits).
- enable PREEN bit at any time during the initialization and force a software update immediately before starting.
Table 229 lists the registers which can be preloaded, together with a summary of available update events.

### Table 229. HRTIM preloadable control registers and associated update sources

<table>
<thead>
<tr>

<td></td>
<td>TIMx or master timer Update, depending on ADxUSRC[2:0] bits in HRTIM_CR1, if PREEN = 1 in the selected timer</td>
</tr>
</tbody>
</table>

The master timer has 4 update options:

1. Software: writing 1 into MSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is cancelled.
2. Update done when the master counter rolls over and the master repetition counter is equal to 0. This is enabled when MREPU bit is set in HRTIM_MCR.
3. Update done once burst DMA is completed (see Section 27.3.23 for details). This is enabled when BRSTDMA[1:0] = 01 in HRTIM_MCR. It is possible to have both MREPU=1 and BRSTDMA=01.
   Note: The update can take place immediately after the end of the burst sequence if SWU bit is set (i.e. forced update mode). If SWU bit is reset, the update is done on the next update event following the end of the burst sequence.
4. Update done when the master counter rolls over following a burst DMA completion. This is enabled when BRSTDMA[1:0] = 10 in HRTIM_MCR.

An interrupt or a DMA request can be generated by the master update event.
Each timer (TIMA..F) can also have the update done as follows:

- By software: writing 1 into TxSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is canceled.
- Update done when the counter rolls over and the repetition counter is equal to 0. This is enabled when TxREPU bit is set in HRTIM_TIMxCR.
- Update done when the counter is reset or rolls over in continuous mode. This is enabled when TxRSTU bit is set in HRTIM_TIMxCR. This is used for a timer operating in single-shot mode, for instance.
- Update done once a burst DMA is completed. This is enabled when UPDGAT[3:0] = 0001 in HRTIM_TIMxCR.
- Update done on the update event following a burst DMA completion (the event can be enabled with TxRSTU, TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0010 in HRTIM_TIMxCR.
- Update done when receiving a request on hrtim_upd_en[3:1]. This is enabled when UPDGAT[3:0] = 0011, 0100, 0101 in HRTIM_TIMxCR.
- Update done on the update event following a request on hrtim_upd_en[3:1] (the event can be enabled with TxRSTU, TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0110, 0111, 1000 in HRTIM_TIMxCR.
- Update done synchronously with any other timer or master update (for instance TIMA can be updated simultaneously with TIMB). This is used for converters requiring several timers, and is enabled by setting bits MSTU and TxU in HRTIM_TIMxCR register.

The update enable inputs hrtim_upd_en[3:1] allow to have an update event synchronized with on-chip events coming from the general-purpose timers. These inputs are rising-edge sensitive.

Table 210 lists the connections between update enable inputs and the on-chip sources. This allows to synchronize low frequency update requests with high-frequency signals (for instance an update on the counter roll-over of a 100 kHz PWM that has to be done at a 100 Hz rate).

Note: The update events are synchronized to the prescaler clock when CKPSC[2:0] > 5.

The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) can either be taken into account immediately or re-synchronized with the timers reset/roll-over event. This is done with the RSYNCU bit in the HRTIM_TIMxCR register, as shown on Figure 232 below):

- RSYNCU = 0: The update coming from adjacent timers is taken into account immediately
- RSYNCU = 1: The update coming from adjacent timers is taken into account on the following reset/roll-over event.

The RSYNCU bit is significant only when UPDGAT[3:0] = 0000, it is ignored otherwise.

An interrupt or a DMA request can be generated by the Timx update event.
MUDIS and TxUDIS bits in the HRTIM_CR1 register allow to temporarily disable the transfer from preload to active registers, whatever the selected update event. This allows to modify several registers in multiple timers. The regular update event takes place once these bits are reset.

MUDIS and TxUDIS bits are all grouped in the same register. This allows the update of multiple timers (not necessarily synchronized) to be disabled and resumed simultaneously.

The following example is a practical use case. A first power converter is controlled with the master, TIMB and TIMC. TIMB and TIMC must be updated simultaneously with the master timer repetition event. A second converter works in parallel with TIMA, TIMD and TIME, and TIMD, TIME must be updated with TIMA repetition event.

First converter

In HRTIM_MCR, MREPU bit is set: the update occurs at the end of the master timer counter repetition period. In HRTIM_TIMBCR and HRTIM_TIMCCR, MSTU bits are set to have TIMB and TIMC timers updated simultaneously with the master timer.

When the power converter set-point has to be adjusted by software, MUDIS, TBUDIS and TCUDIS bits of the HRTIM_CR register must be set prior to write accessing registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, MUDIS, TBUDIS and TCUDIS bits must be reset. The transfer from preload to active registers is done as soon as the master repetition event occurs.

Second converter

In HRTIM_TIMACR, TAREPU bit is set: the update occurs at the end of the timer A counter repetition period. In HRTIM_TIMDCR and HRTIM_TIMECR, TAU bits are set to have TIMD and TIME timers updated simultaneously with timer A.
When the power converter set-point has to be adjusted by software, TAUDIS, TDUDIS and TEUDIS bits of the HRTIM_CR register must be set prior to write accessing the registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, TAUDIS, TDUDIS and TEUDIS bits can be reset: the transfer from preload to active registers is done as soon as the timer A repetition event occurs.

### 27.3.12 PWM mode with “greater than” comparison

A specific no-latency update mode is available for PWM signals generated with the CMP1 and CMP3 registers. It allows to have a new duty cycle value applied as soon as possible within the PWM cycle, without having to wait the completion of the current PWM period. This reduces the overall delay time in software control loops. As shown on Figure 233 below, this eventually allows to have:

- an early turn-off of the output if the new compare value is below the current counter value and the current compare value is above the counter, at the time the new value is written.
- an early turn-on of the output, re-enabling the output if the new compare value is above the counter value and the current compare value is above the counter, at the time the new value is written.

The output signal is left unchanged when the new compare value and current compare value are both below the counter.

This feature is only available for CMP1 or CMP3 RESET events, and is enabled using the GTCMP1 and GTCMP3 enable bits in the HRTIM_TIMxCR2 register.

The preload mechanism is inactive for a compare register when the corresponding GTCMPx bit is set, whatever the PREEN bit value. This mode is intended to have the new compare value taken into account as soon as possible after a new value write, without waiting for the preload to active register transfer.

These bits are defining the compare 1 and compare 3 operating modes as following

- GTCMPx = 0: the compare x event is generated when the counter is equal to the compare value (compare match mode). If the compare value is changed on-the-fly, the compare event may not be generated.
- GTCMPx = 1: the compare x event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.

The “greater than” compare mode causes the crossbar to act differently depending on comparison result. Let’s consider the CMP1 event is doing an output RESET. When the new compare value is written, two cases are considered

- If the new compare value is below the counter value, the RESET event is issued and can eventually cause an early turn-OFF
- If the new compare value is above the counter value, a SET event is generated so as to re-arm the output value before it is actually RESET when the counter exceeds the counter value (early turn-ON).

The “greater than” compare mode is supported for both SET and RESET actions.

The “greater than” compare mode must only be used for the following configuration:
1. In the fixed frequency configuration, the period event must trigger the output set and the “greater than” compare triggers the output reset (or vice versa the period must trigger the reset if the “greater-than” compare triggers the set).

2. For variable frequency configuration, the event selected as counter reset source must also be selected as set or reset source for the timer output (opposite direction as the “greater than” compare event).

**Note:** The “greater-than” modes must not be used when the CMP1 and/or CMP3 modes are controlled by hardware in half and interleaved modes.

**Figure 233. Early turn-ON and early turn-OFF behavior in “greater than” PWM mode**

The immediate update mode implies that the content of the preload register is transferred into the active register at the very same time the register is written. When GTCMP1 and/or GTCMP3 bits are set, their respective preload mechanism is disabled (for HRTIM_TIMxCMP1 and/or HRTIM_TIMxCMP3 registers), whatever the PREEN bit value.

**Note:** The compare interrupt flags (CMP1 and CMP3 in HRTIM_TIMxISR) are not generated in case of late turn-ON and early turn-OFF, as shown on Figure 233.

