Field	Description
2 RXICMPEROIM	MMC Receive ICMP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_octets counter reaches half of the maximum value or the maximum value.
3 RXICMPGOIM	MMC Receive ICMP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_octets counter reaches half of the maximum value or the maximum value.
4 RXTCPEROIM	MMC Receive TCP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_octets counter reaches half of the maximum value or the maximum value.
5 RXTCPGOIM	MMC Receive TCP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_octets counter reaches half of the maximum value or the maximum value.
6 RXUDPEROIM	MMC Receive UDP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_octets counter reaches half of the maximum value or the maximum value.
7 RXUDPGOIM	MMC Receive IPV6 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_octets counter reaches half of the maximum value or the maximum value.
8 RXIPV6NOPAYOIM	MMC Receive IPV6 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_octets counter reaches half of the maximum value or the maximum value.

Table 767. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
9 RXIPV6HEROIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_octets counter reaches half of the maximum value or the maximum value.
10 RXIPV6GOIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half of the maximum value or the maximum value.
11 RXIPV4UDSBLOIM	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half of the maximum value or the maximum value.
12 RXIPV4FRAGOIM	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half of the maximum value or the maximum value.
13 RXIPV4NOPAYOIM	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value.
14 RXIPV4HEROIM	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value.
15 RXIPV4GOIM	MMC Receive IPV4 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value.
18 RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_pkts counter reaches half of the maximum value or the maximum value.
19 RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_pkts counter reaches half of the maximum value or the maximum value.
20 RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_pkts counter reaches half of the maximum value or the maximum value.
21 RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_pkts counter reaches half of the maximum value or the maximum value.
22 RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_pkts counter reaches half of the maximum value or the maximum value.
23 RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_pkts counter reaches half of the maximum value or the maximum value.
24 RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_pkts counter reaches half of the maximum value or the maximum value.

Table 767. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
25 RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
26 RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value.
27 RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value.
28 RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value.
29 RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value.
30 RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
31 RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value.

47.2.105 MMC IPC Receive Interrupt Register (MMC_IPC_RX_INTERRUPT)

This register maintains the interrupt that the receive IPC statistic counters generate.

Field	Description
0:31 RXIPV6GDPKT	This field indicates the number of good IPv6 datagrams received with the TCP, UDP, or ICMP payload.

47.2.112 Receive IPv6 Header Error Packets (RXIPV6_HEADER_ERROR_PACKETS)

This register provides the number of IPv6 datagrams received by the Ethernet module with header (length or version mismatch) errors.

Figure 734. Layer 3 and Layer 4 Control 0 Register (MAC_L3_L4_CONTROL0)

Table 797. MAC_L3_L4_CONTROL0 field descriptions

Field	Description
3 DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter.
7 DMCHN0	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. 0 Packet is passed by this filter to DMA CH 0 1 Packet is passed by this filter to DMA CH 1
10 L4DPIM0	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high.
11 L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
12 L4SPIM0	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high.
13 L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
15 L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.

Table 797. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
16:20 L3HDBM0	Layer 3 IP DA Higher Bits Match **IPv4 Packets:** This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: 0x00 No bits are masked. 0x01 1 LSb is masked 0x02 Two LSbs are masked ... 0x1F All bits except MSb are masked. **IPv6 Packets:** Bits[29:30] of this field correspond to Bits[25:26] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[30:31] and L3HSBM0 bits: - 0x00 No bits are masked. - 0x01 1 LSb is masked. - 0x02 Two LSbs are masked - … - 0x7F All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
21:25 L3HSBM0	Layer 3 IP SA Higher Bits Match **IPv4 Packets:** This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: 0x00 No bits are masked. 0x01 1 LSb is masked 0x02 Two LSbs are masked … 0x1F All bits except MSb are masked. **IPv6 Packets:** This field contains Bits[27:31] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
26 L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.
27 L3DAM0	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Table 797. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
28 L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
29 L3SAM0	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
31 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. Value After Reset: 0x0

47.2.135 Layer 4 Address 0 Register (MAC_LAYER4_ADDRESS0)

This register holds the TCP source and destination port numbers against which a match is performed.

Offset 0x0904 Access: User Read/Write

Figure 735. Layer4 Address 0 Register (MAC_LAYER4_ADDRESS0)

Table 798. MAC_LAYER4_ADDRESS0 field descriptions

Field	Description
0:15 L4DP0	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
16:31 L4SP0	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

47.2.136 Layer 3 Address 0 Register 0 Register (MAC_LAYER3_ADDRESS0_REG0)

For IPv4 packets, the Layer 3 Address 0 Register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[96:127] of the 128-bit IP Source Address or Destination Address field.

Offset 0x0910 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 740. Timestamp Control Register (MAC_TIMESTAMP_CONTROL)

Table 803. MAC_TIMESTAMP_CONTROL field descriptions

Field	Description
3 AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation.
7 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the MAC_TxTimestamp_Status_Seconds register.
13 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. MAC address registers 0 to 31 is considered for unicast destination address matching.
14:15 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 16 and 17, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.

Table 803. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
16 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.
17 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, refer to Timestamp Snapshot Dependency on Register Bits Table.
18 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.
19 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.
20 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
21 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.
22 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programed correctly depending on the PTP reference clock frequency and the value of this bit.
23 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.
26 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
27 TSTRIG	Enable Timestamp Interrupt Trigger When this bit is set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the Timestamp Trigger Interrupt is generated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table 803. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
28 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
29 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
30 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.
31 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set.

47.2.141 Sub Second Increment Register (MAC_SUB_SECOND_INCREMENT)

In Coarse Update mode [Bit 30 in MAC_Timestamp_Control], the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Figure 741. Sub Second Increment Register (MAC_SUB_SECOND_INCREMENT)

Table 804. MAC_SUB_SECOND_INCREMENT field descriptions

Name	Description
8:15 SSINC	Sub-second Increment Value The value programed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 22 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
16:23 SNSINC	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2 ^ 8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set, and if the required increment is 5.3 ns, then SSINC should be 0x05 and SNSINC should be 0x4C. This field is reserved and read-only when Enable One-Step Timestamp Feature and Enable IEEE 1588 Sub-Nanoseconds Timestamp Support features are not selected.

47.2.142 System Time Seconds Register (MAC_SYSTEM_TIME_SECONDS)

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Figure 744. System Time Seconds Update Register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

Table 807. MAC_SYSTEM_TIME_SECONDS_UPDATE field descriptions

Field	Description
0:31 TSS	Timestamp Seconds The value in this field is the sub-second part of the update. When ADDSUB is reset, this field must be programed with the subsecond part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, then this field must be programed with the complement of the sub-second part of the update value as described below. When TSCTRLSSR is set, then the programed value must be 10^9 - <sub-second value>. When TSCTRLSSR is reset, then the programed value must be 2^31 - <sub-second_value> For example, when TSCTRLSSR bit is set and if 2.000000001 seconds need to be subtracted from the system time, then the TSS field in the MAC_Timestamp Seconds update register must be 0xFFFF_FFFE (that is, 2^32 - 2), ADDSUB bit in this register should be set, and the TSSS field must be 0x3B9A_C9FF (that is, 10^9 - 1).

47.2.145 System Time Nanoseconds Update Register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

Figure 745. System Time Nanoseconds Update Register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

Table 808. MAC_SYSTEM_TIME_NANOSECONDS_UPDATE field descriptions

Field	Description
0 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.
1:31 TSS	Timestamp Sub Seconds The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programed value should not exceed 0x3B9A_C9FF.

47.2.146 Timestamp Addend Register (MAC_TIMESTAMP_ADDEND)

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Figure 748. Timestamp Status Register (MAC_TIMESTAMP_STATUS)

Table 811. MAC_TIMESTAMP_STATUS field descriptions

Field	Description
2:6 ATSNS	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. value equal to 4 indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.
7 ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.

Table 811. MAC_TIMESTAMP_STATUS field descriptions (continued)

Field	Description
14:15 ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. Bit 15: Auxiliary trigger 0 Bit 14: Auxiliary trigger 1 The software can read this register to find the triggers that are set when the timestamp is taken. Access restriction applies. Clears on read. Self-set to 1 on internal event.
16 TXTSSIS	Tx Timestamp Status Interrupt Status When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. This bit is cleared when the MAC_TxTimestamp_Status_Seconds register is read.
28 TSTRGTERR 0	Timestamp Target Time Error This bit is set when the latest target time programed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.149 Transmit Timestamp Status Nanoseconds Register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

This register contains the nanosecond part of timestamp captured for Transmit when Tx status is disabled.

The MAC_TxTimestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TxTimestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [16] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

Figure 751. Auxiliary Control Register (MAC_AUXILIARY_CONTROL)

Table 814. MAC_AUXILIARY_CONTROL field descriptions

Field	Description
26 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored.
27 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored.
31 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.152 Auxiliary Timestamp Nanoseconds Register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4.

You can store multiple snapshots in this FIFO. Bits[2:6] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

Figure 754. Timestamp Ingress Asymmetry Correction Register (MAC_TIMESTAMP_INGRESS_ASYM_CORR)

Table 817. MAC_TIMESTAMP_INGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 0 representing the sign bit.

47.2.155 Timestamp Egress Asymmetry Correction Register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

Figure 755. Timestamp Egress Asymmetry Correction Register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

Table 818. MAC_TIMESTAMP_EGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000 (2.5 * 216). Similarly, if the required correction is -3.3 ns, the programed value is 0x0003_4CCC (3.3 * 216).

47.2.156 Timestamp Ingress Correction Nanosecond Register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Figure 758. PPS Control Register (MAC_PPS_CONTROL)

Table 821. MAC_PPS_CONTROL field descriptions

Field	Description
25:26 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS0 output signal: 00 Target Time registers are programed only for generating the interrupt event. 01 Reserved 10 Target Time registers are programed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11 Target Time registers are programed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.

Table 821. MAC_PPS_CONTROL field descriptions (continued)

Field	Description
27 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[28:31] function as PPSCMD. When this bit is reset, Bits[28:31] function as PPSCTRL (Fixed PPS mode).
28:31 PPSCTRL _PPSCMD	**PPS Output Frequency Control** This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 0001 The binary rollover is 2 Hz, and the digital rollover is 1 Hz 0010 The binary rollover is 4 Hz, and the digital rollover is 2 Hz 0011 The binary rollover is 8 Hz, and the digital rollover is 4 Hz 0100 The binary rollover is 16 Hz, and the digital rollover is 8 Hz ... 1111 The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz **Note:** In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second.(1) or **Flexible PPS Output (ptp_pps_o[0]) Control** Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000 No Command - 0001 START Single Pulse. This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. - 0010 START Pulse Train. This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011 Cancel START. This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programed start time. - 0100 STOP Pulse train at time. This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programed in the Target Time registers elapses. - 0101 STOP Pulse Train immediately. This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 0110 Cancel STOP Pulse train. This command cancels the STOP pulse train at time command if the programed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111 Reserved - 1111 Reserved Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

1. For example:
When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and 537 ms period. Second clock of 463 ms period (268 ms low and 195 ms high)
When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and 268 ms period. Fourth clock of 195 ms period (134 ms low and 61 ms high)
This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

47.2.159 PPS0 Target Time Seconds Register (MAC_PPS0_TARGET_TIME_SECONDS)

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 30 of MAC_Timestamp_Status] when the system time exceeds the value programed in these registers

Figure 759. PPS0 Target Time Seconds Register (MAC_PPS0_TARGET_TIME_SECONDS)

Table 822. MAC_PPS0_TARGET_TIME_SECONDS field descriptions

Field	Description
0:31 TSTRH0	PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register.

47.2.160 PPS0 Target Time Nanoseconds Register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

Offset 0x0B84 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 760. PPS0 Target Time Nanoseconds Register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

Table 823. MAC_PPS0_TARGET_TIME_NANOSECONDS field descriptions

Field	Description
0 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programed time gets corrupted.
1:31 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [25:26]) in MAC_PPS_Control. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.161 PPS0_Interval Register (MAC_PPS0_INTERVAL)

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B88 Access: User Read/Write

Figure 761. PPS0_Interval Register (MAC_PPS0_INTERVAL)

Table 824. MAC_PPS0_INTERVAL field descriptions

Field	Description
0:31 PPSINT0	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

47.2.162 PPS0 Width Register (MAC_PPS0_WIDTH)

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B8C Access: User Read/Write

Figure 762. PPS0 Width Register (MAC_PPS0_WIDTH)

Table 825. MAC_PPS0_WIDTH field descriptions

Field	Description
0:31 PPSWIDTH0	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. **Note:** The value programed in this register must be lesser than the value programed in MAC_PPS0_Interval.

47.2.163 Operation Mode Register (MTL_OPERATION_MODE)

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

Offset 0x0C00 Access: User Read/Write

Figure 764. Debug Access Control Register (MTL_DBG_CTL)

Table 827. MTL_DBG_CTL field descriptions

Field	Description
16 STSIE	Transmit Status Available Interrupt Status Enable When this bit is set, an interrupt is generated when Transmit status is available in slave mode.
17 PKTIE	Receive Packet Available Interrupt Status Enable When this bit is set, an interrupt is generated when EOP of received packet is written to the Rx FIFO.
18:19 FIFOSEL	FIFO Selected for Access This field indicates the FIFO selected for debug access: 00 Tx FIFO 01 Tx Status FIFO (only read access when SLVMOD is set) 10 Reserved 11 Rx FIFO
20 FIFOWREN	FIFO Write Enable When this bit is set, it enables the Write operation on selected FIFO. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
21 FIFORDEN	FIFO Read Enable When this bit is set, it enables the Read operation on selected FIFO. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
22 RSTSEL	Reset Pointers of Selected FIFO When this bit is set, the pointers of the currently-selected FIFO are reset. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
23 RSTALL	Reset All Pointers When this bit is set, the pointers of all FIFOs are reset. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets.
25:26 PKTSTATE	Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO / Rx FIFO: 00 Packet Data / Packet Data 01 Control Word/ Normal Status 10 SOP Data / Last Status 11 EOP Data / EOP
28:29 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid

Table 827. MTL_DBG_CTL field descriptions (continued)

Field	Description
30 DBGMOD	Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: Write access to the Tx FIFO Read access to the Rx FIFO and Tx Status FIFO
31 FDBGEN	FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface.

47.2.165 Debug Status Register (MTL_DBG_STS)

The FIFO Debug Status register contains the status of FIFO debug access.

Offset 0x0C0C Access: User Read/Write

Figure 765. Debug Status Register (MTL_DBG_STS)

Table 828. MTL_DBG_STS field descriptions

Field	Description
0:16 LOCR	Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively.
22 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit.
23 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit.
27:28 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid
29:30 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. Tx FIFO: 00 Packet Data 01 Control Word 10 SOP Data 11 EOP Data Rx FIFO: 00 Packet Data 01 Normal Status 10 Last Status 11 EOP This field is applicable only for Tx FIFO and Rx FIFO during Read operation.
31 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: All other fields of this register All fields of the MTL_FIFO_Debug_Data register

47.2.166 FIFO Debug Data register (MTL_FIFO_DEBUG_DATA)

The FIFO Debug Data register contains the data to be written to or read from the FIFOs.

Figure 768. Receive Queue and DMA Channel Mapping 0 Register (MTL_RXQ_DMA_MAP0)

Table 831. MTL_RXQ_DMA_MAP0 field descriptions

Field	Description
19 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programed in the Q1MDMACH field (Bits[21:23]).
23 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: 0 DMA Channel 0 1 DMA Channel 1 This field is valid when the Q1DDMACH field is reset.
27 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programed in the Q0MDMACH field.
31 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: 0 DMA Channel 0 1 DMA Channel 1 This field is valid when the Q0DDMACH field is reset.

47.2.169 Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)

The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Figure 769. Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)

Table 832. MTL_TXQ0_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 4096, the width of this field is 4 bits: LOG2(4096/256) = LOG2(16) = 4 bits A value of 0 indicates 256 bytes
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 00 Not enabled 01 Reserved 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.170 Queue 0 Underflow Counter Register (MTL_TXQ0_UNDERFLOW)

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 Access: User Read

Figure 770. Queue 0 Underflow Counter Register (MTL_TXQ0_UNDERFLOW)

Table 833. MTL_TXQ0_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.171 Queue 0 Transmit Debug Register (MTL_TXQ0_DEBUG)

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 Access: User Read

Figure 771. Queue 0 Transmit Debug Register (MTL_TXQ0_DEBUG)

Table 834. MTL_TXQ0_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 834. MTL_TXQ0_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

47.2.172 Queue 0 ETS Status Register (MTL_TXQ0_ETS_STATUS)

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

Figure 773. Queue 0 Quantum or Weights Register (MTL_TXQ0_QUANTUM_WEIGHT)

Table 836. MTL_TXQ0_QUANTUM_WEIGHT field descriptions

Field	Description
11:31 ISCQW	When DWRR algorithm is enabled for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When WRR algorithm is enabled for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [11:24] must be written to zero.

47.2.174 Interrupt Control Status Register (MTL_Q0_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue 0 interrupts.

Offset 0x0D2C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 774. Interrupt Control Status Register (MTL_Q0_INTERRUPT_CONTROL_STATUS)

Table 837. MTL_Q0_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[10]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

47.2.175 Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command.

Figure 775. Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)

Table 838. MTL_RXQ0_OPERATION_MODE field descriptions

Bits	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one and the reset value is 0x0. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size. For example, if the memory size is 8192, the width of this field is 5 bits: LOG2(8192/256) = LOG2(32) = 5 bits
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.

Table 838. MTL_RXQ0_OPERATION_MODE field descriptions (continued)

Bits	Description
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

47.2.176 Queue 0 Missed Packet and Overflow Counter Register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 Access: User Read

Figure 776. Queue 0 Missed Packet and Overflow Counter Register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

Table 839. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 839. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.177 Queue 0 Receive Debug Register (MTL_RXQ0_DEBUG)

The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 Access: User Read

Figure 778. Queue Receive Control Register (MTL_RXQ0_CONTROL)

Table 841. MTL_RXQ0_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.

47.2.179 Transmit Q*n* Operation Mode register (MTL_TXQ*n*_OPERATION_MODE)

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Offset 0x0D00 + *n**0x40 (n=1) Access: User Read/Write

Figure 779. Transmit Q*n* Operation Mode register (MTL_TXQ*n*_OPERATION_MODE)

Table 842. MTL_TXQ*n*_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(4096/256) = LOG2(16) = 4 bits
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue n. 00 Not enabled 01 Enable in AV mode 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.180 Transmit Q*n* Underflow register (MTL_TXQ*n*_UNDERFLOW)

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 + *n**0x40 (n=1) Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 780. Transmit Q*n* Underflow register (MTL_TXQ*n*_UNDERFLOW)

Table 843. MTL_TXQ*n*_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.181 Transmit Q*n* Debug register (MTL_TXQ*n*_DEBUG)

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 + *n**0x40 (*n*=1) Access: User Read

Table 844. MTL_TXQ*n*_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 844. MTL_TXQ*n*_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

47.2.182 Transmit Q*n* ETS Control register (MTL_TXQ*n*_ETS_CONTROL)

The Queue ETS Control register controls the enhanced transmission selection operation.

Offset 0x0D10 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 782. MTL_Transmit Q*n* ETS Control register (MTL_TXQ*n*_ETS_CONTROL)

Table 845. MTL_TXQ*n*_ETS_CONTROL field descriptions

Field	Description
25:27 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of 125 µs duration) over which the average transmitted bits per slot, provided in the MTL_TxQ1_ETS_Status register, need to be computed for Queue 1. The encoding is as follows: 000 1 Slot 001 2 Slots 010 4 Slots 011 8 Slots 100 16 Slots 101 Reserved 110 Reserved 111 Reserved
28 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated.
29 AVALG	AV Algorithm When Queue 1 is programed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected.

47.2.183 Transmit Q*n* ETS Status register (MTL_TXQ*n*_ETS_STATUS)

The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

Field	Description
8:31 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. For AV operation for Queue 1, this field is computed over number of slots, programed in the SLC field of MTL_TxQ1_ETS_CONTROL register, for Queue 1 traffic. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps. Bits [8:14] are always read as zero.

47.2.184 Transmit Q*n* Quantum Weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Offset 0x0D18 + *n**0x40 (n=1) Access: User Read/Write

Figure 784. Transmit Q*n* Quantum Weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

Table 847. MTL_TXQ*n*_QUANTUM_WEIGHT field descriptions

Filed	Description
11:31 ISCQW	idleSlopeCredit, Quantum or Weights **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. **Weights** When enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [11:24] must be written to zero.

47.2.185 Transmit Q*n* Send Slope Credit register (MTL_TXQ*n*_SENDSPLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D1C + *n**0x40 (n=1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 785. Transmit Q*n* Send Slope Credit register (MTL_TXQ*n*_SENDSPLOPECREDIT)

Table 848. MTL_TXQ*n*_SENDSPLOPECREDIT field descriptions

Field	Description
18:31 SSC	sendSlopeCredit With AV operation enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x1000 in 100 Mbps mode. This field should be programed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.

47.2.186 Transmit Q*n* High Credit register (MTL_TXQ*n*_HICREDIT)

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D20 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 786. MTL_Transmit Q*n* High Credit register (MTL_TXQ*n*_HICREDIT)

Table 849. MTL_TXQ*n*_HICREDIT field descriptions

Field	Description
3:31 HC	hiCredit When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

47.2.187 Transmit Q*n* Low Credit register (MTL_TXQ*n*_LOCREDIT)

The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D24 + *n**0x40 (*n*=1) Access: User Read/Write

Figure 787. Transmit Q*n* Low Credit register (MTL_TXQ*n*_LOCREDIT)

Table 850. MTL_TXQ*n*_LOCREDIT field descriptions

Field	Description
3:31 LC	loCredit When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxFrameSize transmitted from this queue, that is, 16384 * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programed value is 2's complement of the value, that is, 0x1800_0000.

47.2.188 Q*n* Interrupt Control Status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue 1 interrupts.

Offset 0x0D2C + *n**0x40 (n=1) Access: User Read/Write

Figure 788. Q*n* Interrupt Control Status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

Table 851. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

47.2.189 Receive Q*n* Operation Mode register (MTL_RXQ*n*_OPERATION_MODE)

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 + *n**0x40 (*n*=1)

Figure 789. MTL_Receive Q*n* Operation Mode register (MTL_RXQ*n*_OPERATION_MODE)

Table 852. MTL_RXQ*n*_OPERATION_MODE field descriptions

Field	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one and the reset value is 0x0. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 8192, the width of this field is 5 bits: LOG2(8192/256) = LOG2(32) = 5 bits
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Table 852. MTL_RXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_RX_ERR, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

47.2.190 Receive Q*n* Missed Packet and Overflow Counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 + *n**0x40 (*n*=1) Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 790. Receive Q*n* Missed Packet and Overflow Counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

Table 853. MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.191 Receive Q*n* Debug register (MTL_RXQ*n*_DEBUG)

The Queue 1 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 + *n**0x40 (n=1) Access: User Read

Figure 792. Receive Q*n* Control register (MTL_RXQ*n*_CONTROL)

Table 855. MTL_RXQ*n*_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.

47.2.193 DMA_Mode Register (DMA_MODE)

The Bus Mode register establishes the bus operating modes for the DMA.

Offset 0x1000 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 793. DMA_Mode Register (DMA_MODE)

Table 856. DMA_MODE field descriptions

Field	Description
14:15 INTM	Interrupt Mode This field defines the interrupt mode of the Ethernet module. The behavior of the following outputs changes depending on the following settings: sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) interrupt (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status.
17:19 PR	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. 000 The priority ratio is 1:1 001 The priority ratio is 2:1 010 The priority ratio is 3:1 011 The priority ratio is 4:1 100 The priority ratio is 5:1 101 The priority ratio is 6:1 110 The priority ratio is 7:1 111 The priority ratio is 8:1
20 TXPR	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.
27:29 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000 Fixed priority In fixed priority, Channel 0 has the lowest priority and the last channel has the highest priority. 001 Weighted Strict Priority (WSP) 010 Weighted Round-Robin (WRR) 011 Reserved ... 111 Reserved

Table 856. DMA_MODE field descriptions (continued)

Field	Description
30 DA	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: 0 Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[17:19] and the priority weight is specified in the TXPR bit. 1 Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.
31 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all Ethernet module clock domains. Before reprogramming any Ethernet module register, a value of zero should be read in this bit. **Note:** The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.194 System Bus Mode Register (DMA_SYSBUS_MODE)

The System Bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

Offset 0x1004 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 794. System Bus Mode Register (DMA_SYSBUS_MODE)

Table 857. DMA_SYSBUS_MODE field descriptions

Field	Description
16 RB	Rebuild INCRx Burst When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.
17 MB	Mixed Burst When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).
19 AAL	Address-Aligned Beats When this bit is set to 1, AHB master performs address-aligned burst transfers on Read and Write channels.
31 FB	Fixed Burst Length When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE). When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.

47.2.195 Interrupt Status Register (DMA_INTERRUPT_STATUS)

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Offset 0x1008 Access: User Read

Figure 795. Interrupt Status Register (DMA_INTERRUPT_STATUS)

Table 858. DMA_INTERRUPT_STATUS field descriptions

Field	Description
14 MACIS	MAC Interrupt Status This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.
15 MTLIS	MTL Interrupt Status This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.
30 DC1IS	DMA Channel 1 Interrupt Status This bit indicates an interrupt event in DMA Channel 1. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 1 to get the exact cause of the interrupt and clear its source.
31 DC0IS	DMA Channel 0 Interrupt Status This bit indicates an interrupt event in DMA Channel 0. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 0 to get the exact cause of the interrupt and clear its source.

47.2.196 Debug Status 0 Register (DMA_DEBUG_STATUS0)

The Debug Status 0 register gives the Receive and Transmit process status for DMA Channel 0-Channel 1 for debugging purpose.

Offset 0x100C Access: User Read

Figure 796. Debug Status 0 Register (DMA_DEBUG_STATUS0)

Table 859. DMA_DEBUG_STATUS0 field descriptions

Field	Description
8:11 TPS1	DMA Channel 1 Transmit Process State This field indicates the Tx DMA FSM state for Channel 1. This field is similar to the TPS0 field.
12:15 RPS1	DMA Channel 1 Receive Process State This field indicates the Rx DMA FSM state for Channel 1. This field is similar to the RPS0 field.
16:19 TPS0	DMA Channel 0 Transmit Process State This field indicates the Tx DMA FSM state for Channel 0: 000 Stopped (Reset or Stop Transmit Command issued) 001 Running (Fetching Tx Transfer Descriptor) 010 Running (Waiting for status) 011 Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO)) 100 Timestamp write state 101 Reserved for future use 110 Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow) 111 Running (Closing Tx Descriptor) This field does not generate an interrupt.
20:23 RPS0	DMA Channel 0 Receive Process State This field indicates the Rx DMA FSM state for Channel 0: 000 Stopped (Reset or Stop Receive Command issued) 001 Running (Fetching Rx Transfer Descriptor) 010 Reserved for future use 011 Running (Waiting for Rx packet) 100 Suspended (Rx Descriptor Unavailable) 101 Running (Closing the Rx Descriptor) 110 Timestamp write state 111 Running (Transferring the received packet data from the Rx buffer to the system memory) The MSB of this field always returns 0. This field does not generate an interrupt.
31 AXWHSTS	AHB Master Status When high, this bit indicates that the AHB master FSMs are in the non-idle state.

47.2.197 DMA Channel *n* Control register (DMA_CH*n*_CONTROL)

The DMA Channel*n* Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as 8xPBL mode.

Offset 0x1100 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 797. DMA Channel *n* Control register (DMA_CH*n*_CONTROL)

Table 860. DMA_CH*n*_CONTROL field descriptions

Field	Description
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programed in Bits[10:15] in DMA_CH0_Tx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

47.2.198 DMA Channel *n* Transmit Control register (DMA_CH*n*_TX_CONTROL)

The DMA Channel Transmit Control register controls the Tx features such as PBL, and Tx Channel weights.

Offset 0x1104 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 798. DMA Channel *n* Transmit Control register (DMA_CH*n*_TX_CONTROL)

Table 861. DMA_CH*n*_TX_CONTROL field descriptions

Field	Description
10:15 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in DMA_CH0_Control register. – Set the PBL.
27 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.
28:30 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
31 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: – The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. – The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.

47.2.199 DMA Channel *n* Receive Control register (DMA_CH*n*_RX_CONTROL)

The DMA Channel *n* Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset 0x1108 + *n**0x80 (n=0 to 1) Access: User Read/Write

Figure 799. DMA Channel *n* Receive Control register (DMA_CH*n*_RX_CONTROL)

Table 862. DMA_CH*n*_RX_CONTROL field descriptions

Field	Description
0 RPF	DMA Rx Channel0 Packet Flush When this bit is set to 1, the DMA will automatically flush the packet from the Rx Queues destined to DMA Rx Channel 0 when the DMA Rx Channel 0 is stopped after a system bus error has occurred. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0 the EQOS will not flush the packet in the Rx Queue destined to DMA Rx Channel 0 after the DMA is stopped due to a system bus error.
10:15 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in the DMA_CH0_Control register. – Set the PBL.

Table 862. DMA_CH*n*_RX_CONTROL field descriptions (continued)

Field	Description
17:30 RBSZ	Receive Buffer size This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. **Note:** The buffer size must be a multiple of 4, 8, or 16 depending on the bus widths (32, 64, or 128 respectively). This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, 8, or 16, it may result into undefined behavior. The 3 LSB bits for 64-bit bus width are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).
31 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

47.2.200 DMA Channel *n* Transmit Descriptor List Address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

The Channel *n* Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset 0x1114 + *n**0x80 (*n*=0 to 1) Access: User Read/Write

Figure 800. DMA Channel *n* Transmit Descriptor List Address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

Table 863. DMA_CH*n*_TXDESC_LIST_ADDRESS field descriptions

Field	Description
0:31 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the 3 LSB bits for 64-bit data bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

47.2.201 DMA Channel *n* Receive Descriptor List Address register (DMA_CH*n*_RXDESC_LIST_ADDRESS)

The Channel*n* Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programed descriptor base address.

Table 869. DMA_CH*n*_INTERRUPT_ENABLE field descriptions

Field	Description
16 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 31: Transmit Interrupt – Bit 29: Transmit Buffer Unavailable – Bit 25: Receive Interrupt – Bit 20: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled.
17 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 30: Transmit Process Stopped – Bit 24: Rx Buffer Unavailable – Bit 23: Receive Process Stopped – Bit 22: Receive Watchdog Timeout – Bit 21: Early Transmit Interrupt – Bit 19: Fatal Bus Error When this bit is reset, the abnormal interrupt summary is disabled.
18 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.
19 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.
20 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.
21 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.
22 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.
23 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.
24 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.
25 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Table 869. DMA_CH*n*_INTERRUPT_ENABLE field descriptions (continued)

Field	Description
29 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.
30 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.
31 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.

47.2.207 DMA Channel *n* Receive Interrupt Watchdog Timer register (DMA_CH*n*_Rx_INTERRUPT_WATCHDOG_TIMER)

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH*n*_Status register.

Field	Description
14:15 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. 00 256 01 512 10 1024 11 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
24:31 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[1]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[1] of any received packet.

47.2.208 DMA Channel *n* Slot Function Control Status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset 0x113C + *n**0x80 (n=0 to 1) Access: User Read/Write

Table 871. DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS field descriptions

Field	Description
12:15 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
30 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programed in the Tx descriptor is – equal to the reference slot number given in the RSN field or – ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set.
31 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is – equal to the reference slot number or – ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed.

10:12 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 10 1'b1: Error during data transfer by Rx DMA 1'b0: No Error during data transfer by Rx DMA Bit 11 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 12 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
13:15 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 13 1'b1: Error during data transfer by Tx DMA 1'b0: No Error during data transfer by Tx DMA Bit 14 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 15 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Table 876. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
16 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 31: Transmit Interrupt Bit 29: Transmit Buffer Unavailable Bit 25: Receive Interrupt Bit 20: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
17 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 30: Transmit Process Stopped Bit 24: Receive Buffer Unavailable Bit 23: Receive Process Stopped Bit 21: Early Transmit Interrupt Bit 19: Fatal Bus Error Bit 18: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
18 CDE	Context Descriptor Error This bit indicates that the DMA Tx engine received a context descriptor in the middle of a packet (in an intermediate descriptor), and the DMA Tx engine ignored it. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
19 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
20 ERI	Early Receive Interrupt This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 876. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
21 ETI	Early Transmit Interrupt This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.
23 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
24 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
25 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 0 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
29 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 0 of TDES0. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 876. DMA_CH*n*_STATUS field descriptions (continued)

Field	Description
30 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 0 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

47.2.214 DMA Channel *n* Miss Frame Counter register (DMA_CH*n*_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in DMA_CH0_Rx_Control register.

Field	Description
16 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 MFC	This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH0_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.3 Functional Description

47.3.1 AHB Master Interface

The DMA controller interfaces with the application through the AMBA AHB interface. The AHB master interface converts the internal DMA request cycles into AHB cycles. The AHB master interface has the following features:

- The AHB master interface is AMBA 2.0-compliant AHB master with no restrictions
- The AHB master interface supports the following burst length modes: fixed, unspecified, and mixed. These modes are explained in *Section 47.3.1.1: AHB Burst Length Modes*
- The AHB master interface can handle the AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response halts all further transactions for that DMA and indicates the error as fatal through CSR and interrupt. The application can choose to give a hard or soft reset to the module to restart the operation
- The AHB master interface can handle the AHB 1 K boundary breaking
- The AHB master interface can handle all 64-bit data transfers except for Descriptor Status Write accesses (which may be 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size
- The AHB master interface can align all AHB burst transfers to an address value. For more information, refer to *Section 47.3.1.2: Aligning AHB Burst Transfers to an Address Value*
- The DMA requests an AHB Burst Read transfer only when it can completely accept the received burst data. The data read from the AHB is always pushed into the DMA without any delay or Busy cycles. However, when multiple channels are selected, there may be some delay and busy cycles may be inserted because of the shared-memory architecture for the channels
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to completely transfer the burst. The AHB interface always assumes that it has the data available to push into the AHB bus. However, the DMA can prematurely indicate end-of-valid data (because of the transfer of EOP of an Ethernet packet) during the burst
- In Fixed Burst Length mode, the AHB master interface continues the burst with dummy data until the specified length is completed. In INCR mode, it ends the burst transfer prematurely

47.3.1.1 AHB Burst Length Modes

The AHB master interface supports the following burst length modes:

- Fixed Burst Length: In fixed burst length mode, the AHB master always initiates a burst with SINGLE, INCR4, INCR8, or INCR16 type. However, when such a burst is responded with SPLIT, RETRY, or Early Burst Termination (EBT), by default, the AHB master again initiates the pending transfers of the burst with INCR or SINGLE burst length type. When only one beat is remaining, the AHB master performs a SINGLE transfer. If more than one beat is remaining, the AHB master performs an INCR transfer. The AHB master terminates such INCR bursts when remaining beats of the original requested fixed burst are transferred.
  To ensure that the AHB master always performs the INCRx and SINGLE transfers even when a part of the burst is initiated again after a SPLIT, RETRY, or EBT response, use the RIB bit of the register. However, when you enable this mode, the pending burst may

further get split into multiple transfers as per the following rules before any new transfer is initiated:

   – If the DMA requests a burst transfer that is not equal to INCR4, INCR8, or INCR16, the AHB application interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4, and three SINGLE transactions
   – If the burst length is more than 16, the AHB master interface splits it into multiple burst transfers. For example, if the burst length is 32 and the DMA starts a 32-beat transfer, the AHB master splits the burst into two INCR16

- Unspecified Burst Length: In unspecified burst mode, the AHB master always initiates a transfer with INCR and completes the DMA requested burst in one transfer
- Mixed Burst Mode: In mixed burst mode, the AHB master always initiates the bursts with fixed-size (INCRx) when the DMA requests transfers of size less than or equal to 16 beats. When the DMA requests bursts of length more than 16, the AHB master initiates such transfers with INCR and completes the request in one transfer

To ensure that the pending burst of a transfer is rebuilt only with INCRx transfers when an INCRx transfer is interrupted by RETRY, SPLIT, or EBT response, use the RB bit of the DMA_SysBus_Mode register. However, if an INCR burst initiated in this mode is interrupted, the AHB master rebuilds the burst only with INCR transfers.

You can choose the burst modes by programming the FB bit in the DMA_SysBus_Mode register.

Note: The AHB master does not generate the WRAP bursts.

The AHB master does not generate the locked or protected transfers. Therefore, the Ethernet IP does not have the HLOCK or HPROT output signals.

47.3.1.2 Aligning AHB Burst Transfers to an Address Value

The AHB master interface can align all AHB burst transfers to an address value. You can enable this by using the AAL bit in the DMA_SysBus_Mode register. If Bit 31 and Bit 19 of DMA_SysBus_Mode register are set to 1, the AHB interface and the DMA ensure that all initiated beats are aligned to the address, completing the packet transfer in the minimum number of required beats.

The AHB interface and the DMA split unaligned address beats for a 64-bit data bus and initiate INCR16 beats only when the seven least-significant bits of the address have a zero value.

47.3.2 DMA Controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The DMA supports up to 2 Tx and 2 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. You can control the offset by the DSL field of DMA_CH*n*_Control register. The number of descriptors in the list is programed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The Ethernet IP supports the ring structure for the DMA descriptor. For more information on the descriptor, refer to *Section 47.3: Functional Description* that describes the descriptor structure and how the DMA accesses the descriptors.

47.3.2.1 Application Bus Burst Access

When configured through Bit 31 of the DMA_SysBus_Mode register, the DMA attempts to execute the fixed-length burst transfers on the AHB master interface. The PBL field of Transmit Control and Receive Control registers of respective DMA channel indicates and limits the maximum burst length. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB Interface is configured for fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the AHB interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise, (Bit 31 of DMA_SysBus_Mode register is reset), the DMA transfers the data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AHB is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16) for AHB interface because it does not support more than INCR16.

47.3.2.1.1 Application Data Buffer Alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 878. Application Data Buffer Alignment Examples

Data Buffer	Examples
Buffer Read	If the Tx buffer address is 32’h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32’h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32’h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32’h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

47.3.2.1.2 Buffer Size Calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FS bit of TDES2 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LS bit of TDES2), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FS bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits[17:30] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (FL bits of RDES3[17:31]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

Note: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to have a 0x1002 offset. The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programed as 1024 bytes, because of the start address offset.

47.3.2.1.3 DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface. The following two types of arbitrations are supported:

- Round-Robin Arbitration: When Bit 30 of the DMA_Mode register is reset and both Tx and Rx DMAs are simultaneously requesting for access, the arbiter allocates the data bus in ratio set by Bits[17:19] of DMA_Mode register
- Fixed-Priority Arbitration: When Bit 30 of the DMA_Mode register is set, the Rx DMA always gets priority over the Tx DMA for data access by default. When Bit 20 of DMA_Mode register is also set, the Tx DMA gets priority over the Rx DMA

47.3.2.2 DMA Transmission

47.3.2.2.1 TX DMA Operation: Default (Non-OSP) Mode

The TX DMA engine in default mode proceeds as follows:

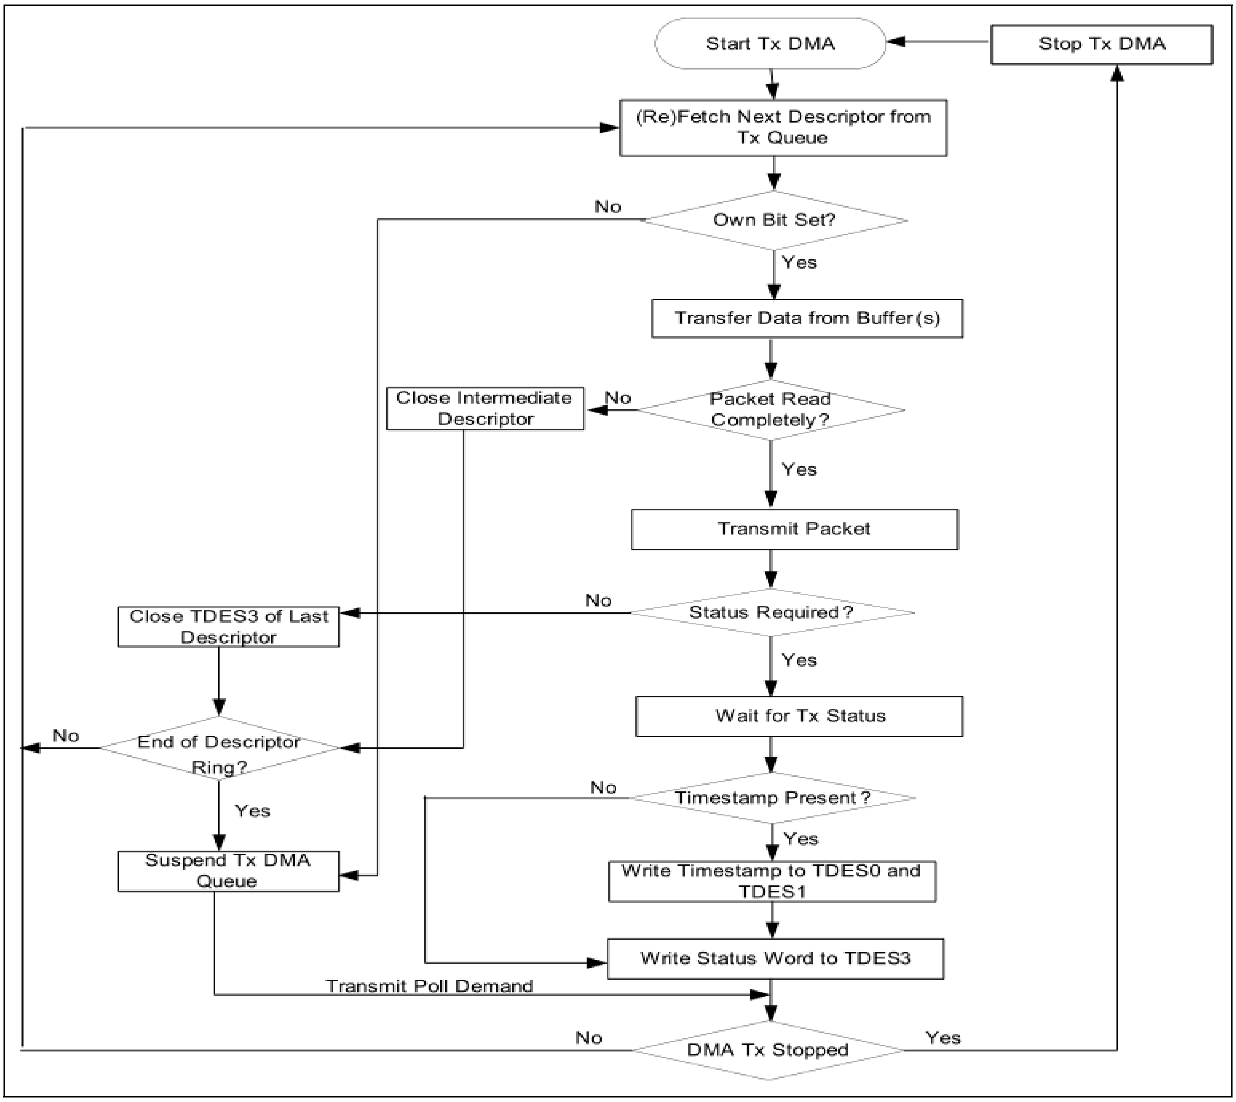
1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[0]) after setting up the corresponding data buffer(s) with Ethernet Packet data
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and Bit 29 and Bit 15 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to Step *11*:
   a) The descriptor is flagged as owned by the application (TDES3 [0] = 1'b0)
   b) The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   c) An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[0] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Step *3* through Step *7* are repeated until the end-of-Ethernet-packet data is transferred to the MTL
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The

status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.
If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1

10. Bit 31 of Status Register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[0]) set in its Last Descriptor. The DMA engine returns to Step 3
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to Step 3). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state

The Tx DMA transmission flow in default mode is shown in Figure 815.

Figure 815. TX DMA Operation in Default Mode



47.3.2.2.2 TX DMA Operation: OSP Mode

In the Run state, if Bit 27 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:

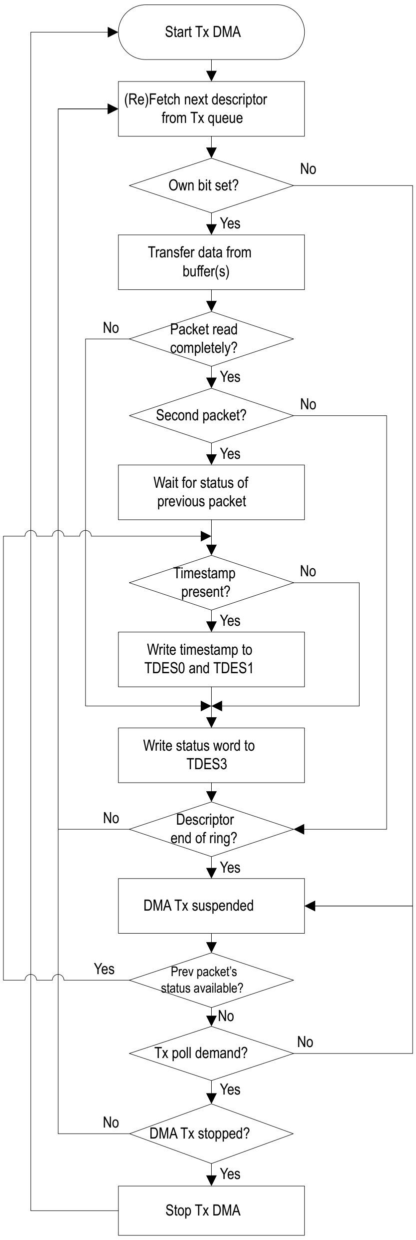
1. The DMA operates as described in Step *1* – Step *7* of the Tx DMA (default mode)
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step *7*
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES0 and TDES1
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to Step *3* (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step *7*)
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:
   a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1
   b) Writes the status to the corresponding TDES3
   c) Sets relevant interrupts and returns to Suspend mode

   If no status is pending and the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state
8. The DMA can exit Suspend mode and enter the Run state (goes to Step *1* or Step *2* depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel

Note: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. It is recommended to have a minimum descriptor length of four.

The basic flow is described in *Figure 816*.

Figure 816. Tx DMA Operation in OSP Mode



47.3.2.2.3 Transmit Packet Processing

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[2]) and the Last Descriptor (TDES3[3]). As transmission starts, the First Descriptor must have TDES3[2] set. When this occurs, the packet data is transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[3]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[2] clear. If TDES3[3] is clear, it indicates an intermediary buffer. If TDES3[3] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor Bit set in Transmit Descriptor 3 (TDES3[3]). At this time, if Interrupt on Completion (TDES2[0]) is set, Bit 31 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (Bits[25:27] of Transmit Operation Mode register of corresponding MTL Transmit Queue)
- A full packet is contained in the FIFO

You can also use the store-and-forward mode (Bit 30 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[0] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[3]) set.

47.3.2.2.4 Transmit Polling Suspended

Transmit polling can be suspended by any of the following conditions:

- The DMA detects a descriptor owned by the application (TDES3[0]=0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, Bit 16 and Bit 29 of Status Register of corresponding DMA channel are set
- A packet transmission is aborted when a Transmit error is detected because of underflow.
  The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 17 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_Interrupt_Status
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by it.
  To resume, the software driver must modify the Tail Pointer register

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

47.3.2.2.5 Transmit Channel Arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). *Figure 817* shows the DMA Tx Channel Arbitration Process.

When there is any request in the Tx queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the

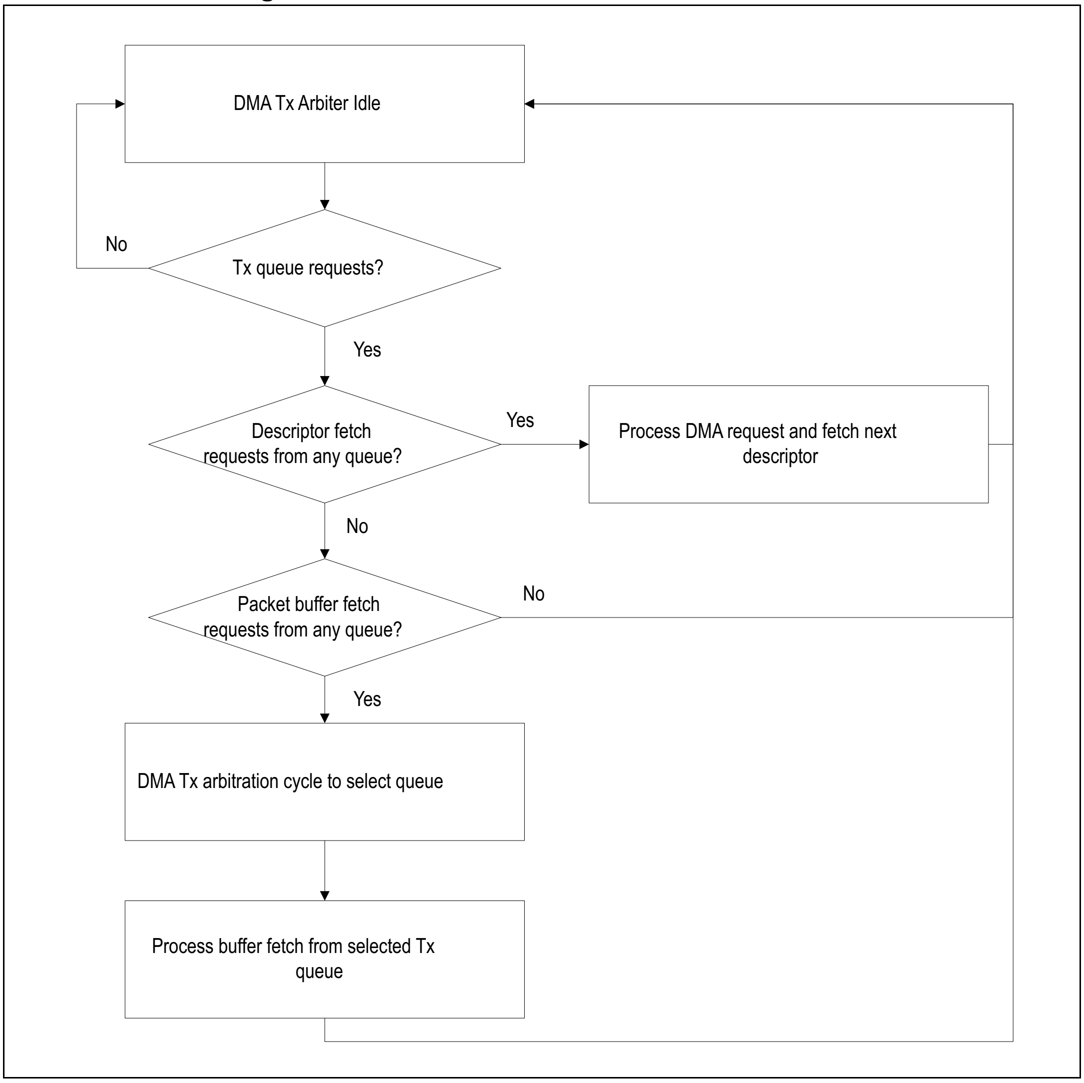
DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0). For packet buffer fetches, the DMA arbiter uses the programed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 1 (or the last enabled channel) and then Channel 0. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to Channel1 (or last enabled channel). If Channel 1 has no frames to transmit, the remaining weight is assigned to Channel 0
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programed in the Transmit Control register of a channel is ignored

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

Figure 817. DMA Tx Channel Arbitration Process



47.3.2.3 DMA Reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 818 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

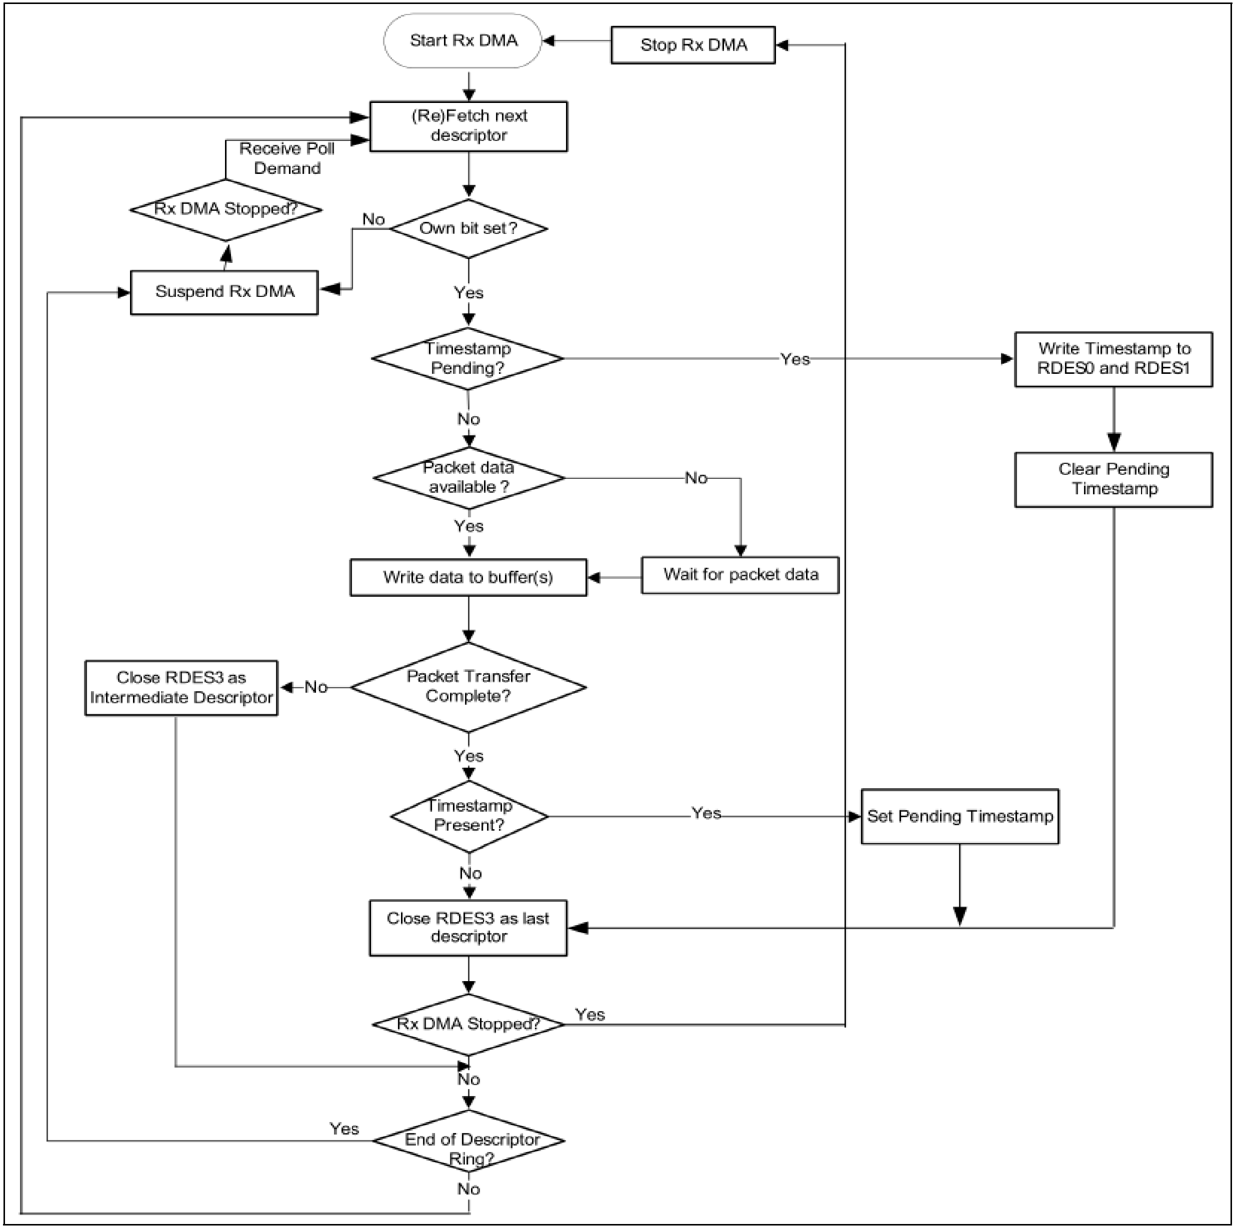
1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[0]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel
2. When Bit 31 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state.
   The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor

Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to Step *11*

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the RDES3[CTXT] field
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to Step *10*
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor)
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step *3*; otherwise, go to the Suspend state (Step *11*)
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel

The engine proceeds to Step *2* and re-fetches the next descriptor.