**Note:** The “Greater than” comparison must not be done on both CMP1 and CMP3 for the same output (GTCMP1 and GTCMP3 bits must not be set simultaneously).

### 27.3.13 Events propagation within or across multiple timers

The HRTIM offers many possibilities for cascading events or sharing them across multiple timing units, including the master timer, to get full benefits from its modular architecture. These are key features for converters requiring multiple synchronized outputs.

This section summarizes the various options and specifies whether and how an event is propagated within the HRTIM.
**TIMx update triggered by the master timer update**

The sources listed in *Table 230* are generating a master timer update. The table indicates if the source event can be used to trigger a simultaneous update in any of TIMx timing units.

Operating condition: MSTU bit is set in HRTIM_TIMxCR register.

**Table 230. Master timer update event propagation**

27.3.14 Output management

Each timing unit controls a pair of outputs. The outputs have three operating states:

- **RUN**: this is the main operating mode, where the output can take the active or inactive level as programmed in the crossbar unit.

- **IDLE**: this state is the default operating state after an HRTIM reset, when the outputs are disabled by software or during a burst mode operation (where outputs are temporarily disabled during a normal operating mode; refer to Section 27.3.15 for more details). It is either permanently active or inactive.

- **FAULT**: this is the safety state, entered in case of a shut-down request on FAULTx inputs. It can be permanently active, inactive or Hi-Z.

The output status is indicated by TxyOEN bit in HRTIM_OENR register and TxyODS bit in HRTIM_ODSR register, as in Table 234.

### Table 234. Output state programming, x= A..F, y = 1 or 2

<table>
<thead>
<tr>
<th>TxyOEN (control/status) (set by software, cleared by hardware)</th>
<th>TxyODS (status)</th>

<td>RUN</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>IDLE</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>FAULT</td>
</tr>
</tbody>
</table>

TxyOEN bit is both a control and a status bit: it must be set by software to have the output in RUN mode. It is cleared by hardware when the output goes back in IDLE or FAULT mode. When TxyOEN bit is cleared, TxyODS bit indicates whether the output is in the IDLE or FAULT state. A third bit in the HRTIM_ODISR register allows to disable the output by software.

**Figure 234. Output management overview**

*Figure 235* summarizes the bit values for the three states and how the transitions are triggered. Faults can be triggered by any external or internal fault source, as listed in...
Section 27.3.17, while the Idle state can be entered when the burst mode or delayed protections are active.

Figure 235. HRTIM output states and transitions

The FAULT and IDLE levels are defined as active or inactive. Active (or inactive) refers to the level on the timer output that causes a power switch to be closed (or opened for an inactive state).

The IDLE state has the highest priority: the transition FAULT → IDLE is possible even if the FAULT condition is still valid, triggered by ODIS bit set.

The FAULT state has priority over the RUN state: if TxyOEN bit is set simultaneously with a fault event, the FAULT state is entered. The condition is given on the transition IDLE → FAULT, as in Figure 235: fault protection needs to be enabled (FAULTx[1:0] bits = 01, 10, 11) and the Txy OEN bit set with a fault active (or during a breakpoint if DBG_HRTIM_STOP = 1).

The output polarity is programmed using POLx bits in HRTIM_OUTxR. When POLx = 0, the polarity is positive (output active high), while it is active low in case of a negative polarity (POLx = 1). Practically, the polarity is defined depending on the power switch to be driven (PMOS versus NMOS) or on a gate driver polarity.

The output level in the FAULT state is configured using FAULTx[1:0] bits in HRTIM_OUTxR, for each output, as follows:

- 00: output never enters the fault state and stays in RUN or IDLE state
- 01: output at active level when in FAULT
- 10: output at inactive level when in FAULT
- 11: output is tri-stated when in FAULT. The safe state must be forced externally with pull-up or pull-down resistors, for instance.

Note: FAULTx[1:0] bits must not be changed as long as the outputs are in FAULT state.
The level of the output in IDLE state is configured using IDLESx bit in HRTIM_OUTxR, as follows:
- 0: output at inactive level when in IDLE
- 1: output at active level when in IDLE

When TxyOEN bit is set to enter the RUN state, the output is immediately connected to the crossbar output. If the timer clock is stopped, the level is either inactive (after an HRTIM reset) or corresponds to the RUN level (when the timer is stopped and the output disabled).

During the HRTIM initialization, the output level can be prepositioned prior to have it in RUN mode, using the software forced output set and reset in the HRTIM_SETx1R and HRTIM_RSTx1R registers.

27.3.15 Burst mode controller

The burst mode controller allows to have the outputs alternatively in IDLE and RUN state, by hardware, so as to skip some switching periods with a programmable periodicity and duty cycle.

Burst mode operation is of common use in power converters when operating under light loads. It can significantly increase the efficiency of the converter by reducing the number of transitions on the outputs and the associated switching losses.

When operating in burst mode, one or a few pulses are outputs followed by an idle period equal to several counting periods, typically, where no output pulses are produced, as shown in the example on Figure 236.

**Figure 236. Burst mode operation example**

The burst mode controller consists of:
- A counter that can be clocked by various sources, either within or outside the HRTIM (typically the end of a PWM period).
- A compare register to define the number of idle periods: HRTIM_BMCMP.
- A period register to define the burst repetition rate (corresponding to the sum of the idle and run periods): HRTIM_BMPER.
The burst mode controller is able to take over the control of any of the 10 PWM outputs. The state of each output during a burst mode operation is programmed using IDLESx and IDLEMx bits in the HRTIM_OUTxR register, as in Table 235.

Table 235. Timer output programming for burst mode

<table>
<thead>
<tr>
<th>IDLEMx</th>
<th>IDLESx</th>
<th>Output state during burst mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>X</td>
<td>No action: the output is not affected by the burst mode operation.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Output inactive during the burst</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Output active during the burst</td>
</tr>
</tbody>
</table>

*Note: IDLEMx bit must not be changed while the burst mode is active.*

The burst mode controller only acts on the output stage. A number of events are still generated during the idle period:

- Output set/reset interrupt or DMA requests
- External event filtering based on Tx2 output signal
- Capture events triggered by output set/reset

During the burst mode, neither start nor reset events are generated on the hrtim_out_sync[2:1] output, even if TxBM bit is set.

**Operating mode**

It is necessary to have the counter enabled (TxCEN bit set) before using the burst mode on a given timing unit. The burst mode is enabled with BME bit in the HRTIM_BMCR register.

It can operate in continuous or single-shot mode, using BMOM bit in the HRTIM_BMCR register. The continuous mode is enabled when BMOM = 1. The burst operation is maintained until BMSTAT bit in HRTIM_BMCR is reset to terminate it.

In single-shot mode (BMOM = 0), the idle sequence is executed once, following the burst mode trigger, and the normal timer operation is resumed immediately after.

The duration of the idle and run periods is defined with a burst mode counter and 2 registers. The HRTIM_BMCMPR register defines the number of counts during which the selected timer(s) are in an idle state (idle period). HRTIM_BMPER defines the overall burst mode period (sum of the idle and run periods). Once the initial burst mode trigger has occurred, the idle period length is HRTIM_BMCMPR+1, the overall burst period is HRTIM_BMPER+1.

*Note: The burst mode period must not be less than or equal to the deadtime duration defined with DTRx[8:0] and DTFx[8:0] bitfields.*

The counters of the timing units and the master timer can be stopped and reset during the burst mode operation. HRTIM_BMCR holds 6 control bits for this purpose: MTBM (master) and TABM..TEBM for timer A..E.

When MTBM or TxBM bit is reset, the counter clock is maintained. This allows to keep a phase relationship with other timers in multiphase systems, for instance.

When MTBM or TxBM bit is set, the corresponding counter is stopped and maintained in reset state during the burst idle period. This allows to have the timer restarting a full period when exiting from idle. If SYNCSRC[1:0] = 00 or 10 (synchronization output on the master
start or timer A start), a pulse is sent on the HRTIM_SCOUT output when exiting the burst mode.

**Note:** *TxBM bit must not be set when the balanced idle mode is active (DLYPRT[1:0] = 0x11).*

**Burst mode clock**

The burst mode controller counter can be clocked by several sources, selected with BMCLK[3:0] bits in the HRTIM_BMCR register:

- **BMCLK[3:0] = 0000 to 0101:** master timer and TIMA..E reset/roll-over events. This allows to have burst mode idle and run periods aligned with the timing unit counting period (both in free-running and counter reset mode).
- **BMCLK[3:0] = 0110 to 1001:** The clocking is provided by the hrtim_bm_ck[4:1] inputs connected to general purpose timers, as in Table 211. In this case, the burst mode idle and run periods are not necessarily aligned with timing unit counting period (a pulse on the output may be interrupted, resulting a waveform with modified duty cycle for instance.
- **BMCLK[3:0] = 1010:** The \( f_{\text{HRTIM}} \) clock prescaled by a factor defined with BMPRSC[3:0] bits in HRTIM_BMCR register. In this case, the burst mode idle and run periods are not necessarily aligned with the timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with a modified duty cycle, for instance.

The pulse width on TIMx OC output must be at least \( N \ f_{\text{HRTIM}} \) clock cycles long to be detected by the HRTIM burst mode controller.

**Burst mode triggers**

To trigger the burst operation, 32 sources are available and are selected using the HRTIM_BMTRGR register:

- Software trigger (set by software and reset by hardware)
- 6 master timer events: repetition, reset/roll-over, compare 1 to 4
- 5 x 4 events from timers A..F: repetition, reset/roll-over, compare 1 and 2
- External event 7 (including TIMA event filtering) and 8 (including TIMD event filtering)
- Timer A period following external event 7 (including TIMA event filtering)
- Timer D period following external event 8 (including TIMD event filtering)
- An on-chip event on the hrtim_bm_trg input (connected to the general-purpose timer TRGO output), see Table 206 for details.

These sources can be combined to have multiple concurrent triggers.

Burst mode is not re-triggerable. In continuous mode, new triggers are ignored until the burst mode is terminated, while in single-shot mode, the triggers are ignored until the current burst completion including run periods (HRTIM_BMPER+1 cycles). This is also valid for software trigger (the software bit is reset by hardware even if it is discarded).

*Figure 237* shows how the burst mode is started in response to an external event, either immediately or on the timer period following the event.
For TAEVEV7 and TDEEV8 combined triggers (trigger on a timer period following an external event), the external event detection is always active, regardless of the burst mode programming and the on-going burst operation:

- When the burst mode is enabled (BME=1) or the trigger is enabled (TAEVEV7 or TDEEV8 bit set in the BMTRG register) in between the external event and the timer period event, the burst is triggered.
- The single-shot burst mode is re-triggered even if the external event occurs before the burst end (as long as the corresponding period happens after the burst).

**Note:** TAEVEV7 and TDEEV8 triggers are valid only after a period event. If the counter is reset before the period event, the pending hrtim_eev7 or hrtim_eev8 event is discarded.

**Burst mode delayed entry**

By default, the outputs are taking their idle level (as per IDLES1 and IDLES2 setting) immediately after the burst mode trigger.

It is also possible to delay the burst mode entry and force the output to an inactive state during a programmable period before the output takes its idle state. This is useful when driving two complementary outputs, one of them having an active idle state, to avoid a deadtime violation as shown on Figure 238. This prevents any risk of shoot through current in half-bridges, but causes a delayed response to the burst mode entry.
The delayed burst entry mode is enabled with DIDLx bit in the HRTIM_OUTxR register (one enable bit per output). It forces a deadtime insertion before the output takes its idle state. Each TIMx output has its own deadtime value:

- DTRx[8:0] on output 1 when DIDL1 = 1
- DTFx[8:0] on output 2 when DIDL2 = 1

DIDLx bits can be set only if one of the outputs has an active idle level during the burst mode (IDLES = 1) and only when positive deadtimes are used (SDTR/SDTF set to 0).

**Note:** The delayed burst entry mode uses deadtime generator resources. Consequently, when any of the 2 DIDLx bits is set and the corresponding timing unit uses the deadtime insertion (DTEN bit set in HRTIM_OUTxR), it is not possible to use the timerx output 2 as a filter for external events (Tx2 filtering signal is not available).

When durations defined by DTRx[8:0] and DTFx[8:0] are lower than 3 f_{HRTIM} clock cycle periods, the limitations related to the narrow pulse management listed in Section 27.3.7 must be applied.

When the burst mode entry arrives during the regular deadtime, it is aborted and a new deadtime is re-started corresponding to the inactive period, as on Figure 239.
**Burst mode exit**

The burst mode exit is either forced by software (in continuous mode) or once the idle period is elapsed (in single-shot mode). In both cases, the counter is re-started immediately (if it was hold in a reset state with MTBM or TxBM bit = 1), but the effective output state transition from the idle to active mode only happens after the programmed set/reset event.

A burst period interrupt is generated in single-shot and continuous modes when BMPERIE enable bit is set in the HRTIM_IER register. This interrupt can be used to synchronize the burst mode exit with a burst period in continuous burst mode.

Figure 240 shows how a normal operation is resumed when the deadtime is enabled. Although the burst mode exit is immediate, this is only effective on the first set event on any of the complementary outputs.

Two different cases are presented:

1. The burst mode ends while the signal is inactive on the crossbar output waveform. The active state is resumed on Tx1 and Tx2 on the set event for the Tx1 output, and the Tx2 output does not take the complementary level on burst exit.

2. The burst mode ends while the crossbar output waveform is active: the activity is resumed on the set event of Tx2 output, and Tx1 does not take the active level immediately on burst exit.
Figure 240. Burst mode exit when the deadtime generator is enabled

The behavior described above is slightly different when the push-pull mode is enabled. The push-pull mode forces an output reset at the beginning of the period if the output is inactive, or symmetrically forces an active level if the output was high during the preceding period.

Consequently, an output with an active idle state can be reset at the time the burst mode is exited even if no transition is explicitly programmed. For symmetrical reasons, an output can be set at the time the burst mode is exited even if no transition is explicitly programmed, in case it was active when it entered in idle state.

**Burst mode registers preloading and update**

BMPREN bit (burst mode preload enable) allows to have the burst mode compare and period registers preloaded (HRTIM_BMCMP and HRTIM_BMPER).

When BMPREN is set, the transfer from preload to active register happens:
- when the burst mode is enabled (BME = 1),
- at the end of the burst mode period.

A write into the HRTIM_BMPER period register disables the update temporarily, until the HRTIM_BMCMP compare register is written, to ensure the consistency of the two registers when they are modified.

If the compare register only needs to be changed, a single write is necessary. If the period only needs to be changed, it is also necessary to re-write the compare to have the new values taken into account.
When BMPREN bits is reset, the write access into BMCMPR and BMPER directly updates the active register. In this case, it is necessary to consider when the update is done during the overall burst period, for the 2 cases below:

a) Compare register update

If the new compare value is above the current burst mode counter value, the new compare is taken into account in the current period.

If the new compare value is below the current burst mode counter value, the new compare is taken into account in the next burst period in continuous mode, and ignored in single-shot mode (no compare match occurs and the idle state lasts until the end of the idle period).

b) Period register update

If the new period value is above the current burst mode counter value, the change is taken into account in the current period.

Note: If the new period value is below the current burst mode counter value, the new period is not taken into account, the burst mode counter overflows (at 0xFFFF) and the change is effective in the next period. In single-shot mode, the counter rolls over at 0xFFFF and the burst mode re-starts for another period up to the new programmed value.

Burst mode emulation using a compound register

The burst mode controller only controls one or a set of timers for a single converter. When the burst mode is necessary for multiple independent timers, it is possible to emulate a simple burst mode controller using the DMA and the HRTIM_CMP1CxR compound register, which holds aliases of both the repetition and the compare 1 registers.

This is applicable to a converter which only requires a simple PWM (typically a buck converter), where the duty cycle only needs to be updated. In this case, the CMP1 register is used to reset the output (and define the duty cycle), while it is set on the period event.