Figure 818. RX DMA Operation



47.3.2.3.1 Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 31 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed
- A Receive poll demand is issued (update of the Tail Pointer register)

47.3.2.3.2 Receive Packet Processing

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless Bit 0 of MAC_Packet_Filter register is set)
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue
3. When the DMA application Interface (AHB) becomes ready, it transfers the data and sets the following:
   a) If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[3]) and First Descriptor (RDES3[2])
   b) If the packet fits into more than one descriptor, the DMA sets the First Descriptor (RDES3[2]) to delimit the packet
4. The DMA releases the descriptors by resetting the Own (RDES3[0]) bit to 0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor
5. If Interrupt Enabled on Completion (RDES3[1]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and Bit 25 of Interrupt Enable Register of corresponding DMA channel is set, the DMA sets Bit 25 of Status register of corresponding DMA channel.
   The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if Bit 24 of Interrupt Enable Register of corresponding DMA channel is set, the Receive Process sets Bit 24 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained

47.3.2.4 DMA Error Response

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to Ethernet IP or re-initialize the DMA descriptor list and start again. The rest of the DMA channels are not affected by such errors. In AHB the DMA receives the error response through hresp_i signal.

47.3.3 MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The data path for both directions is 64-bit wide.

47.3.3.1 MTL Transmit Path

The DMA pushes the Ethernet packets read from the application or system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application. The fill level of the queue is indicated to the internal DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the application or system memory. The following two modes of operation trigger reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue
- Store-and-forward mode: In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the Queue
  - The Tx FIFO becomes almost full
  - The ATI watermark becomes low

The watermark becomes low when the requested Queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx Queue size.

The application can flush complete content of the Tx Queue by setting Bit 31 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

47.3.3.1.1 Initialization Flow

Upon reset, the MTL is ready to manage the flow of data to and from the application or DMA, and MAC.

First you need to initialize the Queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. You also need to initialize the MAC block. The internal DMA controllers must be individually enabled through their respective Cars.

47.3.3.1.2 Data Flow between the DMA and the MTL

This section describes the interaction process between the MTL and the DMA.

47.3.3.1.2.1 Single-Packet Transmit Operation

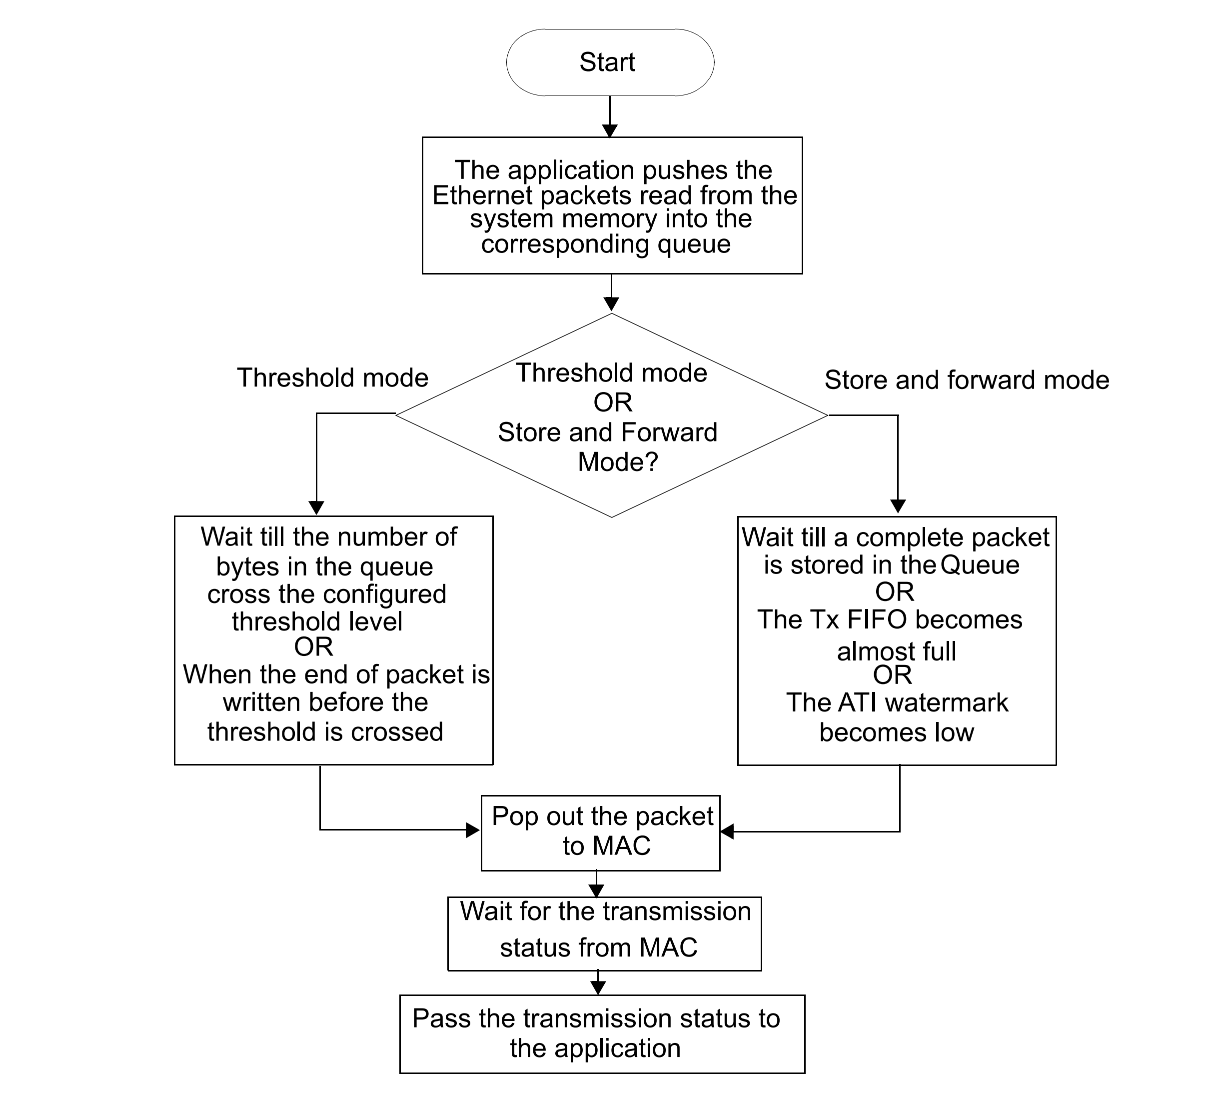
The following flow is valid when the core is operating in non-OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 0.

During a Transmit operation, the MTL block is a slave for the DMA controller. The general sequence of events for a Transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller (if enabled) fetches the data from the application through the AHB master interface and starts forwarding it to the MTL. The DMA descriptor memory contains the information related to packet control which is used to drive the MTL Control Word. The DMA data buffer memory contains the packet data
2. The MTL pushes the data received from the DMA into the corresponding queue. This process continues until the EOP is transferred
3. When the threshold level is crossed or a full packet of data is received into the queue, the MTL reads the packet data and drives it to the MAC
4. The queue controller continues to transfer data from the queue until a complete packet is transferred to the MAC
5. When the packet transfer is complete, the MTL receives the status from the MAC and notifies the DMA controller

Figure 819 illustrates the MTL single-packet transmit operation.

Figure 819. MTL Single Packet Transmit Flow



Note: When Bit 30 (DTXSTS) of Section 47.2.163 register is set, the MTL does not provide any status to the DMA.

47.3.3.1.2.2 Transmit Operation: Two Packets in the Buffer

The following flow is valid when the core is operating in OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 1.

The flow is similar to the flow described in Single-Packet Transmit Operation. However after fetching a packet, the DMA instead of waiting for the status, it continues to fetch another packet if available in the system memory. So, MTL can receive the second packet while it is processing the first packet. This flow improves the performance because the DMA can process two packets back to back before waiting for the status of the first packet.

47.3.3.1.2.3 Relationship between the Number of TX DMA Channels and Tx Queues

The number of Tx DMA channels is always equal to the Tx queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Bursts Lengths). However, the Tx queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and Tx queues to maintain the packet-level coherency.

47.3.3.1.2.4 Retransmission during Collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a Retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes are read out towards the MAC, the Queue Controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

When a packet transmission is aborted because of underflow and a collision event immediately follows (initiating a retry), retry has higher priority than abort.

Note: Before issuing the Transmit Queue Flush command, make sure that the Tx Queue is not empty, that is, Bit 27 (TXQSTS) of Transmit Debug Register of corresponding queue is reset.

47.3.3.1.2.5 Transmit Status Word

At the end of transfer of the Ethernet packet to the MAC and after the MAC completes the transmission of the packet, the MTL provides the Transmit status on respective queues. The detailed description of the Transmit Status is the same as for Bits[17:31] of TDES3 normal descriptor in write-back format. If IEEE 1588 Timestamp feature is enabled, the MTL returns 64-bit timestamp of the packet, along with the Transmit status.

If Bit 30 (DTXSTS) of MTL_Operation_Mode register is set then it disables the dependency of the DMA to read the status words from the Status FIFO thus the DMA can push as many packets as possible into the Tx queues because the application or DMA is not required to read the status words from the Status FIFO.

47.3.3.2 Receive Path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured Receive threshold (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

47.3.3.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data
2. The MAC indicates the SOP and EOP delimiters
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. For the 64-bit bus, one additional location is taken
6. The MTL takes the data out of the queue and sends it to the DMA depending on the below two modes
7. Threshold mode: In the (default) Threshold mode, the MTL reads the data and indicates its availability to DMA when one of the following happens:
   a) data bytes equal to the threshold amount are written to the Rx queue (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue)
   b) a full packet of data is received into the queue
8. Store-and-forward mode: In the store-and-forward mode (when Bit 26 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 27 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application

Note: In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.

47.3.3.2.2 Receive Operation Multi-Packet Handling

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

47.3.3.2.3 Error Handling

If the MTL Rx queue is full before it receives the EOP data from the MAC, the following happens:

1. An overflow is declared
2. The whole packet (including the status word) is dropped
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented

This is true even if Bit 27 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. The MTL then starts the transfer of next packet (if available).

47.3.3.2.4 Receive Status Word Format

The Rx packet status words are sent to the application after the packet data in Threshold mode and before the packet data in the Store and Forward Mode.

47.3.4 MAC

The MAC supports MII and RMII interfaces towards the PHY chip. The PHY interface can be selected only once after reset.

47.3.4.1 MAC Transmission

The transmission process is as follows:

1. Transmission is initiated when the MTL pushes in data with the SOP
2. When the SOP is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the packet data to the MII after the application initiates the transmission depends on delay factors such as IPG delay, time to transmit preamble or SFD, and any back-off delays for half-duplex mode. While the packets data is being transmitted, the MAC can throttle the MTL
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   a) The MAC completes the normal transmission and gives the transmission status to the MTL
   b) If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till either the packet is successfully transmitted or maximum retry requests expire
4. When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until

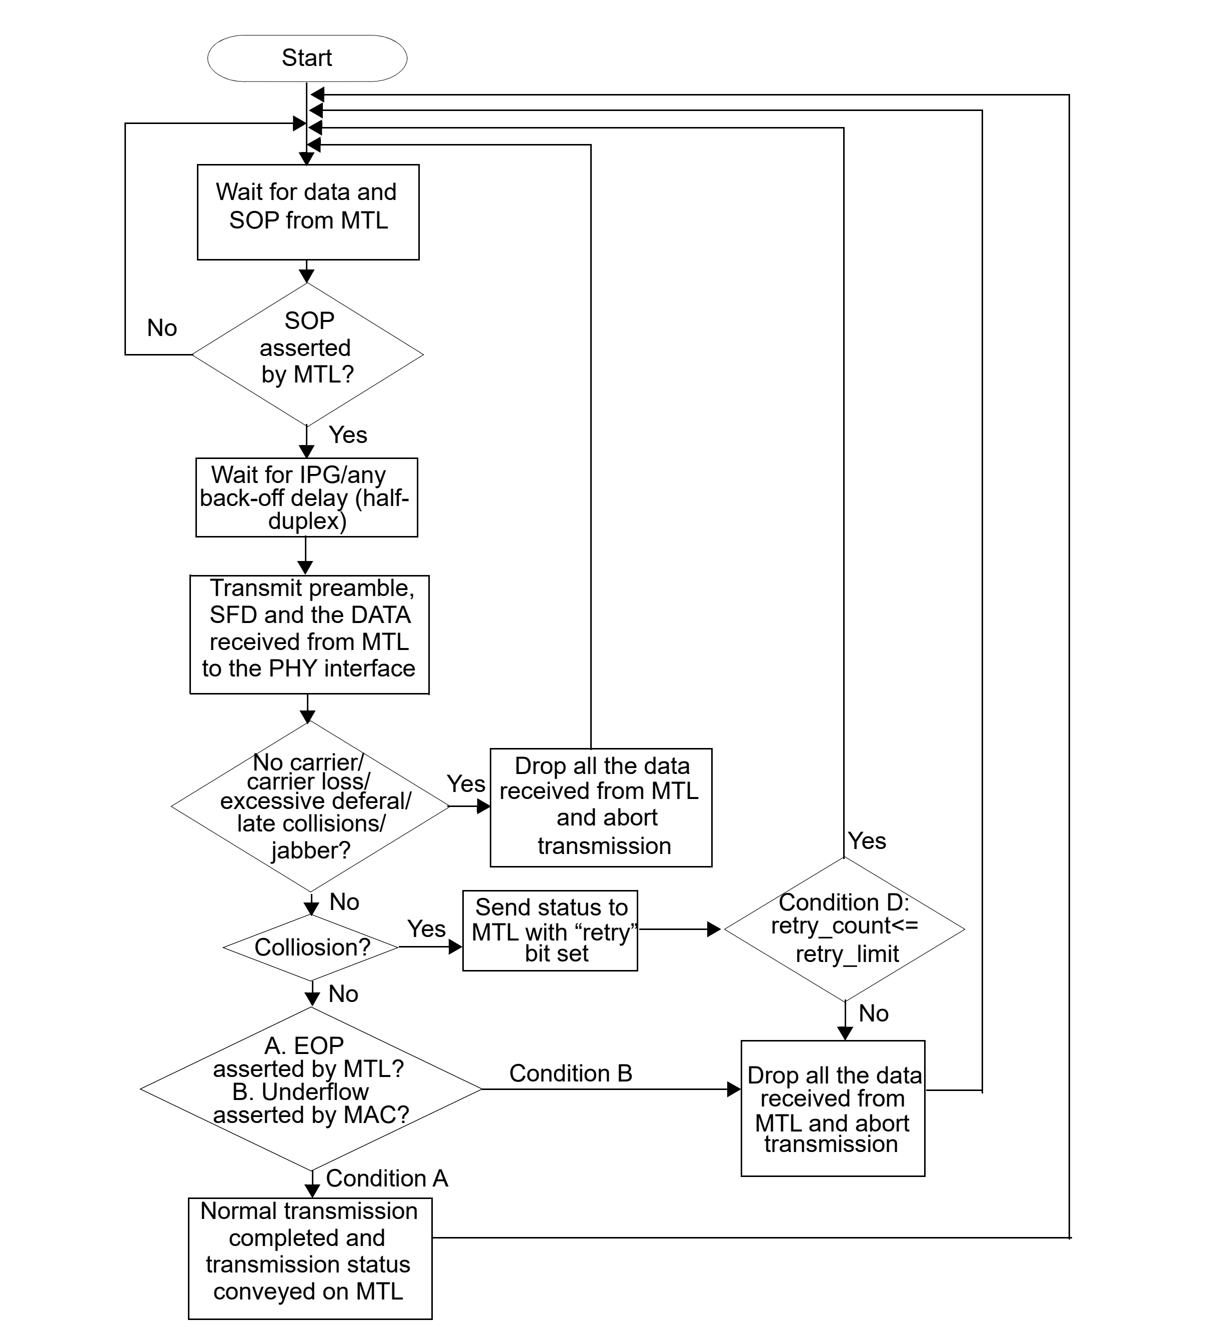
the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC

5. The MAC aborts the packet transmission under the following conditions:
   a) No carrier (half-duplex mode)
   b) Loss of carrier (half-duplex mode)
   c) Excessive deferral (half-duplex mode)
   d) Late collisions (half-duplex mode)
   e) Jabber

   The MAC accepts and drops all further data until the next SOP is received
6. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received
7. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet

Figure 820 illustrates the MAC transmission process flow.

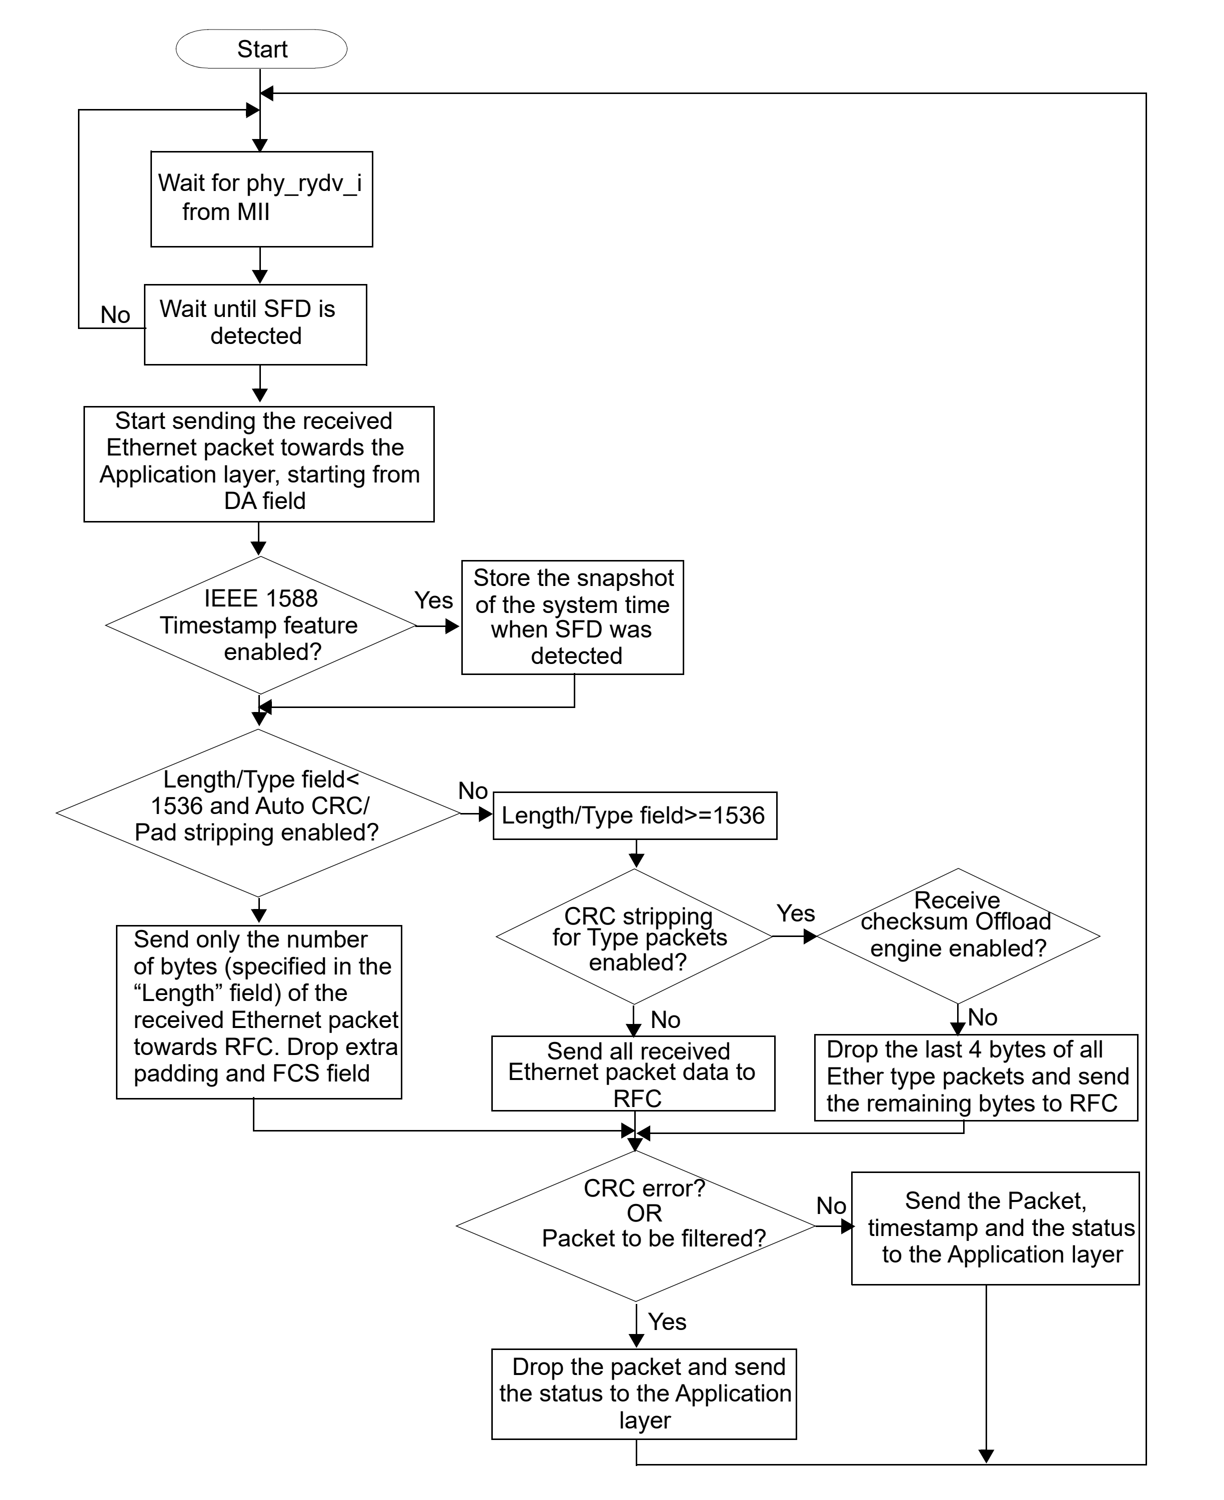
Figure 820. Overview of MAC Transmission Process Flow



47.3.4.2 MAC Reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

Figure 821. Overview of MAC RX Operation



47.3.5 Multiple Channels and Queues Support

The Ethernet module supports 2- queues and 2-channels on Tx and Rx paths. *Figure 593* shows the architecture of the Ethernet module with multiple queues and channels. This section describes how the Ethernet module supports multiple queues and channels. It contains the following sub-sections:

- DMA with Multiple Channels
- MTL with Multiple Queues

47.3.5.1 DMA with Multiple Channels

This section describes how multiple queues are supported in the Transmit and Receive DMA paths.

47.3.5.1.1 Multi-Channel DMA Transmit Path

The Ethernet module supports 2- Tx channels with the following priority schemes:

- Fixed Priority Scheme
- Weighted Strict Priority
- Weighted Round Robin

47.3.5.1.1.1 Fixed Priority Scheme

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. Fixed Priority Scheme for DMA Channels provides information about the priority levels of DMA channels.

Table 879. Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1 (high)	Channel 1

47.3.5.1.1.2 Weighted Strict Priority

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. Channel 1 has the highest priority and Channel 0 has the lowest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

47.3.5.1.1.3 Weighted Round Robin

In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the DMA_CHIn Weighted Round Robin (WRR), all channels are _Tx_Control register provides the weight for each Transmit channel as shown in Weights for DMA Channels.

Table 880. Weights for DMA Channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

47.3.5.1.2 Multi-Channel DMA Receive Path

The Ethernet module supports 2- Rx channels. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programed priorities.

47.3.5.1.3 Priority Scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the register. For round-robin arbitration, you can use the PR field of the register to specify the weighted priority between the Tx DMA and Rx DMA. Table 5-1 Priority Scheme for Tx DMA and Rx DMA5-1 provides information about the priority scheme between Tx DMA and Rx DMA.

Table 881. Priority Scheme for Tx DMA and Rx DMA(1)

Bit 17	Bit 18	Bit 19	Bit 20	Bit 30	Priority Scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

1. Bits 17, 18, 19, 20 and 30 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

47.3.5.1.4 Slot Number Function

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals. You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels.

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated every 125 µs of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the second’s field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program Bit 31 of the Slot Function Control and Status register of the corresponding DMA channel.

You can enable the check for slot number by setting Bit 31 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, Bits [12:15] indicate the value of the reference slot number in DMA.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

47.3.5.1.5 Rx Queue to DMA RX Channel Mapping

The packets in the MTL Rx Queues can be routed to any one of the 2-RX DMA channels by programming the MTL_RxQ_DMA_Map0 Register. The following types of Rx Queue to DMA mapping is possible through programming:

- Static Mapping
- Dynamic (Per Packet) Mapping

47.3.5.1.5.1 Static Mapping

In this mode, all the packets of an Rx Queue is connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[28:31]) and Q0DDMACH (bit[24] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

47.3.5.1.5.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from an Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: When the Layer 3 and Layer 4 Packet Filter is enabled, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If the L3-L4 Registers do not give a comparison match, then the Ethernet module proceeds to the next step below
2. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programed DA values in MAC Address Registers. If the address matches any of the programed values, the corresponding DCS field (when enabled) determines the destination DMA channel number

If none of the above operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default

47.3.5.1.6 Selection of Tag Priorities assigned to Tx and Rx Queues

The VLAN Tag priorities can be assigned to Tx Queues by programming the corresponding PSTQIn field in the *Section 47.2.14: Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)* (for Tx Queues 0 and 1).

The bit corresponding to the VLAN Tag priority can be set in the PSTQIn field for assigning that priority to the Tx Queue. For example, if you want to assign VLAN Tag priority of 3 to Tx Queue 0, set bit [3] in PSTQ0 field.

The same VLAN Tag priority can be set for multiple Tx queues. The Tx packet association to particular Tx Queue is governed by the application, so the MAC does not route the packet based on Tx Queue priority mapping; it is only used for Pause Flow Control (PFC). The settings in the PSTQ*n* field determines the Tx Queues blocked for transmission when the PFC packet is received with corresponding VLAN Tag priorities enabled.

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field are used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

47.3.5.1.7 Rx Side Routing from MAC to Queues

The MAC routes the Rx packets to the Rx Queues based on the following packet types:

- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged IEEE1588 PTP over Ethernet packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for generic through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the AVPTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

47.3.5.1.8 Rx Side Arbitration between DMA and MTL

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

47.3.5.2 MTL with Multiple Queues

The Ethernet module supports 2xTx and 2xRx queues. The number of Tx queues is equal to the number of DMA channels. You can control a Tx queue through *Section 47.2.169: Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)*. You can control an Rx queue through *Section 47.2.175: Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)*.

47.3.5.2.1 Queue Memory

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of *Section 47.2.169: Queue 0 Transmit Operation Mode Register (MTL_TXQ0_OPERATION_MODE)* and the Rx queue size in the RQS field of the *Section 47.2.175: Queue 0 Receive Operation Mode Register (MTL_RXQ0_OPERATION_MODE)*.

47.3.5.2.2 Queue Modes

You can enable a Tx queue for generic, AV, or all types of traffic. Generic Tx queues use WRR or WSP queuing algorithms. AV Tx queue uses CBS or SP queuing algorithms.

You can enable an Rx queue for generic, AV, or all types of traffic. A particular queue enabled for generic or AV based routing is determined by the RXQ*n*EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Generic Rx queues: All queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. Untagged packets are routed through Queue 0. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register
- Multiple Rx queues with AV feature: When you select the *Enable Audio Video Bridging* option, AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register

47.3.5.2.3 Queue Priorities

You can program the priority of a Tx queue in the MAC_TxQ_Prty_Map0 register. You can program the priority of an Rx queue in Bits[16:23] of corresponding Rx Flow Control Register. The priority should be assigned in the following order:

a) AV queue (high priority)

b) Best-effort queue (low priority)

The software should put packets with correct priorities in the respective programed queue on Tx side. The MAC uses the programed priorities for blocking the Tx queues when a PFC packet is received. If a single queue is selected for multiple priorities and PFC is enabled, the entire queue is paused if one or more priorities in the queue are paused.

47.3.5.2.4 AV Feature

The Ethernet module supports the AV data transfer in 100 Mbps mode. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration

47.3.5.2.4.1 Transmit Path Functions

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets
- The credit for the queue is positive as per the algorithm

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue, as shown in *Figure 593*. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit
- If the higher priority queue has no packet waiting in the FIFO

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Fixed Priority Scheme for DMA Channels.

47.3.5.2.4.2 Receive Path Functions

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in *Section 47.4.1.4: Receive Descriptor*. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programed priority value. To specify the channel to which an AV packet with a given priority must be sent, program Bits[16:23] in the Transmit Flow Control Register of the corresponding queue
- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these

packets on any other queue, you can program Bits[29:31] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programed priority value

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[25:27] of the MAC_RxQ_Ctrl1 register.

47.3.5.2.4.3 Credit-Based Shaper Algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

Credit Value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in Credit Value Per Transmit Cycle Example.

Table 882. Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	– portTransmitRate = 100 Mbps – idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) – sendSlope = 30 Mbps	– credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. – credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The Ethernet module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 30 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programed in Bits[25:27] of the CBS control register of the respective queue. For example, if you have programed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

47.3.5.2.5 Tx Side Arbitration between DMA and MTL

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX Checksum Engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

47.3.6 Double VLAN Processing

The Ethernet module supports the double VLAN tagging feature in which the MAC can process up to two VLAN tags (inner and outer). The Ethernet module supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

47.3.6.1 VLAN Processing in Transmit Path

Table 883 describes the double VLAN processing features supported by the MAC on the Transmit side.

Table 883. Double VLAN Processing Features in Tx Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_Incl and MAC_Inner_VLAN_Incl registers. The Ethernet module supports processing of any sequence of outer and inner VLAN tags. **Note:** The Ethernet module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: – The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. – The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. – The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. – The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields. Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in *Table 884*

Table 884. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) – VLAN Tag field with the Content of the VT field of Transmit context descriptor of the packet.
VLTI bit is reset	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) – VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets. To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_Incl register
- Enabling VLAN insertion, replacement, or deletion for selective packets. To enable this feature for selective packets, Program the VTIR field of TDES2 Normal Descriptor

47.3.6.2 VLAN Processing in Receive Path

Table 885 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 885. Double VLAN Processing in Rx Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.

Table 885. Double VLAN Processing in Rx Path (continued)

Feature	Description
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

47.3.7 Source Address Insertion, Replacement, or Deletion

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- To enable this feature for all packets, program the SARC field of the MAC_Configuration register
- To enable this feature for selective packets, use the following method:
  Program the SA Insertion Control field (Bits[6:8] of TDES3 Normal Descriptor (Read Format)) in the first Transmit descriptor of the packet. When Bit 6 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 6 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers
- If both MAC_Configuration Register and TDES3 are programed for SA insertion, then setting of MAC_Configuration register takes precedence

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

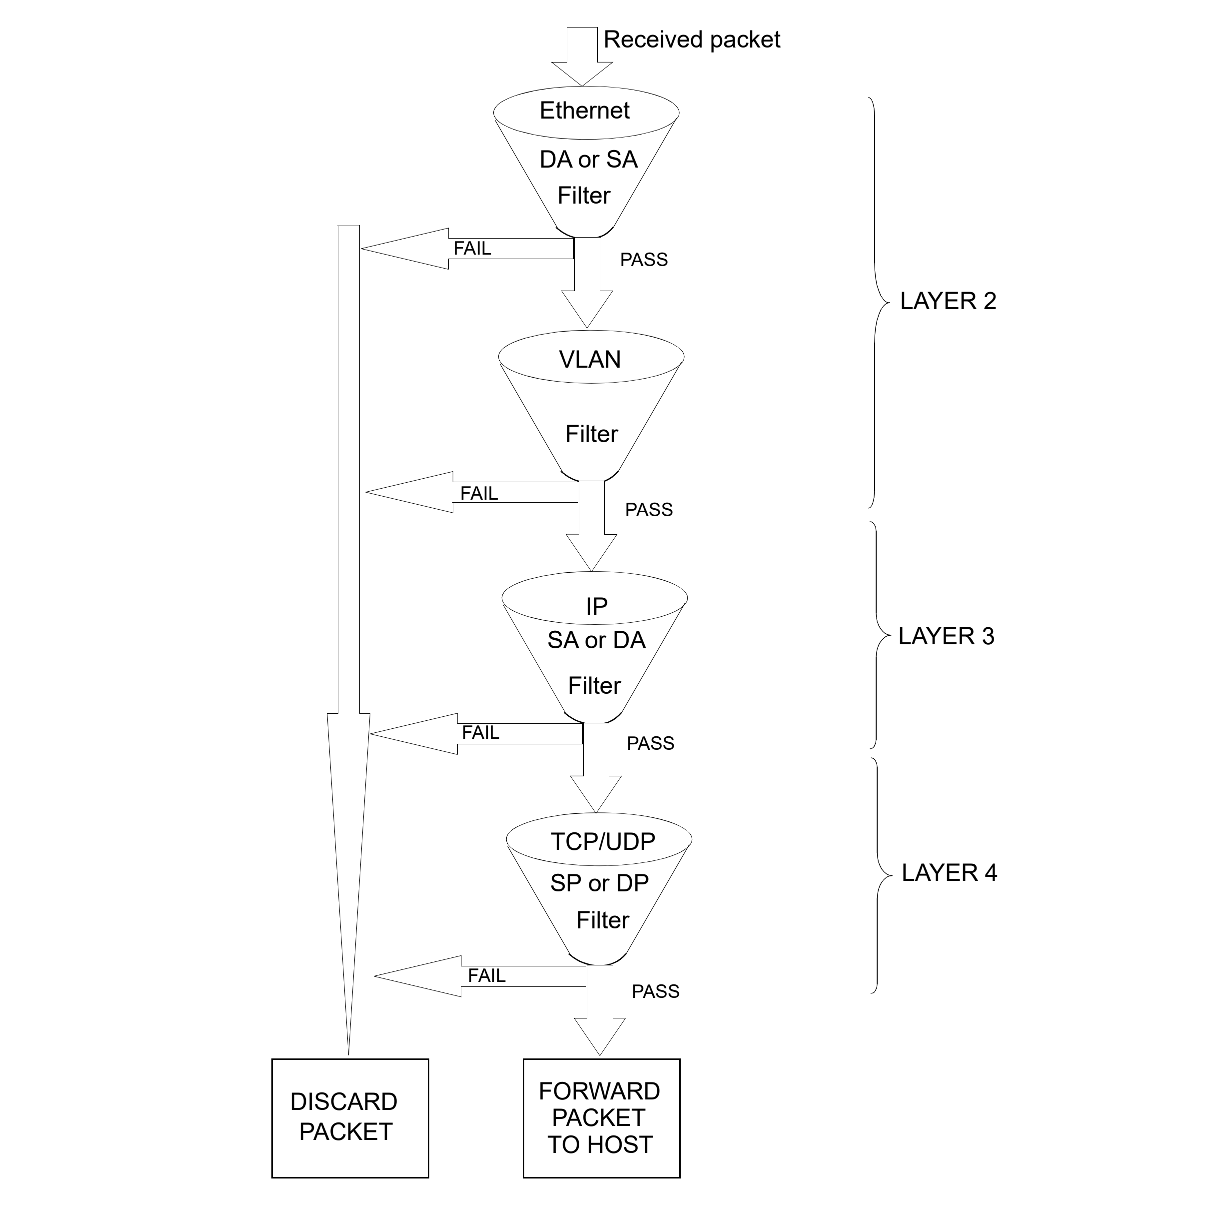
47.3.8 Packet Filtering

The Ethernet module supports the following types of filtering for Rx packets:

- Source Address or Destination Address Filtering: The Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet
- VLAN Filtering: The Ethernet module supports the VLAN tag-based and VLAN hash filtering
- Layer 3 and Layer 4 Filtering: Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering

Figure 822 shows the filtering sequence for Rx packets.

Figure 822. Packet Filtering Sequence



47.3.8.1 Source Address or Destination Address Filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

47.3.8.1.1 Unicast Destination Address Filtering

The MAC supports up to 128 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr127 addresses are selected with an individual enable bit. For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA. The MacAddr32 to MacAddr127 addresses do not have mask control and all 6-bytes of the MAC address are compared with the received 6-bytes of DA.

In hash filtering mode (when HUC of MAC_Packet_Filter register bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects Bit 63 of selected register, and a value of 11111 selects Bit 0 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

47.3.8.1.2 Multicast Destination Address Filtering

To program the MAC to pass all multicast packets, set the PM bit in *Section 47.2.3: MAC Packet Filter Register (MAC_PACKET_FILTER)*. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

In Perfect filtering mode, the multicast address is compared with the programed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 63 of selected register and a value of 111111 selects Bit 0 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

47.3.8.1.3 Hash or Perfect Address Filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in *Section 47.2.3: MAC Packet Filter Register (MAC_PACKET_FILTER)*. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

47.3.8.1.4 Broadcast Address Filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

47.3.8.1.5 Unicast Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 1 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and

DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

47.3.8.1.6 Inverse Filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 886 and *Table 887* summarize the DA and SA filtering based on the type of packets received.

Table 886. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 887. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

47.3.8.2 VLAN Filtering

The Ethernet module supports the following types of VLAN filtering:

- VLAN Tag Perfect Filtering
- VLAN Tag Hash Filtering

47.3.8.2.1 VLAN Tag Perfect Filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. The VLAN packet status bit (Bit 21 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

47.3.8.2.2 VLAN Tag Hash Filtering

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 888 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of the MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in the MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail. In Table 888, value *X* means that this column can have any value.

When VLAN VID is programed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 888. VLAN Match Status(1)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

1. In this table, X represents any value.

Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_Tag register. When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.

47.3.8.3 Layer 3 and Layer 4 Filtering

The Ethernet module supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the MAC_Configuration register to enable the Rx Checksum Offload Engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled
- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

47.3.8.3.1 Layer 3 and Layer 4 Filters Register Set

The MAC implements a set of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_Control0, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address0
- MAC_Layer3_Address0_Reg0
- MAC_Layer3_Address1_Reg0
- MAC_Layer3_Address2_Reg0
- MAC_Layer3_Address3_Reg0

47.3.8.3.2 Layer 3 Filtering

The Ethernet module supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

47.3.8.3.3 Layer 4 Filtering

The Ethernet module supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

47.3.9 IEEE 1588 Timestamps

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

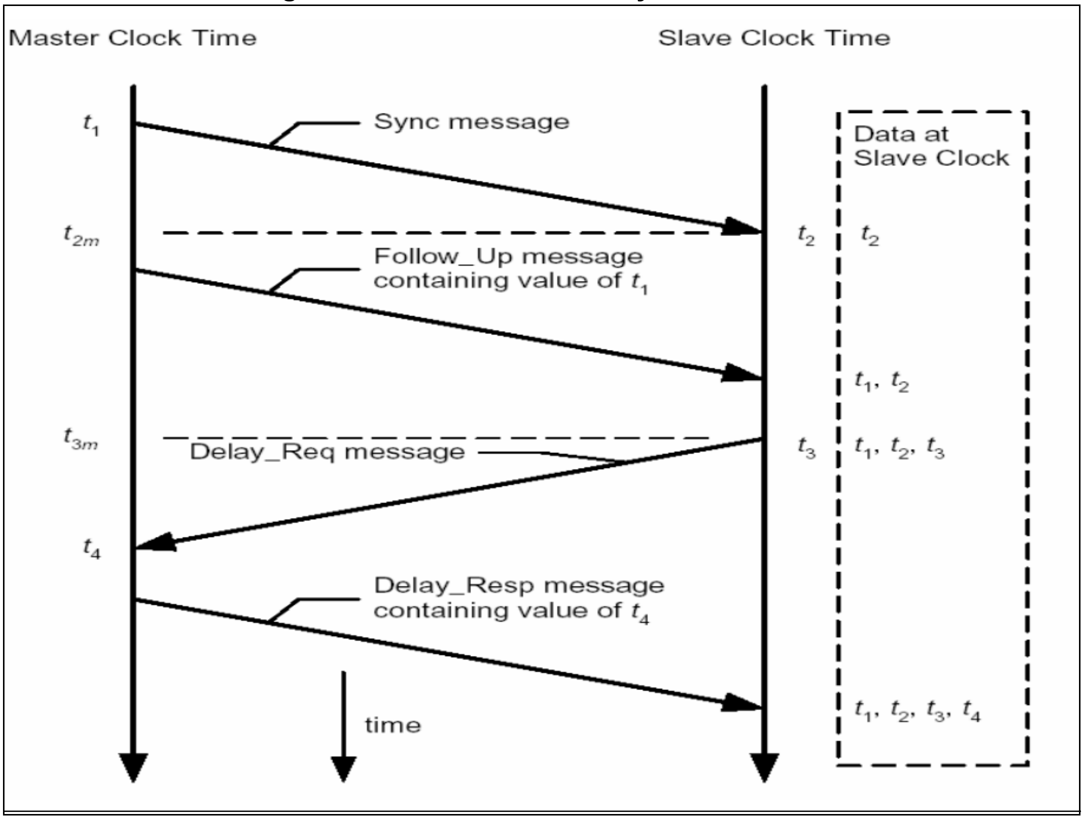
The Ethernet module supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet module provides programmable support for both standards. It supports the following features:

- Supports both timestamp formats
- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

47.3.9.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. *Figure 823*, shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 823. Networked Time Synchronization



As shown, the PTP uses the following process:

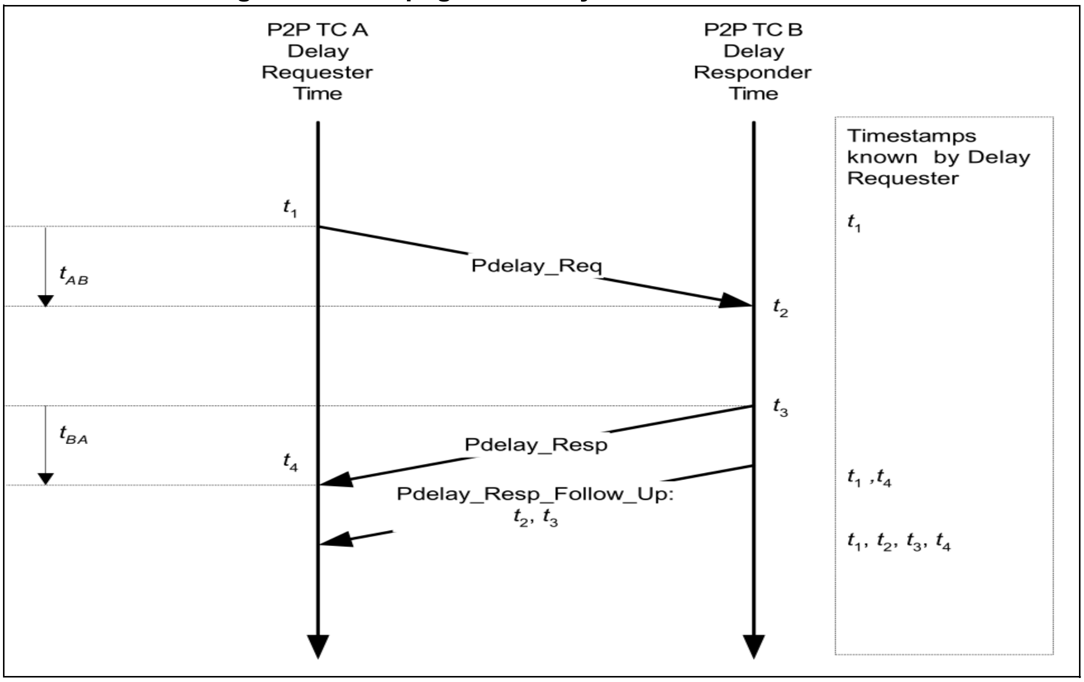
1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference
3. The master sends a Follow_up message to the slave, which contains t1 information for later use
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface
5. The master receives the message, capturing the exact time t4, at which the message enters its system
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

47.3.9.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 824 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 824. Propagation Delay Calculation in Clocks



As shown, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message

To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

   a) Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   b) Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   c) Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message
5. Port 1 uses all four timestamps to compute the mean link delay

47.3.9.3 Clock Types

The Ethernet module supports the following clock types defined in the IEEE 1588-2008:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

47.3.9.3.1 Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled
- Maintains the data sets such as timestamp values

Table 889 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 889. Ordinary Clock: PTP Messages for Snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control Register.

47.3.9.3.2 Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock
- The local clock is common to all ports of the boundary clock

47.3.9.3.3 End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in the bullet points below. The snapshot is taken by setting the SNAPTYPSEL bits to ‘10’ in the MAC_Timestamp_Control register.
End to End Transparent Clock: PTP Messages for Snapshot:

- SYNC
- Delay_Req

47.3.9.3.4 Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as mentioned in the below bullet points.
Peer-to-Peer Transparent Clock: PTP Messages for Snapshot:

- SYNC
- Pdelay_Req
- Pdelay_Resp

The snapshot is taken by setting the SNAPTYPESEL bit to ‘11’ in MAC_Timestamp_Control register.

47.3.9.4 Reference Timing Source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

The Ethernet module provides an Internal Reference Time (80-bit). It takes the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

- UInteger48 secondsField: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002
- UInteger32 nanosecondsField: The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001

The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit

These modes are set through TSCTRLSSR bit in MAC_Timestamp_Control register.

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. You can read the values of the upper 16-bits of the seconds field from the CSR register.

The Ethernet module supports the following reference timing source features:

- Fixed Pulse-Per-Second OutputPulse-Per-Second Output
- Flexible Pulse-Per-Second OutputPulse-Per-Second Output
- Auxiliary Snapshots with External Events

47.3.9.4.1 Fixed Pulse-Per-Second Output

The Ethernet module supports the pulse-per-second (PPS) output that is given to indicate 1 second interval (default). You can change the frequency of the PPS output by setting the PPSCTRL0 field in the MAC_PPS_Control register.

47.3.9.4.2 Flexible Pulse-Per-Second Output

The Ethernet module also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. The Ethernet module provides the following features with the flexible PPS output:

- Supports programming the start or stop time in terms of system time
- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time
- Supports programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed
- Supports programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programed in the MAC_Sub_Second_Increment register. You can program the width of pulse from 1 to 2^{32}-1 units of sub-second increment value
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^{32}-1 units of sub-second increment value
- Provides the option to cancel the programed PPS start or stop request
- Indicates error if the start or stop time being programed has already elapsed

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of MAC_Timestamp_Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated (using incr_sub_sec_reg shown in Figure 825).

47.3.9.4.2.1 PPS Start or Stop Time

You can initially program the start time in the Target Time register. If required, you can again program the start or stop time but you can do it only after the earlier programed value is synchronized to the PTP clock domain. Bit 0 of MAC_PPS*n*_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the

MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

47.3.9.4.2.2 PPS Width and Interval

The PPS width and interval are programed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

47.3.9.4.3 Auxiliary Snapshots with External Events

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the ptp_aux_ts_trig_i sideband signal.

The Ethernet module has two auxiliary snapshot inputs and depth 4 of a single common auxiliary snapshot FIFO. The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Timestamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

The MAC stores these snapshots in a FIFO. Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from the MAC_System_Time_Higher_Word_Seconds register. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in Bits[4:6] of MAC_Timestamp_Status register.

47.3.9.5 System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the MII interface.

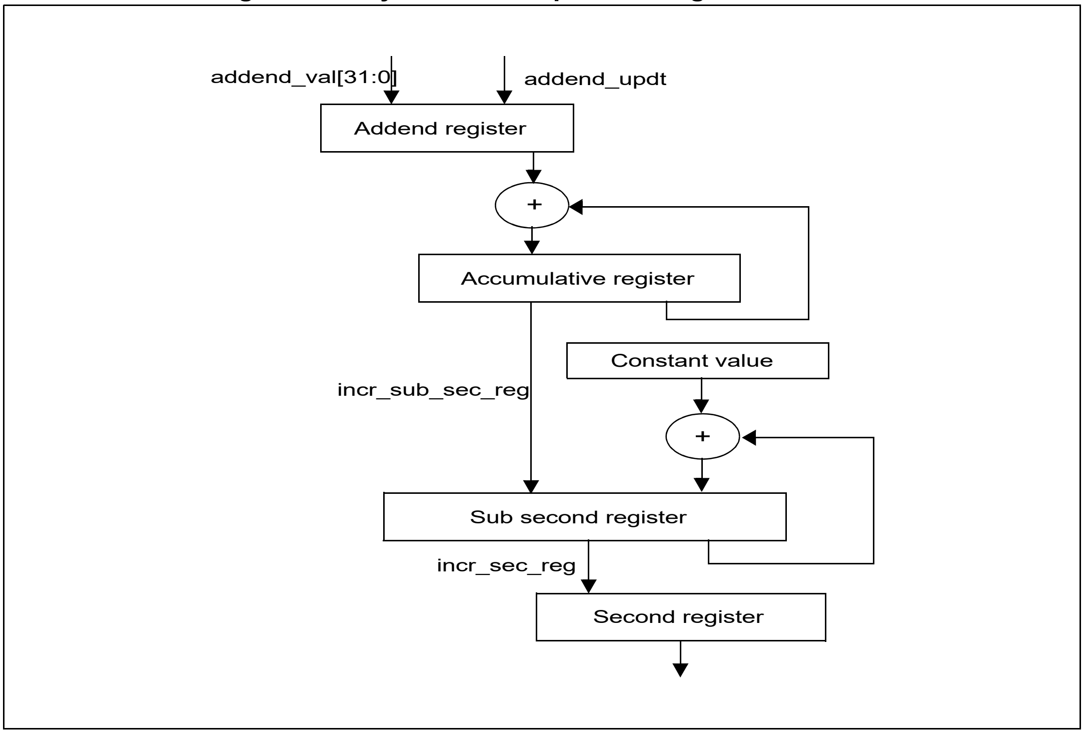
The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in *Figure 825*. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

This algorithm is shown in *Figure 825*.

Figure 825. System Time Update Using Fine Method



The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programed.

In 5-12, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32} / FreqDivisionRatio$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

47.3.9.6 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can do this by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

47.3.9.7 Receive Path Functions

The MAC can be programed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register.

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Note: The Ethernet module also supports the PTP messages over VLAN packets.

47.3.9.8 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock ***clk_ptp_ref_i***) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

47.3.9.8.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programed in the Ingress Correction register. The value that needs to be programed in the ingress correction register is calculated as mentioned below:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value.

```
INGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp.

```
Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY
```

Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

It is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programed value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <ingress_correction_value> represented in binary.

47.3.9.8.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value) programed in the Egress Correction register. The value that needs to be programed in the egress correction register as mentioned below:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value.

When Enable one step timestamp feature is selected,

```
EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)
```

Otherwise,

```
EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp.

```
Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY
```

Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The value must not exceed 0x3B9A_C9FF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <egress_correction_value> represented in binary.

47.3.9.9 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, that is, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

47.3.9.9.1 Maximum PTP Clock Frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

47.3.9.9.2 Minimum PTP Clock Frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the MII clock domain. This relationship is given in the following equation:

Equation 31

3 * PTP clock period + 4 * MII clock period <= Minimum gap between two SFDs

The MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in *Table 890*.

Note: It is recommended that you use a clock that has constant frequency, preferably a divided application clock.
When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Increment register limits the minimum PTP frequency that can be used to ~4 MHz.

Table 890. Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with Internal Timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
10 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
100 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz

47.3.9.10 PTP Processing and Control

Table 891 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 891. Message Format Defined in IEEE 1588-2008

Bits								Octets	Offset
0	1	2	3	4	5	6	7		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField(1)								1	32
logMessageInterval								1	33

1. ControlField is used in version 1. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets over IPv4Packets over IPv4
- PTP Frames over IPv6Frames over IPv6
- PTP Packets over EthernetPackets over Ethernet

47.3.9.10.1 PTP Packets over IPv4

Table 892 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 892*.

Table 892. IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP Primary multicast address: 224.0.1.129 PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	0x013F: PTP event message[1] 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only)

47.3.9.10.2 PTP Frames over IPv6

Table 893 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 893*.

47.3.9.10.3 PTP Packets over Ethernet

Table 893. IPv6-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [0:3])	0x6	IP version is IPv6
Layer 4 Protocol	20(1)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57(1)	0x013F, 0x140	0x013F: PTP event message 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94(1)	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management (version1)
PTP Message Type Field (IEEE 1588 version 2)	62(1) (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The Extension Header is not defined for PTP packets.

Table 894 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in Table 5-12 Message Format Defined in IEEE 1588-2008n 5-12.

47.3.9.11 One-Step Timestamp

Table 894. Ethernet PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address(1)	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses(2): 01-1B-19-00-00-00 01-80-C2-00-00-0E(3)
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, *Annex F*
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

The Ethernet module supports the one-step timestamp feature. When this feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application at that offset.

You can enable the one-step timestamp feature for a packet by setting Bit 11 (OSTC) in ATI Control Word. The inserted timestamp consists of 80-bits, the 64-bit TSSL and TSSH received from the application and the content of higher 16 bits of Higher Timestamp Word Register.

Note: The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets because the timestamp insertion happens in the MAC and the IP payload checksum needs to be updated. However, the checksum computation happens in the MTL.

47.3.9.11.1 MAC Transmit PTP Mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- Correction Field in the PTP header of messages
- OriginTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 895 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the *Section 47.2.140: Timestamp Control Register (MAC_TIMESTAMP_CONTROL)* and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Table 895. MAC Transmit PTP Mode and One-Step Timestamping Operation

Programming			Mode	Per Packet Control[1]			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE[2]	OSTC[3]	TTS[4]	
X	X	X	N/A	1	X	X	Timestamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
2'b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)

Table 895. MAC Transmit PTP Mode and One-Step Timestamping Operation (continued)

Programming			Mode	Per Packet Control[1]			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE[2]	OSTC[3]	TTS[4]	
2’b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2’b01	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

1. The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programed mode.
2. TTSE represents TTSE bit of transmit descriptor in EQOS-AXI configuration, TTSE bit in TX control word in EQOS-MTL configuration, mti_ena_timestamp_i signal in EQOS-CORE configuration. The TTSE function is independent of the OST function and the programed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.
3. OSTC represents OSTC bit of transmit descriptor in EQOS-AXI configuration, OSTC bit in TX control word in EQOS-MTL configuration, mti_ost_en_i signal in EQOS-CORE configuration.

4. TTS represents the timestamp value provided in the TTSH, TTSL fields of transmit descriptor in EQOS-AXI configuration, timestamp provided in the TTSH, TTSL fields in the TX control word in EQOS-MTL configuration, mti_ost_i signal in EQOS-CORE configuration.
Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp.
When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy.
Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

47.3.10 IPv4 ARP Offload

The Ethernet module supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. The Ethernet module generates the ARP reply packets for appropriate ARP request packets**.** The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programed in the L3 register of the MAC
2. The MAC generates an ARP reply packet
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   – DA field of the Ethernet packet header
   – Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet
5. The MAC places its MAC address in the following fields:
   – SA field of the Ethernet packet header
   – Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet
9. The MAC transmitter sends the ARP reply

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 21) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of an ARP request Packet. The ARP request Packet must always have a valid CRC. It can generate an ARP response packet if the other conditions are valid.

47.3.11 Memory Access in Debug Mode

The Ethernet module supports the debug access to the FIFO memory. When you enable this feature, you must program the entire selected Tx memory to Tx Queue 0 and Rx memory to Rx Queue 0. In addition, the offload features such as Checksum Offload Engine and IEEE timestamp should not be enabled with this feature.

When this feature is enabled, the MAC insert the pad (if required) and computed CRC in the Transmit packet. The FIFOs operate in the store-and-forward mode.

47.3.11.1 Slave Mode Access

You can use this mode to send or receive a packet through a slave interface. The following sections describe how to transmit or receive a packet through a slave interface.

47.3.11.1.1 Transmitting Packets through a Slave Interface

To write a packet to the Tx memory through a slave interface, complete the steps given in *Table 896*.

Table 896. Steps to Write a Packet to Tx memory through a Slave Interface

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the Packet control word.
MTL_DBG_CTL	Complete the following: a. Set the PKTSTATE field to Control field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Reset the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write the SOP, the first word of the packet data.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to SOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write subsequent data words.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to Packet Data. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL and MTL_DBG_STS	Repeat Write subsequent data words. and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). till the penultimate word of the packet data.

Table 896. Steps to Write a Packet to Tx memory through a Slave Interface

Register Name	Step Number and Description
MTL_FIFO_DEBUG_DATA	Write the last data word in the FDBGDATA field.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to EOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Set the number of valid bytes in the field.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.

After Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations. in *Table 896*, the core automatically initiates the packet transmission. The status of the packet transmission can be obtained as explained in *Table 896*. To get the status of a Tx packet, complete the steps given in *Table 897*.

Table 897. Steps to Get the Status of a Tx Packet

Register Name	Step Number and Description
MTL_DBG_STS	Wait for the STSI interrupt bit to set.
MTL_DBG_CTL	Complete the following steps: a. Set the FIFOSEL field to Tx Status FIFO. b. Reset the FIFWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_CTL	Read the FIFOBUSY bit and wait till this bit is low.
MTL_FIFO_DEBUG_DATA	Read the FDBGDATA field.

47.3.11.1.2 Receiving Packets through a Slave Interface

To read a packet from the Rx memory through a slave interface, complete the steps given in *Table 898*.

Table 898. Steps to Read a Packet from Rx memory through a Slave Interface

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_DBG_STS	Wait for the PKTI interrupt.
MTL_DBG_CTL	Complete the following: a. Set the FIFOSEL field to Rx FIFO. b. Reset the FIFOWREN bit. c. Set the FIFORDEN bit.

Table 898. Steps to Read a Packet from Rx memory through a Slave Interface

Register Name	Step Number and Description
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low.
MTL_DBG_CTL	Read the PKTSTATE and fields.
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field to know the number of available locations.
MTL_DBG_STS, MTL_DBG_CTL, MTL_FIFO_DEBUG_DATA	Repeat Read the FIFOBUSY bit and wait till this bit is low. through Read the LOCR field to know the number of available locations. till the complete packet, along with the Rx status, is received. **Note:** The format of the received packet is as follows First (One or multiple words) Last Status Word (One Word. Acts as delimiter between the status and data) Frame Data Word (multiple) Last Frame Data Word (One Word. Acts as a delimited among subsequent packets on the received Queue)

47.3.11.2 Debug Mode Access

Debug Mode enables you to do both the following operations:

- Write and Read back the Tx Queue
- Read and Write to the Tx Queue

This mode is useful for Memory BIST applications.

47.3.11.2.1 Writing to FIFO Memory in Debug Mode

To write to FIFO memory in the debug mode, complete the steps given in *Table 899*.

Table 899. Steps to Write to FIFO memory in Debug Mode

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the data in the FDBGDATA field.
MTL_DBG_CTL	Complete the following: – Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. – Reset the FIFORDEN bit. – Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL - MTL_DBG_STS	Repeat Complete the following: and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). twice to write one complete data word in 64-bit mode.

47.3.11.2.2 Reading from FIFO Memory in Debug Mode

To read from FIFO memory in the debug mode, complete the steps given in Table 900.

Table 900. Steps to Read from FIFO Memory in Debug Mode

Register Name	Step Number and Description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. b. Reset the FIFOWEN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field (if required).
MTL_DBG_CTL, MTL_DBG_STS, MTL_FIFO_DEBUG_DATA	Repeat Complete the following: and Read the LOCR field (if required). twice to read one complete data word in 64-bit mode.

47.3.12 Loopback

The MAC supports Loopback of transmitted packets to its receiver. By default, the MAC Loopback function is disabled. You can enable this feature by programming the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block. The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping
- If the loopback mode is enabled without connecting a PHY chip, you should externally generate the Tx and Rx clocks and provide these clocks to the MAC
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO
- The MAC does not process ARP or PMT packets that are looped back

47.3.13 MAC Flow Control

This section describes the flow control for Transmit and Receive paths.

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

In the Receive path, the Flow Control is functional only in the full-duplex mode. The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

47.3.13.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

The Transmit Flow Control is enabled independently for each Rx queue when TFE bit is set in MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

SW can request the MAC to send a Pause packet or initiate backpressure by setting the FCB_BPA bit in the corresponding MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

HW can automatically trigger TX flow control based on the Rx Queue Threshold**.** The HW flow control operation of the MAC is enabled when the EHFC bit of the corresponding MTL_RxQ*n*_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in the RFA field of the MTL_RxQ*n*_Operation_Mode register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field.

Table 901, describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE bit of the MAC_Q0_Tx_Flow_Ctrl register
- DM bit of the MAC_Configuration register
- RFA field of the MTL_RxQ0_Operation_Mode register
- RFD field of the MTL_RxQ0_Operation_Mode register
- FCB_BPA bit of the MAC_Q0_Tx_Flow_Ctrl

Flow control is similar for Queue1.

Table 901. TX MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX performs backpressure when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the pause packet when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	1	The MAC transmitter sends the pause packet when FCB_BPA of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX sends a pause packet when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.

47.3.13.1.1 Flow Control in Full-Duplex Mode

In full-duplex mode, the Ethernet module uses IEEE 802.3x Pause packets for flow control. *Table 902*, describes the fields of a Pause packet. When the FCB_BPA bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Table 902. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets
PT	Contains Pause time specified in the PT field of the MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register

47.3.13.1.2 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

47.3.13.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet. You can enable the Pause flow control by setting the RFE bit in the MAC_Rx_Flow_Ctrl register. *Table 903*, describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 903. RX MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

When the RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   - Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001)
   - Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set.
     If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address
2. The MAC decodes the following fields of the received packet:
   - Type field: This field is checked for 16'h8808
   - Opcode field: This field is checked for 16'h0001 (Pause packet)
   - Pause Time: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times)
3. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register
4. If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value

47.3.14 Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path. On the transmit path the Checksum Offload Engine is present in Queue0 only.

47.3.14.1 Transmit Checksum Offload Engine

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[14:15]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the Ethernet module is configured for Threshold (cut-through) mode.
You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. When reading starts, the COE fails and consequently all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the following number of bytes in size: TXFIFO_SIZE – ((PBL + N)(DATAWIDTH/8)), Where N= 5*

47.3.14.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 31). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
  - The total packet length is less than the value given in the IPv4 Header Length field
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received

47.3.14.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 19). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 904 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 904. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2 K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	No
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Authentication	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No

Table 904. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

47.3.14.2 Receive Checksum Offload Engine

You can enable the Receive Checksum Offload Engine (Rx COE) by setting the IPC bit of MAC_Configuration register. When enabled, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is sent in the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 905, describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status*Table 906*.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 905. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	Yes
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

47.3.15 MAC Management Counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the CSR. Each register is 32-bits wide. The width of each MMC counter is 32-bit.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, you should set Bit 31 in the MAC_Packet_Filter register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

The following definitions define the terminology.

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - MII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN Frame maxsize = 1,522
  - Jumbo Frame maxsize = 9,018
  - JumboVLAN Frame maxsize = 9,022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in *Table 906*.

Table 906. Size of the Maximum Receive Packet Size

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maxsize in bytes	Single VLAN Frame maxsize in bytes	Double VLAN Frame maxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

47.3.16 Low Power Modes

This chapter describes the low power modes supported by the Ethernet module. It contains the following sections:

- Energy Efficient Ethernet
- Power Management

47.3.16.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities, negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Note: The EEE feature is not supported when the MAC is configured to use the RMII PHY interface. Even if the MAC supports multiple PHY interfaces, you should activate the EEE mode only when the MAC is operating with the MII interface.
According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

47.3.16.1.1 Transmit Path Functions

In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Timers_Control register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

Note: According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN
2. Asserts TX_ER
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:

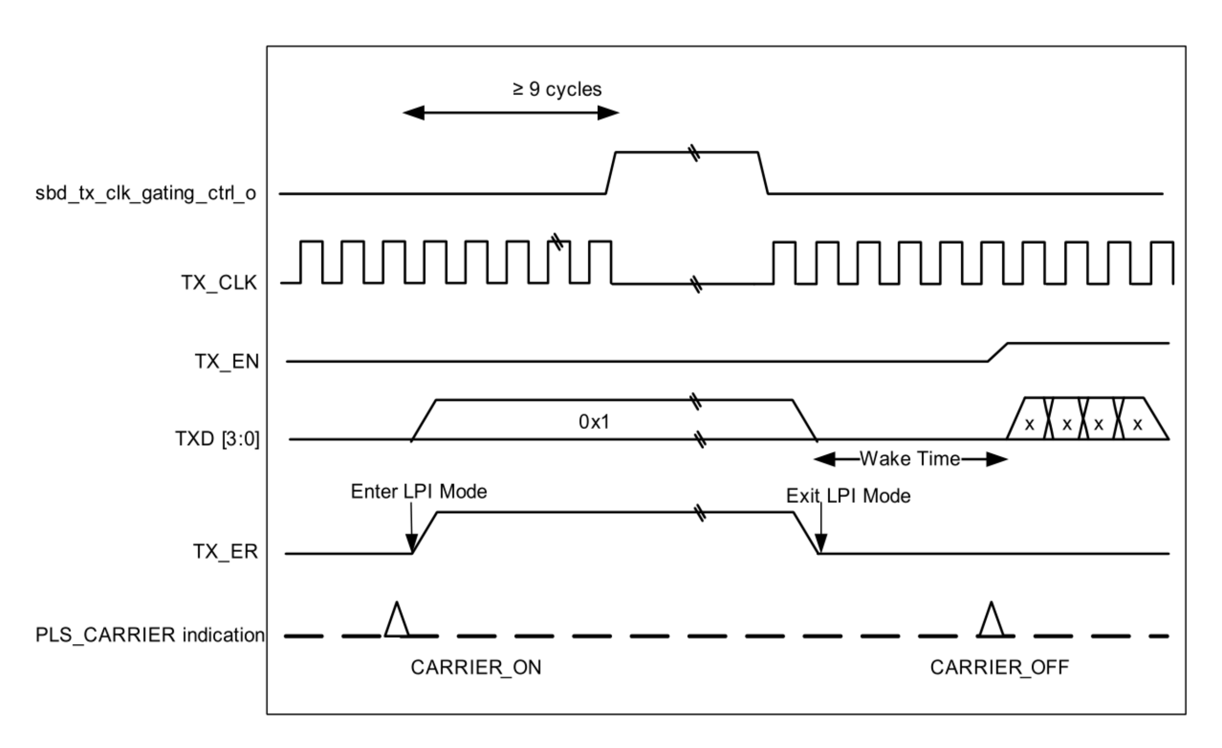
1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMER
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programed in the TWT field of the MAC_LPI_Timers_Control register
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt

Figure 826 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

The MAC does not stop the TX_CLK clock. You can stop this clock (as shown in Figure 826) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1.
The sbd_tx_clk_gating_ctrl_o signal is asserted after 9 Tx Clock Cycles, one Pulse Synchronizer delay (BCM22), and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status Register.
If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

Figure 826. LPI Transitions (Transmit)



47.3.16.1.1.1 Automated Entry/Exit of LPI mode in TX Path

The MAC transmitter can be programed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[12]) and LPITXEN (Bit[15]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[11] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

47.3.16.1.2 Receive Path Functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER
2. The PHY sets RXD[7:0] to 0x01
3. The PHY de-asserts RX_DV
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt

Note: If the LPI pattern is detected for a very short duration (that is, less than 2 cycles of Rx clock), the MAC does not enter the Rx LPI mode.
If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than 2 cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.

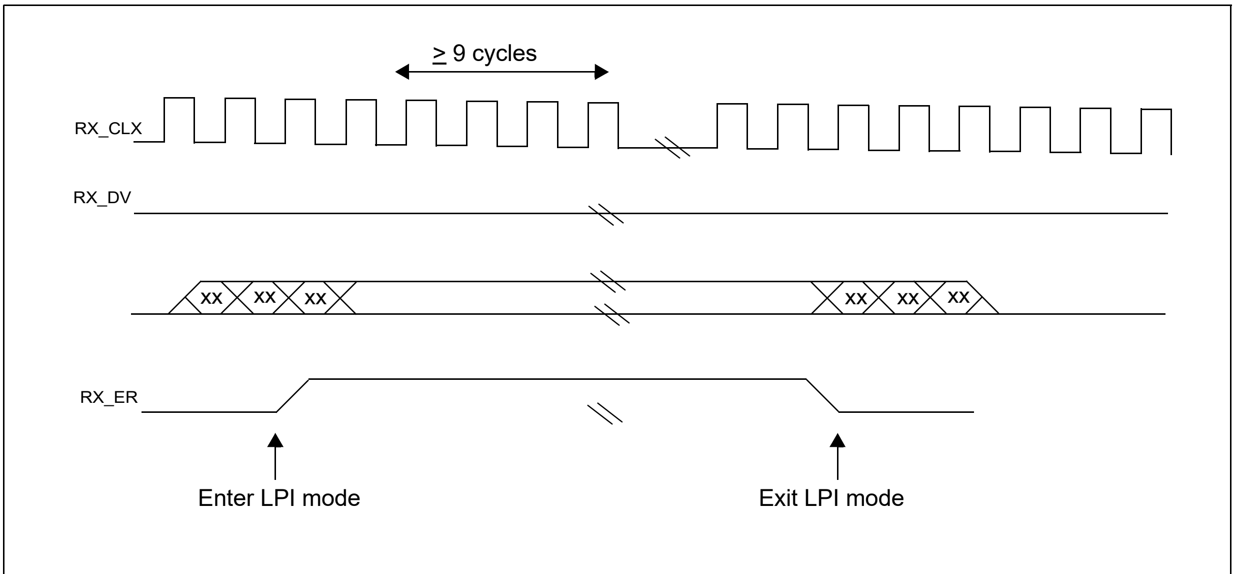
The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 827 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 827. LPI Transitions (Receive)



Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in Figure 827.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.
When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically

enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

47.3.16.1.3 LPI Timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER: The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.
  This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programed in Bits[6:15] of the MAC_LPI_Timers_Control register. The MII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.
- LPI TW TIMER: The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programed in Bit[16:31] of MAC_LPI_Timers_Control register. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.
  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µs.
- LPI AUTO ENTRY TIMER: This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

47.3.16.2 Power Management

The power management (PMT) block supports the reception of network (remote) wake-up packets and magic packets. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up packets and magic packets that the MAC receives.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up packet is received and the corresponding detection is enabled.

The PMT block is available in the receive path of MAC. You can select both types of power management packet (remote wake-up packet and magic packet). You can use the RWKPKTEN and MGKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

Note: The magic packet feature is implemented based on the Magic Packet Technology white paper. The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

47.3.16.2.1 PMT Block Registers

The following are the PMT block registers:

- MAC_PMT_Control_Status
- MAC_RWK_Packet_Filter

47.3.16.2.2 Remote Wake-Up Packet Detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status, the normal operation is resumed after a remote wake-up packet is received. The application writes all eight wake-up filter registers, by performing a sequential Write to address (00C4H). The application enables remote wake-up by writing 1 to the RWKPKTEN bit of the MAC_PMT_Control_Status register.

The PMT block supports 4 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wake-up packet.

The Filter Offset determines the offset from which the packet is to be examined. The Filter Byte Mask determines which bytes of the packet must be examined. The bit 0 of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up packet is checked only for length error, FCS error, dribble bit error, MII error, and collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wake-up packet detection is updated in the PMT Control and Status register for every remote wake-up packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wake-up packet.

Note: The watchdog timeout limit for a remote wake-up frame is 2,048 bytes irrespective of the value programed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programed in DCRCC bit of MAC_Ext_Configuration register is applicable to a remote wake-up frame only when Enable IPv4 ARP Offload is selected in the configuration.

47.3.16.2.3 Magic Packet Detection

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wake-up packet data format of 6 bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wake-up by writing 1 to the MGKPKTEN bit of the MAC_PMT_Control_Status register. The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48’hFF_FF_FF_FF_FF_FF pattern following the destination and source address field.

The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48’hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48’hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

Destination Address Source Address ……………….. FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

The Ethernet module checks the remote wake-up packet only for length error, FCS error, dribble bit error, MII error, collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, the Ethernet module considers it a valid packet.

The magic packet detection is updated in the MAC_PMT_Control_Status register for the received magic packet. A PMT interrupt to the Application triggers a read to the MAC_PMT_Control_Status register to determine whether a magic packet has been received.

Note: The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet only when Enable IPv4 ARP Offload is selected in the configuration.

47.3.16.2.4 System Considerations during Power Down

The Ethernet module neither gates nor stops clocks when the power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during the power-down mode, because it is involved in the magic packet or remote wake-up packet detection. However, the application path clock can be gated during the power-down mode. The transmit Path clock must be gated during the power-down mode only if ARP Offload is not enabled.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt [Bit 31 of the register] is received
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the_ MAC_Configuration register
3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. You can do this by reading the appropriate bits of Debug registers in the DMA and MTL CSR space
4. Enable Power-Down mode by appropriately configuring the PMT registers
5. Enable the MAC Receiver and enter the Power-Down mode
6. Gate the application and transmit clock (transmit clock must be gated only if ARP Offload is not enabled) inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode
7. On receiving a valid remote wake-up packet, the Ethernet module asserts the pmt_intr_o signal and exits the Power-Down mode
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation

47.3.17 Interrupts

Interrupt can be generated as a result of various events in the Ethernet IP core. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (interrupt) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the DMA_Interrupt_Status register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH*n*_Status register
- MTL_Interrupt_Status register
- MAC_Interrupt_Status register

The interrupt is a level signal and will get de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

47.3.17.1 DMA Interrupts

The DMA_CH*n*_Status register captures all the interrupt events of that TxDMA and RxDMA channel pair. The DMA_CH*n*_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[16:17] of DMA_CH*n*_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[25] of DMA_CH*n*_Status register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the register for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of the DMA_Interrupt_Status register are cleared.

47.3.17.1.1 Periodic scheduling of DMA Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet IP gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[0]) once for every “required” number of packets to be transmitted
2. Similarly, set the IOC (RDES3[1]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated

In addition to above, an interrupt timer (DMA_CH*n*_Rx_Interrupt_Watchdog_Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programed with a non-zero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[1]) is not set. When this timer runs out as per the programed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH*n*_Interrupt_Enable register. The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

47.3.17.1.2 Per DMA channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CH*n*_Status register. The TI bit is set whenever the Tx DMA channel closes the a descriptor in which the IOC (Interrupt On Completion - TDES2[0]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[1]) bit is set.

The common interrupt output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH*n*_Interrupt_Enable register.

47.3.17.2 MTL Interrupts

In MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the Transmit and Receive paths respectively. The interrupt status are captured and organized in a hierarchical manner in order to identify the root cause quickly.

The MTL_Interrupt_Status register identifies the top level modules that can cause the interrupt to be asserted.

- Bits[30:31] identify 2 Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Q*n*_Interrupt_Status register to identify the exact cause and set the corresponding bits to 1 to clear the interrupt event. The assertion of interrupt due to these events is enabled by the corresponding enable bits in MTL_Q*n*_Interrupt_Enable register
- Bit[15] is made high in case the event is present in the MAC core. The application should in turn read the MTL_Interrupt_Status register to identify the cause
- Bit[14] is related to indirect access completion events to the TxFIFO and RxFIFO memory in Debug Mode

47.3.17.3 MAC Interrupts

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_Interrupt_Status register describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the MAC_Interrupt_Enable register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, Bit 26 of the MAC_Interrupt_Status register indicates that the LPI interrupt status has changed. You must read the TLPIEN bit of MAC_LPI_Control_Status register to clear this interrupt event.

The interrupts from the MAC are combined (OR'ed) and given as the MACIS bit in the DMA_Interrupt_Status register.

47.3.17.4 LPI Interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt mci_intr_o (interrupt in EQOS-DMA configurations) is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the mci_intr_o (interrupt in EQOS-DMA configurations), the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. You can use the lpi_intr_o signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state. If you do not want to gate-off the application clock during the Rx LPI state, you can leave the lpi_intr_o signal unconnected and use the mci_intr_o (interrupt in EQOS-DMA configurations) signal to detect Rx LPI exit.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

47.3.17.5 PMT Interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. In addition to the interrupt, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode.

You can use the pmt_intr_o interrupt to trigger the external clock-gating circuitry to restore the application clock and Tx clock to the MAC. If you do not want to gate-off these clocks during the power-down mode, you can leave the pmt_intr_o signal unconnected and use the interrupt to detect the MAC wake-up operation.

The pmt_intr_o signal is generated in the Rx clock domain. It is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

When software resets the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

47.4 Descriptors

47.4.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The Ethernet module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted

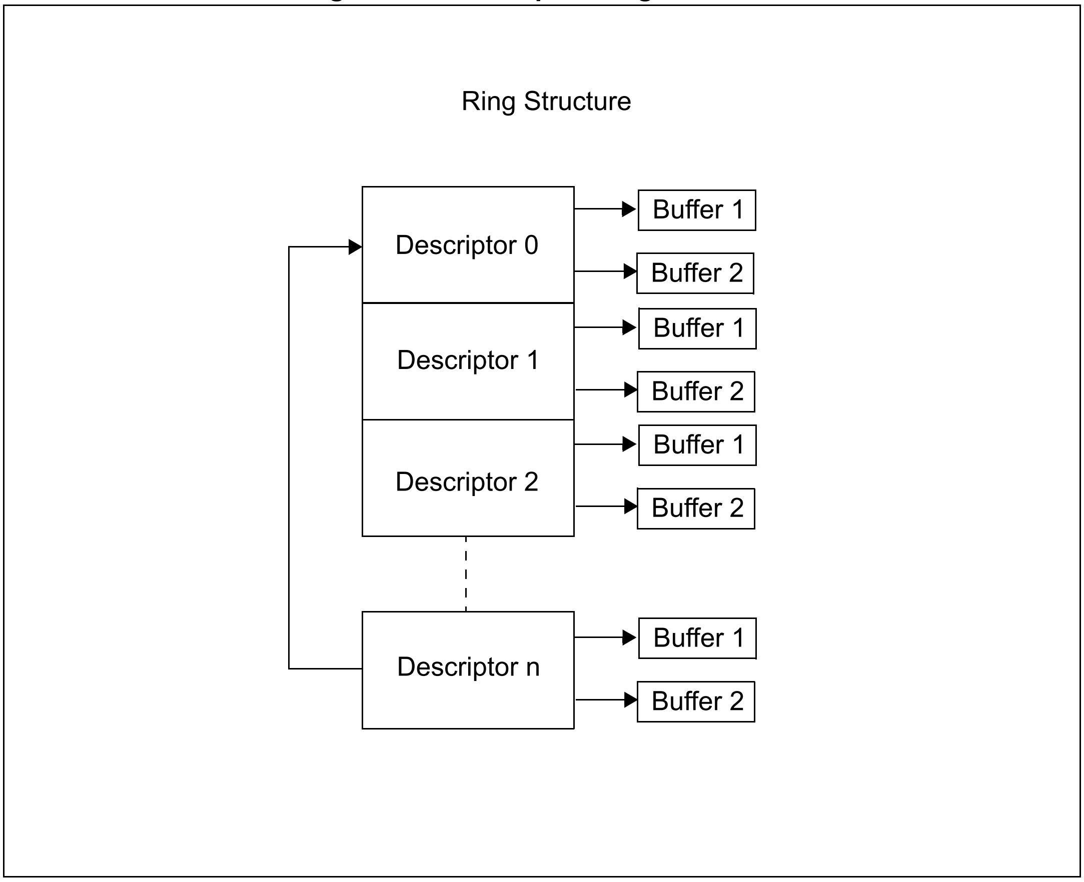
Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for number of descriptors that can be used for a single packet.

47.4.1.1 Descriptor Structure

The Ethernet module supports the ring structure for DMA descriptor.

Figure 828. Descriptor Ring Structure



In Ring structure, descriptors are separated by the DWord number programed in the DSL field of the DMA_CH*n*_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH*n*_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH*n*_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (*N*). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (*N* – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