In this case, a single 32-bit write access in CMP1CxR is sufficient to define the duty cycle (with the CMP1 value) and the number of periods during which this duty cycle is maintained (with the repetition value). To implement a burst mode, it is then only necessary to transfer by DMA (upon repetition event) two 32-bit data in continuous mode, organized as follows:

CMPC1xR = {REP_Run; CMP1 = Duty_Cycle}, {REP_Idle; CMP1 = 0}

For instance, the values:

{0x0003 0000}: CMP1 = 0 for 3 periods

{0x0001 0800}: CMP1 = 0x0800 for 1 period

provide a burst mode with 2 periods active every 6 PWM periods, as shown on Figure 241.
27.3.16 Chopper

A high-frequency carrier can be added on top of the timing unit output signals to drive isolation transformers. This is done in the output stage before the polarity insertion, as shown on Figure 242, using CHP1 and CHP2 bits in the HRTIM_OUTxR register, to enable chopper on outputs 1 and 2, respectively.
The chopper parameters can be adjusted using the HRIM_CHPxR register, with the possibility to define a specific pulsewidth at the beginning of the pulse, to be followed by a carrier frequency with programmable frequency and duty cycle, as in Figure 243.

CARFRQ[3:0] bits define the frequency, ranging from 664 kHz to 10.625 MHz (for \( f_{\text{HRTIM}} = 170 \) MHz) following the formula \( F_{\text{CHPFRQ}} = f_{\text{HRTIM}} / (16 \times (\text{CARFRQ}[3:0]+1)) \).

The duty cycle can be adjusted by 1/8 step with CARDTY[2:0], from 0/8 up to 7/8 duty cycle. When CARDTY[2:0] = 000 (duty cycle = 0/8), the output waveform only contains the starting pulse following the rising edge of the reference waveform, without any added carrier.

The pulsewidth of the initial pulse is defined using the STRPW[3:0] bitfield as follows: \( t_{\text{STPW}} = (\text{STRPW}[3:0]+1) \times 16 \times t_{\text{HRTIM}} \) and ranges from 94 ns to 1.51 \( \mu \)s (for \( f_{\text{HRTIM}} = 170 \) MHz).

The carrier frequency parameters are defined based on the \( f_{\text{HRTIM}} \) frequency, and are not dependent from the CKPSC[2:0] setting.

In chopper mode, the carrier frequency and the initial pulsewidth are combined with the reference waveform using an AND function. A synchronization is performed at the end of the initial pulse to have a repetitive signal shape.

The chopping signal is stopped at the end of the output waveform active state, without waiting for the current carrier period to be completed. It can thus contain shorter pulses than programmed.

**Figure 243. HRTIM outputs with Chopper mode enabled**

![HRTIM outputs with Chopper mode enabled](MS32335V3)

*Note:* CHP1 and CHP2 bits must be set prior to the output enable done with TxyOEN bits in the HRTIM_OENR register.

CARFRQ[2:0], CARDTY[2:0] and STRPW[3:0] bitfields cannot be modified while the chopper mode is active (at least one of the two CHPx bits is set).

### 27.3.17 Fault protection

The HRTIM has a versatile fault protection circuitry to disable the outputs in case of an abnormal operation. Once a fault has been triggered, the outputs take a predefined safe state. This state is maintained until the output is re-enabled by software. In case of a permanent fault request, the output remains in its fault state, even if the software attempts to re-enable them, until the fault source disappears.

The HRTIM has 6 FAULT input channels; all of them are available and can be combined for each of the 6 timing units, as shown on Figure 244.
Each fault channel is fully configurable using HRTIM_FLTINR1 and HRTIM_FLTINR2 registers before being routed to the timing units. FLTxSRC FLTxSRC[1:0] bit selects the source of the fault signal, that can be either a digital input or an internal event (built-in comparator output).

Table 214 details the 3 available sources for each of the 6 faults channels.

The EEVx_muxout event mentioned in Figure 244 above is taken after the hrtim_eevx[4:1] input multiplexer controlled by the EExSRC[1:0] bits. Refer to Figure 216 for details.

The polarity of the signal can be selected to define the active level, using the FLTxP polarity bit in HRTIM_FLTINRx registers. If FLTxP = 0, the signal is active at low level; if FLTxP = 1, it is active when high.

The fault information can be filtered after the polarity setting. If FLTxF[3:0] bitfield is set to 0000, the signal is not filtered and acts asynchronously, independently from the fHRTIM clock. For all other FLTxF[3:0] bitfield values, the signal is digitally filtered. The digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered,
depending on the sampling clock and on the filter length (number of valid samples expected). Figure 245 shows how a spurious fault signal is filtered.

**Figure 245. Fault signal filtering (FLTxF[3:0] = 0010: fSAMPLING = fHRTIM, N = 4)**

The filtering period ranges from 2 cycles of the \( f_{HRTIM} \) clock up to 8 cycles of the \( f_{FLTS} \) clock divided by 32. \( f_{FLTS} \) is defined using FLTSD[1:0] bits in the HRTIM_FLTINR2 register. Table 236 summarizes the sampling rate and the filter length. A jitter of 1 sampling clock period must be subtracted from the filter length to take into account the uncertainty due to the sampling and have the effective filtering.

**Table 236. Sampling rate and filter length vs FLTFxF[3:0] and clock setting**

</table>

A fault counter also allows to discard multiple spurious fault events and define an acceptance criteria.

The FLTxCNT[3:0] bitfield selects the FAULTx counter threshold. A fault is considered valid when the number of events is equal to the FLTxCNT[3:0] value.

This FLTxRSTM selects the FAULTx counter reset mode
- 0: fault counter hardware reset on reset / roll-over event, as per the Table 238 below.
- 1: fault counter reset on each reset / roll-over event only if no event occurs during last counting period, as shown on Figure 246 below.

The fault counter can be reset by software with the FLTxCRES bit at anytime.

**Figure 246. Fault counter cumulative mode (FLTxRSTM = 1, FLTxCNT[3:0] = 2)**

![Fault counter cumulative mode diagram](MSv47426V1)
A given FLTx input counter can be reset by a single source. The Table 238 indicates which timer unit associated with a given fault. This does not prevent to have a fault line shared by multiple timer (e.g. FLT1 with event counter enabled, acting on timer A, timer B and timer C simultaneously).

System fault input (hrtim_sys_flt)

This fault is provided by the MCU Class B circuitry (see the system configuration controller (SYSCFG) section for details) and corresponds to a system fault coming from:

- the clock security system
- the SRAM parity checker
- the Cortex®-M4 with FPU lockup signal
- the PVD detector
- the Flash ECC double error detection

This input overrides the FAULT inputs and disables all outputs having FAULTy[1:0] = 01, 10, 11.

For each FAULT channel, a write-once FLTxLCK bit in the HRTIM_FLTxR register allows to lock FLTxE, FLTxP, FLTxSRC, FLTxF[3:0] bits (it renders them read-only), for functional safety purpose. If enabled, the fault conditioning set-up is frozen until the next HRTIM or system reset.

Once the fault signal is conditioned as explained above, it is routed to the timing units. For any of them, the 6 fault channels are enabled using bits FLT1EN to FLT6EN in the HRTIM_FLTxR register, and they can be selected simultaneously (the sysfault is automatically enabled as long as the output is protected by the fault mechanism). This allows to have, for instance:

- One fault channel simultaneously disabling several timing units
- Multiple fault channels being ORed to disable a single timing unit

A write-once FLTLCK bit in the HRTIM_FLTxR register allows to lock FLTxEN bits (it renders them read-only) until the next reset, for functional safety purpose. If enabled, the timing unit fault-related set-up is frozen until the next HRTIM or system reset.

For each of the timers, the output state during a fault is defined with FAULT1[1:0] and FAULT2[1:0] bits in the HRTIM_OUTxR register (see Section 27.3.14).
27.3.18 Auxiliary outputs

Timer A to E have auxiliary outputs in parallel with the regular outputs going to the output stage. They provide the following internal status, events and signals:

- SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset
- External event filters following a Tx2 output copy (see details in Section 27.3.9)

The auxiliary outputs are taken either before or after the burst mode controller, depending on the HRTIM operating mode. An overview is given on Figure 247.