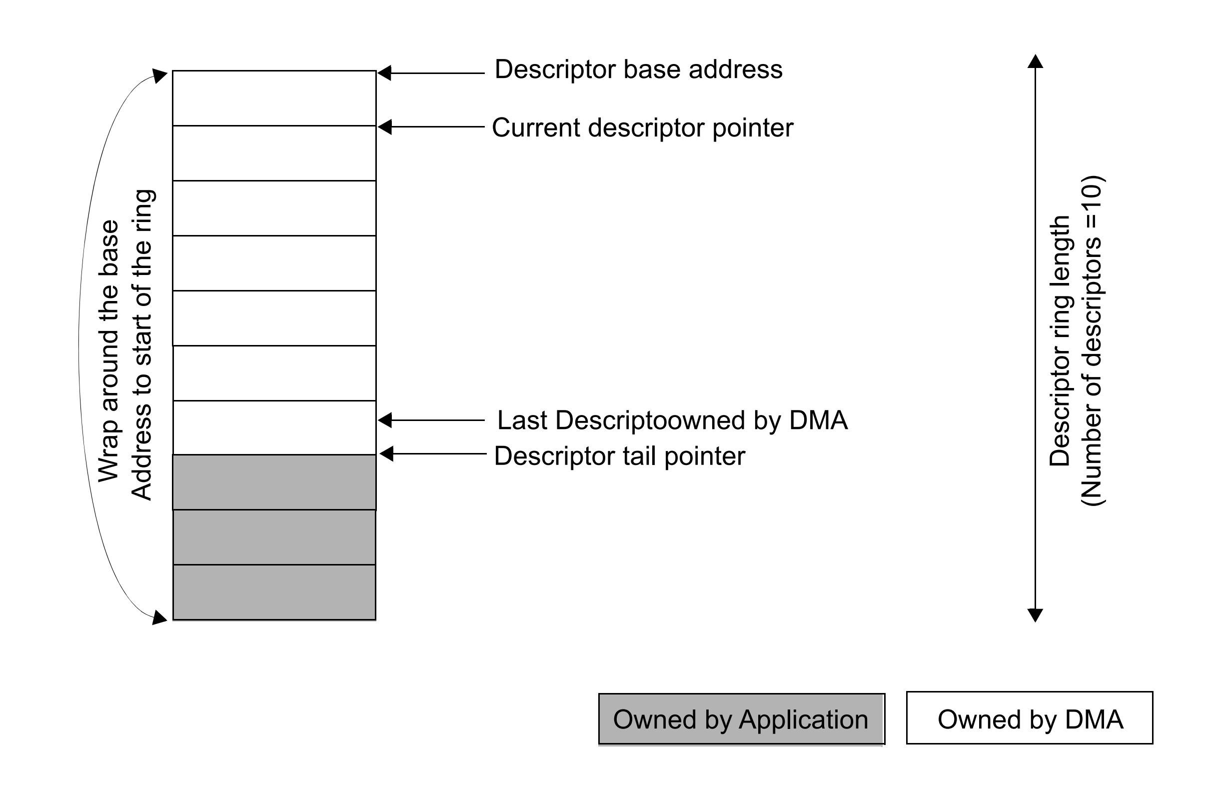
```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in *Figure 829*.

Figure 829. DMA Descriptor Ring



For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

47.4.1.2 Descriptor Endianness

The descriptor addresses must be aligned to configured bus width (DWord for 64-bit bus). The data bus can be configured for either little-endian or big-endian format.

Figure 830 shows the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is little-endian or big-endian and the endian mode of descriptors is reverse-endian.

Figure 830. Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus

63	31 0
DES1	DES0
DES3	DES2

Figure 830 and *Figure 831* show the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is big-endian and the endian mode of descriptors is reverse-endian. In 64-bit big-endian data bus systems, when the descriptors are configured for reverse endianness, the order of the descriptor subset is reversed from the default (7-3 Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus). For example, Bits[63:32] are DES0 while Bits[31:0] are DES1.

Figure 831. Rx/Tx Descriptors in Reverse-Endian Mode for 64-Bit, Big-Endian Data Bus

63	31 0
DES0	DES1
DES2	DES3

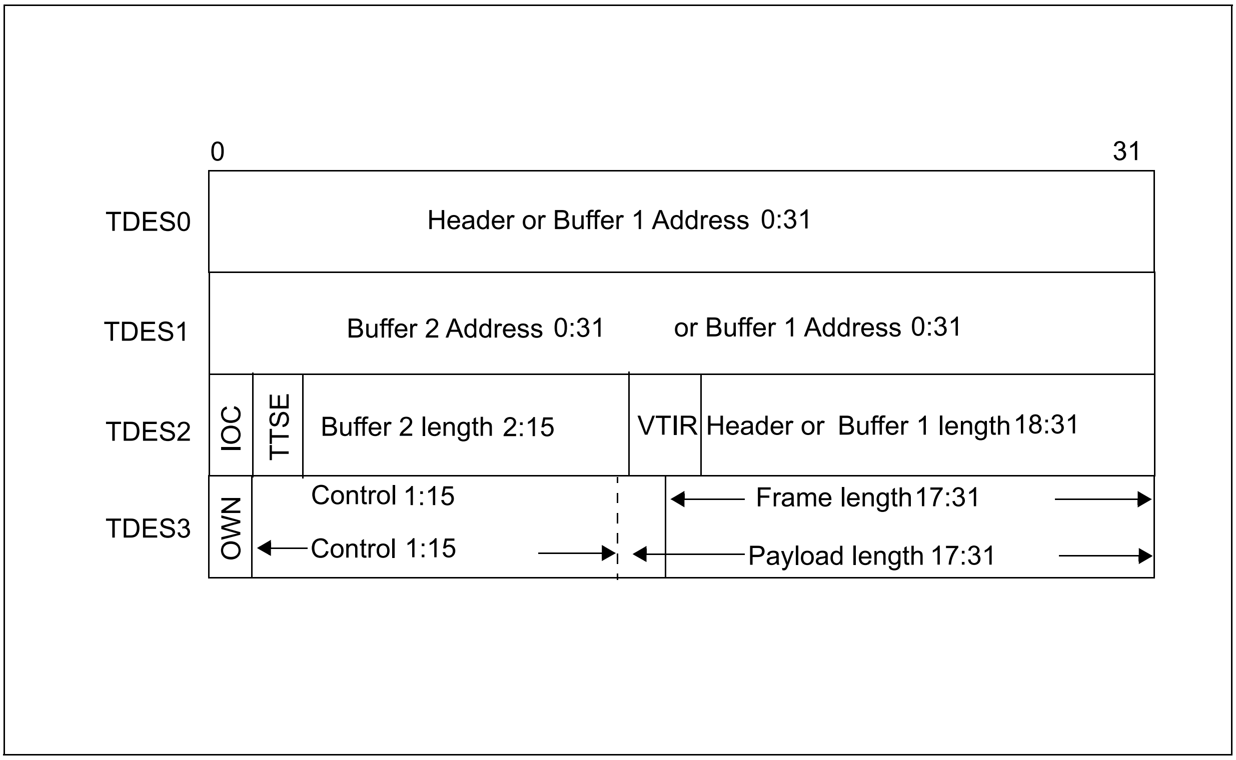
47.4.1.3 Transmit Descriptor

The DMA in the Ethernet module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has the following two formats: Read format and Write-Back format

47.4.1.3.1 Transmit Normal Descriptor (Read Format)

Figure 832 shows the Read Format for a Transmit normal descriptor.

Figure 832. Transmit Descriptor Read Format



47.4.1.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 907. TDES0 Normal Descriptor (Read Format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1.

47.4.1.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 908. TDES1 Normal Descriptor (Read Format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

47.4.1.3.1.3 TDES2 Normal Descriptor (Read Format)

Figure 833. TDES2 Normal Descriptor (Read Format)

0	1	2:15	16:17	18:31
IOC	TTSE	B2L	VTIR	B1L

Table 909. TDES2 Normal Descriptor (Read Format)

Field	Description
0 IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CH*n*_Status register after the present packet has been transmitted.
1 TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor.
2:15 B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
16:17 VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: 00 Do not add a VLAN tag. 01 Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. 10 Insert a VLAN tag with the tag value programed in the MAC_VLAN_Incl register or context descriptor. 11 Replace the VLAN tag in packets with the tag value programed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets.
18:31 B1L	Buffer 1 Length

47.4.1.3.1.4 TDES3 Normal Descriptor (Read Format)

Figure 834. TDES3 Normal Descriptor (Read Format)

0	1	2	3	4:5	6:8	9:12	13	14:15	16	17:31
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM	Rsvd	CIC	Reserved	FL

Table 910. TDES3 Normal Descriptor (Read Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
1 CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
2 FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.

Table 910. TDES3 Normal Descriptor (Read Format) (continued)

Field	Description
3 LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
4:5 CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[2]) is set. The following list describes the values of Bits[4:5]: 00 CRC and Pad Insertion - The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. 01 CRC Insertion (Disable Pad Insertion) - The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. 10 Disable CRC Insertion - The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. 11 CRC Replacement - The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.
6:8 SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 6 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[7:8]: 00 Do not include the source address 01 Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 Reserved
9:12 SLOTNUM	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH*n*_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.
13	Reserved

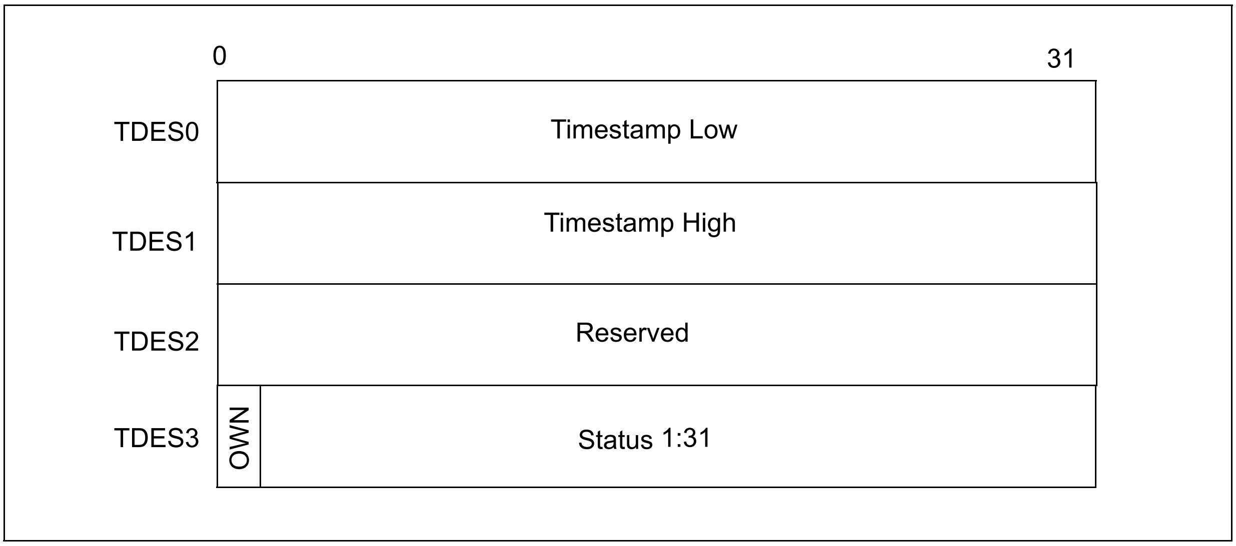
Table 910. TDES3 Normal Descriptor (Read Format) (continued)

Field	Description
14:15 CIC	Checksum Insertion Control These bits control the checksum calculation and insertion. The following list describes the bit encoding: 00 Checksum Insertion Disabled. 01 Only IP header checksum calculation and insertion are enabled. 10 IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.
16	Reserved
17:31 FL	Packet Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length

47.4.1.3.1.5 Transmit Normal Descriptor (Write-Back Format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[3]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 835. Transmit Descriptor Write-Back Format



47.4.1.3.1.6 TDES0 Normal Descriptor (Write-Back Format)

This format is only applicable to the last descriptor of a packet.

Table 911. TDES0 Normal Descriptor (Write-Back Format)

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

47.4.1.3.1.7 TDES1 Normal Descriptor (Write-Back Format)

This format is only applicable to the last descriptor of a packet.

Table 912. TDES1 Normal Descriptor (Write-Back Format)

Field	Description
0:31 TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding Receive packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

47.4.1.3.1.8 TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 913. TDES2 Normal Descriptor (Write-Back Format)

Field	Description
0:31	Reserved

47.4.1.3.1.9 TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Figure 836. TDES3 Normal Descriptor (Write-Back Format)

0	1	2	3	4:13	14	15	16	17	18	19	20	21	22	23	24:27	28	29	30	31

Table 914. TDES3 Normal Descriptor (Write-Back Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
1 CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
2 FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
4:13	Reserved
14 TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [3]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
15	Reserved
16 ES	Error Summary This bit indicates the logical OR of the following bits: TDES3[31]: IP Header Error TDES3[17]: Jabber Timeout TDES3[18]: Packet Flush TDES3[19]: Payload Checksum Error TDES3[20]: Loss of Carrier TDES3[21]: No Carrier TDES3[22]: Late Collision TDES3[23]: Excessive Collision TDES3[28]: Excessive Deferral TDES3[29]: Underflow Error
17 JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
18 FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

Table 914. TDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
19 PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode.
20 LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the MII_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
21 NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
22 LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
23 EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
24:27 CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
28 ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register.
29 UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: The DMA encountered an empty Transmit Buffer while transmitting the packet The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.

Table 914. TDES3 Normal Descriptor (Write-Back Format) (continued)

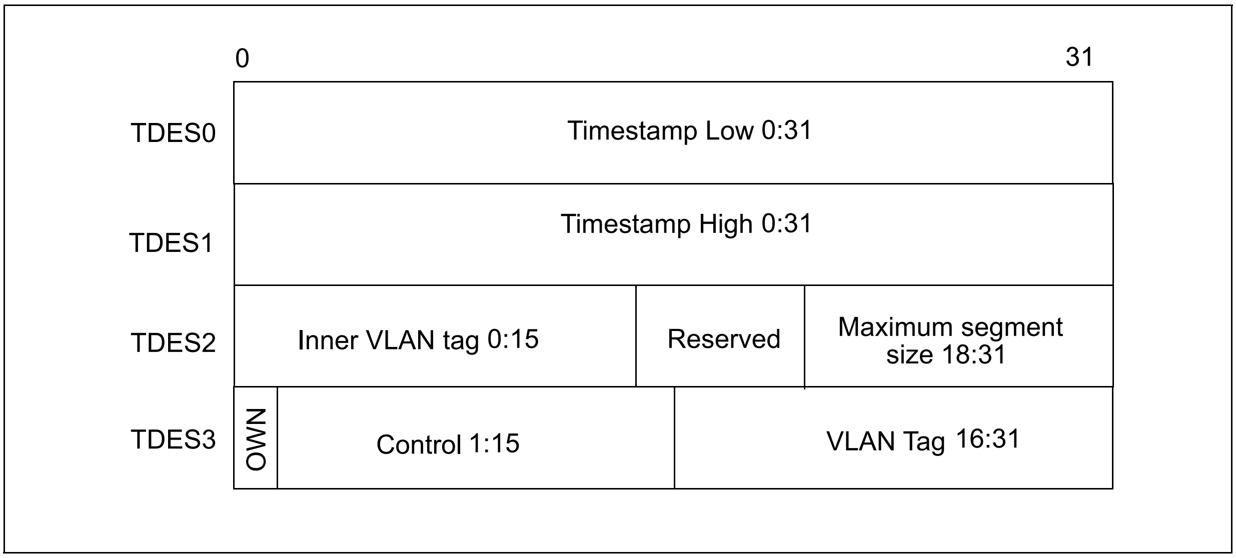
Field	Description
30 DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
31 IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

47.4.1.3.2 Transmit Context Descriptor

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.
When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.
The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 837. Transmit Context Descriptor Format



47.4.1.3.2.1 TDES0 Context Descriptor

Table 915. TDES0 Context Descriptor

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

47.4.1.3.2.2 TDES1 Context Descriptor

Table 916. TDES1 Context Descriptor

Field	Description
0:31 TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

47.4.1.3.2.3 TDES2 Context Descriptor

Table 917. TDES2 Context Descriptor

Field	Description
0:15 IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[0:15] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
16:31	Reserved

47.4.1.3.2.4 TDES3 Context Descriptor

Figure 838. TDES3 Context Descriptor

0	1	2:3	4	5	6:7	8	9:13	14	15	16:31
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 918. TDES3 Context Descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
2:3	Reserved
4 OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
5 TCMSSV	One-Step Timestamp Correction Input When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.
6:7	Reserved
8 CDE	Context Descriptor Error When this bit is set, it indicates that the context descriptor was provided in the incorrect sequence and the DMA ignored it. The DMA sets this bit during write-back while closing the context descriptor.
9:11	Reserved
12:13 IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: 00 Do not add the inner VLAN tag. 01 Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. 10 Insert an inner VLAN tag with the tag value programed in the MAC_VLAN_Incl register or context descriptor. 11 Replace the inner VLAN tag in packets with the tag value programed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames.
14 IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
15 VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
16:13 VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

47.4.1.4 Receive Descriptor

The DMA in the Ethernet module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

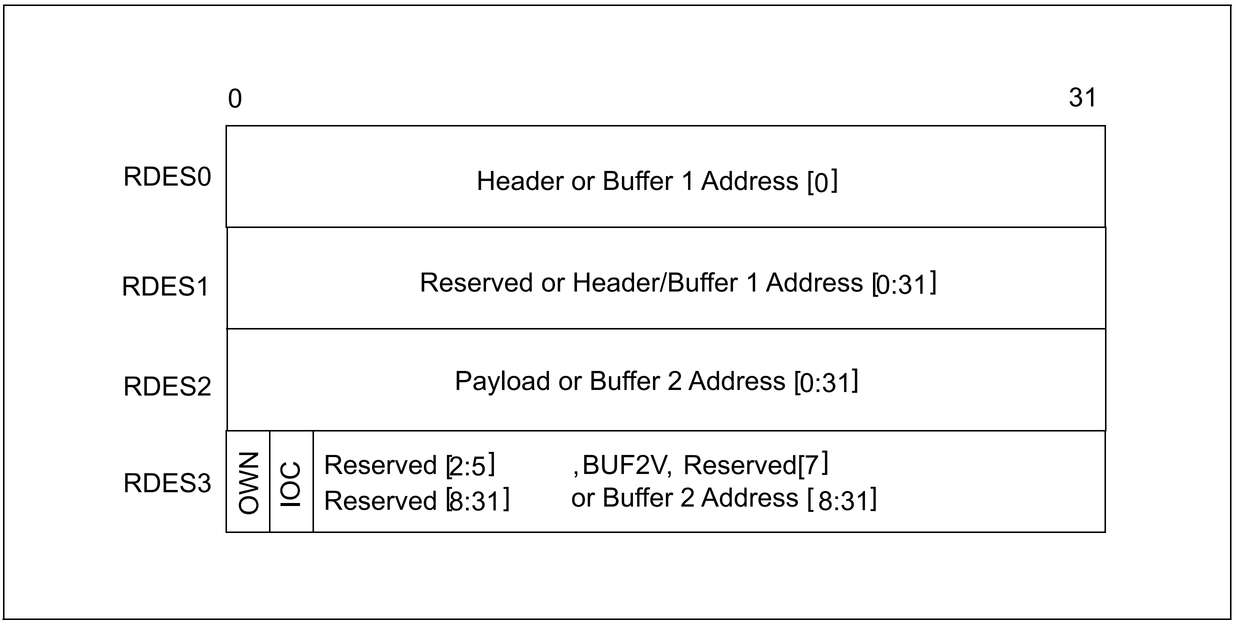
- Normal and
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in *Section 47.4.1.4.1: Receive Normal Descriptor (Read Format)*. The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the *Section 47.4.1.4.2: Receive Normal Descriptor (Write-Back Format)*.

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA will write the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in *Section 47.4.1.4.3: Receive Context Descriptor*.

47.4.1.4.1 Receive Normal Descriptor (Read Format)

Figure 839. Receive Normal Descriptor (Read Format)



Note: In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the Ethernet module does not transfer data to that buffer and skips to the next buffer or next descriptor.

47.4.1.4.1.1 RDES0 Normal Descriptor (Read Format)

Table 919. RDES0 Normal Descriptor (Read Format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[29:31] as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

47.4.1.4.1.2 RDES1 Normal Descriptor (Read Format)

Table 920. RDES1 Normal Descriptor (Read Format)

Field	Description
0:31	This field is reserved.

47.4.1.4.1.3 RDES2 Normal Descriptor (Read Format)

Table 921. RDES2 Normal Descriptor (Read Format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[29:31] and writes to the complete location.

47.4.1.4.1.4 RDES3 Normal Descriptor (Read Format)

Figure 840. RDES3 Normal Descriptor (Read Format)

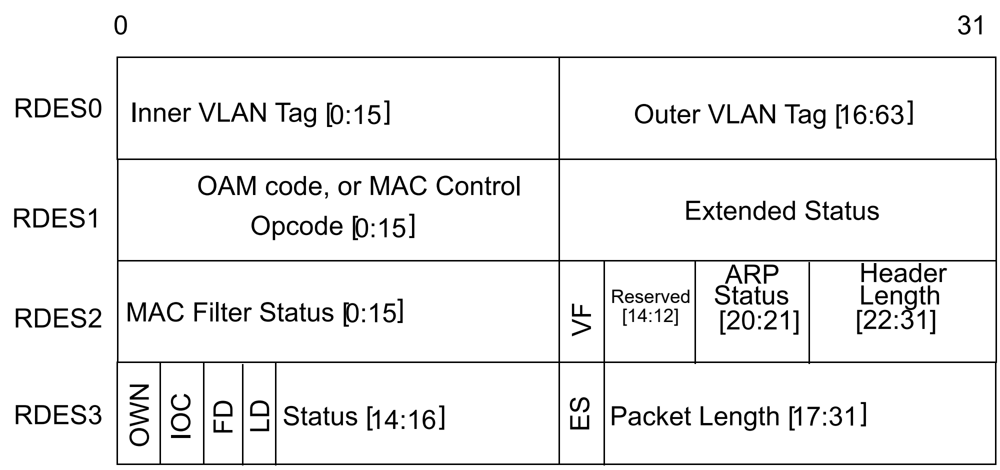
0	1	2:5	6	7	8:31
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 922. RDES3 Normal Descriptor (Read Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
2:5	Reserved
6 BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is Valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
7 BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
8:31	Reserved

47.4.1.4.2 Receive Normal Descriptor (Write-Back Format)

Figure 841. Receive Normal Descriptor (Write-Back Format)



47.4.1.4.2.1 RDES0 Normal Descriptor (Write-Back Format)

Figure 842. RDES0 Normal Descriptor (Write-Back Format)

0:15	16:31
IVT	OVT

Table 923. RDES0 Normal Descriptor (Write-Back Format)

Field	Description
0:15 IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
16:31 OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

47.4.1.4.2.2 RDES1 Normal Descriptor (Write-Back Format)

The status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

Figure 843. RDES1 Normal Descriptor (Write-Back Format)

0:15	16	17	18	19	20:23	24	25	26	27	28	29:31
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 924. RDES1 Normal Descriptor (Write-Back Format)

Field	Description
0:15 OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If bits[13:15] of RDES3 are set to 111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If bits[13:15] of RDES3 are set to 110, this field contains the MAC Control packet opcode field.
16 TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table 924. RDES1 Normal Descriptor (Write-Back Format) (continued)

Field	Description
17 TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [3]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
18 PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
19 PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
20:23 PMT	PTP Message Type These bits are encoded to give the type of the message received: 0000 No PTP message received 0001 SYNC (all clock types) 0010 Follow_Up (all clock types) 0011 Delay_Req (all clock types) 0100 Delay_Resp (all clock types) 0101 Pdelay_Req (in peer-to-peer transparent clock) 0110 Pdelay_Resp (in peer-to-peer transparent clock) 0111 Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) 1000 Announce 1001 Management 1010 Signaling 1011–1110 Reserved 1111 PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
24 IPCE	IP Payload Error When this bit is set, it indicates either of the following: The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 16 (ES) of RDES3 is not set when this bit is set.
25 IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed.
26 IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected.
27 IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected.

Table 924. RDES1 Normal Descriptor (Write-Back Format) (continued)

Field	Description
28 IPHE	IP Header Error When this bit is set, it indicates either of the following: The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. The IP datagram version is not consistent with the Ethernet Type value. Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 26 or bit 27 is set.
29:31 PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): 000 Unknown type or IP/AV payload not processed 001 UDP 010 TCP 011 ICMP 110 AV Tagged Data Packet 111 AV Tagged Control Packet 101 AV Untagged Control Packet 100 IGMP if IPV4 Header Present bit is set else data center bridging (DCB) link layer discovery protocol (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000.

47.4.1.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

Figure 844. RDES2 Normal Descriptor (Write-Back Format)

0:2	3	4	5:12	13	14	15	16	17:20	21	22:31
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	VF	Rsvd	ARPNR	Rsvd

Table 925. RDES2 Normal Descriptor (Write-Back Format)

Field	Description
0:2 L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: 000 Filter 0 001 Filter 1 010 Filter 2 011 Filter 3 100 Filter 4 101 Filter 5 110 Filter 6 111 Filter 7 This field is valid only when Bit 3 or Bit 4 is set high. When more than one filter matches, these bits give the number of lowest filter.
3 L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: Layer 3 fields are not enabled and all enabled Layer 4 fields match All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[0:2].
4 L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[0:2].
5:12 MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register.
13 HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[5:12] indicate the hash value.
14 DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC.
15 SAF	SA Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC.
16 VF	VLAN Filter Status When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter.

Table 925. RDES2 Normal Descriptor (Write-Back Format) (continued)

Field	Description
17:20	Reserved
21 ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).
22:31	Reserved

47.4.1.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Figure 845. RDES3 Normal Descriptor (Write-Back Format)

0	1	2	3	4	5	6	7	8	9	10	11	12	13:15	16	17:31
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 926. RDES3 Normal Descriptor (Write-Back Format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor.
2 FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
4 RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
5 RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
6 RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.

Table 926. RDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
7 CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
8 GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). **Note:** Giant packet indicates only the packet length. It does not cause any packet truncation.
9 RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
10 OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. **Note:** This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
11 RE	Receive Error When this bit is set, it indicates that the MII_RXER signal is asserted while the MII_RX_DV signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
12 DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
13:15 LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: 000 The packet is a length packet 001 The packet is a type packet. 011 The packet is a ARP Request packet type 100 The packet is a type packet with VLAN Tag 101 The packet is a type packet with Double VLAN Tag 110 The packet is a MAC Control packet type 111 The packet is a OAM packet type 010 Reserved

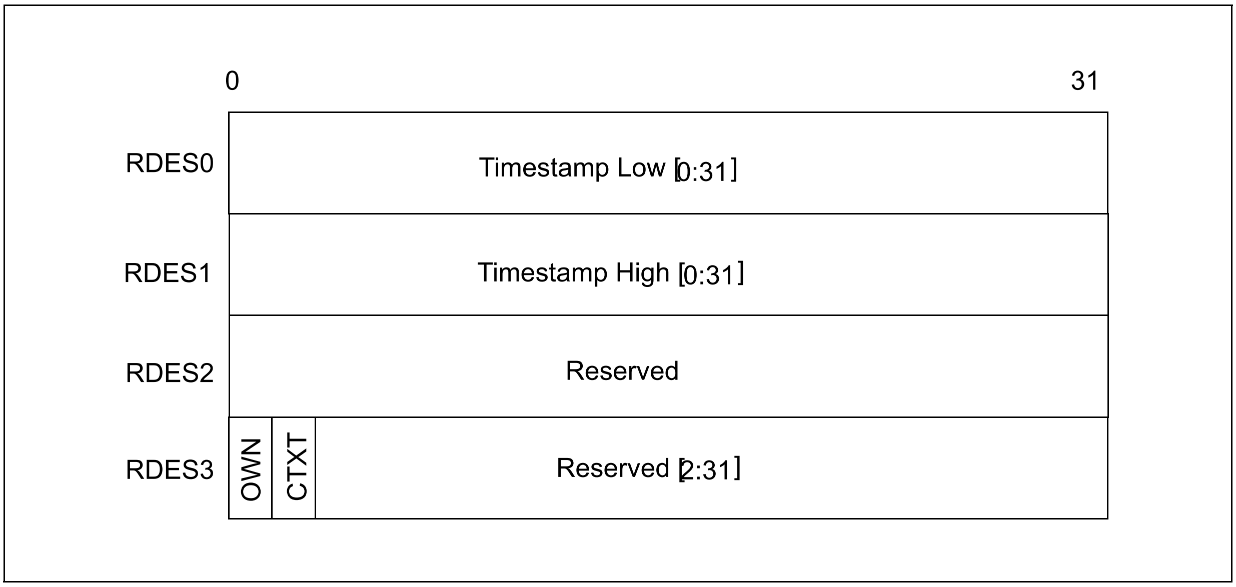
Table 926. RDES3 Normal Descriptor (Write-Back Format) (continued)

Field	Description
16 ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: RDES3[7]: CRC Error RDES3[12]: Dribble Error RDES3[11]: Receive Error RDES3[9]: Watchdog Timeout RDES3[10]: Overflow Error RDES3[8]: Giant Packet This field is valid only when the LD bit of RDES3 is set.
17:31 PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and either the Descriptor Error (RDES3[18]) or Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

47.4.1.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 1 of RDES3 indicates the context type descriptor.

Figure 846. Receive Context Descriptor



47.4.1.4.3.1 RDES0 Context Descriptor

Table 927. RDES0 Context Descriptor

Field	Description
0:31 RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

47.4.1.4.3.2 RDES1 Context Descriptor

Table 928. RDES1 Context Descriptor

Field	Description
0:31 RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

47.5 Programming Guidelines

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

47.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit 31 of *DMA_Mode Register (DMA_MODE)*)
2. Wait for the completion of the reset process (poll bit 31 of the *DMA_Mode Register (DMA_MODE)*, which is only cleared after the reset operation is completed)
3. Program the following fields to initialize the *System Bus Mode Register (DMA_SYSBUS_MODE)*:
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values for AHB bus interface
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 0 of descriptor TDES3/RDES3)

Note: Descriptor address from start to end of the ring should not cross the 4 GB boundary.

5. Program the Transmit and Receive Ring length registers_ (DMA_CH*n*_TxDesc_Ring_Length and DMA_CH*n*_RxDesc_Ring_Length). The ring length programed must be at least 4
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH*n*_TxDesc_List_Address, DMA_CH*n*_RxDesc_List_Address). Also, program transmit and receive tail pointer

registers indicating to the DMA about the available descriptors (DMA_CH*n*_TxDesc_Tail_Pointer and DMA_CH*n*_RxDesc_Tail_Pointer)

7. Program the settings of the following registers for the parameters such as maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   a) DMA_CH*n*_TX_Control
   b) DMA_CH*n*_TX_Control
   c) DMA_CH*n*_TX_Control
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register
9. Start the Receive and Transmit DMAs by setting SR (bit 31) of the DMA_CH*n*_RX_Control and ST (bit 31) of the DMA_CH*n*_TX_Control register
10. Repeat steps *4* to *9* for all the Tx DMA and Rx DMA channels selected in the hardware

47.5.2 Initializing MTL Registers

Complete the following steps to initialize the MTL Registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation for multiple Tx and Rx queues
2. Program the Receive Queue to DMA mapping in the MTL_RxQ_DMA_Map0 register
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   c) Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a) Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d) Receive Queue Size (RQS)
5. Repeat previous two steps for the second MTL Tx and Rx queue

47.5.3 Initializing MAC

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. For more than one MAC address program the MAC addresses appropriately
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   a) Receive All
   b) Promiscuous mode
   c) Hash or Perfect Filter
   d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a) Pause time and other Pause frame control bits
   b) Transmit Flow control bits
   c) Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 31 and 30 in MAC_Configuration registers to start the MAC transmitter and receiver

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive)
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register
   a) DMA_CH*n*_TxDesc_Tail_Pointer
   b) DMA_CH*n*_RxDesc_Tail_Pointer
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process
   a) DMA_CH*n*_Current_App_TxDesc
   b) DMA_CH*n*_Current_App_RxDesc
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process
   a) DMA_CH*n*_Current_App_TxBuffer
   b) DMA_CH*n*_Current_App_RxBuffer

47.5.3.1 For Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time.

Note: The steps are provided for Channel 0.

1. Disable the transmit DMA (if applicable) by clearing Bit 31 (ST) of the DMA_CH*n*_TX_Control register
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of the MTL_TxQ0_Debug register (TRCSTS is not 01 and TXQSTS=0)
3. Disable the MAC transmitter and MAC receiver by clearing Bit 31 (RE) and Bit 30(TE) of the MAC_Configuration register
4. Disable the receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of the MTL_RxQ0_Debug register, PRXQ=0 and RXQSTS=00)
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register)
6. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver

Note: Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. The Software should change these parameters only when the MAC transmitter and receiver are not active.
Similarly the DMA related configuration should not be changed when Transmit and Receive DMA are in active.

47.5.4 Programming Guidelines for Multi-Channel Multi-Queuing

Following are the steps for Transmit:

1. Program the Transmit queue size in the TQS field of MTL_TxQ*n*_Operation_Mode register. Based on the value programed in TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel to Queue mapping is fixed
2. Enable ST bit of DMA_CH*n*_TX_Control register and corresponding TXQEN in MTL_TxQ*n*_Operation_Mode register
3. The scheduling method need to be programed in SCHALG of the MTL_Operation_Mode register
4. In case of CBS algorithm in AVB queues, the following registers also needs to be programed as required:
   a) MTL_TxQ*n*_ETS_Control
   b) MTL_TxQ*n*_SendSlopeCredit
   c) MTL_TxQ*n*_HiCredit
   d) MTL_TxQ*n*_LoCredit

Following are the steps for Receive:

1. Program the Receive queue size in the RQS field of MTL_RxQ*n*_Operation_Mode Register. Based on the value programed in RQS field, the size of the queue is determined
2. Enable the Receive Queues 0 to 1 in the fields RXQ0EN to RXQ1EN in MAC_RxQ_Ctrl0 Register for AV. In DMA configurations, SR bit of statically or

dynamically mapped DMA_CH*n*_RX_Control Register and corresponding RXQ*n*_EN in MAC_RxQ_Ctrl0 Register needs to be enabled

3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a) AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register
   b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 register
   c) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ1-0 of the MAC_RxQ_Ctrl2 register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 1
   d) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 register
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory
   b) Program the MTL_RxQ*n*_Control to decide the weights and the packet arbitration for each RxQ
   c) If static mapping is programed in MTL_RxQ_DMA_Map0 register (RXQ*n*DADMACH is reset to 0), bits RXQx2DMA and others need to be programed to select the channel for which each queue is mapped
   d) Set RXQ*n*DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue
   e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register

Note: The priorities set in PSRQ1-0 should be unique.

47.5.5 Programming Guidelines for MII Link State Transitions

The following steps are to be performed when the link is down but the Transmit and Receive clocks are running:

Note: The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 31 (ST) of DMA_CH*n*_TX_Control Register
2. Disable the MAC receiver by clearing Bit 29 (RE) of the MAC_Configuration register
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01).
   -or-
   Flush the Tx FIFO for faster empty operation
4. Disable the MAC transmitter by clearing Bit 30 (TE) of the MAC_Configuration register
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register)
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver

You do not need to disable the Rx DMA. As the Receiver is disabled, the FIFO does not get any data in the Rx FIFO.

Do the following steps when the link is down and the Transmit and Receive clocks are stopped:

Note: The steps are provided for Channel 0.

1. Disable the MAC Transmitter and Receiver by clearing bits RE & TE of MAC_Configuration register. This will not take effect immediately as the clocks are absent
2. Wait till the link is up and the clocks are restored
3. Wait for the completion of the transfer of any partial frame if any at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug Register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers
5. Restart the MAC Transmitter and Receiver by setting RE & TE bits

47.5.6 Programming Guidelines for IEEE 1588 Timestamping

47.5.6.1 Initialization Guideline for System Time Generation

The timestamp feature is enabled by setting Bit 31 of the MAC_Timestamp_Control register. However, it is essential that the timestamp counter should be initialized after this bit is set. Complete the following steps during for initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 15 of MAC_Interrupt_Enable Register
2. Set Bit 31 of MAC_Timestamp_Control register to enable timestamping
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 26 of MAC_Timestamp_Control register
5. Poll the MAC_Timestamp_Control register until Bit 26 is cleared
6. Program Bit 30 of MAC_Timestamp_Control register to select the Fine Update method (if required)
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value
8. Set Bit 29 in MAC_Timestamp_Control register.
   The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers.
   If one-step timestamping is enabled:
   a) To enable one-step timestamping, program Bit 4 of the TDES Context Descriptor
   b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages
9. Enable the MAC receiver and transmitter for proper timestamping

Note: If timestamp operation is disabled by clearing Bit 31 of MAC_Timestamp_Control Register, you need to repeat all these steps to restart the timestamp operation.

47.5.6.2 System Time Correction

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update)
2. Set Bit 28 (TSUPDT) of the MAC_Timestamp_Control Register.
   The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in System Time Register Module, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_Timestamp_Addend with the new value and set Bit 26 of the MAC_Timestamp_Control Register
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value
4. Program the required target time in the MAC_PPS0_Target_Time_Seconds register and the MAC_PPS0_Target_Time_Nanoseconds register
5. Enable the Timestamp interrupt in bit 19 of MAC_Interrupt_Enable register
6. Set bit 27 in Register MAC_Timestamp_Control
7. When this trigger causes an interrupt, read MAC_Interrupt_Status Register
8. Reprogram MAC_Timestamp_Addend Register with the old value and set bit 26 again

47.5.7 Programming Guidelines for AV Feature

Complete the following steps to initialize the DMA for AV Feature:

1. Provide a software reset to reset all QOS internal registers and logic (bit 31 in DMA_Mode register)
2. Wait for the completion of the reset process. Poll bit 31 of the DMA_Mode register, which is cleared only after the reset operation is completed
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required
5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors
6. Program the Transmit and Receive Ring length registers. The ring length programed must be at least 4. Then initialize receive and transmit descriptor list address with the

base address of transmit and receive descriptor. Finally program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors:

a) DMA_CH*n*_TxDesc_Ring_Length

b) DMA_CH*n*_RxDesc_Ring_Length

c) DMA_CH*n*_TxDesc_List_Address

d) DMA_CH*n*_RxDesc_List_Address

e) DMA_CH*n*_TxDesc_Tail_Pointer

f) DMA_CHn_RxDesc_Tail_Pointer

7. Program the following fields to initialize the mode of operation in the MTL_TxQ1_Operation_Mode register:
   a) Transmit Store And Forward (TSF)
   b) Transmit Threshold Control (TTC)
   c) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d) Transmit Queue Size (TQS)
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register
9. Repeat steps *4* through *9* for all additional channels of AV feature.
10. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues
11. Start the Receive and Transmit DMA by setting bit 31 of the DMA_CH*n*_TX_Control register and bit 31 of the DMA_CH*n*_RX_Control register

47.5.7.1 Enabling Slot Number Checking

The slot number check feature is used to specify the intervals at which the DMA Channels mapped to AV Queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable time-stamping and program the MAC_Sub_Second_Increment register. Complete the following steps to enable the slot number checking:

Note: These steps should be completed after Step 10 and before Step 11 of Section 47.5.7: Programming Guidelines for AV Feature.

1. Enable time-stamping by following the steps described in *Section 47.5.6.1: Initialization Guideline for System Time Generation*
2. Make sure that the SLOTNUM field (bits 9:12) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH*n*_Slot_Function_Control_Status
3. Set Bit 31 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking

47.5.7.2 Enabling Average Bits Per Slot Reporting

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. Enable time-stamping by following the steps described in *Section 47.5.6.1: Initialization Guideline for System Time Generation*
2. Program Bits [25:27], SLC, of the MTL_TxQ*n*_ETS_Control register of a channel with number of slots over which the average transmitted bits per slot need to be computed
3. Enable Bit 22 (ABPSSIE) of the MTL_Q*n*_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt
4. Read Bits [15:31], ABS, from the MTL_TxQ*n*_ETS_Status register of a channel on each interrupt

Note: The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 30 (ABPSIS) of the MTL_TxQn_ETS_Status register indicates that a new value is updated in the ABS field.

The frequency of this interrupt depends on the value programed in the Step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
When not required, you can disable this interrupt to stop the interrupt flooding.

47.5.8 Programming Guidelines for Energy Efficient Ethernet

47.5.8.1 Entering and Exiting the Tx LPI Mode

For entering and exiting the Tx LPI Mode, complete the following steps:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode)
3. Program Bits[6:15] and Bits[16:31] in MAC_LPI_Timers_Control register
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 14 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own
7. Set LPIET and LPITXA (bit[11:12]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state
8. Set Bit 15 of MAC_LPI_Control_Status register to make the MAC Transmitter enter the LPI state.
   The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[31]) after entry to LPI state
9. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission
10. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues
11. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set Bit 12 in MAC_LPI_Control_Status register.
To switch off the MII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.
To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

47.5.8.2 Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

47.5.8.3 Gating Off the CSR Clock in the Rx LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY.

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN interrupt of MAC_LPI_Control_Status register is set
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register

After the interrupt is asserted and the MAC Tx is also in the LPI mode, you can gate-off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status register is read.

47.5.8.4 Gating Off the CSR Clock in the Tx LPI Mode

The following operations are performed when Bit 15 (LPIEN) of MAC_LPI_Control_Status register is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of MAC_LPI_Control_Status register) is set
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register

After the interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR.

For restoring the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. After the CSR clock is resumed, reset Bit 15 (LPIEN) of MAC_LPI_Control_Status register to bring the MAC out of the LPI mode.

47.5.9 Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

47.5.9.1 Generating single Pulse on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control register. This instructs the MAC to use the Target Time registers

(MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output

2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds)
3. Program the width of the PPS signal output in MAC_PPS0_Width Register
4. Program Bits [28:31], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programed in the Target Time registers

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse
2. Program the width of the next PPS signal output in MAC_PPS0_Width
3. Program Bits [28:3], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programed in Target Time registers

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

47.5.9.2 Generating a pulse train on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of the PPS signal output
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds)
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS0_Interval Register
4. Program the width of the PPS signal output in MAC_PPS0_Width Register
5. Program Bits[28:3], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programed in Target Time registers.
   By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.
6. Program the stop value in the Target Time registers. Ensure that Bit 0 (TSTRBUSY) of MAC_PPS0_Target_Time_Nanoseconds Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 28:31) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programed stop time specified in Step *6* elapses.

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programed start time (in Step 2) elapses.

47.5.9.3 Generating an Interrupt without Affecting the PPS

The Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) to do any one of the following:

- Generate only interrupts
- Generate interrupts and the PPS start and stop time
- Generate only PPS start and stop time

To program the Target Time registers to generate only interrupt event:

1. Program 00 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers for target time interrupt
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.
   If Bits [25:26], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programed Target Time register value

47.5.10 Programming Guidelines for VLAN filtering on Receive

1. Program MAC_VLAN_Tag Register for the following bit to select the filtering method:
   a) ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   VTHM: VLAN Tag Hash Table Match Enable
   b) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   c) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   d) DOVLTC: Ignores VLAN Type for Tag Match
   e) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching
2. Program VL of MAC_VLAN_Tag register for the 12 bit or 16 bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table Register. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table

48 Inter-Integrated Circuit (I2C)

48.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- *Section 48.2: Introduction to I2C*
- *Section 48.3: External signal descriptions*
- *Section 48.4: Memory map and register definition*
- *Section 48.5: Functional description*
- *Section 48.6: Initialization and application information*

48.2 Introduction to I2C

This section presents the following topics:

- *Section 48.2.1: Definition: I2C module*
- *Section 48.2.2: Advantages of the I2C bus*
- *Section 48.2.3: Module block diagram*
- *Section 48.2.4: Features*
- *Section 48.2.5: Modes of operation*
- *Section 48.2.6: Definition: I2C conditions*

48.2.1 Definition: I2C module

The I^2C module is a functional unit that provides a two-wire – serial data (SDA) and serial clock (SCL) – bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

48.2.2 Advantages of the I2C bus

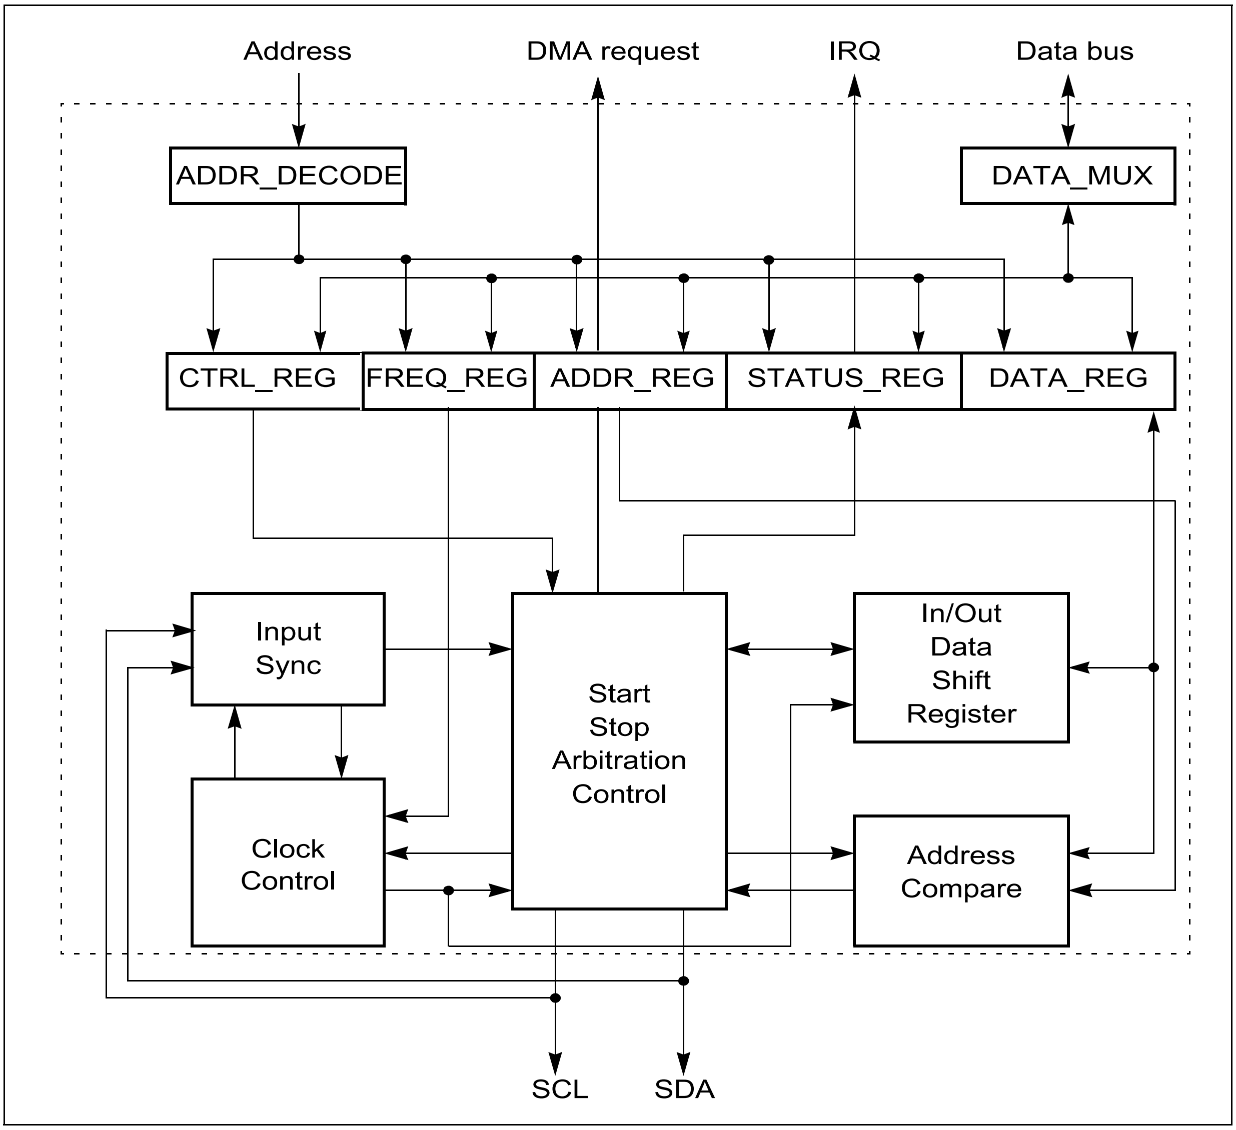
The synchronous, multiple-master two-wire I^2C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

48.2.3 Module block diagram

Figure 848 shows a block diagram of the I^2C module.

Figure 848. I^{2}C block diagram



48.2.4 Features

The I^{2}C module has the following key features:

- Compatible with I^{2}C bus standard[r]
- Operating speeds
  – Up to 100 kbps in Standard Mode
  – Up to 400 kbps in Fast Mode
  – Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

48.2.5 Modes of operation

The I^{2}C module supports the chip modes described in *Table 931*.

Table 931. Chip modes supported by the I^{2}C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^{2}C module	The I^{2}C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. Refer to *Section 48.5.6: IPG STOP mode*.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging.	Refer to *Section 48.5.7: IPG DEBUG mode*.

In addition to chip modes, the I^{2}C module has several module-specific modes. These are described in *Table 932*.

r. Compliant with I^{2}C 2.0 standard with the exception that HS (high speed) mode is not supported

Table 932. Module-specific modes supported by the I^{2}C module

Module mode	Description	Important notes
Master mode	The I^{2}C module is the driver of the SDA line.	– Do not use the I^{2}C module's slave address as a calling address. – The I^{2}C module cannot be a master and a slave simultaneously.
Slave mode	The I^{2}C module is not the driver of the SDA line.	– Enable the I^{2}C module before a START condition from a non-I^{2}C master is detected. – By default the I^{2}C module performs as a slave receiver.

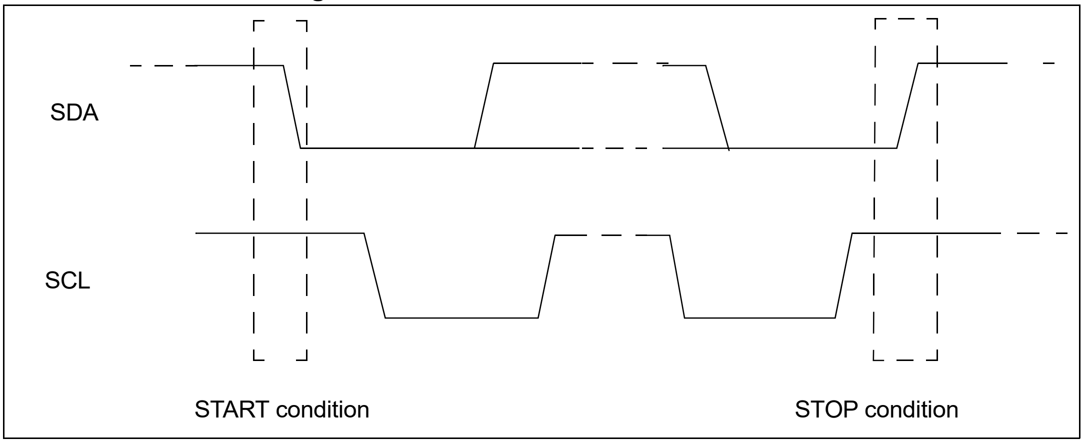
48.2.6 Definition: I^{2}C conditions

Table 933 shows the I^{2}C-specific conditions defined for the I^{2}C module.

Table 933. I^{2}C conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in *Figure 849*.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in *Figure 849*.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

Figure 849. START and STOP conditions



48.3 External signal descriptions

This section presents the following topics:

- Section 48.3.1: Signal overview
- Section 48.3.2: Detailed external signal descriptions

48.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, refer to the data sheet for this chip.

48.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in *Table 934*.

Table 934. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

48.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- Section 48.4.1: I2C memory map
- Section 48.4.2.1: Register accessibility
- Section 48.4.2.2: I2C Bus Address register (IBAD)
- Section 48.4.2.3: I2C Bus Frequency Divider register (IBFD)
- Section 48.4.2.4: I2C Bus Control Register (IBCR)
- Section 48.4.2.5: I2C Bus Status Register (IBSR)
- Section 48.4.2.6: I2C Bus Data I/O Register (IBDR)
- Section 48.4.2.7: I2C Bus Interrupt Config register (IBIC)
- Section 48.4.2.8: I2C Bus Debug register (IBDBG)

48.4.1 I^2C memory map

The memory map for the I^2C module is given below in *Table 935*. The total address for each register is the sum of the base address for the I^2C module and the address offset for each register.

Table 935. I²C memory map

Address offset	Register	Section
0x0000	I²C Bus Address Register (IBAD)	Section 48.4.2.2
0x0001	I²C Bus Frequency Divider Register (IBFD)	Section 48.4.2.3
0x0002	I²C Bus Control Register (IBCR)	Section 48.4.2.4
0x0003	I²C Bus Status Register (IBSR)	Section 48.4.2.5
0x0004	I²C Bus Data I/O Register (IBDR)	Section 48.4.2.6
0x0005	I²C Bus Interrupt Config Register (IBIC)	Section 48.4.2.7
0x0006	I²C Bus Debug Register (IBDBG)	Section 48.4.2.8
0x0007–0x3FFF	Reserved(1)	

1. If enabled at the SoC level, reads or writes to these registers will cause bus aborts. Refer to the System Services Module documentation for more details.

48.4.2 Registers definition

48.4.2.1 Register accessibility

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

48.4.2.2 I²C Bus Address register (IBAD)

This register contains the address the I²C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Offset: 0x0000

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

	0	1	2	3	4	5	6	7
R	ADR							0
W								
Reset	0	0	0	0	0	0	0	0

Figure 850. I²C Bus Address register (IBAD)

Table 936. IBAD field descriptions

Field	Description
0:6 ADR	Slave Address Specific slave address to be used by the I^{2}C Bus module. **Note:** The default mode of I^{2}C Bus is slave mode for an address match on the bus.

48.4.2.3 I^{2}C Bus Frequency Divider register (IBFD)

Offset: 0x0001

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

	0	1	2	3	4	5	6	7
R W	IBC							
Reset	0	0	0	0	0	0	0	0

Figure 851. I^{2}C Bus Frequency Divider register (IBFD)

Table 937. IBFD field descriptions

Field	Description
0:7 IBC	I-Bus Clock Rate This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 0:1 Selects the prescaled shift register (refer to *Table 946*) 2:4 Selects the prescaler divider (refer to *Table 947*) 5:7 Selects the shift register tap point (refer to *Table 948*)

48.4.2.4 I^{2}C Bus Control Register (IBCR)

Offset: 0x0002

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

	0	1	2	3	4	5	6	7
R	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	0
W						RSTA		
Reset	1	0	0	0	0	0	0	0

Figure 852. I^{2}C Bus Control Register (IBCR)

Table 938. IBCR field descriptions

Field	Description
0 MDIS	Module disable This bit controls the software reset of the entire I^{2}C Bus module. 0 The I^{2}C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect. 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled. **Note:** If the I^{2}C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I^{2}C Bus module losing arbitration, after which, bus operation would return to normal.
1 IBIE	I-Bus Interrupt Enable 0 Interrupts from the I^{2}C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I^{2}C Bus module are enabled. An I^{2}C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave mode. 1 Master mode.
3 TXRX	Transmit/Receive mode select This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive. 1 Transmit.
4 NOACK	Data Acknowledge disable This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I^{2}C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **Note:** Values written to this bit are only used when the I^{2}C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, acknowledge bit = 1).

Table 938. IBCR field descriptions (continued)

Field	Description
5 RSTA	Repeat Start Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect. 1 Generate repeat start cycle.
6 DMAEN	DMA Enable When this bit is set, the DMA Tx and Rx lines will be asserted when the I^2C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I^2C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. Refer to the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals. 1 Enable the DMA TX/RX request signals.

48.4.2.5 I^2C Bus Status Register (IBSR)

Offset: 0x0003

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

	0	1	2	3	4	5	6	7
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

Figure 853. I^2C Bus Status Register (IBSR)

Table 939. IBSR field descriptions

Field	Description
0 TCF	Transfer complete While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **Note:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
3 IBAL	Arbitration Lost The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: – SDA is sampled low when the master drives a high during an address or data transmit cycle. – SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. – A start cycle is attempted when the bus is busy. – A repeated start cycle is requested in slave mode. – A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
5 SRW	Slave Read/Write When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave

Table 939. IBSR field descriptions (continued)

Field	Description
6 IBIF	I-Bus Interrupt Flag The IBIF bit is set when one of the following conditions occurs: – Arbitration lost (IBAL bit set) – Byte transfer complete (TCF bit set and DMAEN bit not set) – Addressed as slave (IAAS bit set) – NoAck from Slave (MS and Tx bits set) – I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

48.4.2.6 I^2C Bus Data I/O Register (IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

Note: The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required $R/\overline{W}$ bit (in position D0).

Note: When the I^2C is configured in master mode and receiving data from a slave that is transmitting data bytes on an irregular basis, the master cannot know whether the data received in the IBDR is the old latched data or the new data received from the slave. To avoid this, 2 consecutive intermittent data bytes from slave should be different.

- *Section 48.5.2: Transactions*
- *Section 48.5.3: Arbitration procedure*
- *Section 48.5.4: Clock behavior*
- *Section 48.5.5: Interrupts*
- *Section 48.5.7: IPG DEBUG mode*
- *Section 48.5.8: DMA interface*

48.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

48.5.2 Transactions

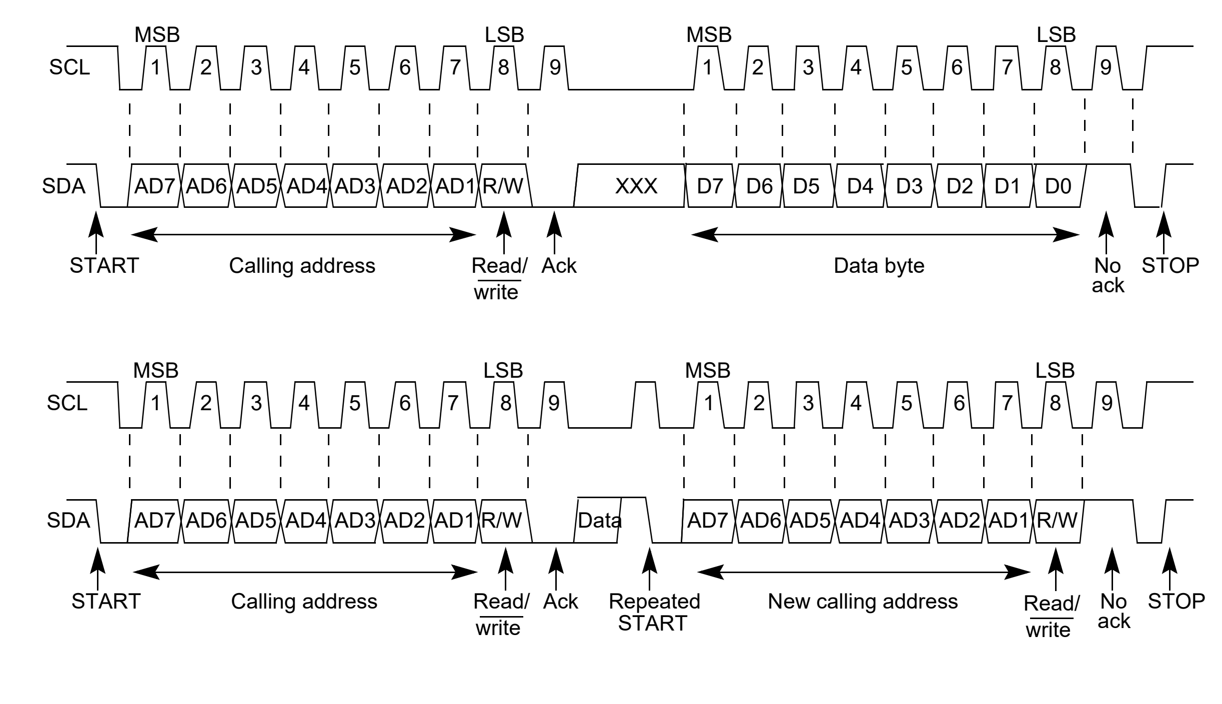
This section presents the following topics:

- *Section 48.5.2.1: Protocol overview*
- *Section 48.5.2.2: Transaction protocol definitions*
- *Section 48.5.2.4: High-level protocol steps*
- *Section 48.5.2.5: START condition*
- *Section 48.5.2.6: Slave address transmission*
- *Section 48.5.2.7: Data transmission*
- *Section 48.5.2.8: STOP condition*
- *Section 48.5.2.9: Repeated START condition*

48.5.2.1 Protocol overview

Figure 857 shows the behavior of SCL and SDA during a typical I^2C transaction.

Figure 857. I²C transaction protocol



48.5.2.2 Transaction protocol definitions

This section defines several important terms presented in *Figure 857*.

Table 943. I²C definitions

Term	Definition
START	A START condition, as defined in *Section 48.2.6: Definition: I2C conditions*
STOP	A STOP condition, as defined in *Section 48.2.6: Definition: I2C conditions*
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in *Section 48.5.2.3: I2C calling address requirements*.
Read/write (R/$\overline{W}$)	A bit that specifies the direction of the data transfer to the slave as follows: 0 The data is being transferred from the master to the slave (“write”). 1 The data is being transferred from the slave to the master (“read”).
Ack	A bit that specifies the acknowledgment of a calling address, indicated by pulling SDA low.

48.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

48.5.2.4 High-level protocol steps

The I^2C protocol conceptually supports two types of transfers, which are illustrated in *Figure 857*. The significant steps in these transfers are presented in *Table 944*. Details of each of these steps are presented in subsequent sections.

Table 944. I^2C high-level protocol steps

Standard transfer	Repeated START transfer
1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. STOP condition 6. (repeat Steps 1–4)	1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. Repeated START condition 6. (repeat Steps 2–4 as needed) 7. STOP condition 8. (repeat Steps 1–7)

48.5.2.5 START condition

When the bus is free, that is no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (refer to *Section 48.2.6*). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

48.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (refer to *Section 48.5.2.5*). The process of slave address transmission is presented in *Table 945*.

Table 945. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the $R/\overline{W}$ bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: – The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. – The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

48.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the $R/\overline{W}$ bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

48.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (refer to *Section 48.2.6*). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, refer to *Section 48.5.2.9*.

48.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of *Figure 857*.

48.5.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic “1” while another master transmits logic “0”. The losing masters immediately switch over to slave receive mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

48.5.4 Clock behavior

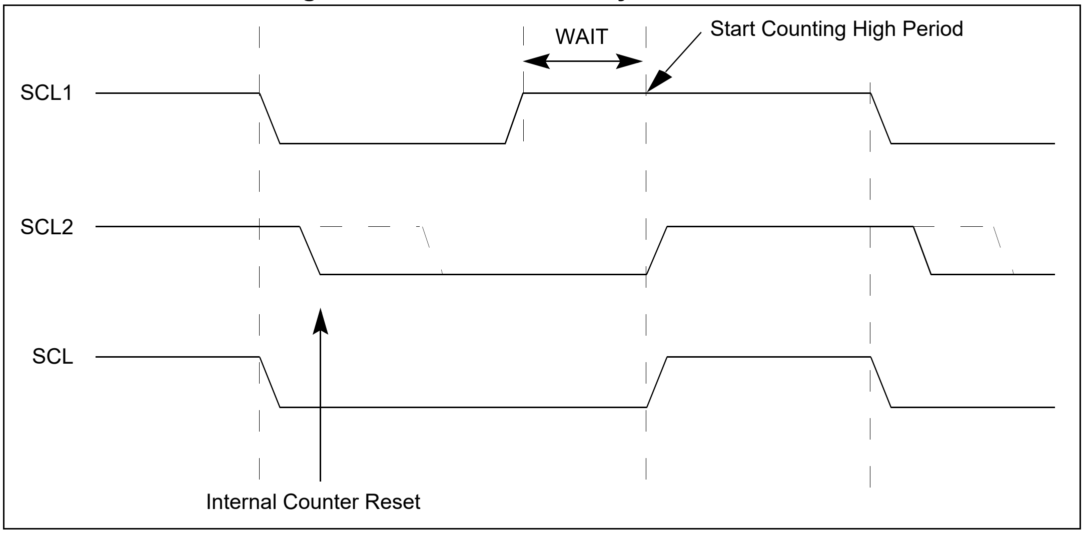
This section presents the following topics:

- *Section 48.5.4.1: Clock synchronization*
- *Section 48.5.4.2: Clock stretching*
- *Section 48.5.4.3: Handshaking*
- *Section 48.5.4.4: Clock rate and IBFD settings*

48.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (refer to *Figure 858*). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

Figure 858. I²C bus clock synchronization



48.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

48.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

48.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (refer to *Section 48.4.2.3: I2C Bus Frequency Divider register (IBFD)*).

Table 946. I-Bus multiplier factor

IBC[0:1]	MUL
00	01
01	02
10	04
11	Reserved

Table 947. I-Bus prescaler divider values

IBC[2:4]	scl2start (clocks)	scl2stop (clocks)	scl2tap (clocks)	tap2tap (clocks)
000	2	7	4	1
001	2	7	4	2
010	2	9	6	4
011	6	9	6	8
100	14	17	14	16
101	30	33	30	32
110	62	65	62	64
111	126	129	126	128

Table 948. I-Bus tap and prescale values

IBC[5:7]	SCL tap (clocks)	SDA tap (clocks)
000	5	1
001	6	1
010	7	2
011	8	2
100	9	3
101	10	3
110	12	4
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of *Table 947*. All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in *Table 947*. The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

Figure 859. SDA Hold time

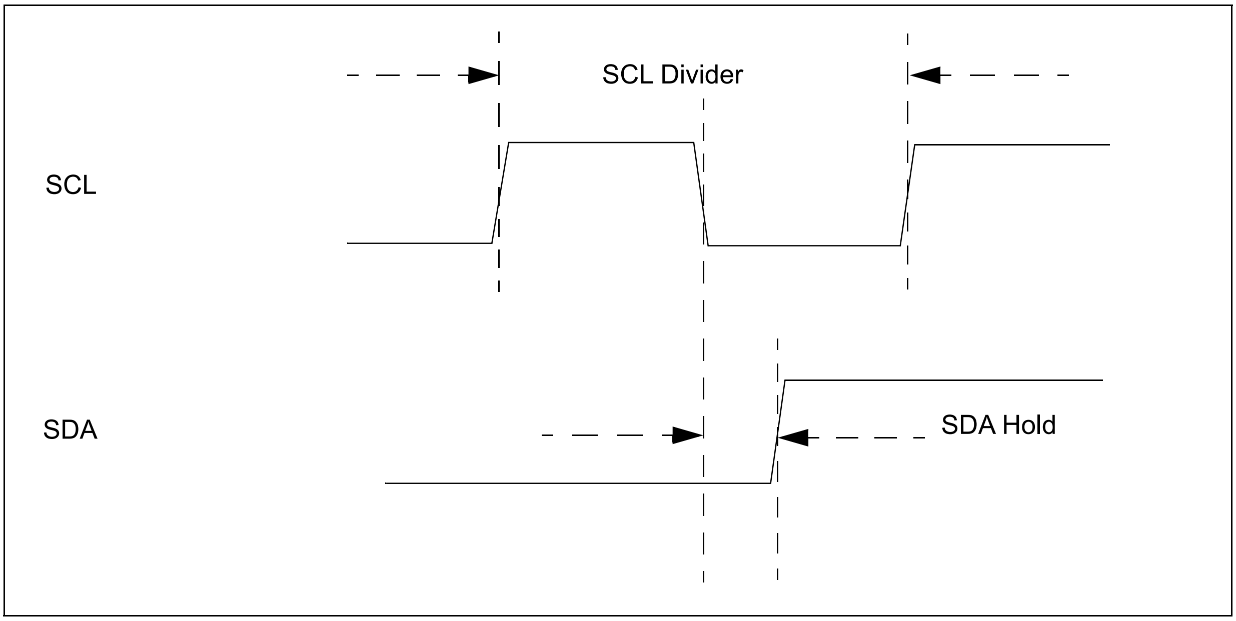


Figure 860. SCL divider and SDA Hold

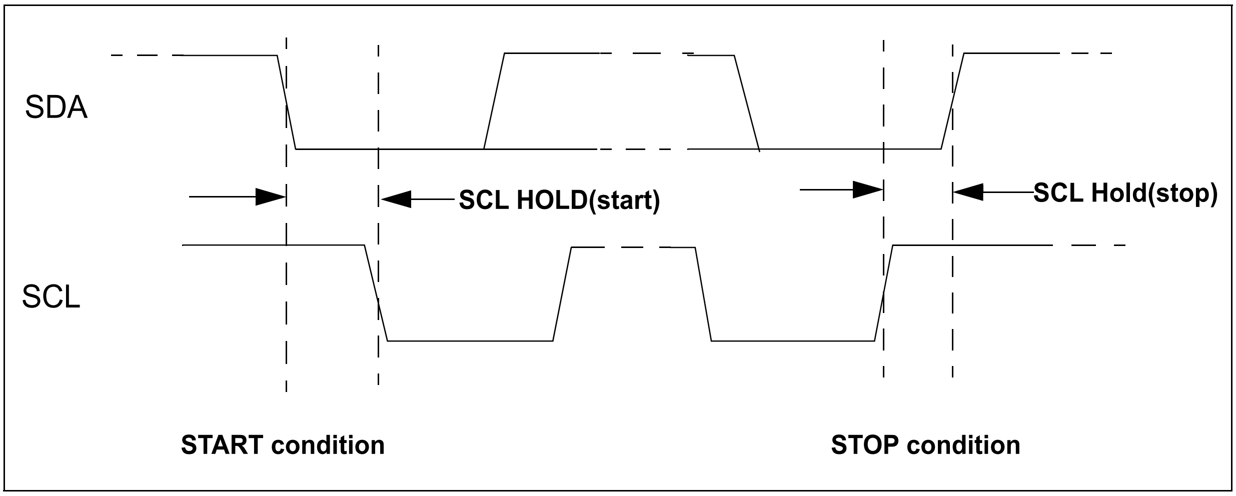

The equation used to generate the divider values from the IBFD bits is:

Equation 32 SCL Divider = MUL x {2 x (scl2tap + [(SCL_Tap -1) x tap2tap] + 2)}

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in *Table 949*. The equation used to generate the SDA Hold value from the IBFD bits is:

Equation 33 SDA Hold = MUL x {scl2tap + [(SDA_Tap - 1) x tap2tap] + 3}

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

Equation 34 SCL Hold(start) = MUL x [scl2start + (SCL_Tap - 1) x tap2tap]

Equation 35 SCL Hold(stop) = MUL x [scl2stop + (SCL_Tap - 1) x tap2tap]

Table 949. I^{2}C divider and hold values

48.5.5 Interrupts

This section presents the following topics:

- *Section 48.5.5.1: Interrupt vector*
- *Section 48.5.5.2: Interrupt description*

48.5.5.1 Interrupt vector

The I^{2}C module uses only one interrupt vector.

Table 950. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I^{2}C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

48.5.5.2 Interrupt description

There are five types of internal interrupts in the I^{2}C. The interrupt service routine can determine the interrupt type by reading the Status register.

I^{2}C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I^{2}C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing ‘1’ to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

48.5.6 IPG STOP mode

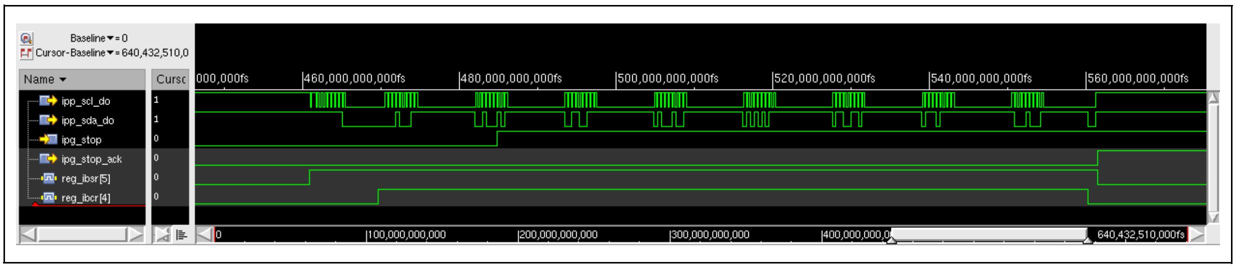
This mode allows the software to put the I^{2}C module in power-down state. Once the STOP request is asserted, the I^{2}C module comes to a graceful halt after completing all the ongoing transactions.

As soon as the I^{2}C module enters IPG STOP mode:

- The I^{2}C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I^{2}C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. Refer to *Figure 861* for more details.

Figure 861. I^{2}C stop mode behavior when master is in Rx and slave is in Tx



48.5.7 IPG DEBUG mode

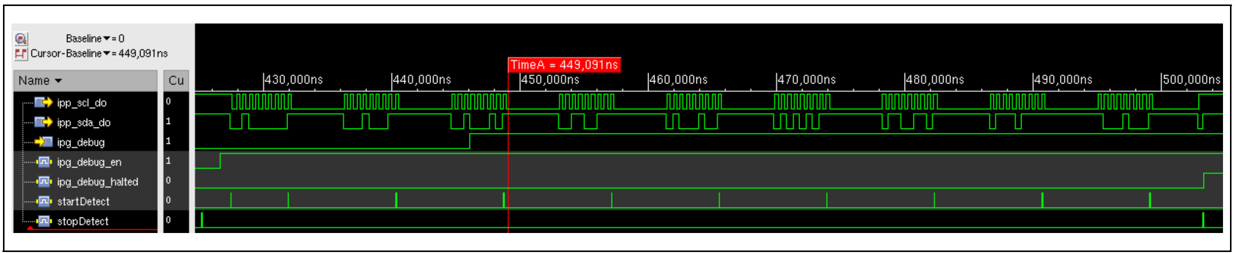
This mode allows CPU to debug the I^{2}C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I^{2}C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^{2}C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

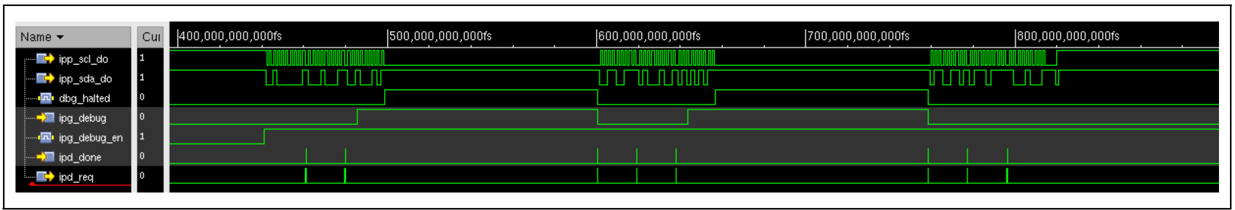
The I^{2}C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. Refer to the simulation result in *Figure 862* for more details.

Figure 862. Simulation result of IPG Debug Halted in case of frame transmission



If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I^{2}C module enters IPG DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits IPG DEBUG mode, transmission or reception of the remaining bytes resumes. Refer to the simulation snapshot shown in *Figure 863* for details where the I^{2}C is transmitting 8 bytes using DMA and IPG DEBUG mode is requested while a second byte is being transmitted. IPG DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits IPG DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

Figure 863. Simulation result of IPG Debug Halted in case of frame transmission using DMA



No more transaction can take place until the debug signal is de-asserted after which the I^{2}C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I^{2}C module has entered the IPG DEBUG mode. Refer to *Figure 864* for more details.

Figure 864. PG DEBUG mode

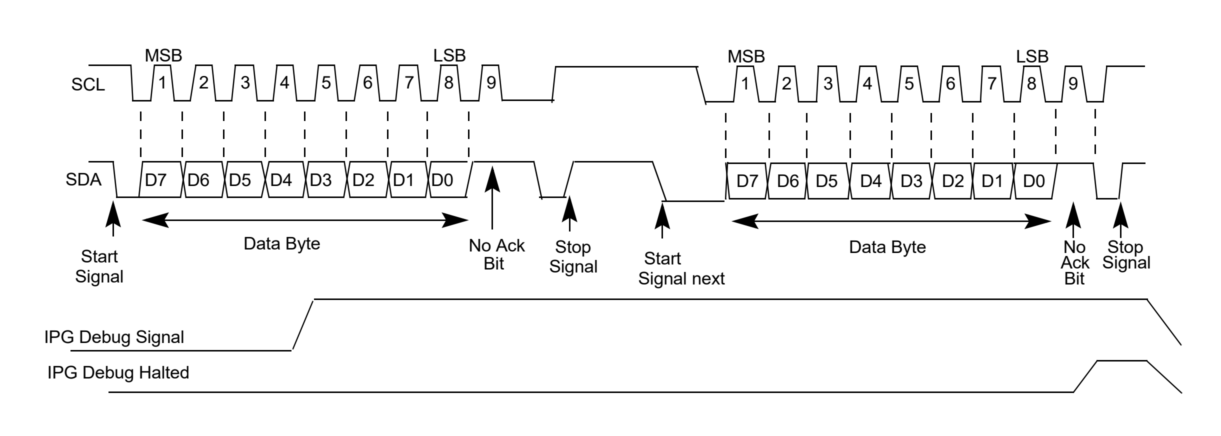


Figure 865 shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters IPG DEBUG mode.

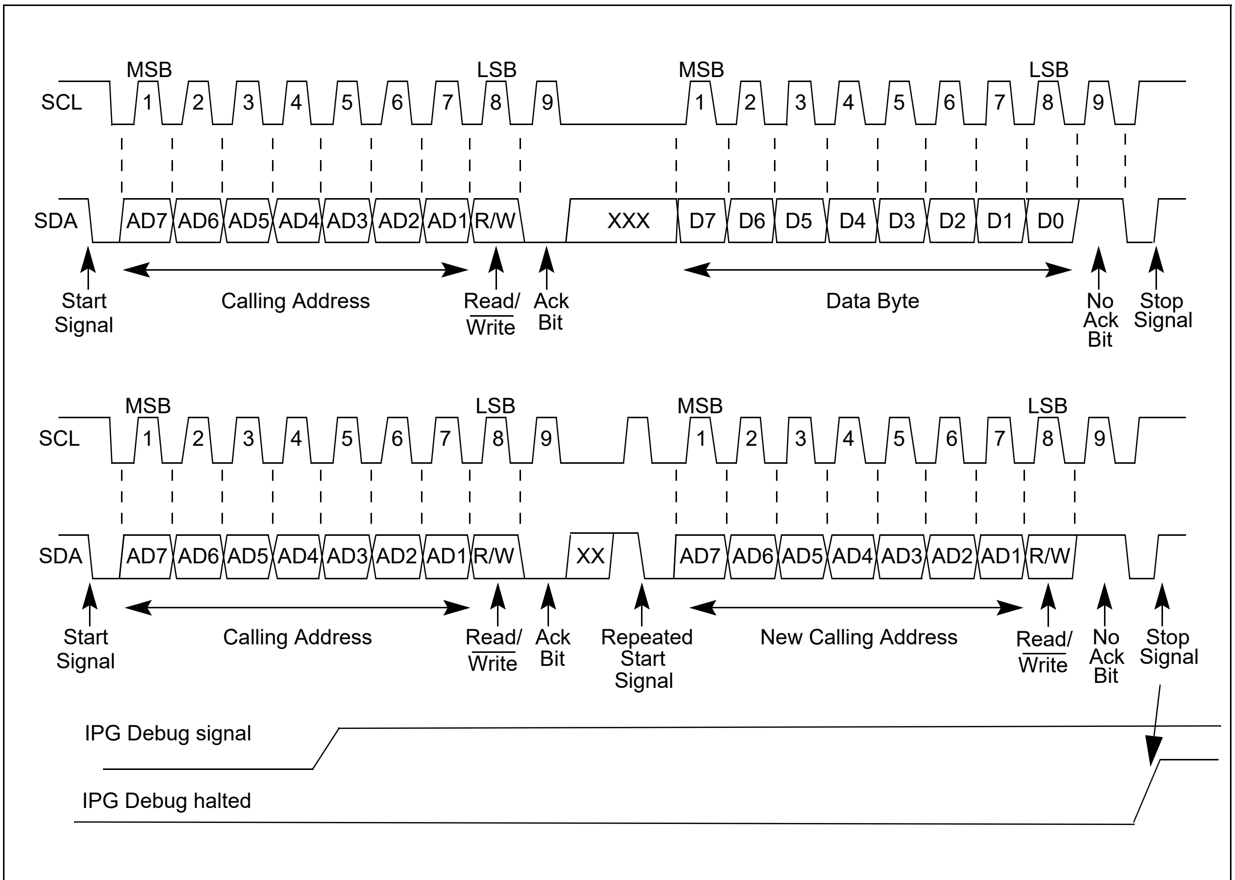
Figure 865. IPG debug mode with repeated start



48.5.8 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (refer to *Section 48.6.5*). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the *Section 48.6*.

48.6 Initialization and application information

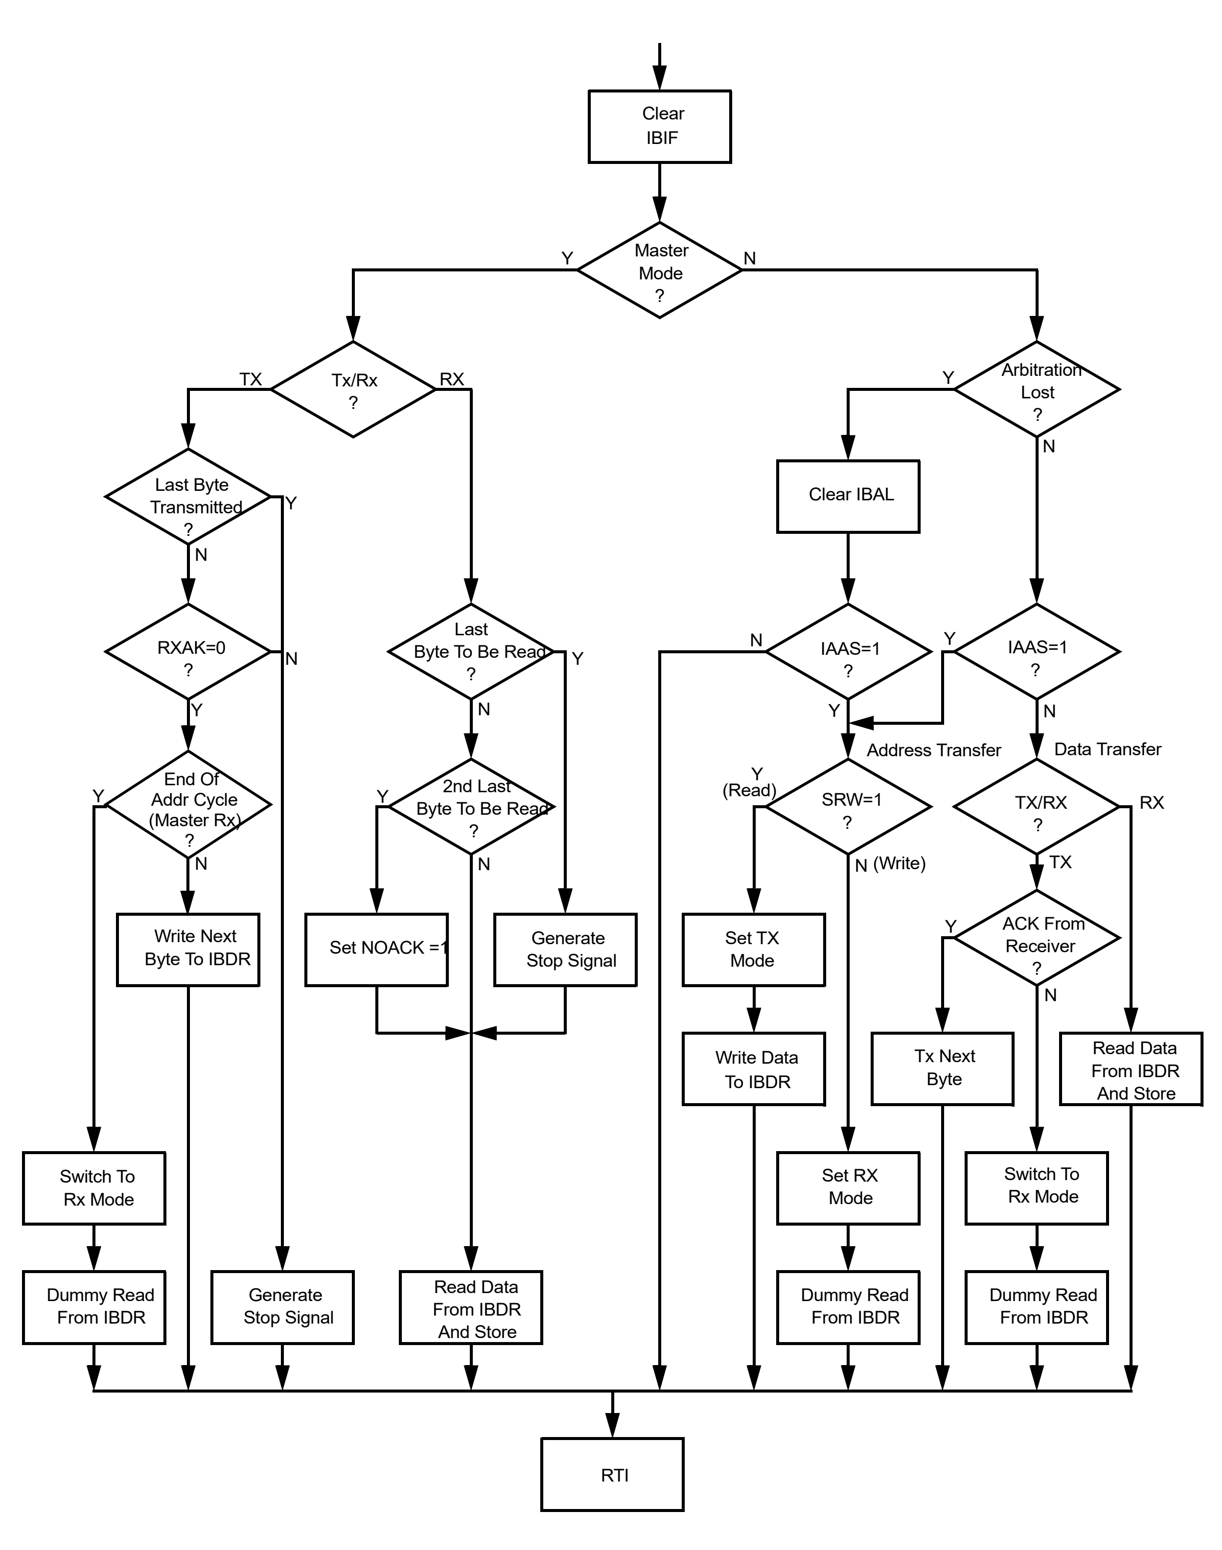
This section presents the following topics:

- *Section 48.6.1: Recommended interrupt service flow*
- *Section 48.6.2: General programming guidelines (for both master and slave mode)*
- *Section 48.6.3: Programming guidelines specific to master mode*
- *Section 48.6.4: Programming guidelines specific to slave mode*
- *Section 48.6.5: DMA application information*

48.6.1 Recommended interrupt service flow

Figure 866 shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

Figure 866. Recommended I²C interrupt service routine flowchart



48.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^2C module in both master and slave mode. It presents the following topics:

- *Section 48.6.2.1: Initializing the I2C module*
- *Section 48.6.2.2: Software response after a transfer*

48.6.2.1 Initializing the I^2C module

The following sequence initializes the I^2C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[IBDIS] bit to enable the I^2C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

48.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^2C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^2C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^2C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a “Transfer Complete” interrupt occurs at the end of the address cycle, the master will always be in transmit mode, that is the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

48.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- *Section 48.6.3.1: Generating START*
- *Section 48.6.3.2: Transmit/receive sequence*
- *Section 48.6.3.3: Generating STOP*
- *Section 48.6.3.4: Generating repeated START*
- *Section 48.6.3.5: Loss of arbitration*

48.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB = 0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (that is the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                    // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1       // master and transmit mode, that is,
                                        // generate start condition
IBDR = calling_address                  // send the calling address to the data
register
while (bit 5, IBSR ==0)                 // wait in loop for IBB flag to be set
```

48.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 951. Master transmit sequence

Step	Action
a	Use the IBFD register to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Use the IBCR to select Master mode, Transmit mode and interrupt enable.
d	Write 0 to IBSR[IBIF].

Table 951. Master transmit sequence (continued)

Step	Action
e	Write data to IBDR.
f	Observe changes in IBSR[TCF]: – When IBSR[TCF] becomes 0, the transfer is in progress. – When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until IBSR[IBIF] = 1.
h	Read the fields in the IBSR to determine what happened: – If TCF = 1, the transfer completed. – If RXAK = 1, a No Acknowledge condition occurred. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** Address Detect (IAAS = 1) can be ignored for master mode (it is valid only for slave mode).
i	Examine IBSR[RXAK] for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 952. Master receive sequence

Step	Action
a	Follow steps a through i in *Table 951* for address dispatch.
b	Write 0 to IBSR[IBIF].
c	Write 0 to IBCR[TXRX] to select Receive mode.
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** The No Acknowledge condition (RXAK = 1) can be ignored in receive mode.
h	Read the IBDR to determine the data received from the slave.

Table 953. Slave transmit sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
c	Write data to IBDR.
d	Wait until IBSR[IBIF] = 1.

Table 953. Slave transmit sequence (continued)

Step	Action
e	Wait until IBSR[RXAK] = 0.
f	Write 0 to IBSR[IBIF].
g	Repeat steps c through for the next consecutive data transfers.

Table 954. Slave receive sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
c	Write 0 to IBSR[IBIF].
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read the IBDR to determine the data received from the master.

48.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the “master” device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or          // check to see if all data bytes have been
transmitted
    (bit 0, IBSR == 1) {       // or if no ACK generated
         clear bit 5, IBCR     // generate stop condition
        }
else {
IBDR = data_to_transmit        // write byte of data to DATA register
         tx_count --           // decrement counter
      }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --                    // decrease the rx counter
if (rx_count ==1)              // 2nd last byte to be read ?
   bit 3, IBCR = 1             // disable ACK
if (rx_count == 0)             // last byte to be read ?
  bit 5, IBCR = 0              // generate stop signal
else
data_received = IBDR           // read RX data and store
```

48.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown below.