Figure 247. Auxiliary outputs

By default, the auxiliary outputs are copies of outputs Tx1 and Tx2. The exceptions are:

- The delayed idle and the balanced idle protections, when the deadtime is disabled (DTEN = 0). When the protection is triggered, the auxiliary outputs are maintained and follow the signal coming out of the crossbar. On the contrary, if the deadtime is enabled (DTEN = 1), both main and auxiliary outputs are forced to an inactive level.
- The burst mode (TCEN=1, IDLEMx=1); there are 2 cases:
  a) If DTEN=0 or DIDLx=0, the auxiliary outputs are not affected by the burst mode entry and continue to follow the reference signal coming out of the crossbar (see Figure 248).
  b) If the deadtime is enabled (DTEN=1) together with the delayed burst mode entry (DIDLx=1), the auxiliary outputs have the same behavior as the main outputs. They are forced to the IDLES level after a deadtime duration, then they keep this level during all the burst period. When the burst mode is terminated, the IDLES level is maintained until a transition occurs to the opposite level, similarly to the main output.
The signal on the auxiliary output can be slightly distorted when exiting from the burst mode or when re-enabling the outputs after a delayed protection, if this happens during a deadtime. In this case, the deadtime applied to the auxiliary outputs is extended so that the deadtime on the main outputs is respected. Figure 249 gives some examples.
27.3.19 Synchronizing the HRTIM with other timers or HRTIM instances

The HRTIM provides options for synchronizing multiple HRTIM instances, as a master unit (generating a synchronization signal) or as a slave (waiting for a trigger to be synchronized). This feature can also be used to synchronize the HRTIM with other timers, either external or on-chip. The synchronization circuitry is controlled inside the master timer.

Synchronization output

This section explains how the HRTIM must be configured to synchronize external resources and act as a master unit.

Four events can be selected as the source to be sent to the synchronization output. This is done using SYNCSRC[1:0] bits in the HRTIM_MCR register, as follows:

- **00**: master timer start
  This event is generated when MCEN bit is set or when the timer is re-started after having reached the period value in single-shot mode. It is also generated on a reset which occurs during the counting (when CONT or RETRIG bits are set).
- **01**: master timer compare 1 event
- **10**: timer A start
  This event is generated when TACEN bit is set or when the counter is reset and re-starts counting in response to this reset. The following counter reset events are not propagated to the synchronization output: counter roll-over in continuous mode, and discarded reset request in single-shot non-retriggerable mode. The reset is only taken into account when it occurs during the counting (CONT or RETRIG bits are set).
- **11**: timer A compare 1 event

SYNCOUT[1:0] bits in the HRTIM_MCR register specify how the synchronization event is generated.

The synchronization pulses can be generated on the HRTIM_SCOUT output pin, with SYNCSRC[1:0] = 1x. SYNCSRC[0] bit specifies the polarity of the synchronization signal. If SYNCSRC[0] = 0, the HRTIM_SCOUT pin has a low idle level and issues a positive pulse of 16 f_HRTIM clock cycles length for the synchronization). If SYNCSRC[0] = 1, the idle level is high and a negative pulse is generated.

*Note:* The synchronization pulse is followed by an idle level of 16 f_HRTIM clock cycles during which any new synchronization request is discarded. Consequently, the maximum synchronization frequency is f_HRTIM/32.

The idle level on the HRTIM_SCOUT pin is applied as soon as the SYNCSRC[1:0] bits are enabled (i.e. the bitfield value is different from 00).

The synchronization output initialization procedure must be done prior to the configuration of the MCU outputs and counter enable, in the following order:

1. SYNCSRC[1:0] and SYNCSRC[1:0] bitfield configuration in HRTIM_MCR
2. HRTIM_SCOUT pin configuration (see the General-purpose I/Os section)
3. Master or timer A counter enable (MCEN or TACEN bit set)

When the synchronization input mode is enabled and starts the counter (using SYNCSTRTM/SYNCTRTx bits) simultaneously with the synchronization output mode (SYNCSRC[1:0] = 00 or 10), the output pulse is generated only when the counter is starting or is reset while running. Any reset request clearing the counter without causing it to start does not affect the synchronization output.
Synchronization input

The HRTIM can be synchronized by external sources, as per the programming of the SYNCIN[1:0] bits in the HRTIM_MCR register:

- **00**: synchronization input is disabled
- **01**: reserved configuration
- **10**: the On-chip timer TRGO output connected to hrtim_in_sync[2] input (refer to Table 208 for details).
- **11**: a positive pulse on the HRTIM_SCIN input pin (hrtim_in_sync[3])

This bitfield cannot be changed once the destination timer (master timer or timing unit) is enabled (MCEN and/or TxCEN bit set).

The HRTIM_SCIN input is rising-edge sensitive. The timer behavior is defined with the following bits present in HRTIM_MCR and HRTIM_TIMxCR registers (see Table 239 for details):

- **Synchronous start**: the incoming signal starts the timer’s counter (SYNCSTRTM and/or SYNCRSTx bits set). TxCEN (MCEN) bits must be set to have the timer enabled and the counter ready to start. In continuous mode, the counter does not start until the synchronization signal is received.
- **Synchronous reset**: the incoming signal resets the counter (SYNCRSTM and/or SYNCRSTx bits set). This event decrements the repetition counter as any other reset event.

The synchronization events are taken into account only once the related counters are enabled (MCEN or TxCEN bit set). A synchronization request triggers a SYNC interrupt.

**Note:** *A synchronized start event resets the counter if the current counter value is above the active period value.*

The effect of the synchronization event depends on the timer operating mode, as summarized in Table 239.

### Table 239. Effect of sync event versus timer operating modes

<table>
<thead>
<tr>

<td>A start occurring when the counter is stopped at the period value resets the counter. A reset request clears the counter but does not start it (the counter can solely be re-started with the synchronization). Any reset occurring during the counting is ignored (as during regular non-retriggerable mode).</td>
</tr>
</tbody>
</table>

When multiple reset requests are selected (from HRTIM_SCIN and from internal events), only the first arriving request is taken into account.
When a synchronization reset event occurs within the same fHRTIM clock cycle as the period event, this reset is postponed to a programmed period event (since both events are causing a counter roll-over). This applies only when the high-resolution is active (CKPSC[2:0] < 5).

</tbody>
</table>
Figure 250 presents how the synchronized start is done in single-shot mode.

**Figure 250. Counter behavior in synchronized start mode**

### 27.3.20 ADC triggers

The ADCs can be triggered by the master and the 6 timing units. 10 independent triggers are available for both the regular and the injected sequencers of the ADCs. The external events can be used as triggers. They are taken right after the conditioning defined in the HRTIM_EECRx registers, and are not depending on the EEFxR1 and EEFxR2 register settings.

Up to 32 events can be combined (ORed) for ADC triggers 1 to 4, in HRTIM_ADC1R to HRTIM_ADC4R registers, as shown on Figure 251. The ADC triggers 1/3 and 2/4 are using the same source set. A multiple triggering is possible within a single switching period by selecting several sources simultaneously. A typical use case is for a non-overlapping multiphase converter, where all phases can be sampled in a row using a single ADC trigger output.
The ADC triggers 5 to 10 are configured in the HRTIM_ADCER register, as shown on Figure 252. The ADC triggers 5/7/9 and 6/8/10 are using the same source set.

A single source can be selected at once for these triggers (1 out of 32 possible events).
HRTIM_ADC1R to HRTIM_ADC4R and HRTIM_ADCER registers are preloaded and can be updated synchronously with the timer they are related to. The update sources are defined with ADxUSRC[2:0] bits in the HRTIM_CR1 and HRTIM_ADCUR registers.

For instance, if ADC trigger 1 outputs timer A CMP2 events (HRTIM_ADC1R = 0x0000 0400), HRTIM_ADC1R is typically updated simultaneously with timer A (AD1USRC[2:0] = 001).

When the preload is disabled (PREEN bit reset) in the source timer, the HRTIM_ADCxR registers are not preloaded either: a write access results in an immediate update of the trigger source.

**ADC post-scaler**

A post-scaling unit allows to reduce the ADC trigger rate with respect to the switching frequency.

Each ADC trigger rate can be individually adjusted using the ADCxPSC[4:0] bits in the HRTIM_ADCxPS1 and HRTIM_ADCxPS2 registers as shown in **Figure 253** below for the up-counting mode.

In the center-aligned mode, the ADC post-scaling is done on events selected with the ADROM[1:0] bitfield, programmed in the source timer, as shown in **Figure 254**.
ADROM[1:0] bitfield is coding for any event that can trigger the ADC: reset, roll-over (period) and compare event:

- ADROM[1:0] = 00: event generated both during up and down-counting phases
- ADROM[1:0] = 01: event generated during down-counting phases
- ADROM[1:0] = 10: event generated during up-counting phases

The ADC post-scaler programming register are preloaded and can be updated on-the-fly without stopping the timers.