```
bit 2, IBCR = 1                // generate another start (restart)
IBDR == calling_address        // transmit the calling address
```

48.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL = 1 and MS/SL = 0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

48.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an “end of data” signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

48.6.5 DMA application information

The DMA interface on the I^{2}C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.

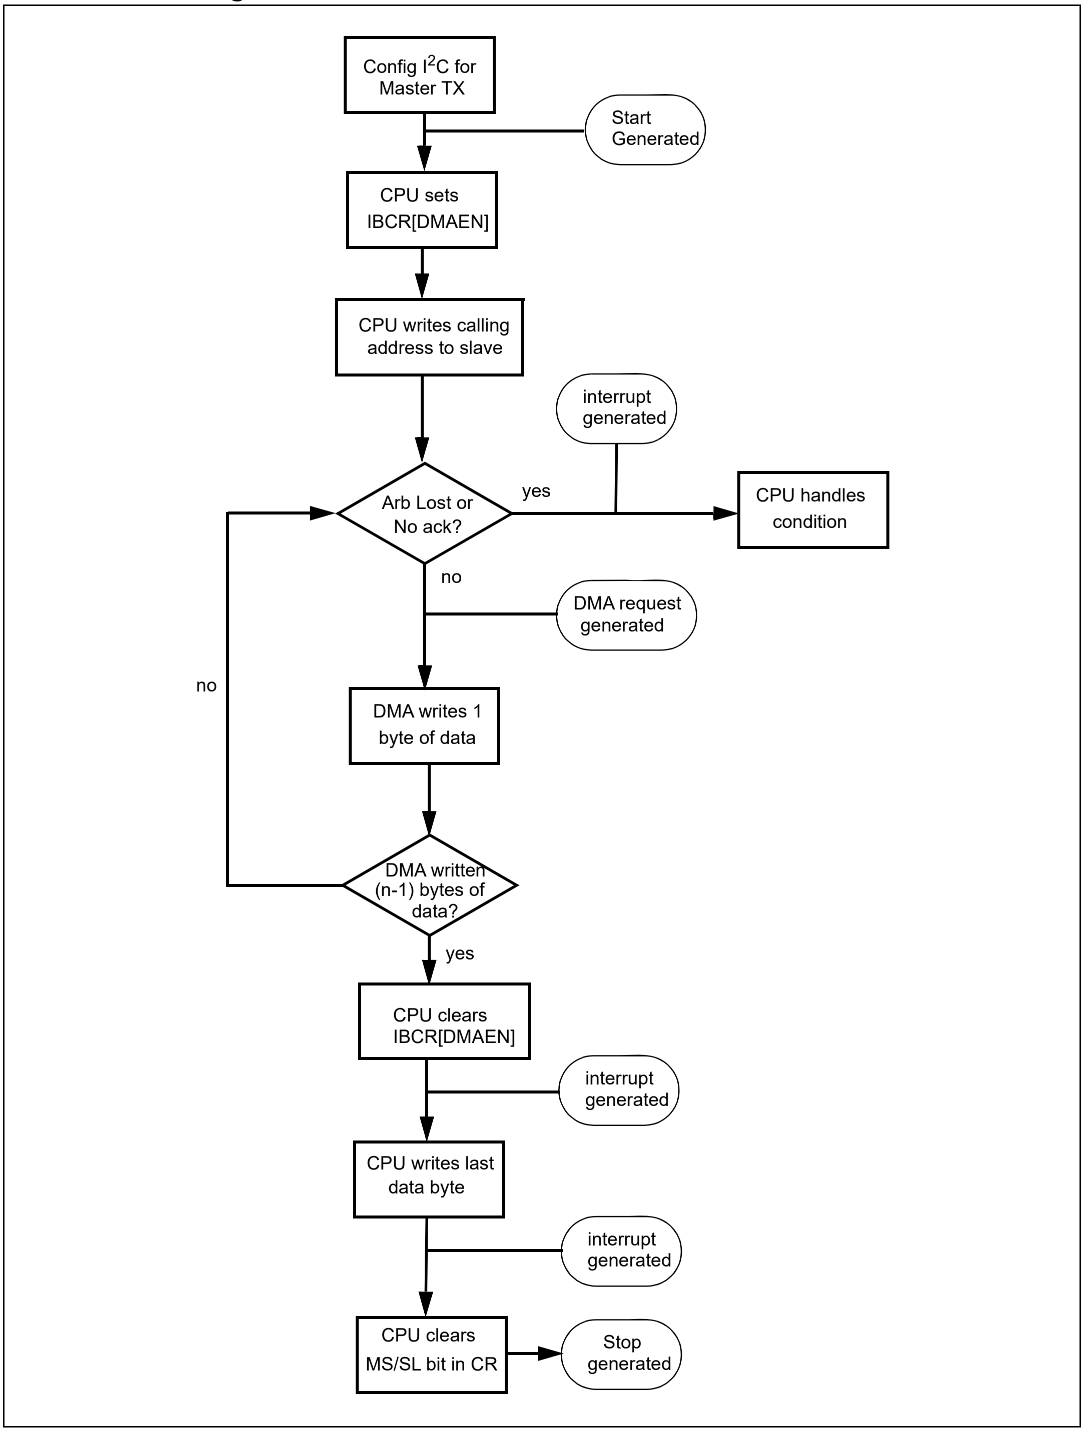
The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- *Section 48.6.5.1: DMA mode, master transmit*
- *Section 48.6.5.2: DMA mode, master reception*
- *Section 48.6.5.3: Exiting DMA mode, system requirement considerations*

48.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit ‘n’ data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

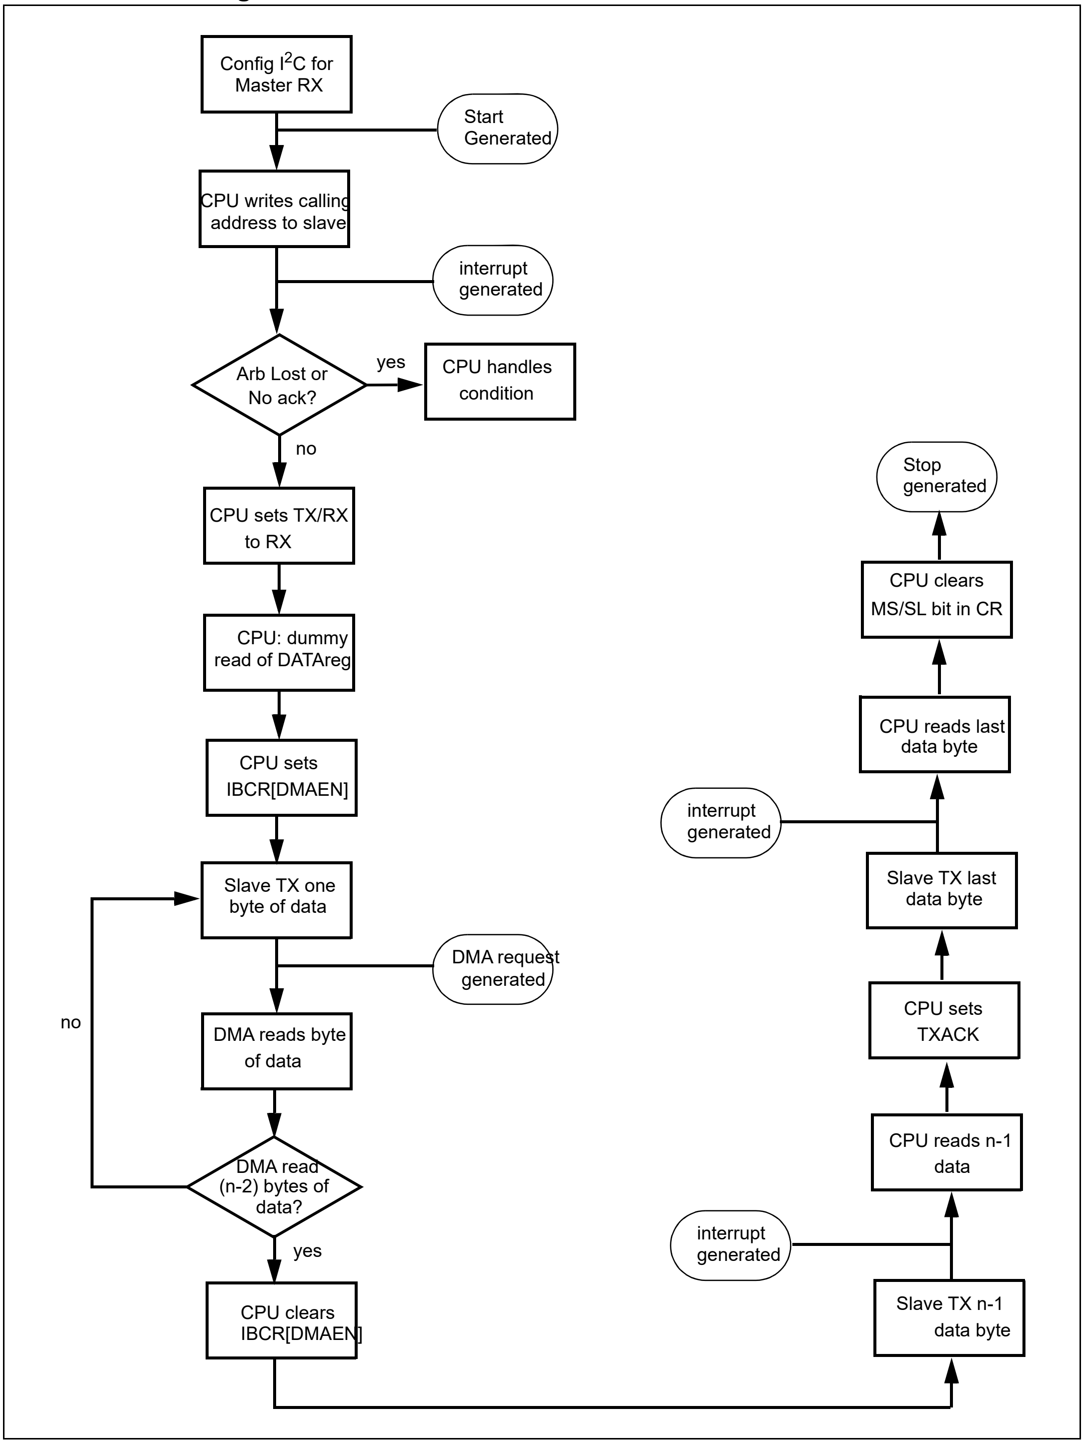
Figure 867. Flow-Chart of DMA mode master transmit



48.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive ‘n’ data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

Figure 868. Flow-Chart of DMA mode master receive



48.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^{2}C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For “fast reaction” the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

Equation 36 $T_R = 8 \times T_{SCL}$

In fast mode, with 400 kbit/s, T_{SCL} is 2.5 µs, so T_R is 20 µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note: The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

Note: Make sure, at system level, that no higher priority DMA requests occur between the two linked TCDs as they could create a slow reaction scenario again.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a “ready-for-I^2C-transfer” state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note: Make sure, at system level, that no higher priority DMA requests occur during the scatter/gather process, as they could create a slow reaction scenario again.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

Equation 37 $4 \times T_{IPI} = 4 / 16\ \mathrm{MHz} = 250\ \mathrm{ns}$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

Equation 38 $8 \times T_{AHB} = 8 / 32\ \mathrm{MHz} = 250\ \mathrm{ns}$

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I2C could be faster):

Equation 39 $4 \times T_{IPI} = 4/150\ \mathrm{MHz} = 26.6\ \mathrm{ns}$

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

Equation 40 $4 \times T_{AHD} = 4/150\ \mathrm{MHz} = 26.6\ \mathrm{ns}$

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

49 Deserial Serial Peripheral Interface (DSPI)

49.1 Introduction

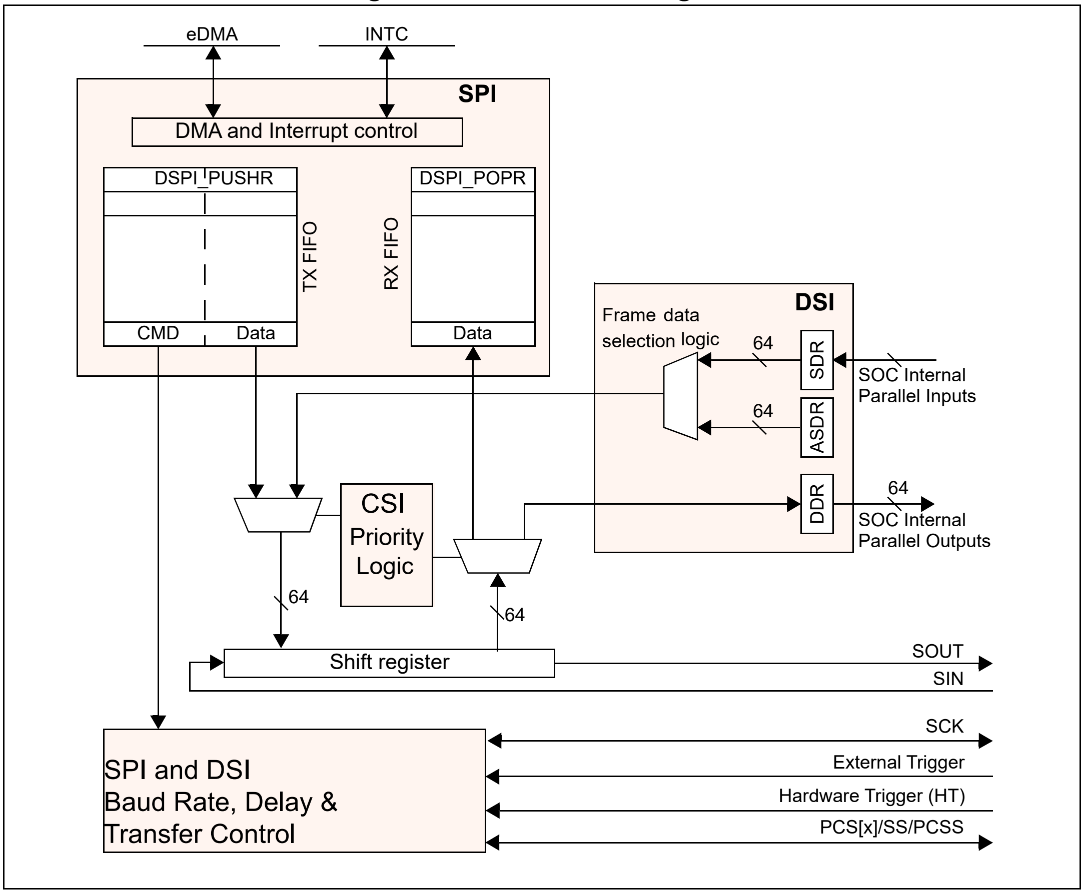
The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note: For the chip-specific implementation details of the instances of this module, refer to the Device Configuration chapter.

49.1.1 Block diagram

Figure 869 provides the block diagram of this module.

Figure 869. DSPI block diagram



49.1.2 Features

The DSPI supports the following features:

- Full-duplex, four-wire synchronous transfers.
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection.
- Buffered transmit operation with 4-entry TX FIFO buffer.
- Buffered receive operation with 4-entry RX FIFO buffer.
- Asynchronous clocking scheme for Register and Protocol interfaces.
- Individual TX and RX FIFOs disabling for low-latency updates to SPI queues.
- Visibility inside TX and RX FIFOs for debugging.
- Programmable transfer attributes on a per-frame basis:
  - 8 transfer attribute registers along with 8 extended transfer attribute registers
  - Serial clock with programmable polarity and phase
  - Various programmable delays
  - programmable serial frame size of 4 to 64 bits, expandable by software control. SPI frames longer than 32 bits are supported using the continuous selection format
  - Continuously held chip select capability
  - Parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer.
- Deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer.
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End Of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame Complete (TCF)
  - Transfers due from current Command frame Complete (CMDTCF)
  - Transfer of current SPI frame Complete (SPITCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
  - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line.
- Modified SPI transfer formats for communication with slower peripheral devices.
- Power-saving architectural features: support for stop mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
  - DSPI memory-mapped register
  - Parallel input signals
  - Programmable selection of source data on bit basis.
- Deserialized data provided as:
  - Parallel output signals
  - Bits in a memory-mapped register
- Interrupt conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
  - Transfer of current DSI frame complete (DSITCF)
  - DSI parity error (DPEF)
- DMA request support for following conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
- Transfer initiation conditions:
  - Continuous
  - Edge sensitive hardware trigger
  - Change in data
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics.
- Continuous serial communications clock.

DSPI supports a combination of SPI and DSI modes of operation (Combined Serial Interface (CSI)) for the downstream Micro Second Channel in either Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration (configurable by software). Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is performed at frame boundaries.
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame.
- Separate interrupts for frame completion from SPI and DSI.

49.1.3 DSPI configurations

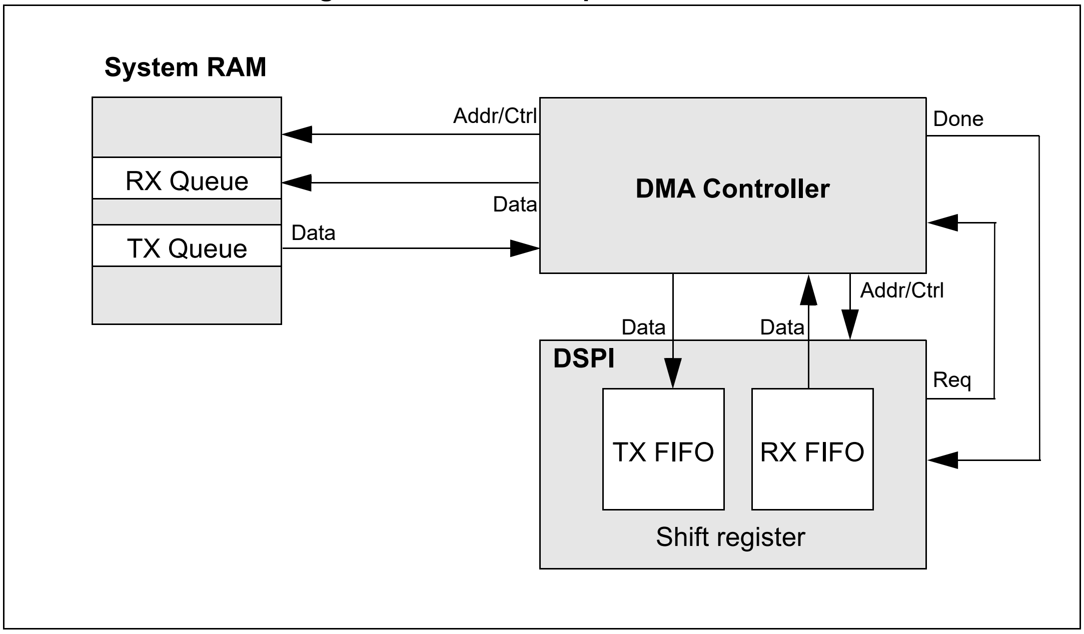
The DSPI module can operate in SPI configuration as well as in DSI, and CSI configuration. Refer to the relevant section in the “Communication interfaces” section of the “Device Configuration” chapter.

49.1.3.1 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. *Figure 870* shows a system example with DMA, DSPI and external queues in system RAM.

Figure 870. DSPI with queues and DMA



49.1.3.2 DSI configuration

In the DSI configuration the DSPI serializes up to 64 parallel input signals or register bits. The DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

TSB mode provides the Micro Second downstream Channel support (MSC), serializing from 4 to 64 parallel input signals or register bits. Refer to *Section 49.4.9: Timed Serial Bus (TSB)*.

49.1.3.3 CSI configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in *Section 49.4.10: Interleaved TSB (ITSB) Mode*.

49.1.4 Modes of operation

The DSPI modes of operation can be divided into two categories:

- Module-specific modes
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes
  - External Stop mode
  - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

49.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

49.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI/DSI bus masters. In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

49.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

49.1.4.4 External Stop mode

External Stop mode is used for MCU power management; the DSPI supports the Peripheral Bus Stop mode mechanism.

Upon a request to enter External Stop mode:

- In Master mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary, it signals that the protocol clock to the DSPI module may be shut off.
- In Slave mode, a request to enter External Stop mode must be run after the last clock cycle or Low-power mode is not entered.

49.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

49.2 DSPI signal description

This section provides the DSPI signals description.

Table 955 lists the signals that may connect off chip depending on device implementation.

Table 955. DSPI signal description

Signal	Description	I/O
PCS0/ SS	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[3:1]	Master mode: Peripheral Chip Select 1–3 Slave mode: Unused	O
PCS4	Master mode: Peripheral Chip Select 4	O
PCS5/ PCSS	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[7:6]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O
HT	Hardware Trigger	I

49.2.1 PCS0/$\overline{SS}$ — Peripheral Chip Select/Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low $\overline{SS}$ signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

49.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

49.2.3 PCS4 — Peripheral Chip Select 4

In master mode, PCS4 is a Peripheral Chip Select output signal.

49.2.4 PCS5/$\overline{PCSS}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

49.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

49.2.6 SIN — Serial Input

SIN is a serial data input signal.

49.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

49.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

49.2.9 HT — Hardware Trigger

In master mode while in DSI or CSI Configurations, the HT signal initiates a data transfer when the DSICR0[TRRE] bit is set and a rising or falling edge is detected on HT. Which edge to trigger on is determined by the DSICR0[TPOL] bit.

49.3 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPI_POPR also results in a transfer error.

Table 956. DSPI memory map

Offset (hex)	Register name	Width (in bits)	Access	Reset value	Location
0000_0000	DSPI Module Configuration Register (DSPI_MCR)	32	R/W	0000_4001h	*Section 49.3.1*

49.3.1 DSPI Module Configuration Register (DSPI_MCR)

The DSPI_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Address: 0x0000 Access: User read/write

Figure 871. DSPI Module Configuration Register (DSPI_MCR)

Table 957. DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2:3 DCONF	DSPI Configuration Selects the DSPI configuration. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. MTFE should not be set in ITSB Mode as Microsecond Channel upstream operation is not supported. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.

Table 957. DSPI_MCR field descriptions (continued)

Field	Description
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/ $\overline{PCSS}$ to operate as a PCS Strobe output signal. 0 PCS[5]/PCSS is used as the Peripheral Chip Select[5] signal (PCS[5]). 1 PCS[5]/PCSS is used as an active-low PCS Strobe signal (PCSS).
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer generating the overflow is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8:15 PCSIS[7:0]	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI, putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is 1. MDIS should be set to ‘0’ in Slave Mode as a slave does not control master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes TX FIFO and CMD FIFO. Writing a ‘1’ to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.

Table 957. DSPI_MCR field descriptions (continued)

Field	Description
21 CLR_RXF	Clear RX FIFO Flushes RX FIFO. Writing a ‘1’ to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22:23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
28 XSPI	Extended SPI Mode Enables use of CTARE (Command and Transfer Attribute Register Extended) registers, which allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled, allowing the user to send multiple Data Frames in a single Command Frame. When MCR[DIS_TXF] is asserted, Extended SPI Mode cannot be used to transmit SPI frames over 16 bits in size. 0 Normal SPI Mode. Up to 16-bit Frames. Command Cycling is not available. 1 Extended SPI Mode. Up to 32-bit SPI Frames. Command Cycling Enabled.
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. The individual delay masks are selected via PUSHR[PE_MASC] and PUSHR{PP_MCSC]. The firmware should select appropriate masks when providing continuous frames via the PUSHR. This masking is not available if Continuous SCK mode is enabled. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers. **Note:** HALT bit starts/stops the internal state machine. All the other MCR bits must be set to their expected value before releasing HALT bit. If one MCR bit needs to be changed in running state, HALT bit must be set first.

49.3.2 Hardware Configuration Register (DSPI_HCR)

Hardware Configuration Register provides particular implementation details about the module, that is number of Receive and Transmit FIFO entries, number of CTAR registers and if DSI features are implemented in the module or not. It is read only register. A write to this register will generate a Transfer Error.

Note: The reset bits in the HCR are set by the configuration parameters.

Address: 0x0004 Access: User read

Figure 872. Hardware Configuration Register (DSPI_HCR)

Table 958. DSPI_HCR field descriptions

Field	Description
0 DSI	DSI features are implemented for the module. 0 DSI features are not implemented, DSI registers do not exist. 1 DSI features are implemented
1 PISR	PISR0-3 and parallel inputs frame positions selection logic (DSI Muxing Logic) are implemented for the module. 0 PISR0-3 registers are not implemented. 1 PISR0-3 registers are implemented.
2 DSI64	DSI features in 64 bit mode are implemented for the module. 0 DSI features for 64 bit mode are not implemented; related registers do not exist. 1 DSI features for 64 bit mode are implemented
3 PISR_EX	PISR4-7 and parallel inputs frame positions selection logic (DSI 64 bit Muxing Logic) are implemented for the module. 0 PISR4-7 registers are not implemented. 1 PISR4-7 registers are implemented.
4 XSPI	Extended SPI Mode feature is implemented for the module. 0 Extended SPI Mode is not implemented. 1 Extended SPI Mode is implemented.
5:7 CTAR	Maximum implemented CTAR register number.
8:11 TXFR	Maximum implemented TXFR register number.
12:15 RXFR	Maximum implemented RXFR register number.

Table 958. DSPI_HCR field descriptions (continued)

Field	Description
16:19 CMDFR	Maximum implemented command FIFO number.
20 MSTR_MODE	Master Mode implementation is enabled
21 SLV_MODE	Slave Mode implementation is enabled
22 TSB_EN	TSB Mode implementation is enabled
23 ITSB_EN	Interleaved TSB Mode implementation is enabled

49.3.3 DSPI Transfer Count Register (DSPI_TCR)

DSPI_TCR has an SPI transfer counter to assist in queue management.

Do not write the TCR when the DSPI is in the Running state.

Address: 0x0008 Access: User read/write

Figure 873. DSPI Transfer Count Register (DSPI_TCR)

Table 959. DSPI_TCR field descriptions

Field	Description
0:15 SPI_TCNT	SPI Transfer Counter The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. A value written to SPI_TCNT presets the counter to that value. The Transfer Counter wraps around; incrementing past 65535 resets the counter to zero.

49.3.4 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTARs are used to define different transfer attributes:

- In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays.
- In slave mode, a subset of the bitfields in CTAR0 and CTAR1 set the slave transfer attributes.

Do not write to the CTARs while the DSPI is in the Running state.

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 874. DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

Table 960. DSPI_CTARn field descriptions

Field	Description
0 DBR	Double Baud Rate. (Master mode only) Doubles the baud rate of the Serial Communications Clock (SCK). It halves the Baud Rate division ratio, supporting faster frequencies and odd division ratios for the Serial Communications Clock (SCK). When DBR is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in *Table 961*. Refer to the BR field description in this table for details on how to compute the baud rate. Refer to *Table 961* for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid value for the number of bits to be transmitted for any mode is 4.There is a constraint on the minimum allowable Frame size, which depends on the register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. Min. Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol Clock Frequency f_r = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by (PBR x BR) / (1 + DBR) The minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'f_p' can be equal to, less than or greater than 'f_r' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is used in 64-bit mode, then DSICR0[FMSZ4] also comes into picture while switching PCS assertion control.
5 CPOL	Clock Polarity. (Master and Slave mode) Selects the inactive state of the Serial Communications Clock (SCK). Devices must have identical clock polarities for successful communication between serial devices. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.

Table 960. DSPI_CTARn field descriptions (continued)

Field	Description
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, this bit is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First. Specifies whether the LSB or MSB of the frame is transferred first. In TSB mode, this bit should comply with the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8:9 PCSSCK	PCS to SCK Delay Prescaler. Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. Refer to the CSSCK field description in this table for calculating the PCS to SCK Delay. Refer to *Section 49.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, PCSSCK has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10:11 PASC	After SCK Delay Prescaler. Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. Refer to the ASC field description in this table for calculating the After SCK Delay. Refer to *Section 49.4.5.3: After SCK delay (tASC)* for more details. In TSB mode, PASC has no effect. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12:13 PDT	Delay after Transfer Prescaler. (Master mode only) Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In TSB mode, the PDT field defines two MSB bits of the Delay after Transfer. Refer to the DT field description for calculating the Delay after Transfer. Refer to *Section 49.4.5.4: Delay after transfer (tDT)* for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.

Table 960. DSPI_CTARn field descriptions (continued)

Field	Description
14:15 PBR	Baud Rate Prescaler. (Master mode only) Selects the prescaler value for the baud rate. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. Refer to the BR field description in this table for calculating the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16:19 CSSCK	PCS to SCK Delay Scaler. (Master mode only) Selects the scaler value for the PCS to SCK delay. PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period calculated by: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$ *Table 962* lists the delay scaler values. Refer to *Section 49.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, the field has no effect.
20:23 ASC	After SCK Delay Scaler. (Master mode only) Selects the scaler value for the After SCK Delay. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period calculated by: $t_{ASC} = (1/f_P) \times PASC \times ASC$ *Table 962* lists the delay scaler values. Refer to *Section 49.4.5.3: After SCK delay (tASC)* for more details.
24:27 DT	Delay After Transfer Scaler (Master mode only) Selects the Delay after Transfer Scaler. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period. The Delay after Transfer is a multiple of the protocol clock period calculated by: $t_{DT} = (1/f_P) \times PDT \times DT$ *Table 962* lists the delay scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer to *Section 49.4.5.2: PCS to SCK delay (tCSC)* for more details.
28:31 BR	Baud Rate Scaler. (Master mode only) Selects the scaler value for the baud rate. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is calculated by: SCK baud rate = $(f_P/PBR) \times [(1+DBR)/BR]$ *Table 963* lists the baud rate scaler values.

Table 961. DSPI SCK duty cycle

49.3.5 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 875. DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

Table 964. DSPI_CTAR*n*_SLAVE field descriptions

Field	Description
0:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ5	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1.

49.3.6 DSPI Status Register (DSPI_SR)

The status register contains DSPI status bits and interrupt/DMA request event flag bits.

Software can clear most of the flag bits in the SR by writing a ‘1’ to them (w1c). Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Figure 876. DSPI Status Register (DSPI_SR)

Table 965. DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag. Indicates that all bits in a frame have been shifted out. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status. Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2 SPITCF	SPI Frame Transfer Complete Flag. Similar to TCF but only asserted on SPI frame transmission completion in CSI Mode This includes ITSB and ‘TSB in CSI’ modes, but not SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag. Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.

Table 965. DSPI_SR field descriptions (continued)

Field	Description
4 TFUF	Transmit FIFO Underflow Flag. Indicates an underflow condition in the TX FIFO. Transmit underflow is detected only for DSPI blocks in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. Similar to TCF but only asserted on DSI frame transmission completion in CSI Mode. This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer to *Section 49.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*. This bit is valid only when DSPI_MCR[XSPI] is enabled. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9 DPEF	DSI Parity Error Flag. Indicates that a DSI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.

Table 965. DSPI_SR field descriptions (continued)

Field	Description
10 SPEF	SPI Parity Error Flag. Indicates that a SPI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits. Indicates that a DSI frame has been received with bits selected by DIMR with active polarity, defined by the DPIR. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag. Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Transmit FIFO Invalid Write Flag. Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag. Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a ‘1’ to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16:19 TXCTR	TX FIFO Counter. Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20:23 TXNXTPTR	Transmit Next Pointer. Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.

Table 965. DSPI_SR field descriptions (continued)

Field	Description
24:27 RXCTR	RX FIFO Counter. Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28:31 POPNXTPTR	Pop Next Pointer. Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

49.3.7 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

The DSPI_RSER controls DMA and interrupt requests.

Do not write to the RSER while the DSPI is in the Running state.

Field	Description
0 TCF_RE	Transmission Complete Request Enable. Enables TCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the Status register to generate a request. DSPI_RSER[CMDFFF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled. 1 Enabled.

Table 966. DSPI_RSER field descriptions (continued)

Field	Description
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. Enables SPITCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. Enables DSITCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the status register to generate a request. DSPI_RSER[TFFF_DIRS] toggles between either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. DSPI_SR[TFFF] flag and DSPI_RSER[TFFF_RE] must be set. 0 Interrupt requests. 1 DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the status register to generate an interrupt requests. 0 Disabled. 1 Enabled.

Table 966. DSPI_RSER field descriptions (continued)

Field	Description
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the status register to generate a request. DSPIRSER[RFDF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled 1 Enabled
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[RFDF] flag and DSPI_RSER[RFDF_RE] must be set. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO FIll DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[CMDFFF] flag and DSPI_RSER[CMDFFF_RE] must be set. 0 Interrupt request. 1 DMA request.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[DDIF] flag and DSPI_RSER[DDIF_RE] must be set. 0 Interrupt request. 1 DMA request.

49.3.8 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.
- The CMD FIFO for writes to the Command field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

When Extended SPI Mode is not enabled (MCR[XSPI] = 0):

- TX FIFO and CMD FIFO must be filled simultaneously.
- Writes must be given to both Data and Command fields of PUSHR for every PUSHR operation.
- TX FIFO and CMD FIFO can be considered a single 32-bit FIFO.

When Extended SPI Mode is enabled (MCR[XSPI] = 1):

- TX FIFO and CMD FIFO can be written independently.
- A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register do not update the FIFO. Reads during Module disable mode return the last PUSHR write performed when Module was enabled.

Figure 878. DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

Table 967. DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable. (SPI master mode) Continuous Selection Format enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame as EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1:3 CTAS	Clock and Transfer Attributes Select. Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI slave mode, CTAR0 is used. Refer to the Device Configuration chapter to determine how many CTARs this device has. Do not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7

Table 967. DSPI_PUSHR field descriptions (continued)

Field	Description
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. DSPI_SR[EOQF] is set at the end of the transfer. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter. Clears the SPI_TCNT field in the Transfer Count register. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame causes this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE: This bit enables parity bit transmission and parity reception check for the SPI frame. MASC: The current frame has the “after SCK” delay masked if this bit is asserted. Refer to *Section 49.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE: No parity bit included/checked. MASC: t_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE: Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC: t_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP: controls the polarity of the parity bit transmitted and checked. MCSC: The next frame has the “PCS to SCK” delay masked if this bit is asserted. Refer to *Section 49.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP: Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC: t_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP: Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC: t_{CSC} delay is masked in the next frame.
8:15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16:31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command

49.3.9 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Field	Description
16:31 TXDATA	Transmit Data Holds SPI data to be transferred.

49.3.10 DSPI POP FIFO Register (DSPI_POPR)

POPR is used to read the RX FIFO.

8- or 16-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register generates a Transfer Error.

Address: 0x0038 Access: User read-only

Field	Description
0:31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

49.3.11 DSPI Transmit FIFO Registers (DSPI_TXFR*n*)

TXFR*n* provide visibility into the TX FIFO for debugging purposes.

Each read-only register is an entry in the TX FIFO. Reading the TXFR*n* registers does not alter the state of the TX FIFO.

Reading DSPI_TXFR*n* registers is invalid for a DSPI Master when used in Extended SPI (XSPI) mode.

Address: 0x003C + *n**0x4 (*n* = 0 to 3) Access: User read-only

Figure 883. DSPI DSI Configuration Register 0 (DSPI_DSICR0)

1. This bit is reserved if the device does not have a hardware trigger input signal (HT).

Table 972. DSPI_DSICR0 field descriptions

Field	Description
1 FMSZ4	MSB of the frame size in master mode when DSI is used in 32-bit mode. If the bit is set, 16 is added to the frame size, as defined by the CTAR*n*[FMSZ] field. The CTAR*n* register is selected by the DSICTAS field.
8 FMSZ5	MSB of the frame size in master mode when DSI is used in 64-bit mode. If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ4], CTAR*n*[FMSZ]} fields. The CTAR*n* register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit is {DSICR0[FMSZ5], DSICR0[FMSZ4], CTAR*n*[FMSZ]}. This field is only valid when DSICR1[DSI64] is enabled.
10 ITSB	Interleaved TSB mode. Enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are sent when either the previous transmission was an SPI frame or the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. ITSB mode requires DSICR0[TSBC] set and should be written only when MCR[HALT] is asserted. If ITSB bit is set without setting DSICR0[TSBC], DSPI operates in Normal Mode depending on MCR[DCONF] bit. Refer to *Section 49.4.10: Interleaved TSB (ITSB) Mode* for more details. 0 Disabled. 1 Enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows up to 64-bit data to be used. It also allows t_{DT} to be programmable. 0 Disabled. 1 Enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either: a) data from host software written to the DSPI DSI Alternate Serialization Data Register (ASDR1/0), or b) parallel input pin states latched into the DSPI DSI Serialization Data Register (SDR1/0). 0 SDR source. 1 ASDR source.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
15 CID	Change In Data Transfer Enable When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. Do not enable CID when DCONT is enabled. 0 Disabled. 1 Enabled.

Table 972. DSPI_DSICR0 field descriptions (continued)

Field	Description
16 DCONT	DSI Continuous Peripheral Chip Select Enable (DSI Master mode only) Enables the PCS signals to remain asserted between transfers. When the TSBC bit is set, DCONT has no effect. Do not enable DCONT when CID is enabled. 0 PCS signals return to inactive. 1 PCS signals remain asserted.
17:19 DSICTAS	DSI Clock and Transfer Attributes Select (DSI Master mode only) Selects the CTAR which provides transfer attributes for DSI frames. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop Stops DSI frame transmissions if DDIF flag is set in the status register. 0 Disabled. 1 Enabled.
21 PES	Parity Error Stop Stops DSI operation if a parity error occurred in the received DSI frame. 0 Disabled. 1 Enabled.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of ‘1’ bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of ‘1’ bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24:31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

49.3.14 DSPI DSI Serialization Data Register 0 (DSPI_SDR0)

Read-only SDR0 contains the states of the 32 LSB parallel input signals.

The states of these signals are latched into the SDR0 on the rising edge of every protocol clock.

When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

When DSICR1[DSI64E] is set, SDR1 is the MSB half and SDR0 is the LSB half of the 64-bit SDR.

Field	Description
0:31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals.

49.3.15 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized.

When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames.

Writes to the ASDR0 take effect on the next frame boundary.

When DSICR1[DSI64E] is set, ASDR1 is the MSB half and ASDR0 is the LSB half of the 64-bit ASDR.

Figure 888. DSPI DSI Configuration Register 1 (DSPI_DSICR1)

Table 977. DSPI_DSICR1 field descriptions

Field	Description
2:7 TSBCNT[5:0]	Timed Serial Bus Operation Count TSBCNT defines the length of the data frame When TSBC is set. The TSBCNT field valid value is from 3 to 63. The TSBCNT field selects the number of data bits to be shifted out during a transfer in TSB mode. Number of data bits in data frame = TSBCNT + 1.
13 DSI64E	DSI 64-bit Mode Enable Allows serialization and deserialization of Data frames up to 64 bits in size. The extended registers DSPI_SDR1, DSPI_ASDR1, DSPI_COMPR1, DSPI_DDR1, DSPI_SSR1, DSPI_PISR4-7, DSPI_DIMR1, DSPI_DPIR1 are valid in this mode. 0 Disabled. DSI Mode operates in the default 32-bit configuration 1 Enabled. DSI Mode operates in 64-bit configuration

Table 977. DSPI_DSICR1 field descriptions (continued)

Field	Description