**Figure 253. ADC trigger post-scaling in up-counting mode**

**Figure 254. ADC trigger post-scaling in up/down counting mode**
27.3.21 DAC triggers

The HRTIM allows to have the embedded DACs updated synchronously with the timer updates.

The update events from the master timer and the timer units can generate DAC update triggers on any of the 3 hrtim_dac_trgx outputs.

Note: Each timer has its own DAC-related control register.

DACSYNC[1:0] bits of the HRTIM_MCR and HRTIM_TIMxCR registers are programmed as follows:
- 00: No update generated
- 01: Update generated on hrtim_dac_trg1
- 10: Update generated on hrtim_dac_trg2
- 11: Update generated on hrtim_dac_trg3

An output pulse of 1 fHRTIM clock periods is generated on the hrtim_dac_trgx output.

When DACSYNC[1:0] bits are enabled in multiple timers, the hrtim_dac_trgx output consists of an OR of all timers’ update events. For instance, if DACSYNC = 1 in timer A and in timer B, the update event in timer A is ORed with the update event in timer B to generate a DAC update trigger on the corresponding hrtim_dac_trgx output, as shown on Figure 255.

Figure 255. Combining several updates on a single hrtim_dac_trgx output

Refer to Table 215: HRTIM DAC triggers connections for connections to the DACs.
**Dual channel DAC trigger**

Slope compensation techniques and hysteretic control to be easily implemented using HRTIM built-in features and the DAC sawtooth generator. The principle is to have a DAC generating a decreasing saw-tooth synchronized with the PWM period, or a square wave synchronized with PWM signal.

This mode is enabled with the DCDE bit in the TIMxCR2 register. This bit cannot be changed once the timer is operating (TxEN bit set).

It uses two trigger outputs, as shown on the Figure 256 below:

- the hrtim_dac_reset_trgx generates DAC reset/update events
- the hrtim_dac_step_trgx generates requests for incremental DAC value changes

The DCDR bit in the TIMxCR2 register defines when the hrtim_dac_reset_trgx trigger is generated:

- **DCDR = 0**: the trigger is generated on counter reset or roll-over event
- **DCDR = 1**: the trigger is generated on output 1 set event

*Note:* The DCDR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

The DCDS bit in the TIMxCR2 register defines when the hrtim_dac_step_trgx trigger is generated:

- **DCDS = 0**: the trigger is generated on compare 2 event
- **DCDS = 1**: the trigger is generated on output 1 reset event

The DCDR and DCDS bits allows the following use cases to be covered:

- Edge-aligned slope compensation (DCDR = DCDS = 0): the DAC’s sawtooth starts on PWM period beginning and multiple triggers are generated during the period
- Center-aligned slope compensation (DCDR = 1 DCDS = 0): the DAC’s sawtooth starts on the output set event and multiple triggers are generated during the period
- Hysteretic controller: the DAC value must be changed twice per period, when the output state changes. 2 triggers are generated per PWM period. In edge-aligned mode (DCDR=0, DCDS =1), the triggers are generated on counter reset or roll-over. In center-aligned mode (DCDR=1, DCDS=1), the triggers are generated when the output is set.

The compare 2 has a particular operating mode when the DCDE is set and the DCDS bit is reset. The active comparison value is automatically updated as soon as a compare match has occurred, so that the trigger can be repeated periodically with a period equal to the CMP2 value, as represented on Figure 256.

The dual channel DAC trigger with DCDS bit reset (compare 2 event used) must not be used simultaneously with modes using CMP2 (triple / quad interleaved and triggered-half modes).

*Note:* The CMP2 value can be changed on-the-fly. The new value is taken into account on the next coming compare match.

*Note:* When the DCDS bit is reset, the CMP2 value must not be modified by other mechanisms: the interleaved, triggered half and balanced idle modes must be disabled.
Table 240 below gives an example, for generating 6 triggers within a PWM period. It shows that it is necessary to round up the division result to the upper value.

Let’s consider a counter period TIMxPER = 8192. Dividing 8192 by 6 yields 1365.33.

- Round down value: 1365: 7 triggers are generated, the 6th and 7th being very close (respectively for counter = 8190 and 8192)
- Round up value: 1366: 6 triggers are generated. The 6th trigger on dac_step_trg (for counter = 8192) is aborted by the counter roll-over from 8192 to 0.

Note: In centered-pattern mode, it is mandatory to have an even number of triggers per switching period, so as to avoid unevenly spaced triggers around counter’s peak value.
Figure 256. DAC triggers for slope compensation

DCDR = 0 (reset on roll-over), DCDT = 0 (step trigger on Compare 2)

DCDR = 1 (reset on output 1 set), DCDT = 1 (step trigger on output 1 reset)

**Figure 257. DAC triggers overview**

27.3.22 Interrupts

7 interrupts can be generated by the master timer:
- Master timer registers update
- Synchronization event received
- Master timer repetition event
- Master compare 1 to 4 event
14 interrupts can be generated by each timing unit:
- Delayed protection triggered
- Counter reset or roll-over event
- Output 1 and output 2 reset (transition active to inactive)
- Output 1 and output 2 set (transition inactive to active)
- Capture 1 and 2 events
- Timing unit registers update
- Repetition event
- Compare 1 to 4 event

8 global interrupts are generated for the whole HRTIM:
- System fault and fault 1 to 6 (regardless of the timing unit attribution)
- DLL calibration done
- Burst mode period completed

The interrupt requests are grouped in 8 vectors as follows:
- hrtim_it1: master timer interrupts (master update, sync Input, repetition, MCMP1..4) and global interrupt except faults (burst mode period and DLL ready interrupts)
- hrtim_it2: TIMA interrupts
- hrtim_it3: TIMB interrupts
- hrtim_it4: TIMC interrupts
- hrtim_it5: TIMD interrupts
- hrtim_it6: TIME interrupts
- hrtim_it7: TIMF interrupts
- hrtim_it8: Dedicated vector all fault interrupts to allow high-priority interrupt handling

Table 241 is a summary of the interrupt requests, their mapping and associated control, and status bits.

Most of the events able to generate an interrupt can also generate a DMA request, even both simultaneously. Each timer (master, TIMA...F) has its own DMA enable register.

The individual DMA requests are ORed into 7 channels as follows:

- 1 channel for the master timer
- 1 channel per timing unit (TIMA...F)

**Note:** Before disabling a DMA channel (DMA enable bit reset in TIMxDIER), it is necessary to disable first the DMA controller.

*Table 242* is a summary of the events with their associated DMA enable bits.

Burst DMA transfers

In addition to the standard DMA requests, the HRTIM features a DMA burst controller to have multiple registers updated with a single DMA request. This allows to:
- update multiple data registers with one DMA channel only,
- reprogram dynamically one or several timing units, for converters using multiple timer outputs.
The burst DMA feature is only available for one DMA channel, but any of the 6 channels can be selected for burst DMA transfers.

The principle is to program which registers are to be written by DMA. The master timer and TIMA..E have the burst DMA update register, where most of their control and data registers are associated with a selection bit: HRTIM_BDMUPR, HRTIM_BDTAUPR to HRTIM_BDTEUPR (this is applicable only for registers with write accesses). A redirection mechanism allows to forward the DMA write accesses to the HRTIM registers automatically, as shown on Figure 258.

**Figure 258. DMA burst overview**

When the DMA trigger occurs, the HRTIM generates multiple 32-bit DMA requests and parses the update register. If the control bit is set, the write access is redirected to the associated register. If the bit is reset, the register update is skipped and the register parsing is resumed until a new bit set is detected, to trigger a new request. Once the 6 update registers (HRTIM_BDMUPR, 5x HRTIM_BDTxUPR) are parsed, the burst is completed and the system is ready for another DMA trigger (see the flowchart on Figure 259).

**Note:** Any trigger occurring while the burst is on-going is discarded, except if it occurs during the very last data transfer.

The burst DMA mode is permanently enabled (there is no enable bit). A burst DMA operation is started by the first write access into the HRTIM_BDMADR register.