14 DSE1	Data Select Enable 1 When DSICR0[TBSC] bit is set, the DSE1 bit enables insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTAR*n* register, selected by the DSICR0[DSICTAS] field. If DSICR1[DSI64] is enabled, then the insertion bit position is defined by concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields. The TSBCNT field value must be greater than the FMSZ field value plus one for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When DSICR0[TSBC] bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the Data frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16:23 TRGPRD	Internal Trigger Period for the ITSB mode. When DSICR0[TRG] bit is cleared and ITSB Mode is enabled, this field determines the trigger period for the internal trigger in number of baud rate clock cycles. The trigger period should be calculated as: Trigger Period = 64 bits (DSI frame maximum size) + 2 selection bits (maximum) + t_{PF} (passive frame time) When DSICR1[DSI64E] is disabled, DSI frame maximum size is 32. Refer CTAR[FMSZ] field for minimum frame size allowed. Refer to Interleaved TSB (ITSB) Mode for more details. 0 – 4 These values are invalid since minimum Command frame size is 5. (that is 1 selection bit + minimum frame size which is 4) 5 – 255 Number of baud rate clock cycles to be used as the trigger period. The trigger period implemented is equal to TRGPRD + 1.
24:31 DPCS1_x	DSI Peripheral Chip Select 0–7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

49.3.19 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0.

Each bit in the SSR0 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR0 register value has no effect.

When DSICR1[DSI64E] is set, SSR1 is the MSB half and SSR0 is the LSB half of the 64-bit SSR.

Address: 0x00D4 Access: User read/write

Figure 889. DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

Table 978. DSPI_SSR0 field descriptions

Field	Description
0:31 SS	Source Select Select the serialization source for the 32 LSB of DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

49.3.20 DSPI DSI Parallel Input Select Register 0 (DSPI_PISR0)

PISR0–3 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 if DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–3 only preselect the parallel input pins. The final selection to the transmitted frame is made with the DSPI_SSR1/0 register bits or the DSICR0[TXSS] bit.

When DSICR1[DSI64E] is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins).

49.3.24 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

DIMR0 selects bits in the 32 LSB of received DSI frame to be checked to generate the DDI interrupt.

When DSICR1[DSI64E] is set, DIMR1 is the MSB half and DIMR0 is the LSB half of the 64-bit DIMR.

49.3.25 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

DPIR0 defines which data bit value in the 32 LSB of received DSI frame generates the DDI interrupt.

When DSICR1[DSI64E] is set, DPIR1 is the MSB half and DPIR0 is the LSB half of the 64-bit DPIR.

49.3.26 DSPI DSI Serialization Data Register 1 (DSPI_SDR1)

Read-only SDR1 contains the states of the 32 MSB parallel input signals.

The states of these signals are latched into the SDR1 on the rising edge of every protocol clock.

When DSICR0[TXSS] is cleared, the data in SDR1 and SDR0 is the source of the DSI frames.

The concatenation of {DSPI_SDR1, DSPI_SDR0} provides the 64-bit data to be serialized.

This register is valid only when DSICR1[DSI64E] is set.

Address: 0x00F0 Access: User read-only

Field	Description
0:31 SER_DATA	Serialized Data

49.3.27 DSPI DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized.

When DSICR0[TXSS] is set, the data in ASDR1 and ASDR0 is the source of the DSI frames.

Writes to the ASDR1 take effect on the next frame boundary.

The concatenation of {DSPI_ASDR1, DSPI_ASDR0} provides the 64-bit alternate serialization data.

This register is valid only when DSICR1[DSI64E] is enabled.

49.3.28 DSPI DSI Transmit Comparison Register 1 (DSPI_COMPR1)

Read-only COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data.

The upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift register.

The concatenation of {DSPI_COMPR1, DSPI_COMPR0} provides the 64-bit transmit comparison data.

This register is valid only when DSICR1[DSI64E] is enabled.

49.3.29 DSPI DSI Deserialization Data Register 1 (DSPI_DDR1)

Read-only DDR1 holds the 32 MSB signal states for the 64 parallel output signals.

Host software can read data from incoming DSI frames.

The concatenation of {DSPI_DDR1, DSPI_DDR0} provides the 64-bit Deserialized data.

This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0x00FC Access: User read-only

49.3.30 DSPI DSI Serialization Source Select Register 1 (DSPI_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and from SDR1.

Each bit in the SSR1 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR1 register value has no effect.

The concatenation of {DSPI_SSR1, DSPI_SSR0} provides the 64-bit Serialization Source Select value.

This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0x0100 Access: User read/write

Figure 900. DSPI DSI Serialization Source Select Register (DSPI_SSR)

Table 989. DSPI_SSR field descriptions

Field	Description
0:31 SS	Source Select 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR1 register

49.3.31 DSPI DSI Parallel Input Select Register 4 (DSPI_PISR4)

PISR4–7 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 when DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–7 only preselect the parallel input pins. The final selection to the transmitted frame is made with the SSR0 and SSR1 register bits or the DSICR0[TXSS] bit.

When 64-bit DSI mode is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins). If DSICR1[DSI64E] is disabled, then DSPI_PISR4-7 registers are invalid.

49.3.37 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame.

These registers are valid only when DSPI_MCR[XSPI] is set.

When the DSPI is configured as:

- an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.
- an SPI bus slave, the CTARE0 register is used.

Table 996. DSPI_CTARE*n* field descriptions

Field	Description
15 FMSZE	Frame Size Extended This field concatenated with DSPI_CTAR[FMSZ] defines the frame size of the SPI frames to be transmitted. Frame size is the concatenation of {DSPI_CTAR[FMSZ], DSPI_CTARE[FMSZE]} + 1. 0 Default Mode. Up to 16-bit SPI frames can be transferred. 1 Up to 32-bit SPI frames can be transferred. Each frame transfer is a result of 2 TX FIFO Pops.
21:31 DTCP	Data Transfer Count Preload This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame that selected this DSPI_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

49.3.38 DSPI Status Register Extended (DSPI_SREX)

The DSPI_SREX contains status fields that reflect the DSPI status and indicate the occurrence of events.

This register is not writable.

49.4 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations:

- SPI Configuration in which the DSPI operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes and deserializes parallel input/output signals or bits from memory-mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI Configuration. Refer to *Section 49.3.1: DSPI Module Configuration Register (DSPI_MCR)* for the DSPI configuration values.

The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows CTAR selection on a frame by frame basis by setting a field in the SPI command. Extended SPI Mode (DSPI_MCR[XSPI]) further allows the usage of CTARE*n* (CTAR*n* Extended) registers to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates which CTAR is used for the data transfer.

Refer to *Section 49.3.4: DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTARn)* for information on CTARs fields.

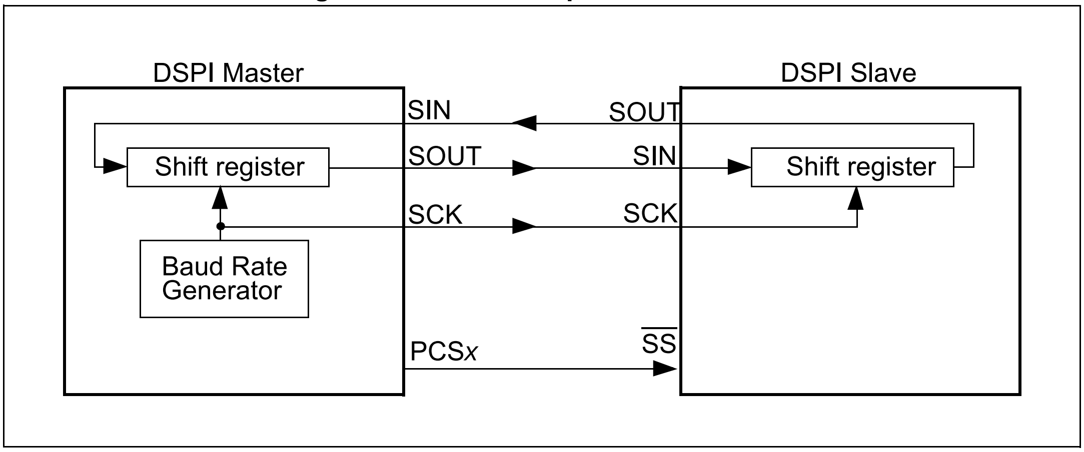
Refer to *Section 49.3.37: DSPI Clock and Transfer Attributes Register Extended (DSPI_CTAREn)* for information on CTAREs fields.

Typical master to slave connections are shown in *Figure 909*.

When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave: the data that was in the master shift register is now in the shift register of the slave, and vice versa.

At the end of a transfer, the TCF bit in the Status register is set to indicate a completed transfer.

Figure 909. SPI serial protocol overview



Generally, more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in *Section 49.4.6: Transfer formats*.

The transfer rate and delay settings are described in *Section 49.4.5: DSPI baud rate and clock delay generation*.

49.4.1 Start and Stop of DSPI transfers

The DSPI has two operating states that are independent of DSPI configuration:

- STOPPED is the default DSPI state: no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results.
- RUNNING is the state when serial transfers take place.

DSPI_SR[TXRXS] indicates what state the DSPI in (‘1’ = RUNNING state).

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

49.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The SPI frames can be 32 bits long.

The DSPI is in SPI Configuration when the DCONF field in the MCR is 0b00.

The host CPU or a DMA controller transfers the SPI data from memory external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer.

Received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI.

The FIFO buffers operation is described in:

- *Section 49.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*,
- *Section 49.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*,
- *Section 49.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism*.

The interrupt and DMA request conditions are described in *Section 49.4.12: Interrupts/DMA requests*.

The SPI Configuration supports two block-specific modes:

- Master mode: the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry.
- Slave mode: the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

49.4.2.1 Master mode

In SPI Master mode, the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals.

The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields.

The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin.

In SPI Master mode, each SPI frame to be transmitted has a command associated with it for transfer attribute control on a frame-by-frame basis.

In Extended SPI Master mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. Extended SPI Mode allows for larger frame sizes of up to 32 bits.

49.4.2.2 Slave mode

In SPI slave mode, the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers.

Certain transfer attributes such as clock polarity, clock phase and frame size must be set in CTAR0 and CTARE0 for successful communication with an SPI master. The data is shifted out with MSB first; shifting out of LSB is not supported in this mode.

49.4.2.3 FIFO Disable operation

The FIFO Disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO.

The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled.

The Transmit and Receive side of the FIFOs are disabled separately:

- MCR[DIS_TXF] disables TX FIFO and CMD FIFO.
  - TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in the status register and the extended status register behave as if there is a one-entry FIFO.
  - The contents of the TXFR registers and TXNXTPTR and CMDNXTPTR are undefined.
- MCR[DIS_RXF] bit disables the RX FIFO.
  - The RFDF, RFOF and RXCTR fields in the status register behave as if there is a one-entry FIFO.
  - The contents of the RXFR registers and POPNXTPTR are undefined.

The FIFO Disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

49.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission.

The TX FIFO holds 4 words, each consisting of SPI data that is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR).

The number of entries in the TX FIFO is device-specific.

TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. This field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

49.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set.When TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete, the TFFF bit is cleared. Writing a ‘1’ to the TFFF bit also clears it. The DSPI ignores attempts to push data to a full TX FIFO; the state of the TX FIFO does not change and no error condition is indicated.

The TFFF can generate a DMA request or an interrupt request. Refer to *Section 49.4.12.2: Transmit FIFO Fill interrupt or DMA request* for details.

49.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled and the frame size of SPI Data to be transmitted is more than 16 bits, then two Data entries are popped from TX FIFO simultaneously and transferred to the shift register. The first of the two popped entries forms the 16 LSB bits of the SPI frame. Such an operation also causes TX FIFO Counter to decrement by two.

At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a ‘1’ to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave’s DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave’s SR is set. Refer to *Section 49.4.12.9: Transmit FIFO Underflow interrupt request* for details.

49.4.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific.

SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPI_MCR[XSPI]) is disabled:

- The TX FIFO and CMD FIFO must be filled together as every CMDFIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled:

- The TX FIFO and CMD FIFO can be filled independently as every CMDFIFO entry can have multiple TXFIFO entries attached to it.
- The CTARE[DTCP] field decides the number of SPI Data Frames of size {FMSZE, FMSZ} to be transmitted using the current Command Entry. FMSZ and FMSZE fields are given in the CTAR/CTARE registers respectively, pointed by the CTAS field in the Command frame.
- The amount of time a command entry is in use is known as a Command Cycle. The busy flag DSPI_SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO entry is used during the next command cycle. This field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

49.4.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin.

The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific.

SPI data is added to the RX FIFO on completion of a transfer when the received data in the shift register is transferred into the RX FIFO.

SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the status register points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR = 2 means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

49.4.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register.

While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the status register is set to indicating an overflow condition. Consequently:

- If the DSPI_MCR[ROOE] bit is set, the incoming data is shifted in to the shift register.
- If the DSPI_MCR[ROOE] bit is cleared, the incoming data is ignored.

49.4.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one.

Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data read from the empty RX FIFO is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the status register is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete, or by writing a ‘1’ to it.

49.4.3 Deserial Serial Interface (DSI) configuration

The DSI Configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in *Section 49.4.6: Transfer formats*. The received serial frames are converted to a parallel form (deserialized) and placed on the parallel output signals or in the DSPI_DDR. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR1/0).

The DSI frames can be from 4 to 32 bits, or 64 bits when DSICR1[DSI64E] is enabled.

49.4.3.1 DSI master mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions (described in *Section 49.4.3.5: DSI transfer initiation control*) that can initiate a transfer:

- Continuous.
- Change in data.
- Trigger signal.
- Trigger signal combined with a change in data.

Transfer attributes are set during initialization. DSICR0[DSICTAS] field determines which of the DSPI_CTARs will control the transfer attributes.

49.4.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers.

Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1.

The data is shifted out with MSB first.

49.4.3.3 DSI serialization

The DSI configuration from 4 to 16 bits can be serialized using two different sources selected by DSICR0[TXSS]:

- DSPI DSI Serialization Data Register (DSPI_SDR1/0). The DSPI_SDR0 holds the latest 32 parallel input signal values which is sampled at every rising edge of the protocol clock.
  When DSICR1[DSI64E] is enabled, 64-bit DSI frames are supported and hence DSPI_SDR1 holds the 32 MSB parallel input signal values which is sampled at every rising edge of the protocol clock.
- DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0). The DSPI_ASDR1/0 registers are written by host software and used as an alternate source of serialized data. DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled.

The DSPI has to sample the (SDR/ASDR) inputs before it transmits a DSI frame. Due to the asynchronous clock structure within DSPI, the sampling of inputs come under Register Clock domain whereas DSI frame transmission logic lies in Protocol Clock domain. Hence the sampled data (from ASDR1/0 or SDR1/0) must be synchronized into the Protocol Domain before being loaded into the Shift register for transmission.

To prevent Clock Domain clocking issues, SDR/ASDR inputs should not change while they are being sampled into the Protocol Domain. This is assured in the following manner:

- For the ASDR0 and ASDR1 inputs:
  - The initial write performed on ASDR register causes the 32-bit ASDR input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain.
  - Once synchronized, the lock is removed and the next ASDR write triggers this process again. If a write is performed on ASDR while the lock is asserted, this is processed as soon as the previous synchronization process completes and the lock is de-asserted. If multiple writes are performed on ASDR when lock is asserted after the first write, only the last value is considered for synchronization once the lock is de-asserted.
- For the SDR0 and SDR1 inputs:
  - The process is the same as ASDR with the only difference being that SDR inputs are delayed internally by a single clock to detect a change in the SDR input pins.

Note: If SDR0 and SDR1 inputs are both changed at the same time instant, then the synchronization logic ensures that both SDR0 and SDR1 contribute to the same DSI frame.

Once the synchronization process for a particular Deserial input begins, it takes up to five Register clock periods and five Protocol clock periods before the synchronization process for the next Deserial input can begin. Hence the writes performed on ASDR0/1 and SDR0/1 are constrained with this timing.

The DSPI_PISR0–3 registers (DSPI_PISR0–7 registers if DSICR1[DSI64E] is enabled) allow changing of the relative position of the parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent parallel inputs by writing IPS*n* fields. The IPS*n* field is treated as a 4-bit integer number, representing numbers from -8 to 7. The parallel input pin number, selected by IPS*n* field is defined by the sum of the IPS*n* field number (*n*) and the IPS*n* field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result. When DSICR1[DSI64E] is enabled, if the above operation result is negative, the number 64 should be added. If the result is higher than 64, 64 should be subtracted from the result.

For example, IPS0, set to minus 1 (binary 1111), preselects parallel input 31 to 0 position in the transmitted frame. (This preselects parallel input 63 to 0 position in the transmitted frame when DSICR1[DSI64E] is set).

IPS6, set to 3 (binary 0011), preselects parallel input 9 to be bit number 6 in the transmitted frame, while the value minus 2 (1110) preselects parallel input 4.

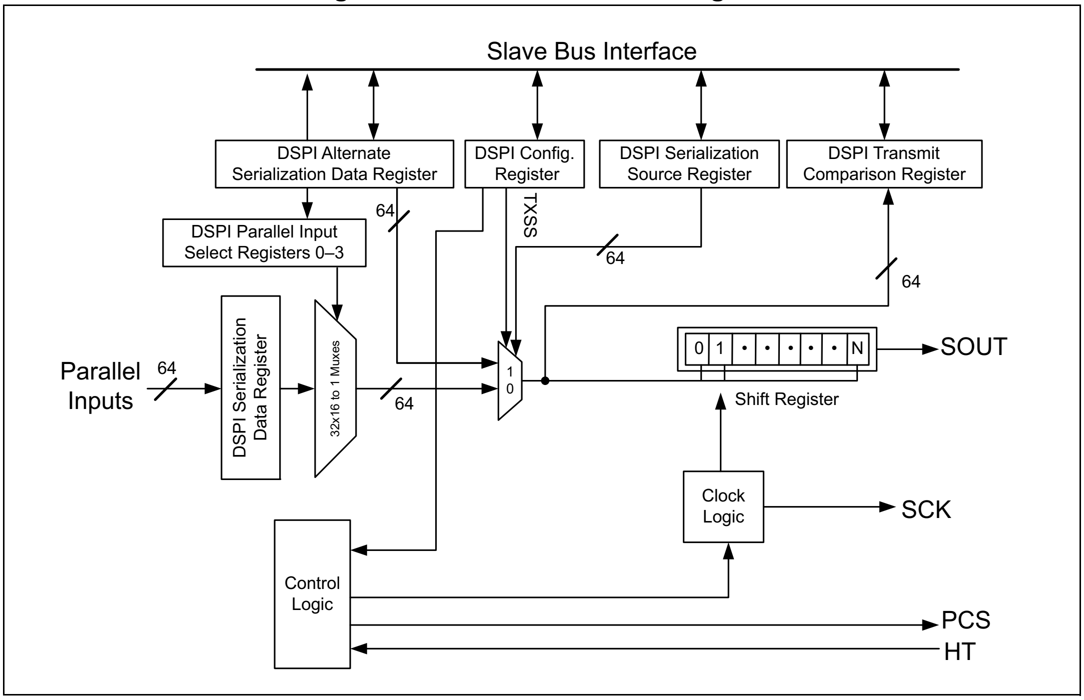
IPS31, set to minus 8 (binary 1000), preselects parallel input 23 to be bit number 31 in the transmitted frame.

The parallel input pin state to be transmitted should be selected by TXSS or DSPI_SSR1/0 registers and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR1/0 registers provide additional way of creating the frame for transmission. Each bit from this register is ORed with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR1/0 and DSPI_ASDR1/0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. The control field may come from DSPI_ASDR1/0 registers set by the CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMPR1/0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. *Figure 910* shows the DSI serialization logic.

Figure 910. DSI serialization diagram

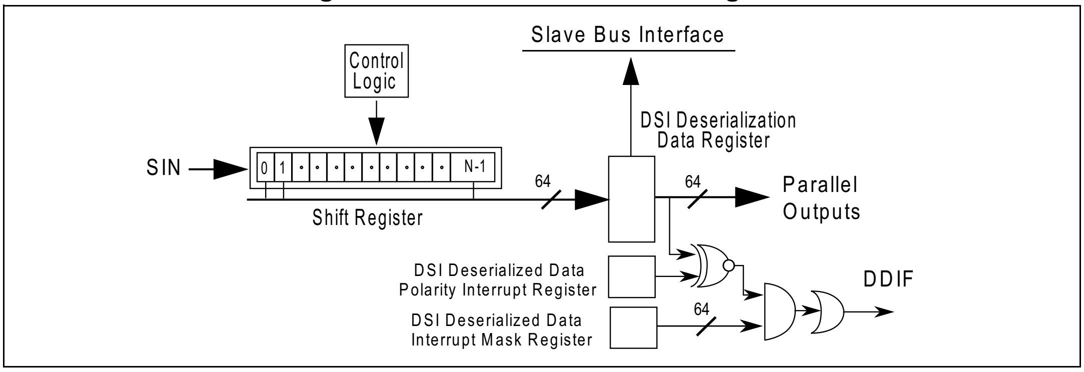


49.4.3.4 DSI deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR1/0). This register presents the deserialized data as parallel output signal values. The DSPI_DDR1/0 is memory-mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR1/0), bit-wise ANDed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR1/0) and the results ORed to produce DDIF flag in the DSPI_SR. Which in turn can cause DDIF interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] and/or stop DSI frame transmissions if DSICR0[DMS] bit is set. *Figure 911* shows the DSI Deserialization logic.

Figure 911. DSI deserialization diagram



49.4.3.5 DSI transfer initiation control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0 register. Table 998 lists the four transfer initiation conditions.

Table 998. DSI data transfer initiation control

DSPI_DSICR0 bits		Transfer initiation control
TRRE	CID	
0	0	Continuous
0	1	Change in Data
1	0	Triggered
1	1	Triggered or Change in Data

49.4.3.5.1 Continuous control

For continuous control, a new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

49.4.3.5.2 Change in data control

For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_COMPR1/0. When the data selected for the transfer from the DSPI_SDR1/0 and DSPI_ASDR1/0 registers is different from the data in the DSPI_COMPR1/0 a new DSI frame is transmitted.

49.4.3.5.3 Triggered control

For Triggered Control, initiation of a transfer is controlled by the Hardware Trigger signal (HT). DSICR0[TPOL] bit selects the active edge of HT. For HT to have any affect, DSICR0[TRRE] bit must be set.

49.4.3.5.4 Change in data or triggered control

For change in data or triggered control, initiation of a transfer is controlled by the detection of a change in data to be serialized or by the HT signal.

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1; since the following statement then holds true:

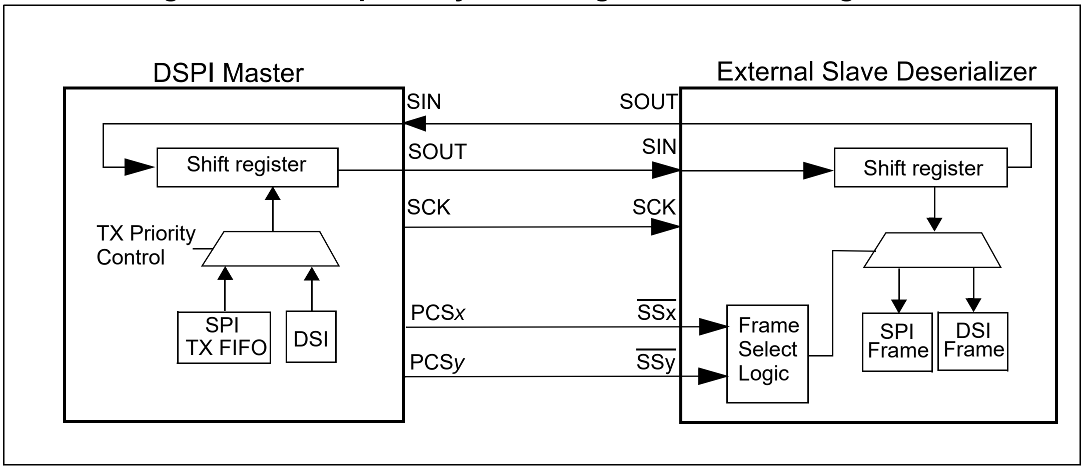
> Once slave select is asserted, there is a very small window (of up to three module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occurs, the next frame to be transmitted would be loaded into the shift register. Since it is not feasible that such a write is initiated and completed within this short span of time, the data transmitted by DSPI slave would lag by one data frame.

49.4.4 Combined Serial Interface (CSI) configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis.

CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the parallel output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. *Figure 912* shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

Figure 912. Example of System using DSPI in CSI Configuration



In CSI Configuration, the DSPI transfers DSI data based on *Section 49.4.3.5: DSI transfer initiation control*. When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTARs associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy.

The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the parallel output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

49.4.4.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR selected by the DSICR0[DSICTAS] field.

The parallel inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR) on the rising edge of every protocol clock and serialized based on the transfer initiation control settings in the DSPI_DSICR1/0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty), they have priority over DSI data and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR1/0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

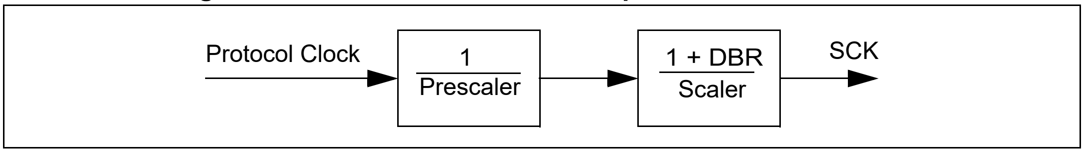
49.4.4.2 CSI deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR1/0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred, the returned frames are deserialized and latched into the DSPI_DDR1/0. When SPI frames are transferred, the returned frames are deserialized and written to the RX FIFO.

49.4.5 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. *Figure 913* shows conceptually how the SCK signal is generated.

Figure 913. Communications clock prescalers and scalers



49.4.5.1 Baud rate generator

The baud rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. *Table 999* shows an example of how to compute the baud rate.

Table 999. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note: The clock frequencies mentioned in Table 999 are given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

49.4.5.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. The PCSSCK and CSSCK fields in the CTAR*n* registers select the PCS to SCK delay by the formula in the CSSCK field description. *Table 1000* shows an example of how to compute the PCS to SCK delay.

Table 1000. PCS to SCK delay computation example

f_P	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1000 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

49.4.5.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. The PASC and ASC fields in the CTAR*n* registers select the After SCK delay by the formula in the ASC field description. Table 1001 shows an example of how to compute the After SCK delay.

Table 1001. After SCK delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 μs

PCASC and ASC fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1001 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

49.4.5.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. The PDT and DT fields in the CTAR*n* registers select the Delay after Transfer by the formula in the DT field description. Table 1002 shows an example of how to compute the delay after transfer.

Table 1002. Delay after transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

Note: The clock frequency mentioned in Table 1002 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

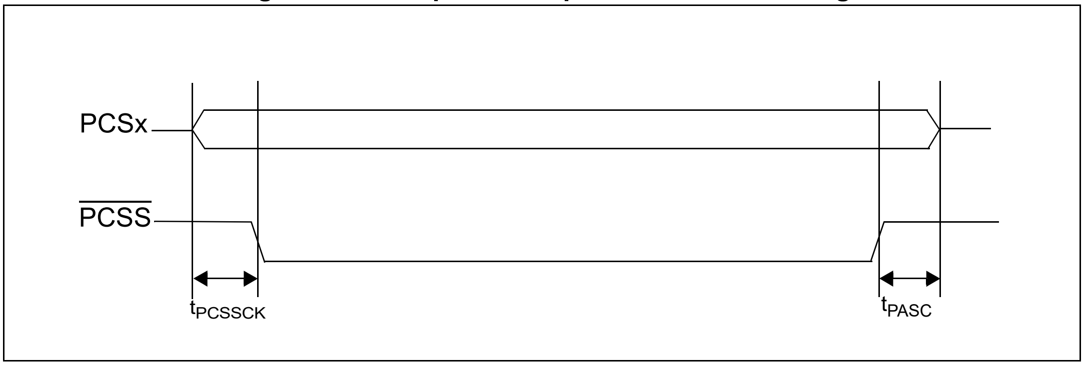
When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode, the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. Refer to detailed information on Section 49.4.9: Timed Serial Bus (TSB).

49.4.5.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs, thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4]and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. Figure 914 shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

Figure 914. Peripheral Chip Select Strobe Timing



The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

Equation 41

$$t_{PCSSCK} = \frac{1}{f_P} \times PCSSCK$$

At the end of the transfer the delay between $\overline{PCSS}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

Equation 42

$$t_{PASC} = \frac{1}{f_P} \times PASC$$

Table 1003 shows an example of how to compute the t_{PCSSCK} delay.

Table 1003. Peripheral Chip Select Strobe Assert Computation Example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

Table 1004 shows an example of how to compute the t_{PASC} delay.

Table 1004. Peripheral Chip Select Strobe Negate Computation Example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK or TSB mode is enabled.

Note: The clock frequency mentioned in the preceding Table 1003 and Table 1004 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

49.4.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTAR*n*) select the polarity and phase of the serial clock, SCK.

- CPOL: selects the idle state polarity of the SCK.
- CPHA: selects if the data on SOUT is valid before or on the first SCK edge.

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

In DSI slave mode, only CTAR1 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0.
- Classic SPI with CPHA = 1.
- Modified Transfer format with CPHA = 0.
- Modified Transfer format with CPHA = 1.

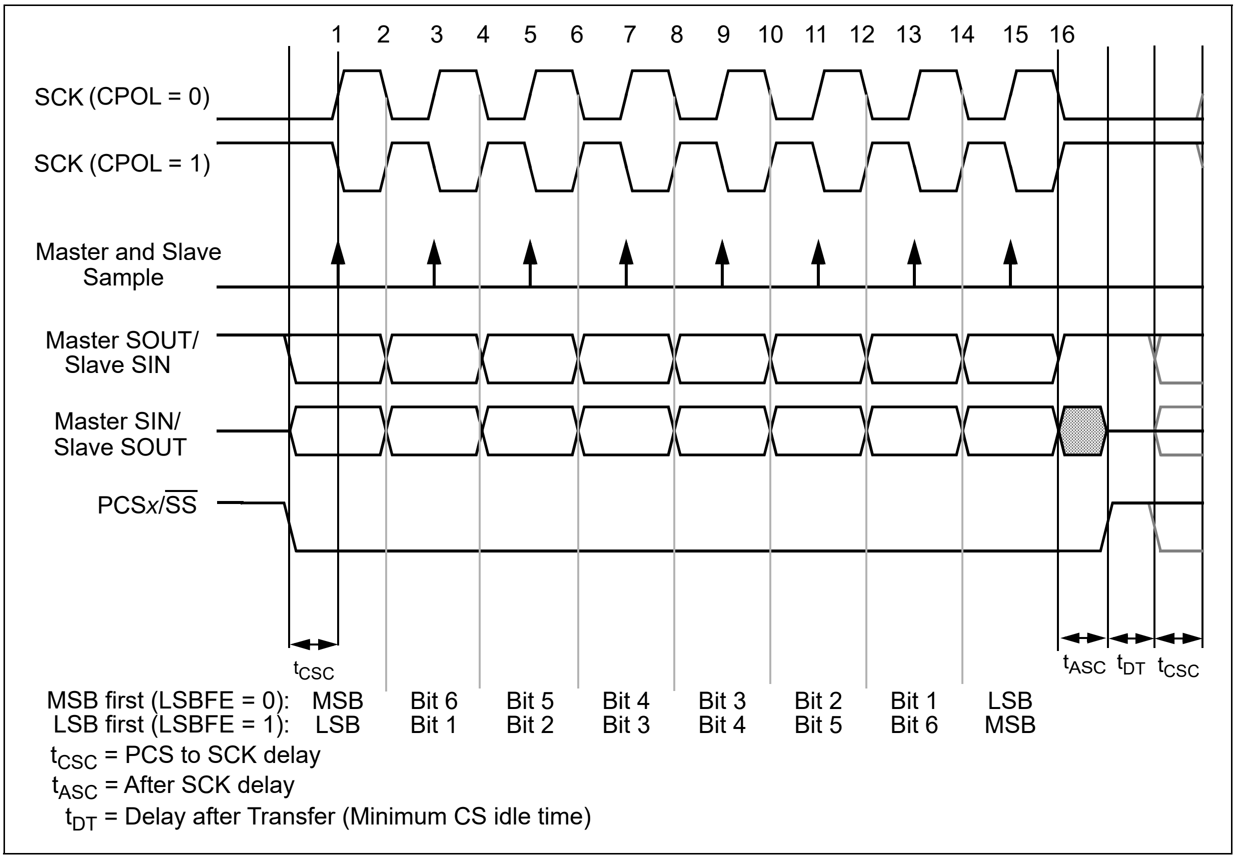
A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. Refer to *Section 49.4.6.5: Continuous Selection Format* for details.

49.4.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in *Figure 915* is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 915. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)



The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals.

At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals.

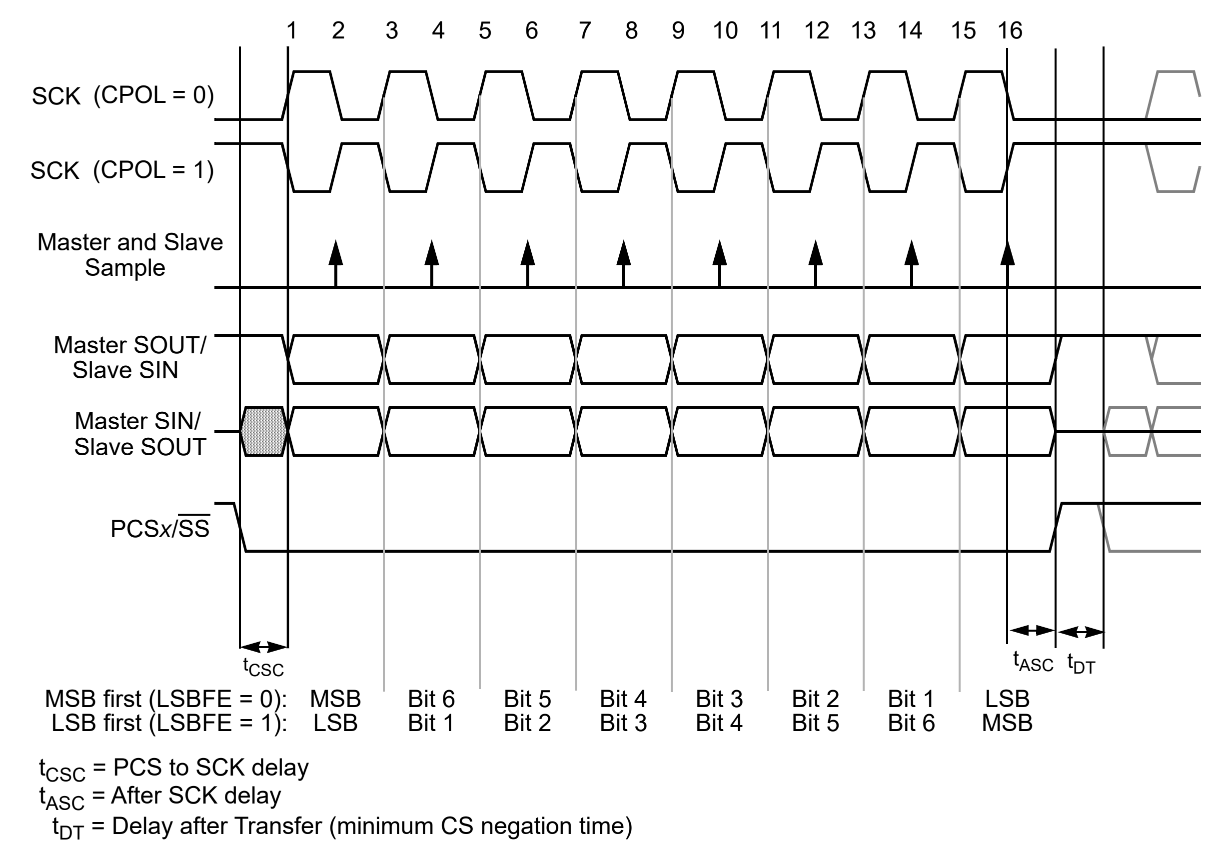
For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

49.4.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in *Figure 916* is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 916. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)



The master initiates the transfer by asserting the PCS signal to the slave.

After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins.

For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

49.4.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_sl} – data hold time on slave data input
- t_p – protocol clock period

Figure 917 shows the modified transfer format for CPHA = 0 and f_p/f_{sck} = 4{s}. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked “SOUT of Ext Slave”, presents regular SPI slave serial output.
- Signal, marked “SOUT of DSPI Slave”, presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according to DSPI master CPHA programming.

Note: *In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.*

Note: *When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.*

Figure 917. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)

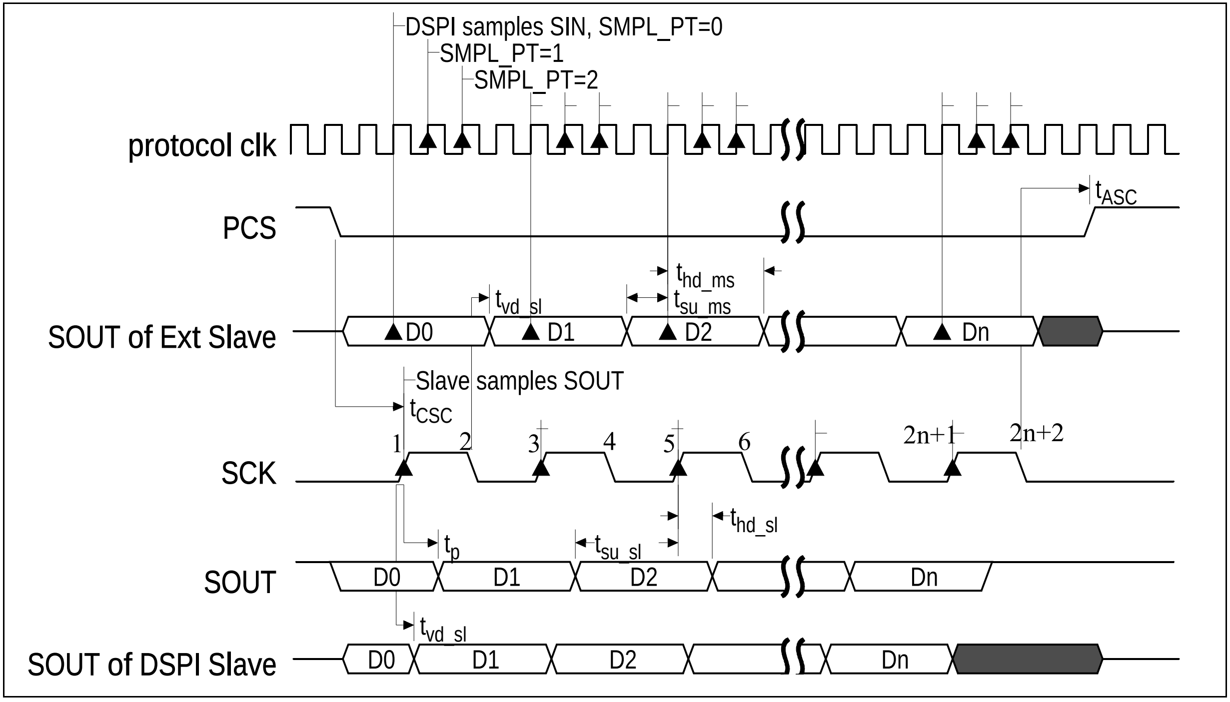


Figure 918. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

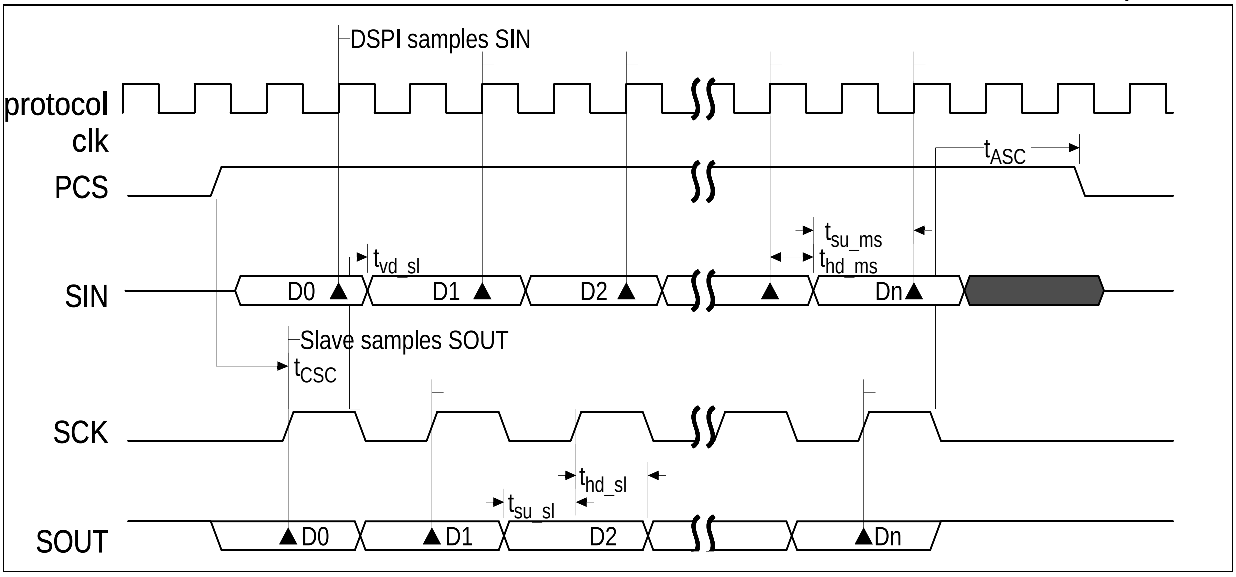

Figure 919. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

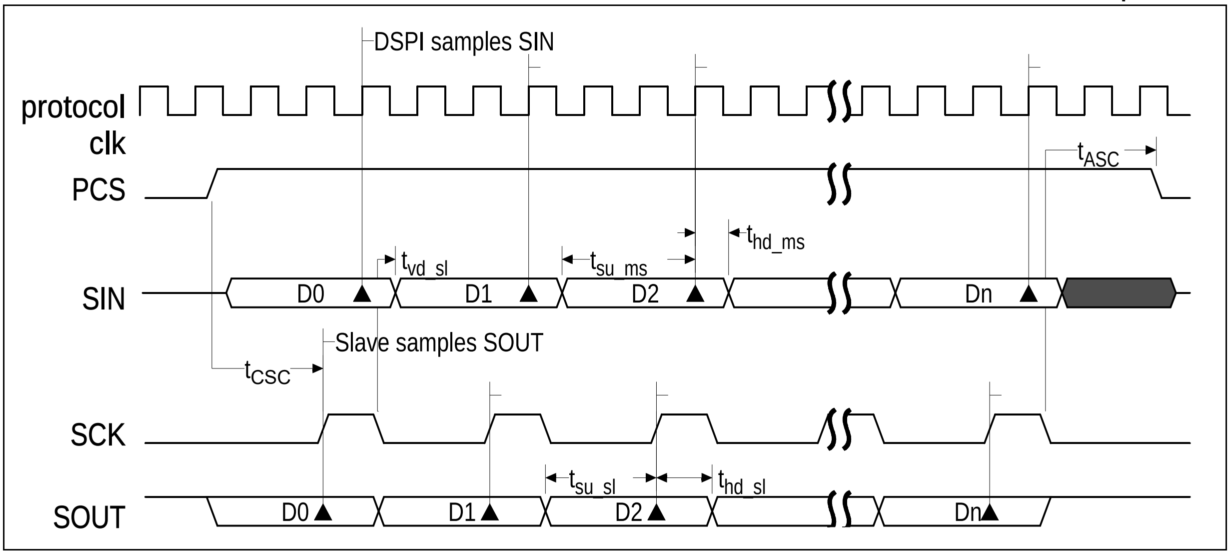

49.4.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. The SCK to PCS delay must be greater than or equal to half of the SCK period.

Figure 920. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)

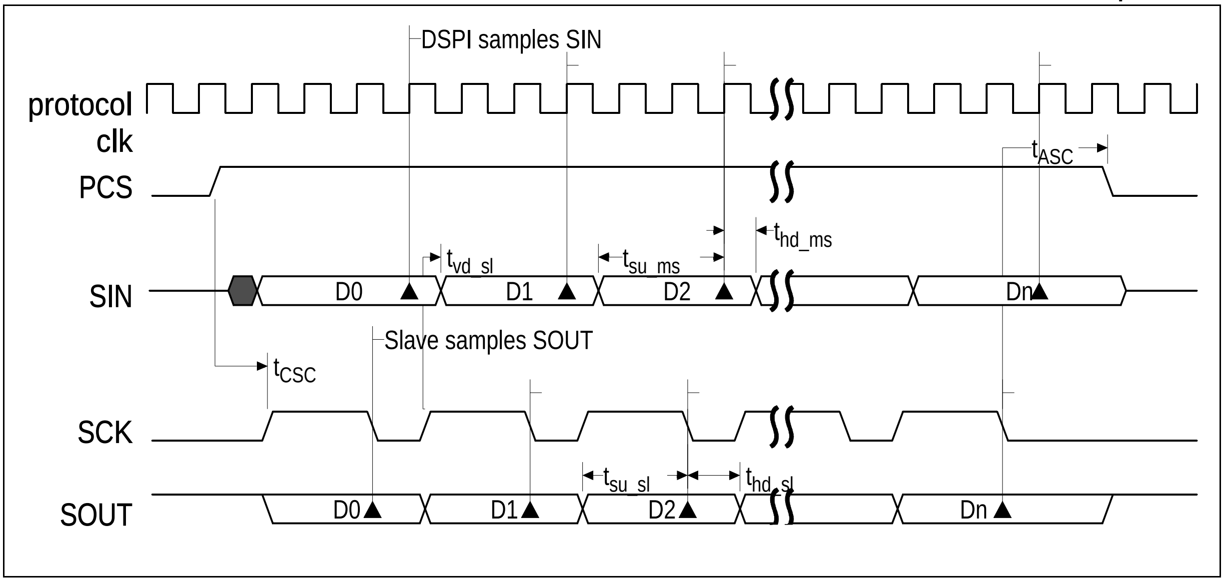

Figure 921. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

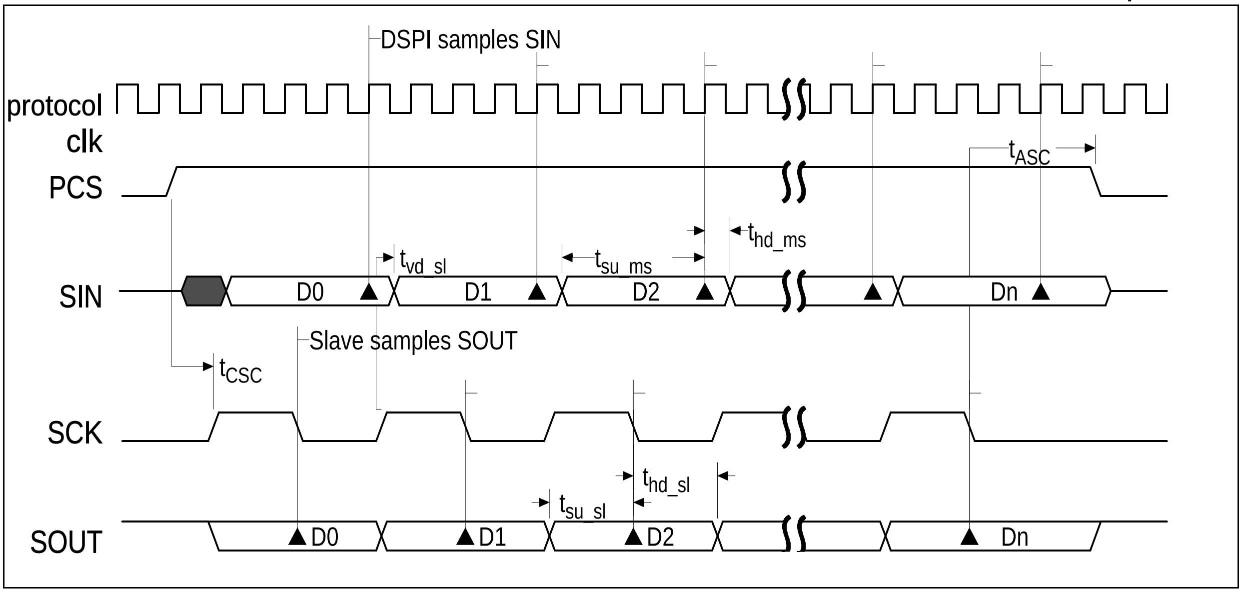

Figure 922. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

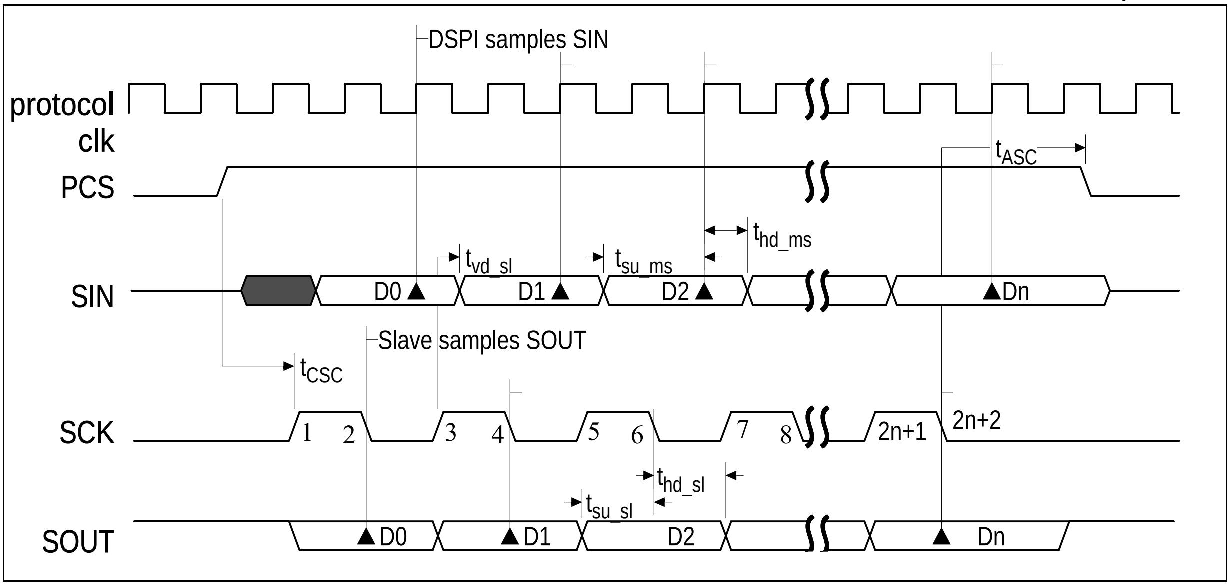
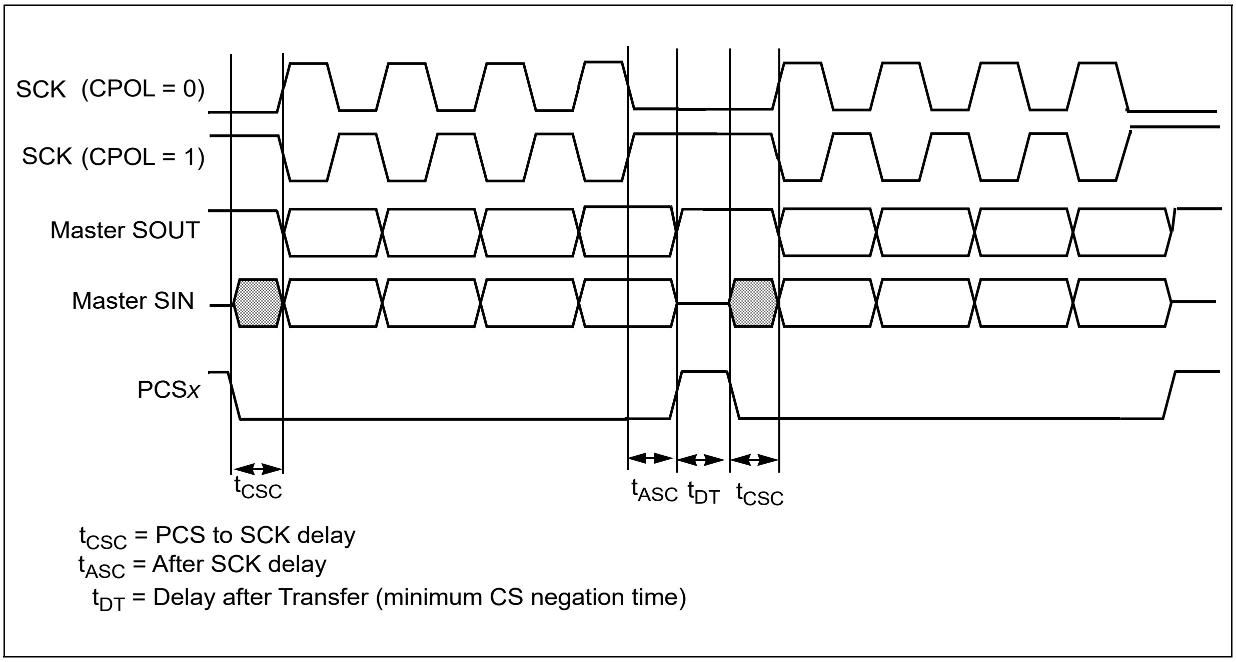


49.4.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI Configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.

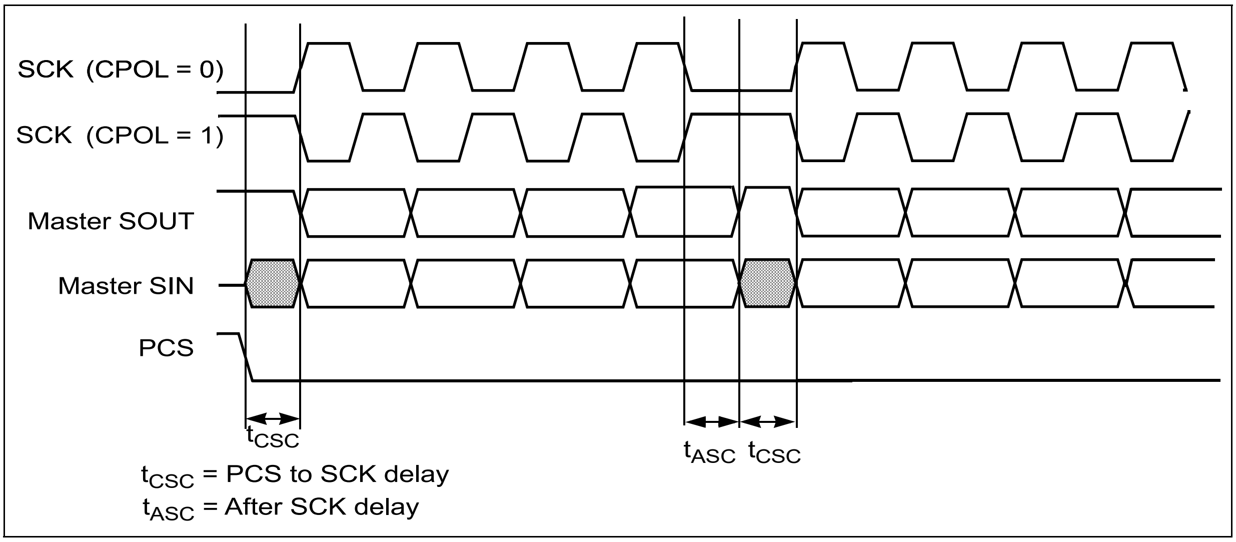
The behavior of the PCS signals in the two configurations is identical so only SPI Configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSIS*n* bits in the MCR. The timing diagram in *Figure 923* is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 923. Example of non-continuous format (CPHA = 1, CONT = 0)



When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. *Figure 924* shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 924. Example of continuous transfer (CPHA = 1, CONT = 1)



When using DSPI with continuous selection follow these rules:

- All transmit commands must have the same PCS*n* bits programming.
- The CTARs selected by transmit commands must be programed with the same transfer attributes. Only FMSZ field can be programed differently in these CTARs.
- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit de-asserted (in master mode) and the user software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCS*n* at end of transmission of last frame.
- The PUSHR[CONT]/DSICR0[DCONT] bits must be de-asserted before asserting MCR[HALT] bit (in master mode). This ensures that the PCS*n* signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCS*n* signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

Note: You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

Note: When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

49.4.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

Note: The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

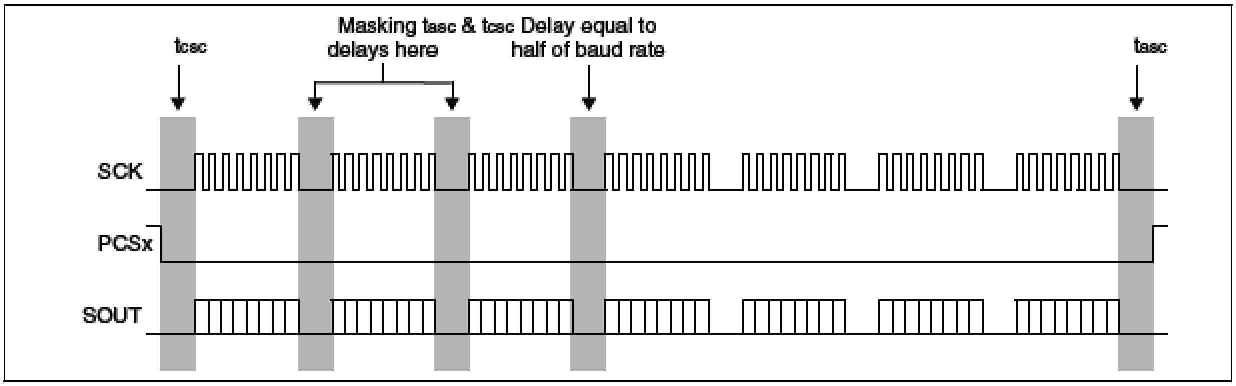
The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR. When this bit is asserted, MASC and MCSC bits of the PUSHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

Figure 925 shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

Figure 925. Example of Fast Continuous Selection Format



In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

49.4.7 Continuous Serial Communications Clock

The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
  - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
  - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