It is only necessary to have the DMA controller pointing to the HRTIM_BDMADR register as the destination, in the memory, to the peripheral configuration with the peripheral increment mode disabled (the HRTIM handles internally the data re-routing to the final destination register).

To re-initialize the burst DMA mode if it was interrupted during a transaction, it is necessary to write at least to one of the 6 update registers.
Several options are available once the DMA burst is completed, depending on the register update strategy.

If the PREEN bit is reset (preload disabled), the value written by the DMA is immediately transferred into the active register and the registers are updated sequentially, following the DMA transaction pace.

When the preload is enabled (PREEN bit set), there are 3 use cases:

1. The update is done independently from DMA burst transfers (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 00 in HRTIM_MCR). In this case, and if it is necessary to have all transferred data taken into account simultaneously, the user must check that the DMA burst is completed before the update event takes place. On the contrary, if the update event happens while the DMA transfer is on-going, only part of the registers is loaded and the complete register update requires 2 consecutive update events.

2. The update is done when the DMA burst transfer is completed (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 01 in HRTIM_MCR). This mode guarantees that all new register values are transferred simultaneously. This is done independently from the counter value and can be combined with regular update events, if necessary (for instance, an update on a counter reset when TxRSTU is set).

3. The update is done on the update event following the DMA burst transfer completion (UPDGAT[3:0] = 0010 in HRTIM_TIMxCR and BRSTDMA[1:0] = 10 in HRTIM_MCR). This mode guarantees both a coherent update of all transferred data and the synchronization with regular update events, with the timer counter. In this case, if a regular update request occurs while the transfer is on-going, it is discarded and the effective update happens on the next coming update request.
The chronogram on Figure 260 presents the active register content for 3 cases: PREEN=0, UPDGAT[3:0] = 0001 and UPDGAT[3:0] = 0001 (when PREEN = 1).

**Figure 260. Registers update following DMA burst transfer**

**27.3.24 HRTIM initialization**

This section describes the recommended HRTIM initialization procedure, including other related MCU peripherals.

The HRTIM clock source must be enabled in the reset and clock control unit (RCC), while respecting the fHRTIM range for the DLL lock.

The DLL calibration must be started by setting CAL bit in HRTIM_DLLCR register.

The HRTIM master and timing units can be started only once the high-resolution unit is ready. This is indicated by the DLLRDY flag set. The DLLRDY flag can be polled before resuming the initialization or the calibration can run in background while other registers of the HRTIM or other MCU peripherals are initialized. In this case, the DLLRDY flag must be checked before starting the counters (an end-of-calibration interrupt can be issued if necessary, enabled with DLLRDYIE flag in HRTIM_IER). Once the DLL calibration is done, CALEN bit must be set to have it done periodically and compensate for potential voltage and temperature drifts. The calibration periodicity is defined using the CALRTE[1:0] bitfield in the HRTIM_DLLCR register.
The HRTIM control registers can be initialized as per the power converter topology and the timing units use case. All inputs have to be configured (source, polarity, edge-sensitivity).

The HRTIM outputs must be set up eventually, with the following sequence:
- the polarity must be defined using POLx bits in HRTIM_OUTxR
- the FAULT and IDLE states must be configured using FAULTx[1:0] and IDLESx bits in HRTIM_OUTxR

The HRTIM outputs are ready to be connected to the MCU I/Os. In the GPIO controller, the selected HRTIM I/Os have to be configured as per the alternate function mapping table in the product datasheet.

From this point on, the HRTIM controls the outputs, which are in the IDLE state.

The outputs are configured in RUN mode by setting TxyOEN bits in the HRTIM_OENR register. The 2 outputs are in the inactive state until the first valid set/reset event in RUN mode. Any output set/reset event (except software requests using SST, SRT) are ignored as long as TxCEN bit is reset, as well as burst mode requests (IDLEM bit value is ignored). Similarly, any counter reset request coming from the burst mode controller is ignored (if TxBM bit is set).

**Note:** When the deadtime insertion is enabled (DTEN bit set), it is necessary to force the output state by software, using SST and RST bits, to have the outputs in a complementary state as soon as the RUN mode is entered.

The HRTIM operation can eventually be started by setting TxCEN or MCEN bits in HRTIM_MCR.

If the HRTIM peripheral is reset with the Reset and Clock Controller, the output control is released to the GPIO controller and the outputs are tri-stated.

### 27.3.25 Debug

When a microcontroller enters the debug mode (Cortex®-M4 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG_HRTIM_STOP configuration bit in DBG module:
- DBG_HRTIM_STOP = 0: no behavior change, the HRTIM continues to operate.
- DBG_HRTIM_STOP = 1: all HRTIM timers, including the master, are stopped. The outputs in RUN mode enter the FAULT state if FAULTx[1:0] = 01,10,11, or keep their current state if FAULTx[1:0] = 00. The outputs in idle state are maintained in this state. This is permanently maintained even if the MCU exits the halt mode. This allows to maintain a safe state during the execution stepping. The outputs can be enabled again by settings TxyOEN bit (requires the use of the debugger).

**Timer behavior during MCU halt when DBG_HRTIM_STOP = 1**

The set/reset crossbar, the dead-time and push-pull unit, the idle/balanced fault detection and all the logic driving the normal output in RUN mode are not affected by debug. The output keeps on toggling internally, so as to retrieve regular signals of the outputs when TxyOEN is set again (during or after the MCU halt). Associated triggers and filters are also following internal waveforms when the outputs are disabled.

FAULT inputs and events (any source) are enabled during the MCU halt.

Fault status bits can be set and TxyOEN bits reset during the MCU halt if a fault occurs at that time (TxyOEN and TxyODS are not affected by DBG_HRTIM_STOP bit state).
Synchronization, counter reset, start and reset-start events are discarded in debug mode, as well as capture events. This is to keep all related registers stable as long as the MCU is halted.

The counter stops counting when a breakpoint is reached. However, the counter enable signal is not reset; consequently no start event is emitted when exiting from debug. All counter reset and capture triggers are disabled, as well as external events (ignored as long as the MCU is halted). The outputs SET and RST flags are frozen, except in case of forced software set/reset. A level-sensitive event is masked during the debug but is active again as soon as the debug is exited. For edge-sensitive events, if the signal is maintained active during the MCU halt, a new edge is not generated when exiting from debug.

The update events are discarded. This prevents any update trigger on hrtim_upd_en[3:1] inputs. DMA triggers are disabled. The burst mode circuit is frozen: the triggers are ignored and the burst mode counter stopped.

DLL calibration is not blocked while the MCU is halted (the DLLRDY flag can be set).

### 27.4 Application use cases

#### 27.4.1 Buck converter

Buck converters are of common use as step-down converters. The HRTIM can control up to 12 buck converters with 7 independent switching frequencies.

The converter usually operates at a fixed frequency and the Vin/Vout ratio depends on the duty cycle D applied to the power switch:

\[ V_{out} = D \times V_{in} \]

The topology is given on Figure 261 with the connection to the ADC for voltage reading.

*Figure 261. Buck converter topology*

*Figure 262* presents the management of two converters with identical frequency PWM signals. The outputs are defined as follows:

- HRTIM_CHA1 set on period, reset on CMP1
- HRTIM_CHA2 set on CMP3, reset on PER

The ADC is triggered twice per period, precisely in the middle of the ON time, using CMP2 and CMP4 events.
Timers A..E provide either 12 buck converters coupled by pairs (both with identical switching frequencies) or 7 completely independent converters (each of them having a different switching frequency), using the master timer as the 7th time base.

### 27.4.2 Buck converter with synchronous rectification

Synchronous rectification allows to minimize losses in buck converters, by means of a FET replacing the freewheeling diode. Synchronous rectification can be turned on or off on the fly depending on the output current level, as shown on Figure 263.

The main difference versus a single-switch buck converter is the addition of a deadtime for an almost complementary waveform generation on HRTIM_CHA2, based on the reference waveform on HRTIM_CHA1 (see Figure 264).
27.4.3 Multiphase converters

Multiphase techniques can be applied to multiple power conversion topologies (buck, flyback). Their main benefits are:

- Reduction of the current ripple on the input and output capacitors
- Reduced EMI
- Higher efficiency at light load by dynamically changing the number of phases (phase shedding)

The HRTIM manages multiple converters. The number of converters that can be controlled depends on the topologies and resources used (including the ADC triggers):

- 5 buck converters with synchronous rectification (SR), using the master timer and the 5 timers
- 4 buck converters (without SR), using the master timer and 2 timers

Figure 265 presents the topology of a 3-phase interleaved buck converter.
The master timer is responsible for the phase management: it defines the phase relationship between the converters by resetting the timers periodically. The phase-shift is 360° divided by the number of phases, 120° in the given example.

The duty cycle is then programmed into each of the timers. The outputs are defined as follows:

- HRTIM_CHA1 set on master timer period, reset on TACMP1
- HRTIM_CHB1 set on master timer MCMP1, reset on TBCMP1
- HRTIM_CHC1 set on master timer MCMP2, reset on TCCMP1

The ADC trigger can be generated on TxCMP2 compare event. Since all ADC trigger sources are phase-shifted because of the converter topology, it is possible to have all of them combined into a single ADC trigger to save ADC resources (for instance 1 ADC regular channel for the full multi-phase converter).

**Figure 266. 3-phase interleaved buck converter control**

---

### 27.4.4 Transition mode power factor correction

The basic operating principle is to build up current into an inductor during a fixed Ton time. This current then decays during the Toff time, and the period is re-started when it becomes null. This is detected using a Zero Crossing Detection circuitry (ZCD), as shown on **Figure 267**. With a constant Ton time, the peak current value in the inductor is proportional to the rectified AC input voltage, which provides the power factor correction.
This converter operates with a constant Ton time and a variable frequency due the Toff time variation (depending on the input voltage). It must also include some features to operate when no zero-crossing is detected, or to limit the Ton time in case of over-current (OC). The OC feedback is usually conditioned with the built-in comparator and routed onto an external event input.

*Figure 268* presents the waveform during the various operating modes, with the following defined parameters:

- Ton Min: masks spurious overcurrent (freewheeling diode recovery current), represented as OC blanking
- Ton Max: practically, the converter set-point. It is defined by CMP1
- Toff Min: limits the frequency when the current limit is close to zero (demagnetization is very fast). It is defined with CMP2.
- Toff Max: prevents the system to be stuck if no ZCD occurs. It is defined with CMP4 in auto-delayed mode.

Both Toff values are auto-delayed since the value must be relative to the output falling edge.
Figure 268. Transition mode PFC waveforms
### 27.5 HRTIM registers

#### 27.5.1 HRTIM master timer control register (HRTIM_MCR)

Bits 31:30 **BRSTDMA[1:0]:** Burst DMA update  
These bits define how the update occurs relatively to a burst DMA transaction.  
00: Update done independently from the DMA burst transfer completion  
01: Update done when the DMA burst transfer is completed  
10: Update done on master timer roll-over following a DMA burst transfer completion. This mode only works in continuous mode.  
11: Reserved

Bit 29 **MREPU:** Master timer repetition update  
This bit defines whether an update occurs when the master timer repetition period is completed (either due to roll-over or reset events). MREPU can be set only if BRSTDMA[1:0] = 00 or 01.  
0: Update on repetition disabled  
1: Update on repetition enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **PREEN:** Preload enable  
This bit enables the registers preload mechanism and defines whether the write accesses to the memory mapped registers are done into HRTIM’s active or preload registers.  
0: Preload disabled: the write access is directly done into the active register  
1: Preload enabled: the write access is done into the preload register

Bits 26:25 **DACSYNC[1:0]:** DAC synchronization  
A DAC synchronization event can be enabled and generated when the master timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to **Section 27.3.21: DAC triggers** for connections details).  
00: No DAC trigger generated  
01: Trigger generated on hrtim_dac_trg1  
10: Trigger generated on hrtim_dac_trg2  
11: Trigger generated on hrtim_dac_trg3

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **TFCEN:** Timer F counter enable  
This bit starts the timer F counter.  
0: Timer F counter disabled  
1: Timer F counter enabled

**Note:** This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.
Bit 21 **TECEN**: Timer E counter enable
This bit starts the timer E counter.
0: Timer E counter disabled
1: Timer E counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bit 20 **TDCEN**: Timer D counter enable
This bit starts the timer D counter.
0: Timer D counter disabled
1: Timer D counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bit 19 **TCCEN**: Timer C counter enable
This bit starts the timer C counter.
0: Timer C counter disabled
1: Timer C counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bit 18 **TBCEN**: Timer B counter enable
This bit starts the timer B counter.
0: Timer B counter disabled
1: Timer B counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bit 17 **TACEN**: Timer A counter enable
This bit starts the timer A counter.
0: Timer A counter disabled
1: Timer A counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bit 16 **MCEN**: Master timer counter enable
This bit starts the master timer counter.
0: Master counter disabled
1: Master counter enabled

*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{\text{HRTIM}}$ clock.

Bits 15:14 **SYNCSRC[1:0]**: Synchronization source
These bits define the source and event to be sent on the synchronization outputs SYNCOUM[2:1]
00: Master timer start
01: Master timer compare 1 event
10: Timer A start/reset
11: Timer A compare 1 event

Bits 13:12 **SYNCOUM[1:0]**: Synchronization output
These bits define the routing and conditioning of the synchronization output event.
00: Disabled
01: Reserved
10: Positive pulse on HRTIM_SCOUT output (16x $f_{\text{HRTIM}}$ clock cycles)
11: Negative pulse on HRTIM_SCOUT output (16x $f_{\text{HRTIM}}$ clock cycles)

*Note*: This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 11 **SYNCSTRTM**: Synchronization starts master
This bit enables the master timer start when receiving a synchronization input event:
0: No effect on the master timer
1: A synchronization input event starts the master timer
Bit 10 **SYNCRSTM**: Synchronization resets master
This bit enables the master timer reset when receiving a synchronization input event:
0: No effect on the master timer
1: A synchronization input event resets the master timer

Bits 9:8 **SYNCIN[1:0]**: Synchronization input
These bits are defining the synchronization input source.
00: Disabled. HRTIM is not synchronized and runs in standalone mode.
01: Reserved
10: Internal event on hrtim_in_sync[2]: the HRTIM is synchronized with the on-chip timer (see Section : Synchronization input).
11: External event on hrtim_in_sync[3]: a positive pulse on HRTIM_SCIN input triggers the HRTIM.
Note: This parameter cannot be changed once the impacted timers are enabled.

Bits 7:6 **INTLVD[1:0]**: Interleaved mode
This bitfield is significant only when the HALF bit is reset. It enables the interleaved mode.
00: Interleaved mode disabled
01: Triple interleaved mode: when HRTIM_MPER register is written, the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/3 value, and the HRTIM_MCMP2R active register is automatically updated with 2x (HRTIM_MPER/3) value.
10: Quad interleaved mode: when HRTIM_MPER register is written, the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/4 value, the HRTIM_MCMP2R active register is automatically updated with HRTIM_MPER/2 value and the HRTIM_MCMP3R active register is automatically updated with 3x (HRTIM_MPER/4) value.
11: Interleaved mode disabled

Bit 5 **HALF**: Half mode
This bit enables the half duty-cycle mode: the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/2 value when HRTIM_MPER register is written.
0: Half mode disabled
1: Half mode enabled

Bit 4 **RETRIG**: Re-triggerable mode
This bit defines the behavior of the master timer counter in single-shot mode.
0: The timer is not re-triggerable: a counter reset can be done only if the counter is stopped (period elapsed)
1: The timer is re-triggerable: a counter reset is done whatever the counter state (running or stopped)

Bit 3 **CONT**: Continuous mode
0: The timer operates in single-shot mode and stops when it reaches the MPER value
1: The timer operates in continuous (free-running) mode and rolls over to zero when it reaches the MPER value

Bits 2:0 **CKPSC[2:0]**: Clock prescaler
These bits define the master timer high-resolution clock prescaler ratio.
The counter clock equivalent frequency (f\_COUNTER) is equal to f\_HRCK / 2^{CKPSC[2:0]}. The prescaling ratio cannot be modified once the timer is enabled.
### 27.5.2 HRTIM master timer interrupt status register (HRTIM_MISR)