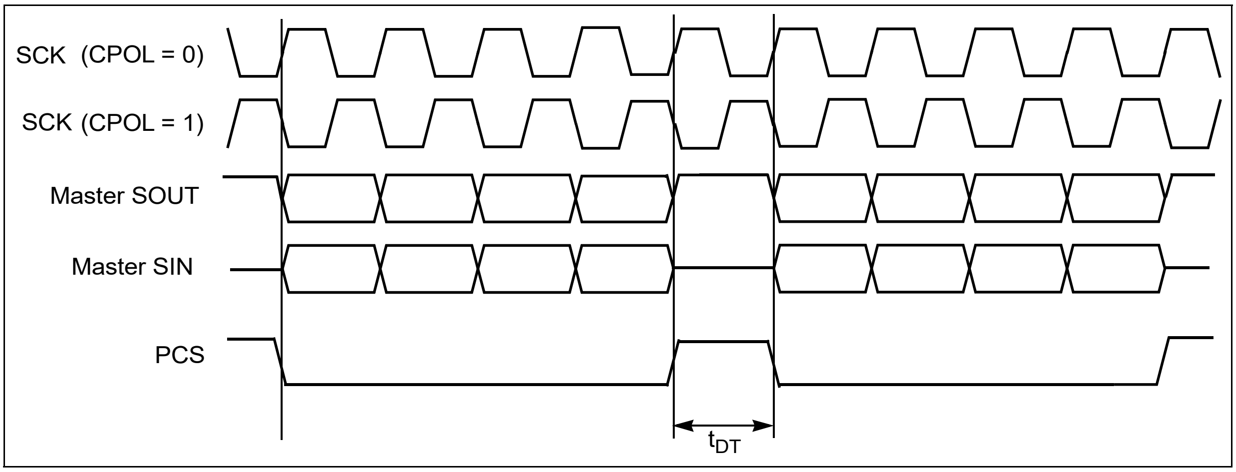
It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles.

Figure 926 is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note: When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 926. Continuous SCK timing diagram (CONT = 0)



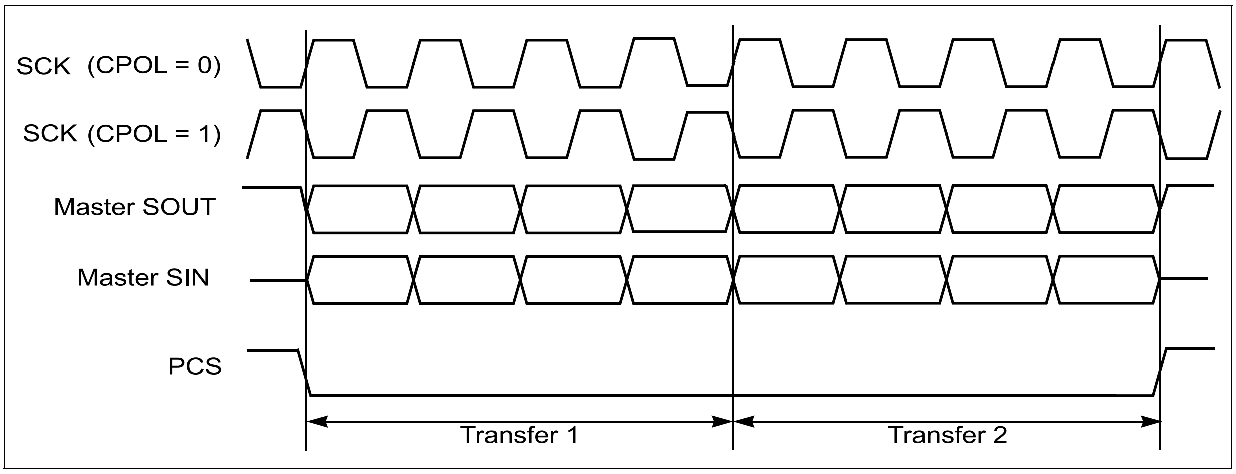
If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with

PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to *Section 49.4.1: Start and Stop of DSPI transfers*).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

Figure 927 shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 927. Continuous SCK Timing Diagram (CONT = 1)



49.4.8 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

49.4.9 Timed Serial Bus (TSB)

The DSPI can be programed in Timed Serial Bus configuration by setting DSICR0[TSBC] bit. Refer to *Section 49.3.13: DSPI DSI Configuration Register 0 (DSPI_DSICR0)* for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the device.

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

Figure 928 shows the signals used in the TSB interface.

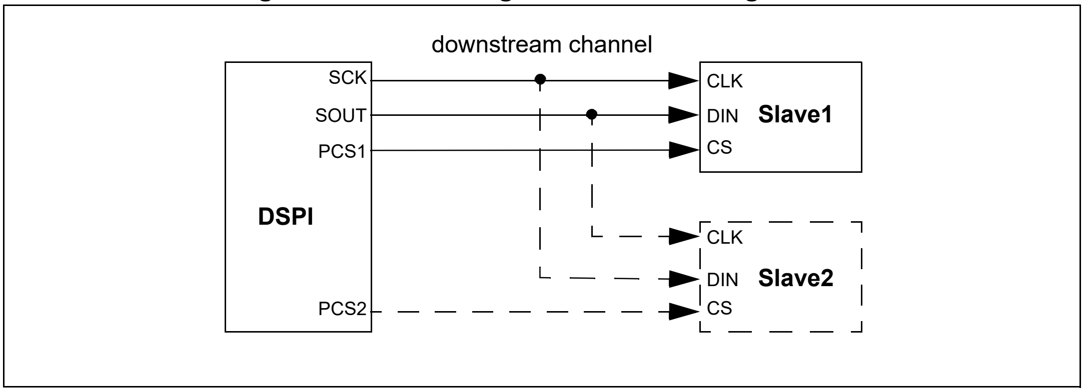
In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0), written by the host software,
- parallel input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR1/0).

DSICR0[TXSS] bit or DSPI_SSR1/0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

Figure 928. DSPI usage in the TSB Configuration



The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTAR*n* PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

Figure 929. TSB Downstream Frames

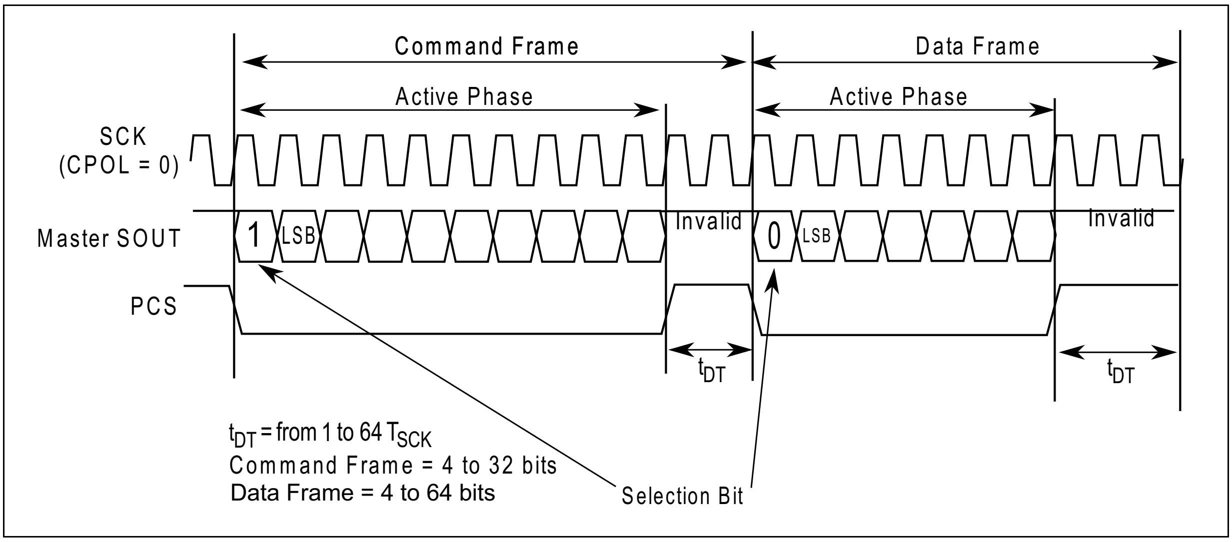


Figure 929 shows two types of MSC downstream frames: command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit ‘0’ indicates a data frame
- The selection bit ‘1’ indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR1/0 or ASDR1/0 registers and up to two zero selection bits. Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSE*n* bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTAR*n*[LSBFE] to transmit least significant bit first.

Regardless of the LSBFE bit setting, the data frame selection bits, if enabled, are always transmitted first, before the corresponding data subframes.

49.4.9.1 MSC Dual Receiver Support with PCS Switchover

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switchover occurs, is defined by FMSZ field of the DSPI_CTAR*n* register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Note: When using Dual receiver support, it must be ensured that the number of bits to be transmitted to each slave must be at least 4.

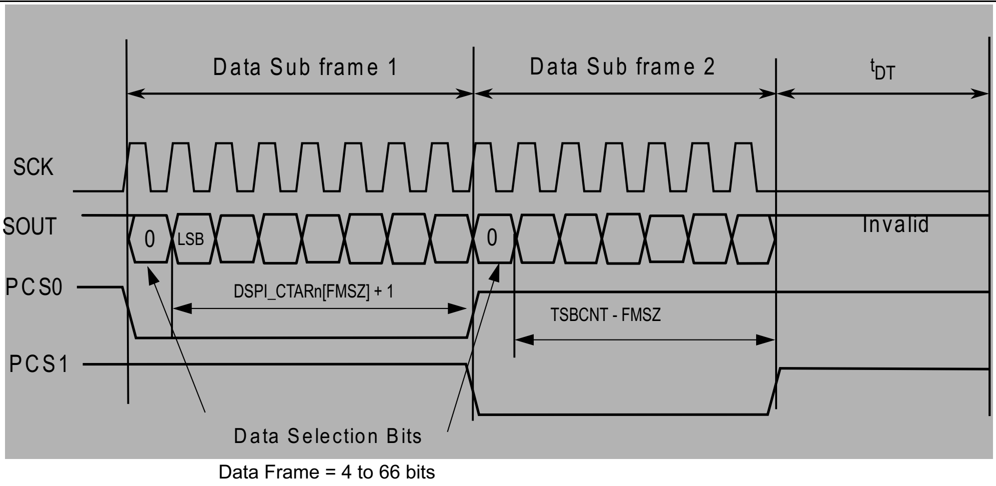
Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switchover occurs at the driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switchover if enabled.

The Data Frame with PCS switchover is shown in *Figure 930*.

Figure 930. TSB Data Frame Format for MSC Dual Receiver Operation



49.4.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB in all aspects except for the differences mentioned in *Table 1005*. In the Interleaved TSB or ITSB mode, frame transmission is governed by the following rules:

- Transmission of frames is executed on a periodic trigger that is generated internally to the DSPI. The trigger period is calculated as follows:
  - Trigger Period = 64 bits (maximum data frame size) + 2 selection bits (maximum bits in data frame) + t_{PT}

    t_{PT} is the passive frame time or dead time inserted to have constant trigger period.
  - The user software shall configure the trigger period and trigger source.
- If the previously transmitted frame was a SPI frame or the TX FIFO (or CMD FIFO) is empty, the frame transmitted on subsequent trigger will always be a DSI frame.
- If the previously transmitted frame was not a SPI frame and the TX_FIFO (and CMD FIFO) is not empty, the frame transmitted on subsequent trigger will always be a SPI frame.

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) in such a way to prevent back to back SPI frames. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits cannot be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

Table 1005 lists the differences between the TSB and ITSB modes.

Table 1005. Differences between TSB and ITSB modes

Mode attribute	TSB mode	ITSB mode
Frame priority	Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Frame selection bit	Selection bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Frame transmission	Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Periodically triggered transmission (that is frames are transmitted continuously on every trigger).
Frame gap	Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is inserted automatically as the whole operation is based on a periodic trigger. If a frame has less than 64-bits to be transmitted, dead or passive time is automatically inserted by waiting for the next trigger pulse. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In TSB and ITSB mode, separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI. MSC dual receiver support with PCS switchover is also supported in ITSB mode. Refer to *Section 49.4.9.1: MSC Dual Receiver Support with PCS Switchover* for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the ITSB mode features listed in the table above.

49.4.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame completion (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in *Section 49.4.10: Interleaved TSB (ITSB) Mode*.

49.4.10.2 Using ITSB mode for MSC downstream channel

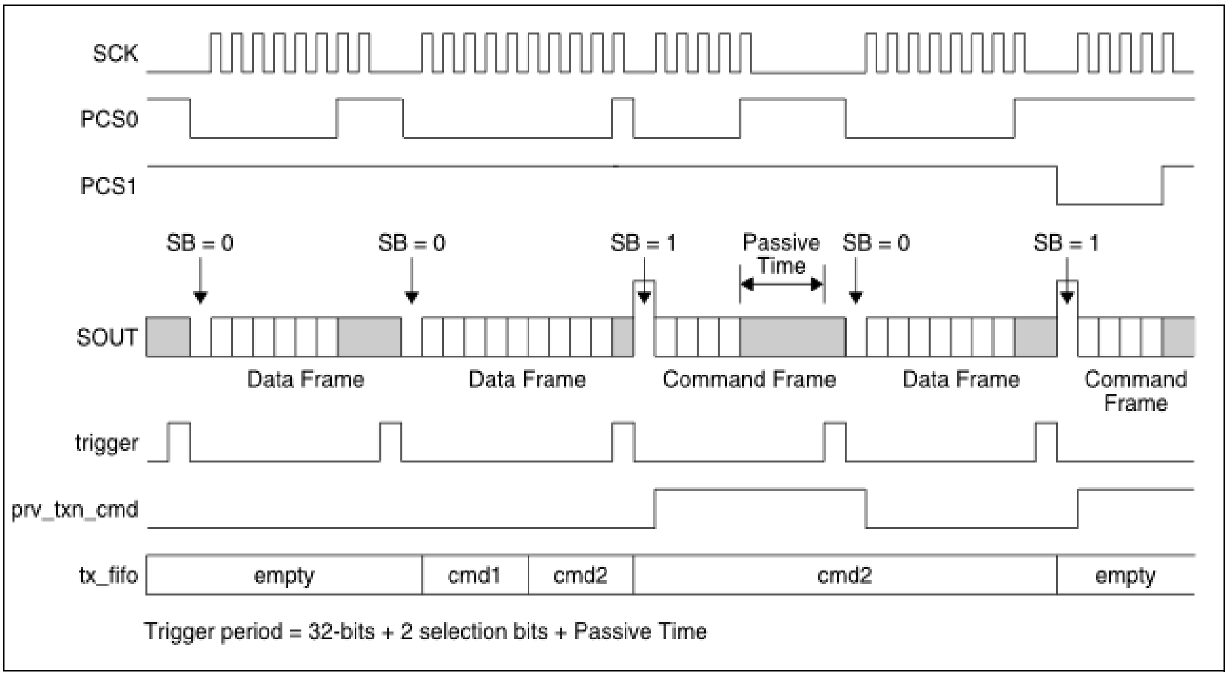
MSC Downstream Channel uses two types of frames: command frames and data frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- If command frame has less bits than data frame, a gap is inserted to ensure next data frame starts at known reference time.
- In dual MSC ASIC, some bits of the data frame (which can be up to 64 bits) goes to first ASIC and remainder bits to second ASIC.
- In dual MSC ASIC, if a command frame is sent to one ASIC, it must not change the timing of the next data frame.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (Refer to *Section 49.4.10.1: Configuring DSPI for ITSB mode*), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in *Section 49.4.4: Combined Serial Interface (CSI) configuration*.

Figure 931 shows a sample MSC Downstream transmission using the ITSB mode.

Figure 931. Sample MSC downstream transmission using ITSB mode



Brief description of operation includes:

- At the first trigger, since there are no command frames, a data frame is transmitted: to send a command frame at the start of operation, the user software must program a command frame in the TX_FIFO before enabling DSPI (MCR[HALT] = 0).
- The second trigger sets off the transmission of another data frame.
- Between the second and third trigger, two command frames are pushed into the TX_FIFO.
- At third trigger, a command frame is transmitted as the TX_FIFO is not empty: since only 16 bits or less are transmitted, no transmission happens till next trigger. This is marked as the “Passive Time”. The passive time is added in all frames after frame transmission completes and until next trigger pulse is detected.
- At fourth trigger, since the previous transmission was a command frame, a data frame is transmitted.
- At fifth trigger, since one command frame is pending in TX_FIFO and last transmitted frame was not a command frame, a command frame is transmitted.
- At sixth trigger (not shown), the process continues.

49.4.11 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

49.4.11.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

49.4.11.2 Parity for DSI frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode, the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation, clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

49.4.12 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. *Table 1006* lists these conditions.

Table 1006. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
DSI Transfer Complete	DSITCF	Yes	—
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—
DSI Parity Error	DPEF	Yes	—
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

49.4.12.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note: This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

49.4.12.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[TFFF] flag clears automatically when DMA is used to fill TXFIFO.

Note: To clear SR[TFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

Wait until SR[TFFF] = 1

Write data to PUSHR using CPU.

Clear SR[TFFF] by writing a '1' to its location. If TXFIFO is not full, this flag will not clear.

49.4.12.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note: SR[CMDFFF] flag clears automatically when DMA is used to fill CMD FIFO.

Note: To clear SR[CMDFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

Wait until SR[CMDFFF] = 1

Write data to Command field of PUSHR using CPU.

Clear SR[CMDFFF] by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.

49.4.12.4 Transmit FIFO Invalid Write interrupt request

The Transfer Fifo Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transfer Fifo Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

49.4.12.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

49.4.12.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

49.4.12.7 SPI Transfer Complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

49.4.12.8 DSI Transfer Complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

49.4.12.9 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

49.4.12.10 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[RFDF] flag clears automatically when DMA is used to drain RXFIFO.

Note: To clear SR[RFDF] when not using DMA, follow these steps for every POP performed using CPU to drain RXFIFO:

Wait until SR[RFDF] = 1

Read data from POPR using CPU.

Clear SR[RFDF] by writing a ‘1’ to its location. If RXFIFO is not empty, this flag will not clear.

Note: Clearing SR[RFDF] by writing a ‘1’ to its location after performing MCR[CLR_RXF], will not happen if RXFIFO is not empty because the data from shift register can be transfered just after clear operation is performed.

49.4.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

49.4.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

49.4.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

49.4.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR1/0 data, masked with DSPI_DIMR1/0, has been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

49.4.13 Power saving features

The DSPI supports the following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

Note: When in Slave Mode, the module can only be put in Low Power Modes (such as STOP and HALT) once the Master module has transitioned to the Low Power Mode as well.

49.4.13.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter External Stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

If a DSPI block is configured in Slave mode, External Stop mode requests must be run after the last clock cycle or Low-power mode is not entered.

49.4.13.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting the MDIS bit in the MCR. The module disable mode can also be initiated by hardware.

When the MDIS bit is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.

If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible.

Certain read or write operations have a different effect when the DSPI is in the module disable mode:

- Reading the RX FIFO Pop register does not change the state of the RX FIFO.
- Writing to the FIFO Push register does not change the state of the TX FIFO or CMD FIFO.
- Clearing of the FIFOs has no effect.
- Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect.
- All status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect.
- Writing to the TCR during module disable mode has no effect.
- Interrupt and DMA request signals cannot be cleared.

49.5 Initialization/application information

This section describes how to initialize the DSPI module.

49.5.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI Configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a ‘1’ to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a ‘1’ to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

49.5.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a ‘1’ to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

49.5.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

49.5.4 Baud rate settings

Table 1007 shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

Table 1007. Baud rate values (bps)

Baud Rate scaler values (DSPIn_CTAR[BR])	Baud rate divider prescaler values (DSPI*n*_CTAR[PBR]) 2	3	5	7
2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
64	781 kHz	521 kHz	312 kHz	223 kHz
128	391 kHz	260 kHz	156 kHz	112 kHz
256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

49.5.5 Delay settings

Table 1008 shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 1008. Delay values

		Delay prescaler values (DSPIn_CTAR[PBR])			
		1	**3**	**5**	**7**
Delay scaler values	**2**	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

49.5.6 Calculation of FIFO pointer addresses

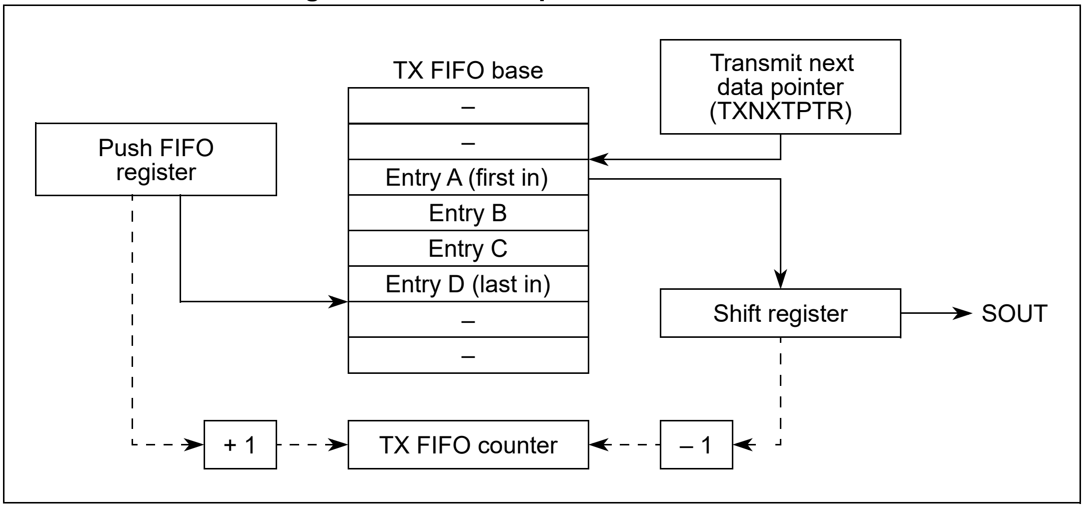
Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped.

- For TX FIFO, the first-in pointer is the Transmit Next Pointer (TXNXTPTR).
- For CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR).
- For RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR).

Figure 932 illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts are applicable to the CMD FIFO and RX FIFO.

Refer to *Section 49.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*, *Section 49.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* and *Section 49.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism* for details on the FIFO operation.

Figure 932. TX FIFO pointers and counter



49.5.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

Equation 43

$$\mathrm{First-inEntryAddress} = \mathrm{TXFIFOBase} + (4 \times \mathrm{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

Equation 44

$$\mathrm{Last-inEntryAddress} = \mathrm{TXFIFOBase} + 4 \times (\mathrm{TXCTR} + \mathrm{TXNXTPTR} - 1)\mathrm{mod}(\mathrm{TXFIFOdepth})$$

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXTPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

49.5.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

Equation 45

$$\mathrm{First-inEntryAddress} = \mathrm{CMDFIFOBase} + (4 \times \mathrm{CMDNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

Equation 46

$$\mathrm{Last-inEntryAddress} = \mathrm{CMDFIFOBase} + 4 \times (\mathrm{CMDCTR} + \mathrm{CMDNXTPTR} - 1) \mathrm{mod}(\mathrm{CMDFIFOdepth})$$

CMD FIFO Base – Base address of CMD FIFO
CMDCTR – CMD FIFO Counter
CMDNXTPTR – Command Next Pointer
CMD FIFO Depth – Command FIFO depth, implementation specific

49.5.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

Equation 47

$$\mathrm{First-inEntryAddress} = \mathrm{RXFIFOBase} + (4 \times \mathrm{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

Equation 48

$$\mathrm{Last-inEntryAddress} = \mathrm{RXFIFOBase} + 4 \times (\mathrm{RXCTR} + \mathrm{POPNXTPTR} - 1) \mathrm{mod}(\mathrm{RXFIFOdepth})$$

RX FIFO Base – Base address of RX FIFO
RXCTR – RX FIFO counter
POPNXTPTR – Pop Next Pointer
RX FIFO Depth – Receive FIFO depth, implementation specific

50 LINFlexD

50.1 Introduction

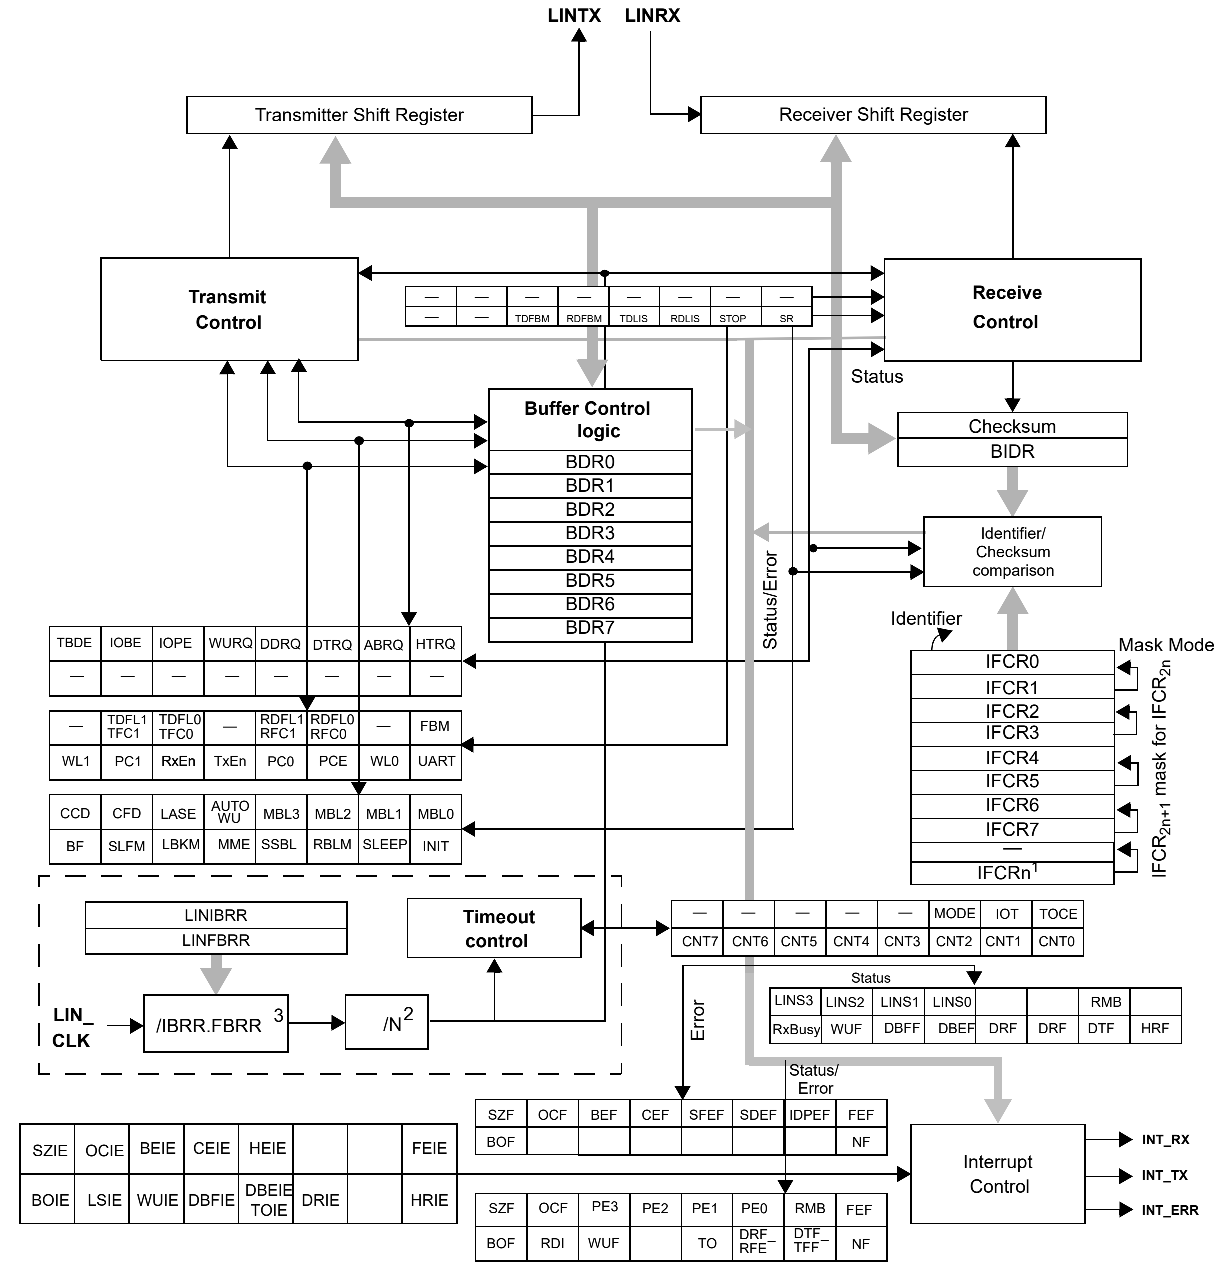
The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 933. Block diagram



Notes:

1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.
2. For LIN mode N = 16 and N is programmable by user in UART mode.
3. FBRR is not usable when reduced over-sampling is enabled in UART mode.

50.2 Main features

LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

50.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)

50.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers (refer to *Section 50.3.2.8: Baud rate generation*)
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management

- The maximum baud rate achievable is 25 Mbit/s.

- For bit rate (BR) <= LIN_CLK/16
  - 16 times oversampling
  - 3:1 majority voting
- For LIN_CLK/16 < BR <= LIN_CLK/8
  - OSR = 8
  - 3:1 majority voting
- For LIN_CLK/8 < BR <= LIN_CLK/4
  - OSR = 4,5,6
  - 1:1 voting

50.2.3 Standard features

DMA2x bus interface.

50.3 Functional description

50.3.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task - all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

50.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 934. Frames

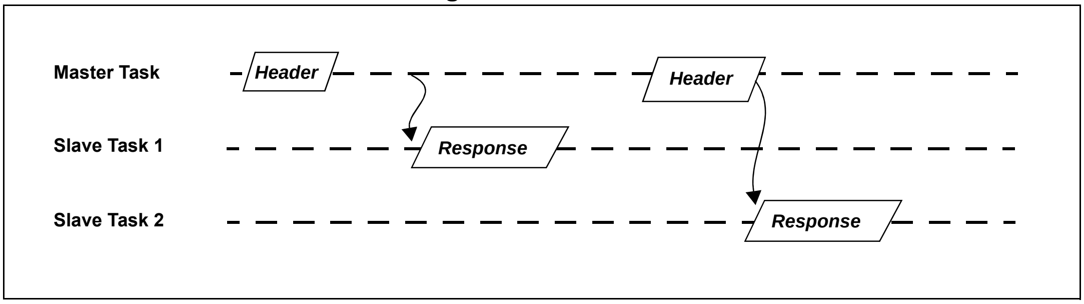


Figure 935. Structure of LIN frame

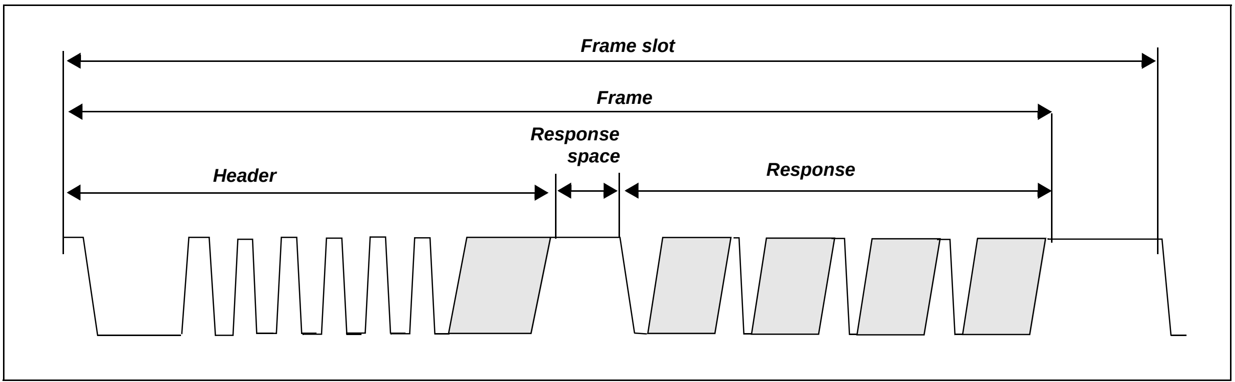
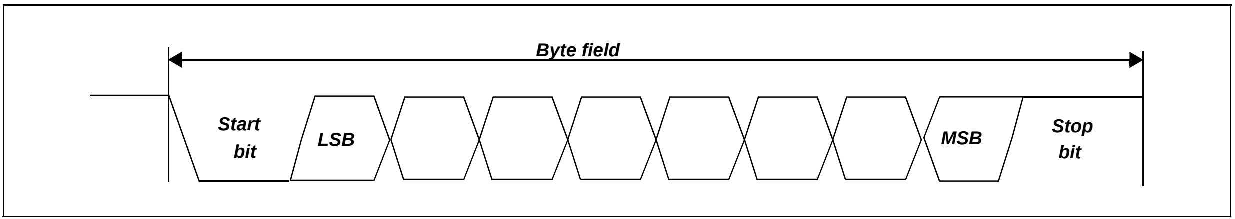


50.3.1.2 Data field

Each byte is transmitted as shown in *Figure 936*. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

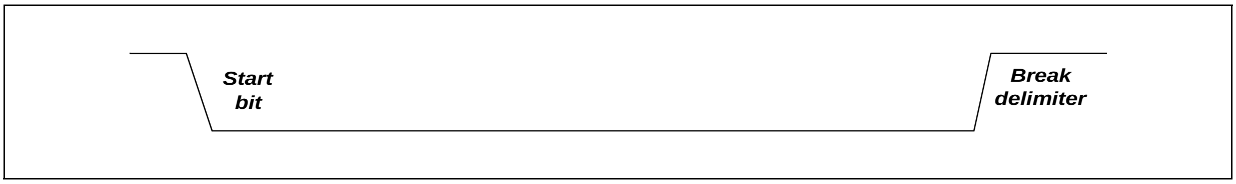
Figure 936. Structure of byte field



50.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in *Figure 937*. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

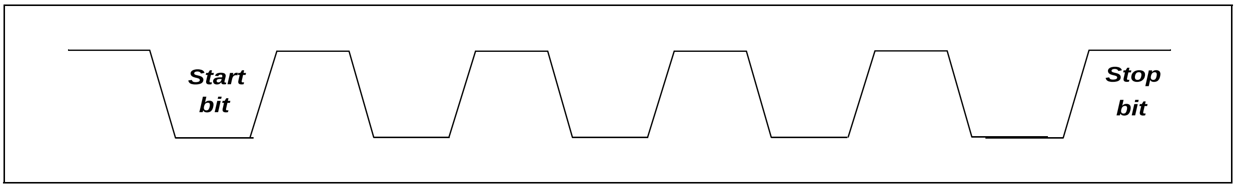
Figure 937. Break field



50.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

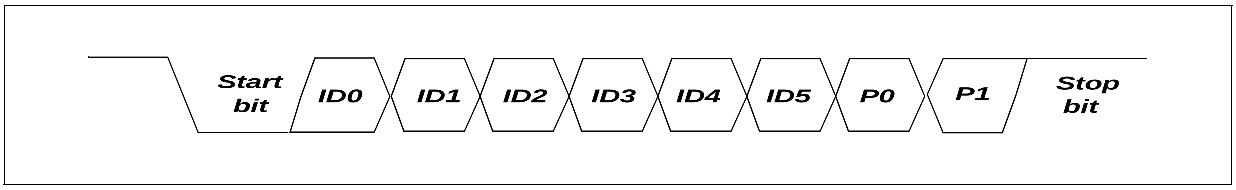
Figure 938. Sync byte field



50.3.1.5 Identifier

The Identifier field consists of two sub fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 939. Identifier field



P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

50.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it used for communication with LIN 2.0 slaves.

50.3.2 LINFlexD features

50.3.2.1 Operating modes

The LINFlexD has three operating modes: Initialization, Normal, and Sleep modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

50.3.2.1.1 Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. Set up the baud rate registers
2. Reset the UART bit
3. Select the mode (Master or Slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

50.3.2.1.2 Normal mode (NM)

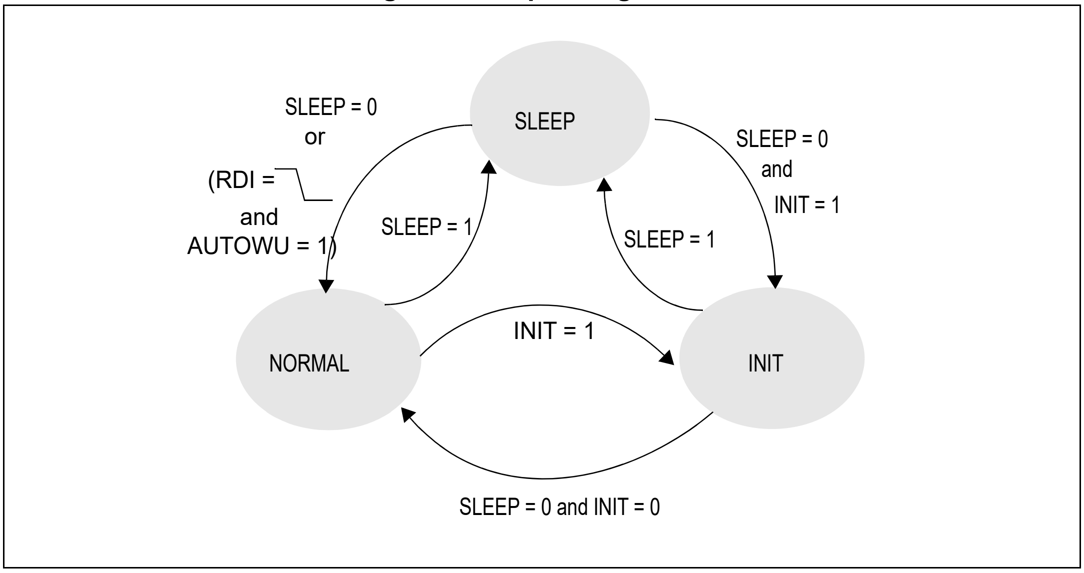
Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

50.3.2.1.3 Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to *Section 50.3.2.10: Wakeup management*.

Figure 940. Operating modes



50.3.2.2 Test mode

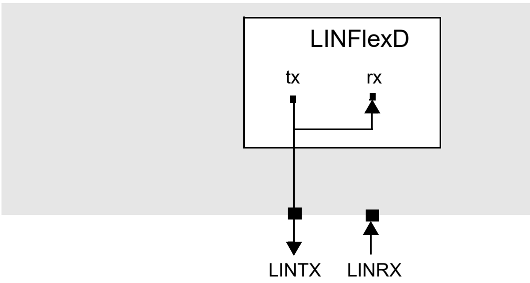
50.3.2.2.1 Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and

Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

Figure 941. Loop Back test mode



50.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

50.3.2.3.1 Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

50.3.2.3.2 Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

50.3.2.3.3 Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

50.3.2.3.4 Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

50.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

50.3.2.4.1 Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

50.3.2.4.2 Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

50.3.2.5 Errors

50.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- That the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,

  or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

   If there is an inconsistent Sync Field error, it means that:

   D > 14.0625%

   If there is no error, it means that:

   D < 14.84375%

   If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.
2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 0)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

1. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

50.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles. Bit error is not checked during break field transmission.

Example 1

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In *this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.*

50.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

50.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINIER.

50.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

50.3.2.5.6 Timeout error

Figure 942. Incomplete response (for example, missing checksum)

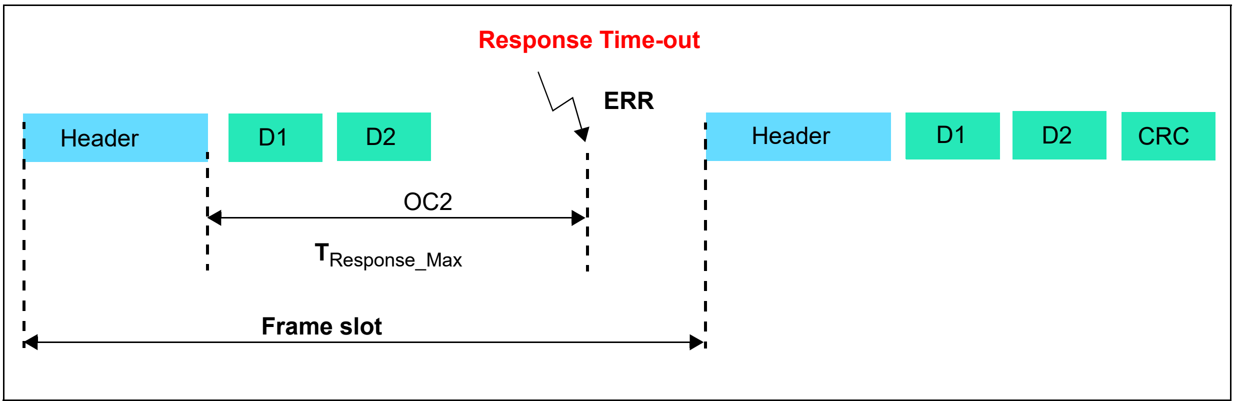


Figure 943. No response

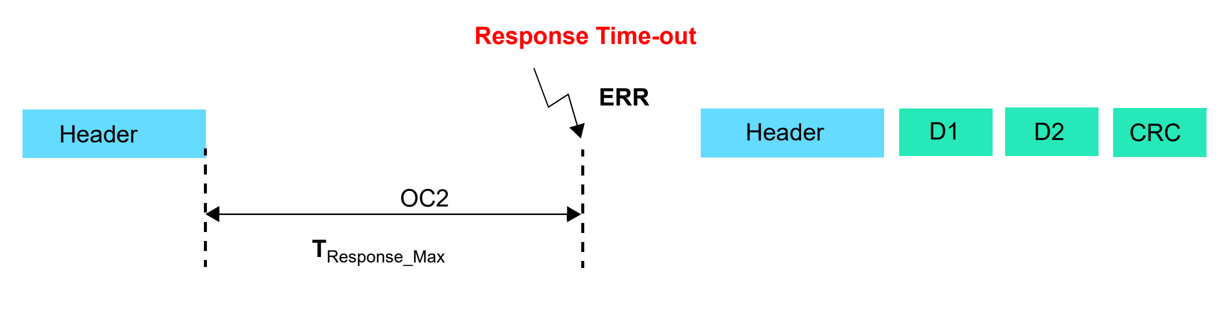


Header timeout mechanism

- Master mode
  - ocr_2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further ocr_2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the ocr_2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the ocr_2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, ocr_2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = 1.4 × (9 × 10 bit time) and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:

    At the end of the ID, ocr_2 is loaded with 36 (maximum possible response space)

    At the end of the first_data_byte it is reloaded again according to DFL

    Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length).
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

  Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit.
  - If the counter starts after 11 Tbit, the HTO value is 56 – 11 = 45 Tbit

  The reset value of HTO is 45 and this register can only be programmed in slave mode.

  As response space is now included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

  The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

50.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8^{th}, 9^{th}, and 10^{th} samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2^{nd}, 3^{rd}, and 4^{th} samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (refer to *Section 50.4.2.4: LIN Error Status Register (LINESR)*).

50.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

50.3.2.6.1 Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2*n* and 2*n*+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2*n* or IFCR2*n*+1 (if the corresponding FACT bit is set).

50.3.2.6.2 Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2*n* is the filter and 2*n*+1 acts as a mask for it. The FACT bit for filter 2*n*+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

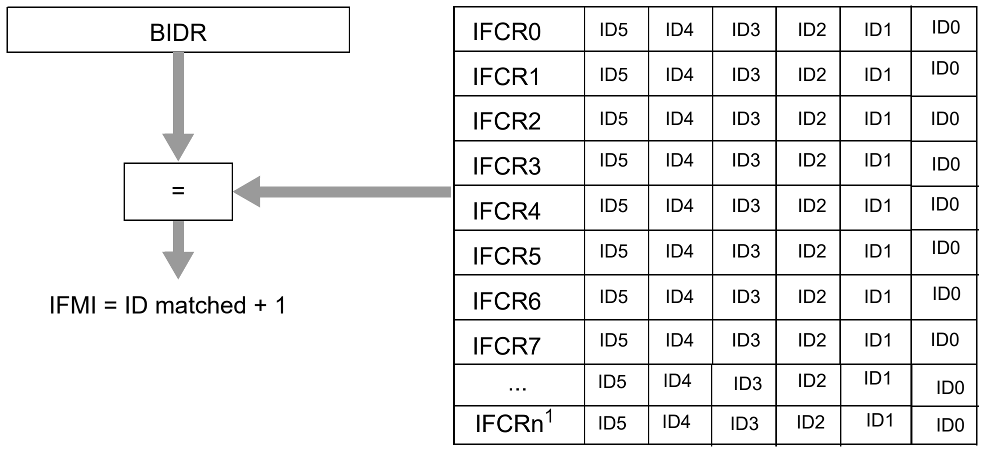
If there is a match of identifier with the *m*th filter in any mode, then *m*+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

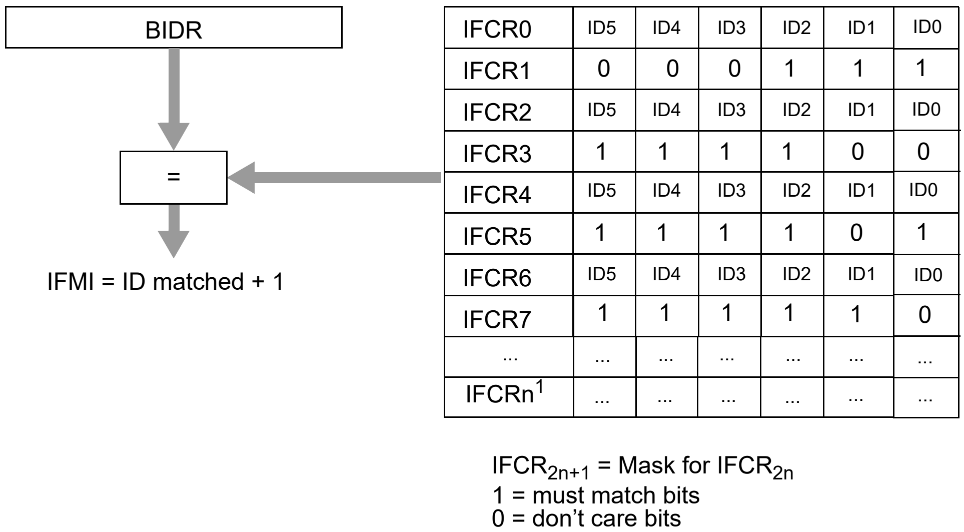
Note: If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.

Figure 944. Identifier List mode



1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.

Figure 945. Identifier Mask mode



1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.

50.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 1009. 10-bit-shift-register sample register

Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x(1)	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: due to sampling during transition of the bit, the bit value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. So ‘x’ refers to an indeterministic value.

50.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to *Table 1009* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to '0' (2 or more), then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to '0' then Noise flag is set.

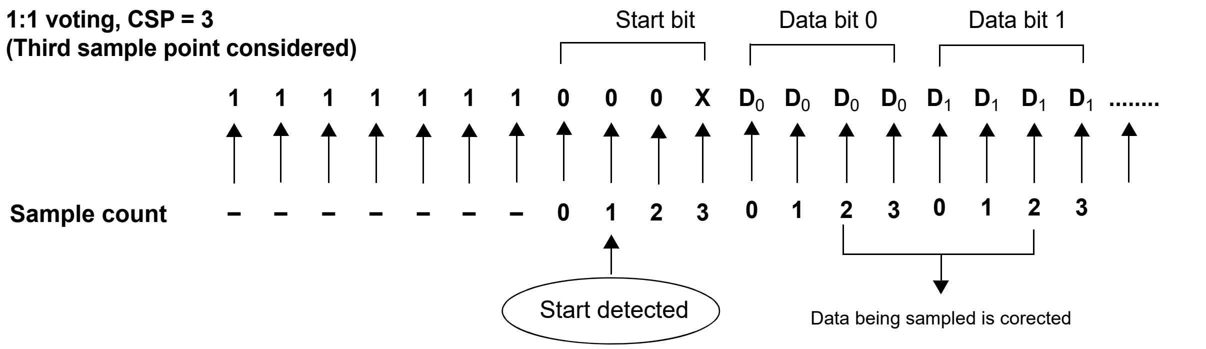
50.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to *Table 1009* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to '1' (2 or more), then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

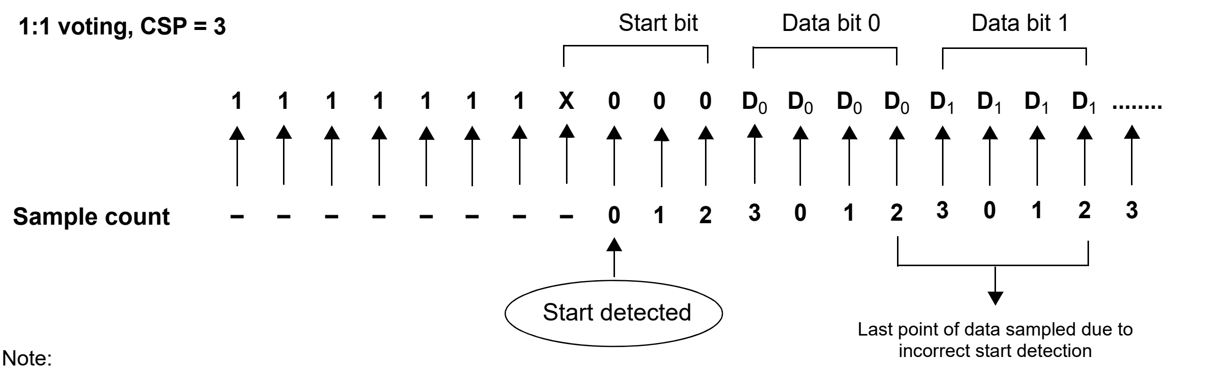
Figure 946. Start detection and sampling for over sampling rate = 4 (Case 1)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time.Therefore ‘X’ refers to a indeterministic value.

Figure 947. Start detection and sampling for over sampling rate = 4 (Case 2a)



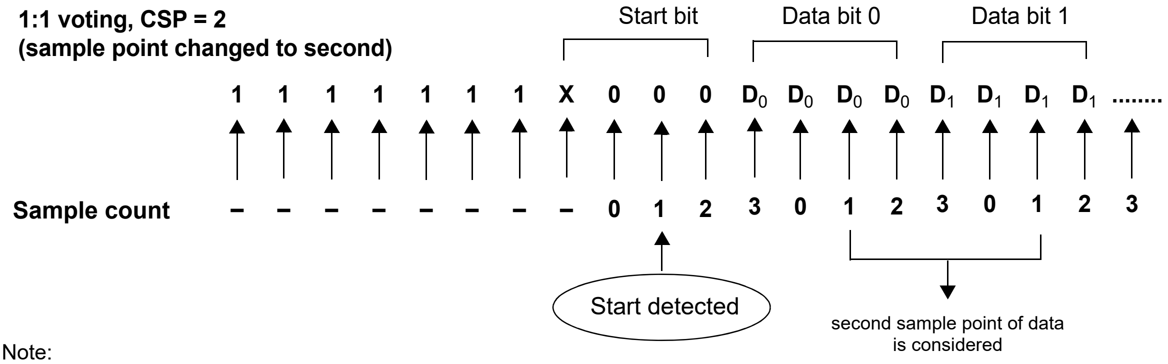
Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two resulting in the following situation:

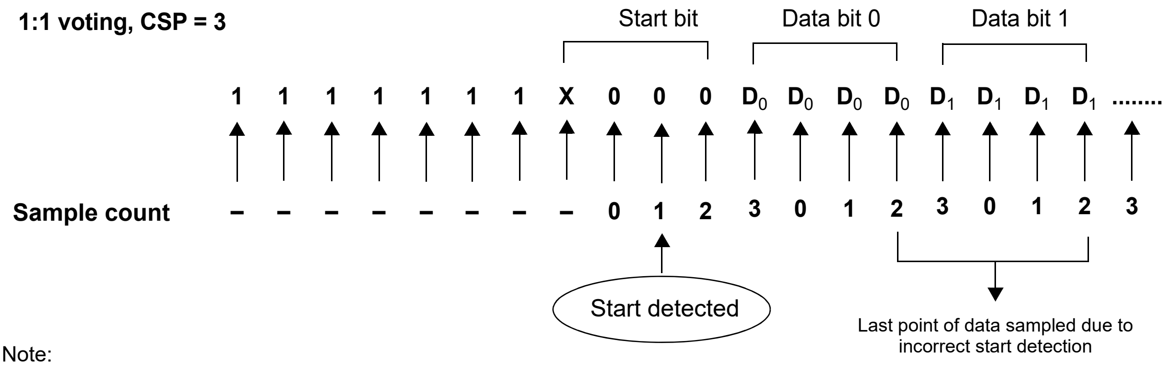
Figure 948. Start detection and sampling for over sampling rate = 4 (Case 2b)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

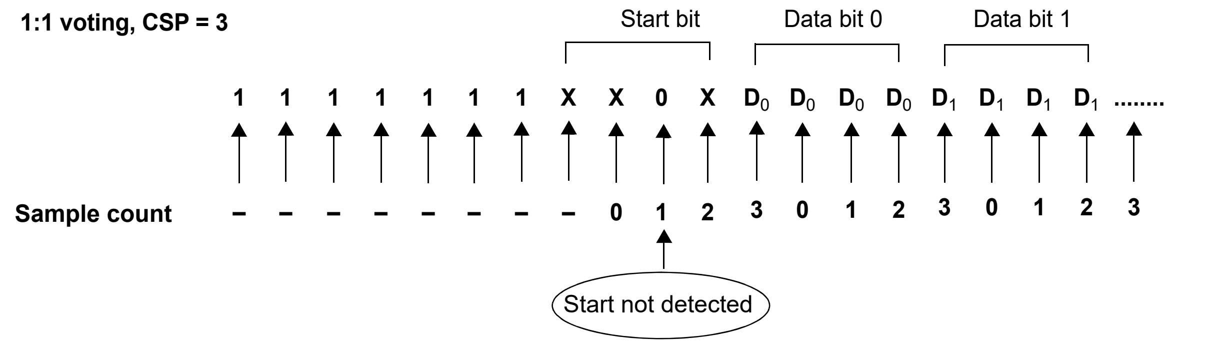
Figure 949. Start detection and sampling for over sampling rate = 4 (Case 3)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

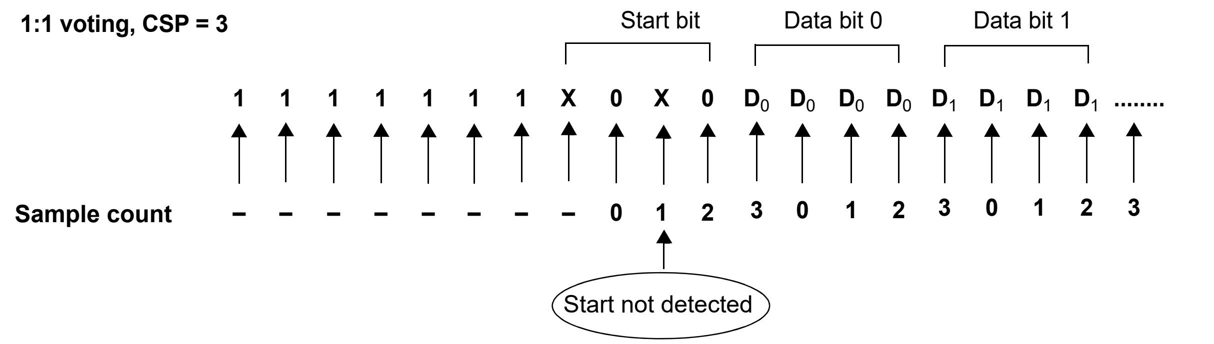
Figure 950. Start detection and sampling for over sampling rate = 4 (Case 4)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

Figure 951. Start detection and sampling for over sampling rate = 4 (Case 5)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

50.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Equation 49 $$Tx = Rx = LIN\_CLK / (16 \times LDIV)$$

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled LINFBRR is not used and LDIV contains only the integer part of LINIBRR.

Example 2

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Baud rate = 80 MHz/(16 x 1041,67) = 4.8 Kbit/s

Example 3

When ROSE = 1 (Only for UART mode):

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, OSR = 4

Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

Note: Due to design constraints the maximum baud rate achievable is 25 Mbit/s.
The relationship "(2/3)* LIN_CLK $\geq$ PBRIDGEx_CLK > 1/3*LIN_CLK" should be maintained)

50.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

50.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

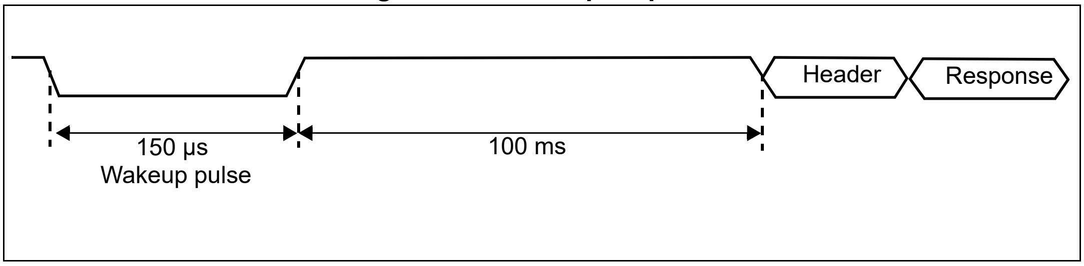
In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1

   On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0

   On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 952. Wakeup sequence



50.3.2.11 Use case and limitations

In LIN mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

50.3.3 Timer

There is an 8-bit counter which has different behavior in different modes.

In Output Compare Mode (LINTCSR[MODE]= 1): This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has soft reset the LIN IP through GCR [SR] bit to get reset the output compare flag (LINESR[OCF]).

In LIN mode: The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

50.3.4 UART mode

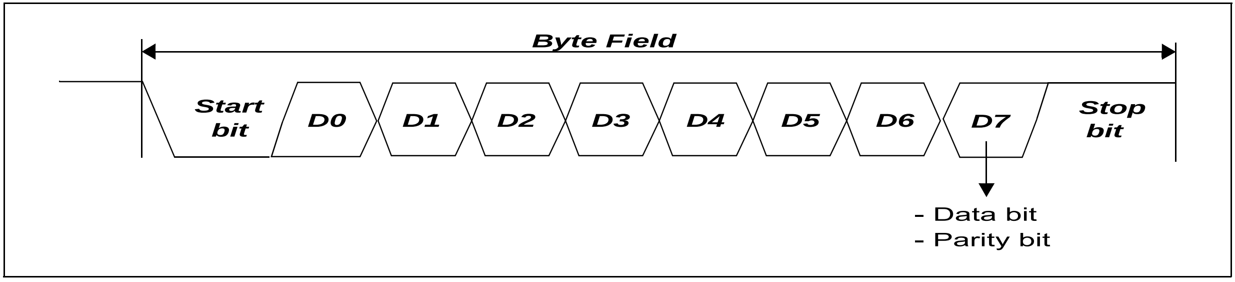
The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames,16-bit frames,17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

50.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

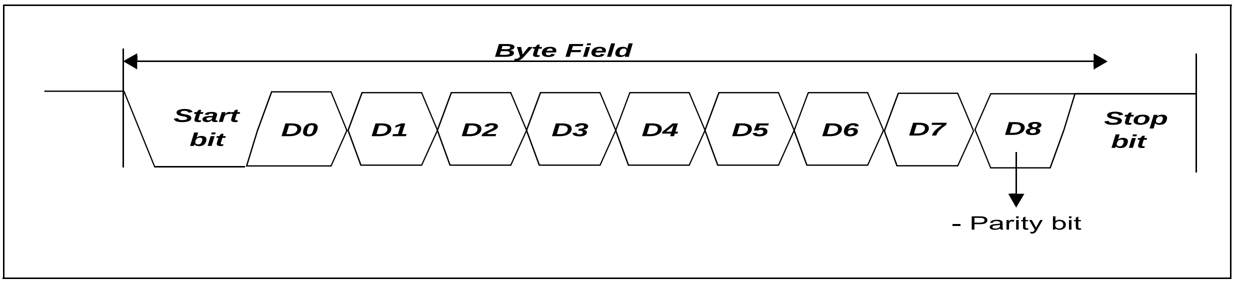
Figure 953. UART mode 8-bit data frame



50.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

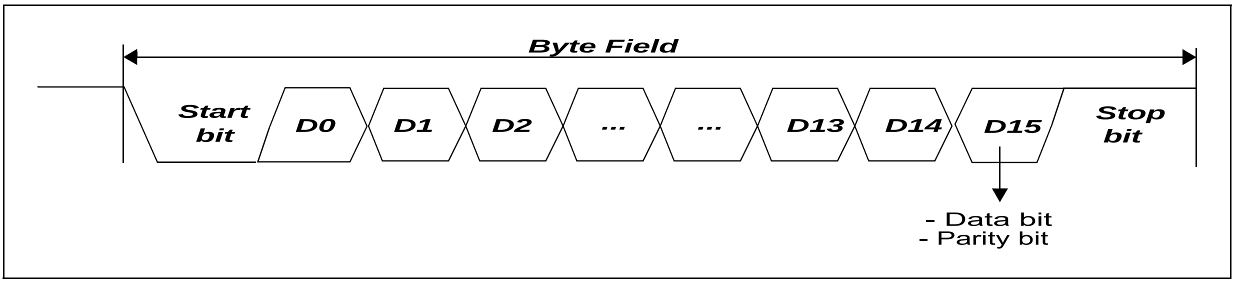
Figure 954. UART mode 9-bit data frame



50.3.4.3 16-bit data frames

The 16th bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

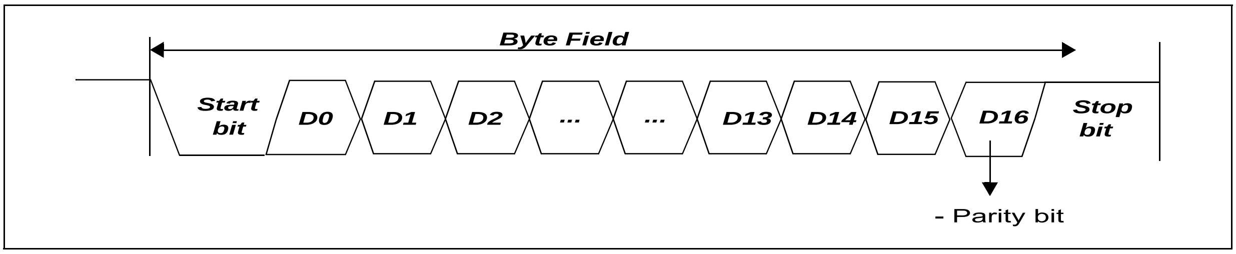
Figure 955. UART mode 16-bit data frame



50.3.4.4 17-bit frames

The 17th bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

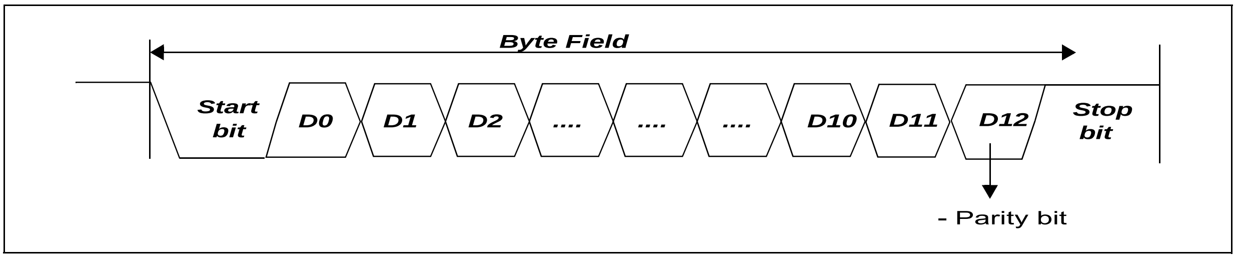
Figure 956. UART mode 17-bit data frame



50.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

Figure 957. UART mode 13-bit data frame



50.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in *Figure 958*.

Figure 958. Structure of 8-byte buffer

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1.

The same applies for reception.

50.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Invalid writes to BDRL which generates IPS transfer error, also triggers data transmission at the same time.

When the FIFO is full, a read to DATA0 of BDRM reflects the content of DATA3 in BDRL. Proper functionality of the IP is not affected by this.

Table 1010. BDRL access in UART mode

IPS operation(1)	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

50.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 1011. BDRM access in UART mode

IPS operation[1]	Register [2]	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.
2. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.

Note: If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the *reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.*

If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.

If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.

If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.

If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.

When WLS bit = 1, BDRM access depends on WL bit setting.

When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.

In UART FIFO mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

50.3.5 DMA interface

50.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

50.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in *Table 1012* and *Table 1013*.

Table 1012. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: 1 8 bytes: normal frames 1 64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full

Table 1012. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
DMATXE[2**TX_CH_NUM][(1)]		High	DMA Tx channel enable (read/write) In UART or LIN master mode only channel 0 can be programmed. In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1. DMATXE[x] = 0b → TX channel x disabled DMATXE[x] = 1b → TX channel x enabled
DMARXE[2**RX_CH_NUM][(1)]		High	DMA Rx channel enable (read/write) In UART or LIN master mode only the channel 0 can be programmed. In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1. DMARXE[x] = 0b → RX channel x disabled DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation

Table 1013. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the Tranfer Control Descriptors (TCDs) referred to in this document are described in *Table 1014*.

Table 1014. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.

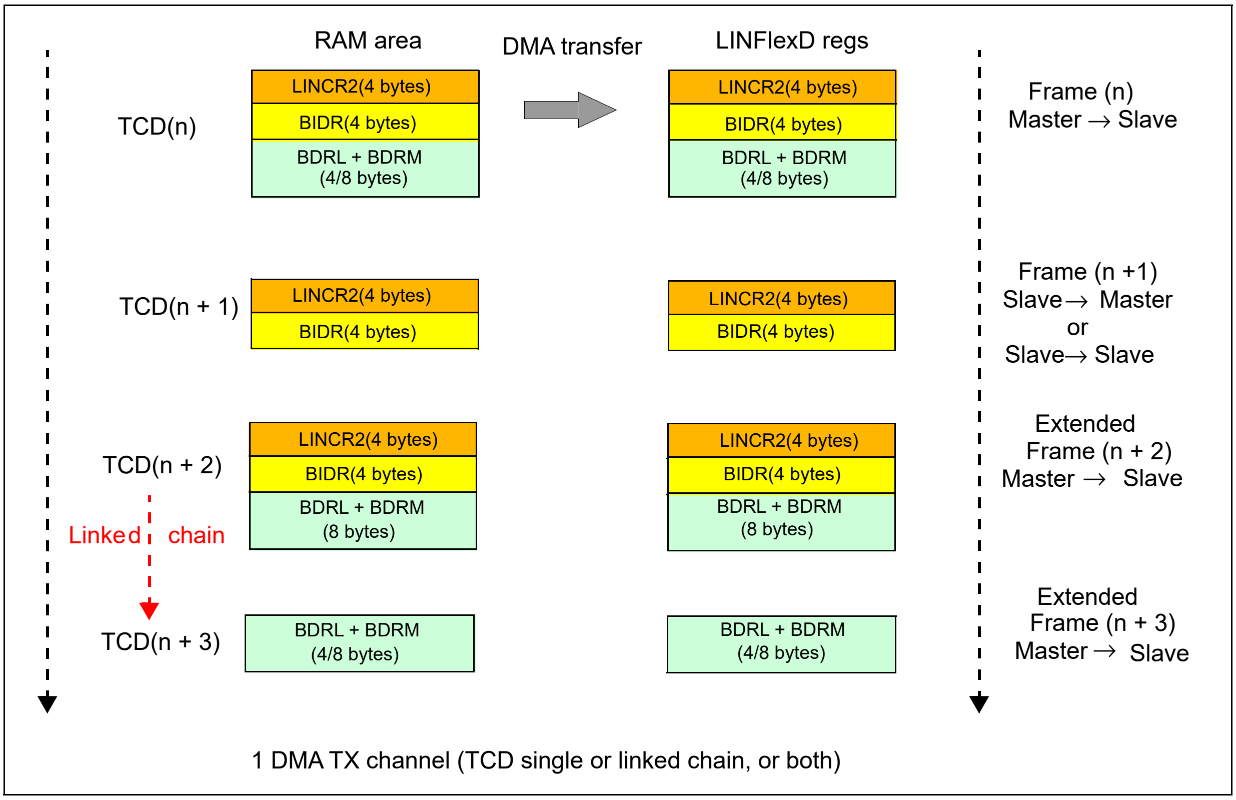
Table 1014. TCD control fields description (continued)

TCD field	Level	Description
SSIZE[2:0]	—	Source data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

50.3.5.3 Master node: TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 959*.

Figure 959. Master node: TX memory map



The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

Table 1015 provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 1015. Master node: Tx mode - Register setting

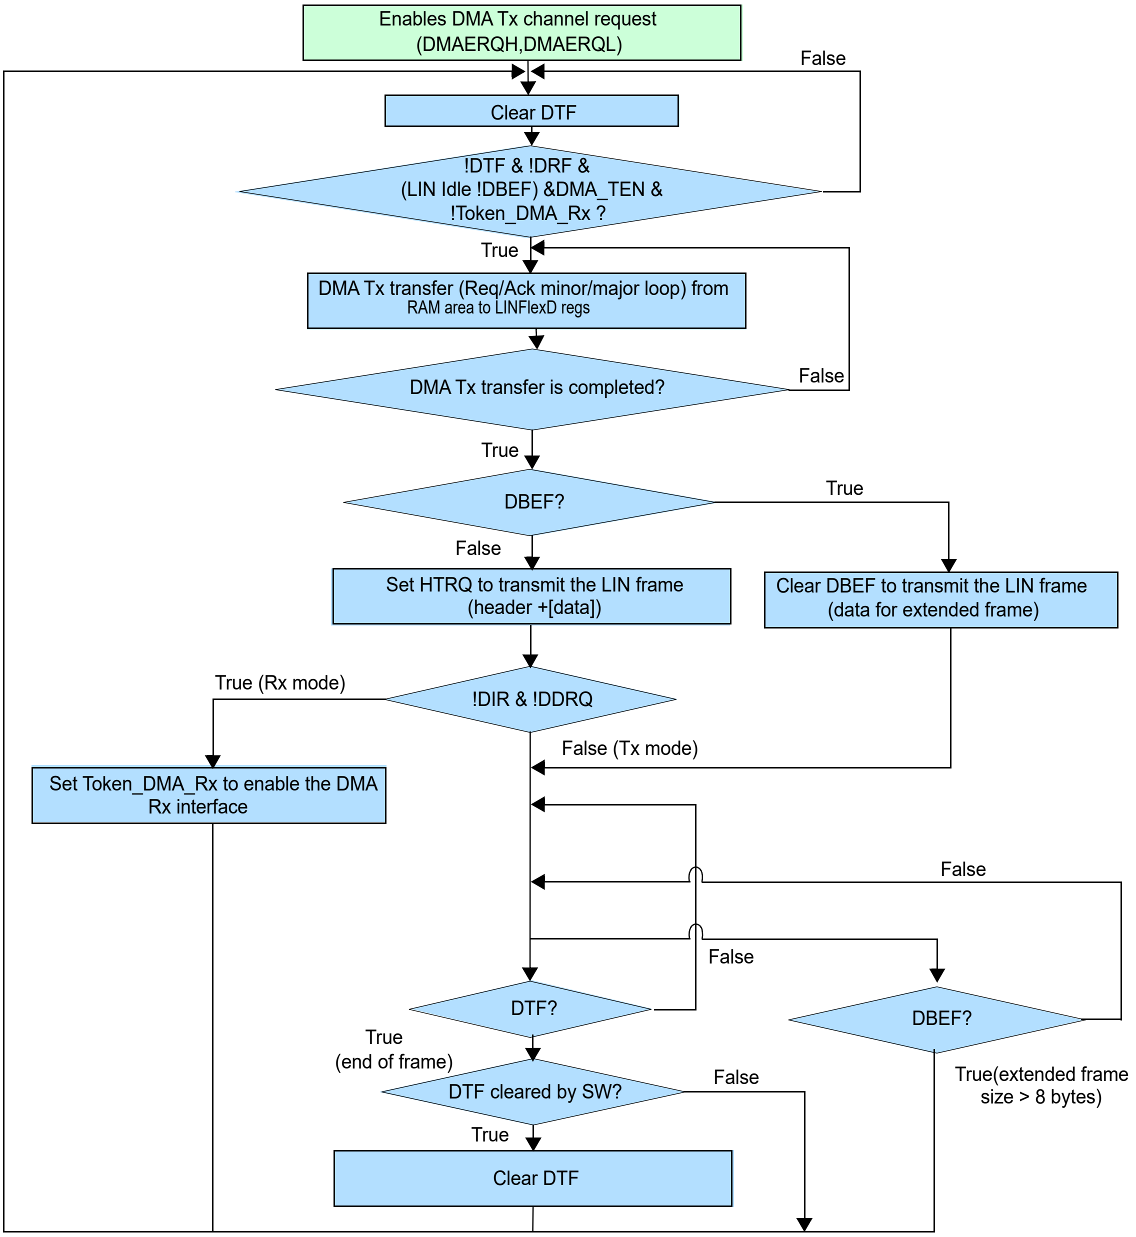
LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in *Figure 960*. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in *Table 1016*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1016. TCD setting: Master node -Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 960. Master node: DMA Tx FSM (concept scheme)

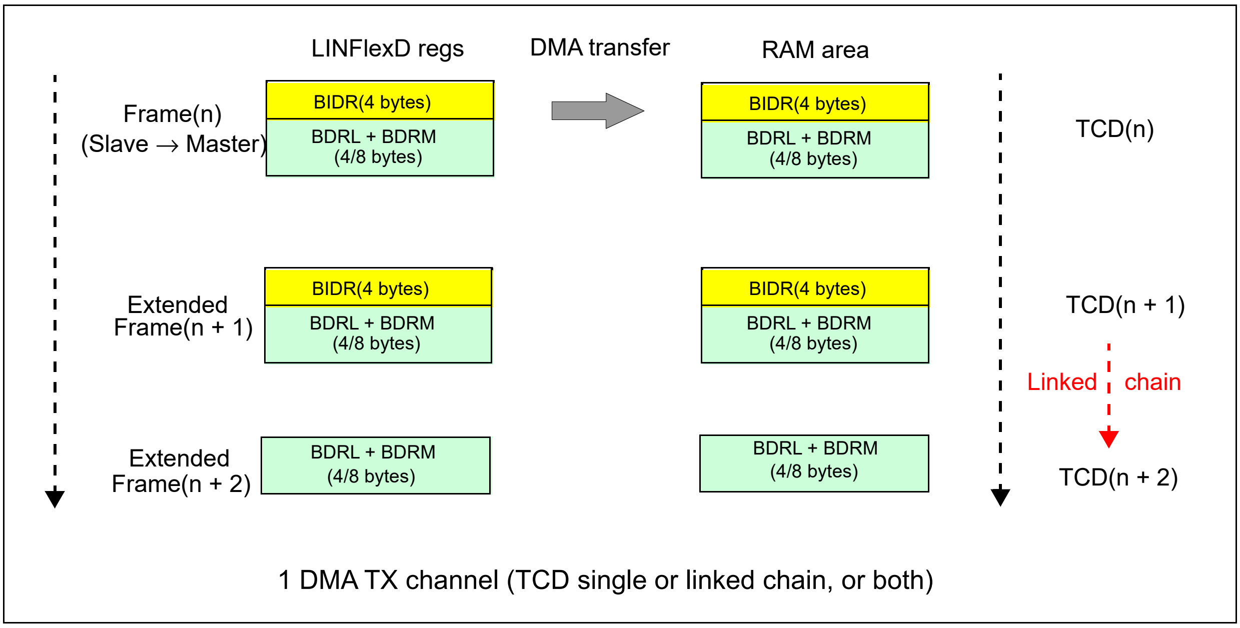


Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

50.3.5.4 Master node: RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 961*.

Figure 961. Master node: RX memory map



The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in *Figure 962*. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in *Table 1017*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

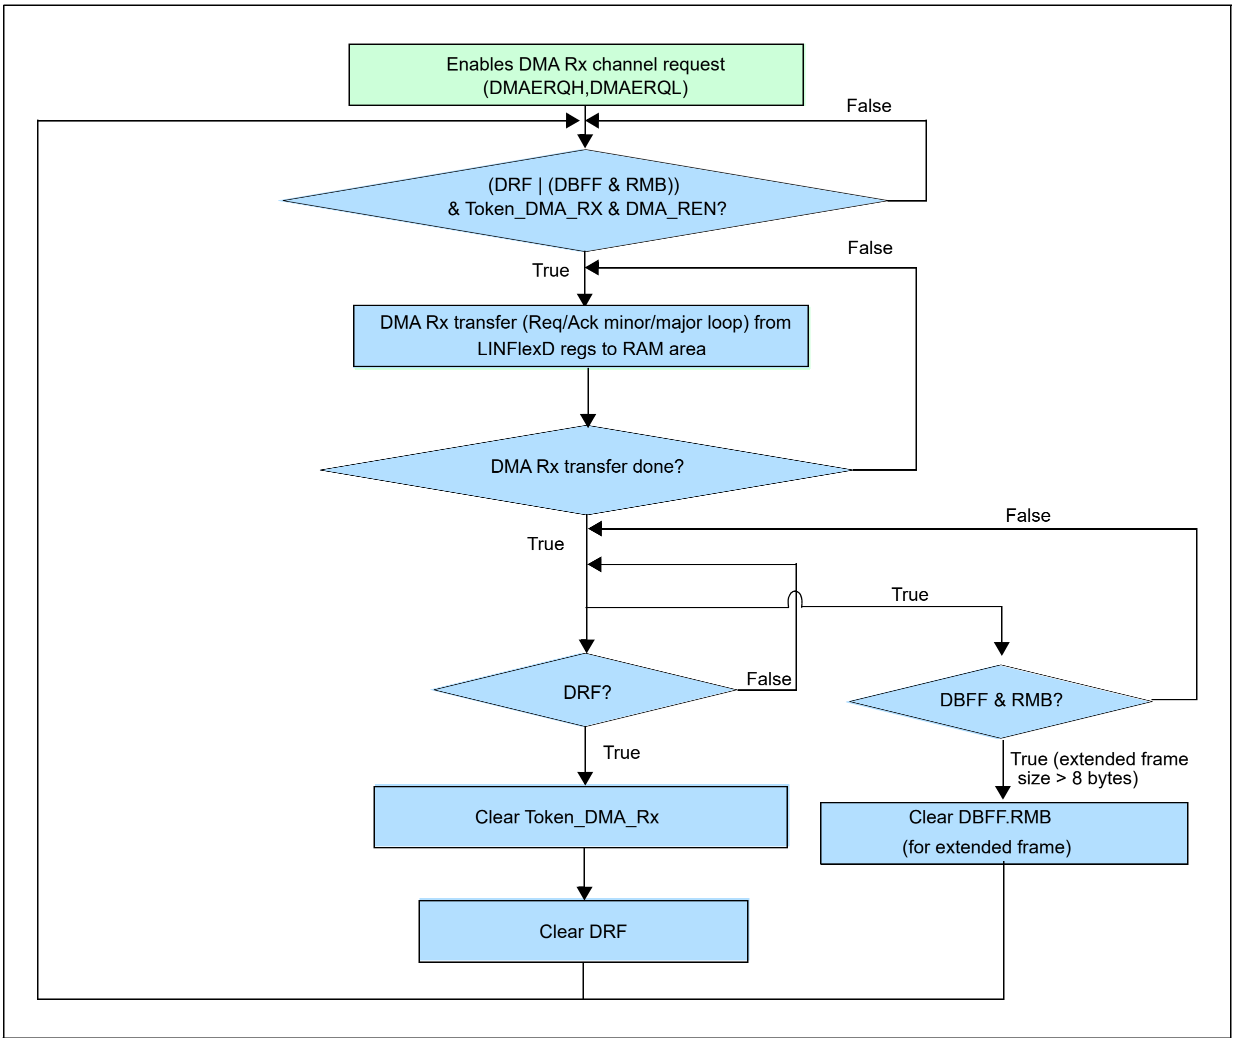
Table 1017. TCD setting: Master node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 1017. TCD setting: Master node - Rx mode (continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

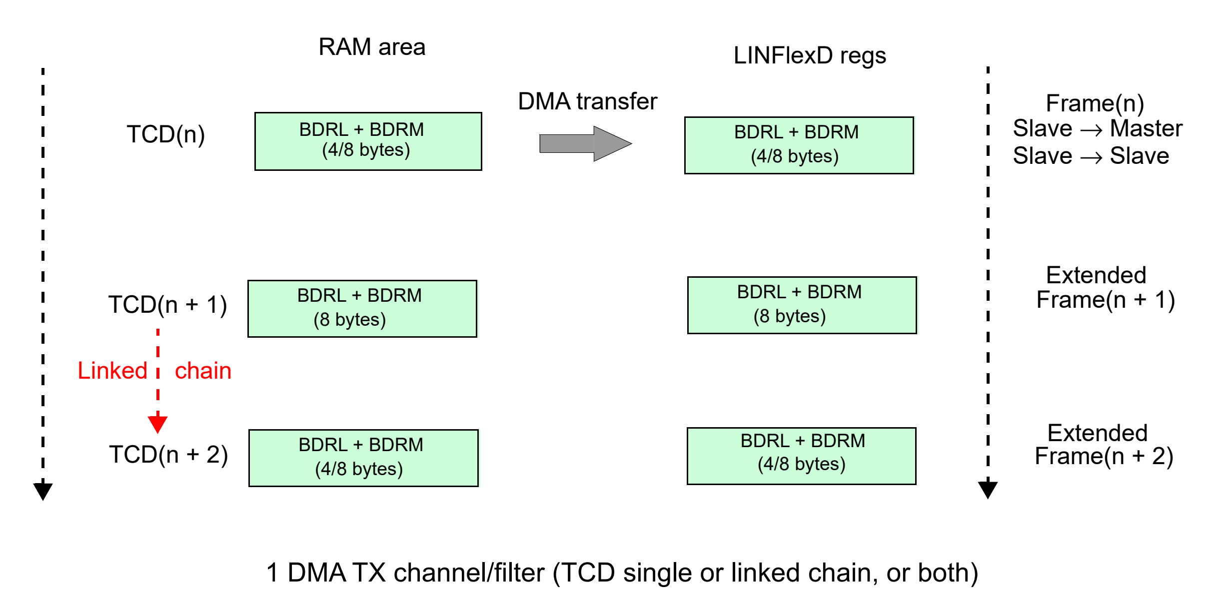
Figure 962. Master node — DMA Rx FSM (concept scheme)



50.3.5.5 Slave node: TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 963*.

Figure 963. Slave node — TX memory map



The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1018*.

Table 1018. Slave node: Tx mode - Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in *Figure 964*. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1019*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

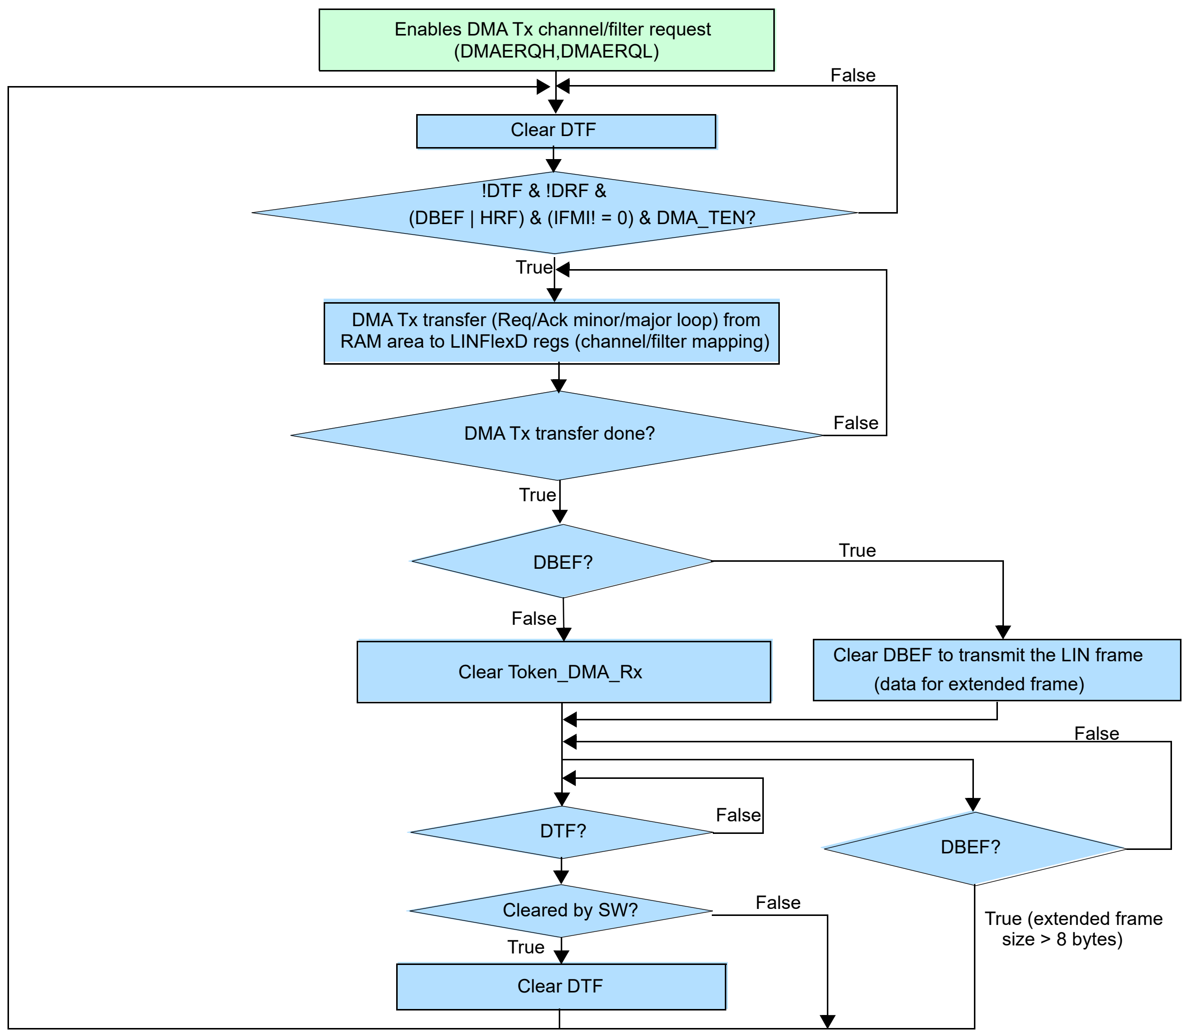
Table 1019. TCD setting: Slave node - Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 1019. TCD setting: Slave node - Tx mode (continued)

TCD field	Value	Description
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 964. Slave node: DMA Tx FSM (concept scheme)

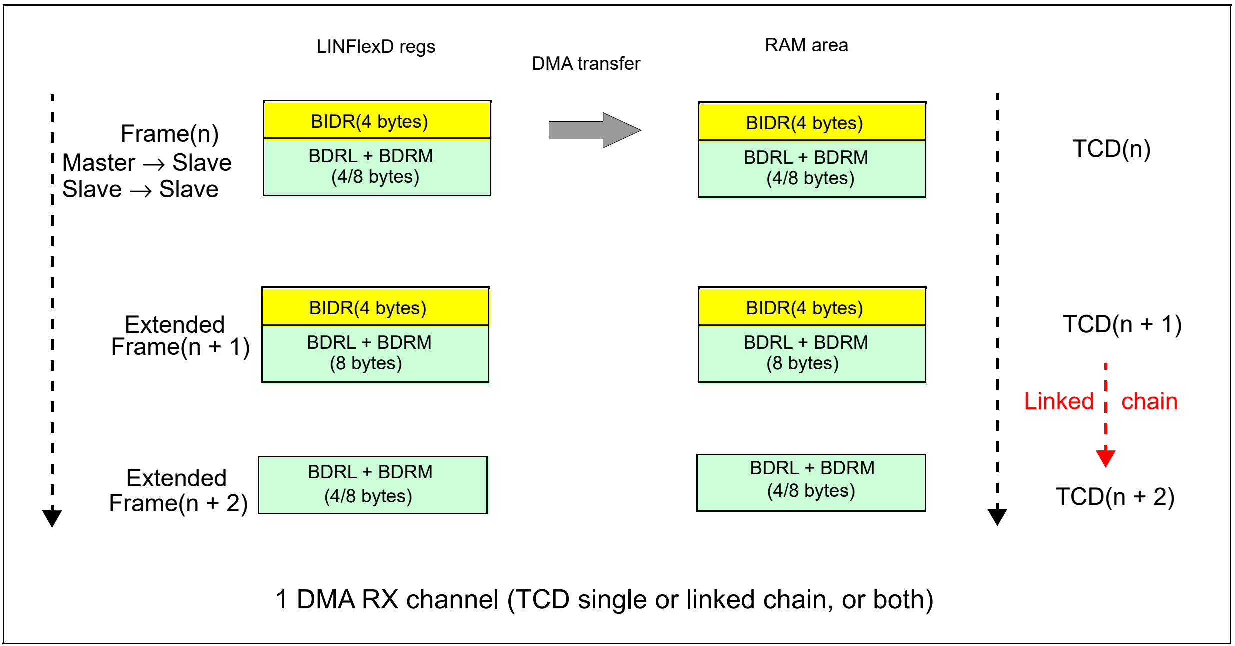


Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

50.3.5.6 Slave node: RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 965*.

Figure 965. Slave node: RX memory map



The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1020*.

Table 1020. Slave node: Rx mode - Register setting

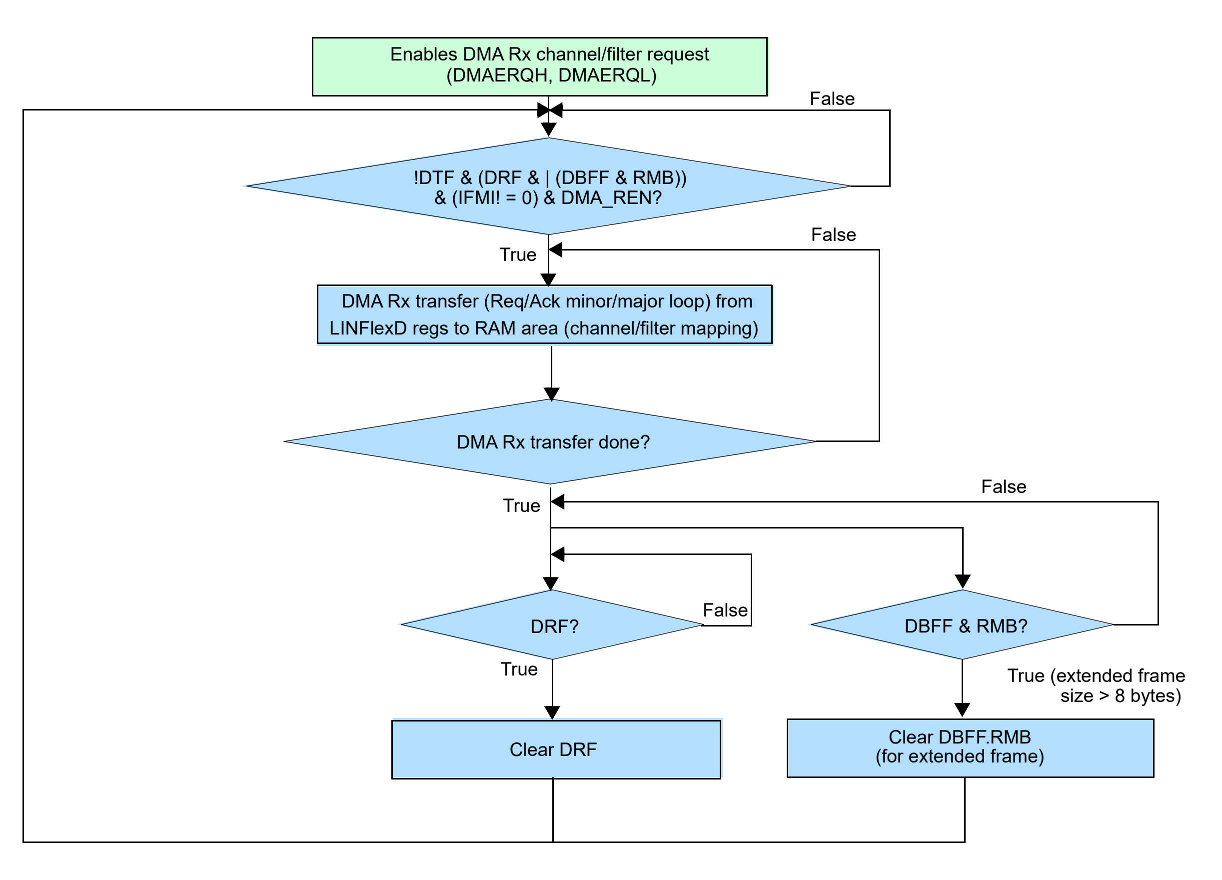
LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in *Figure 966*. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1021*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1021. TCD setting: Slave node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

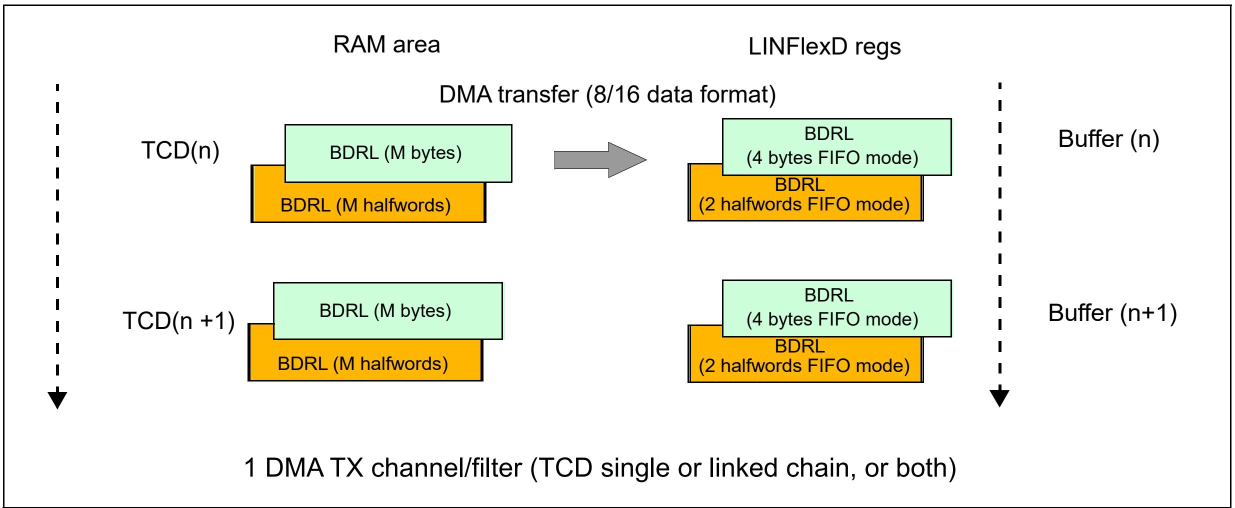
Figure 966. Slave node — DMA Rx FSM (concept scheme)



50.3.5.7 UART: TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 967*.

Figure 967. UART: TX memory map



The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

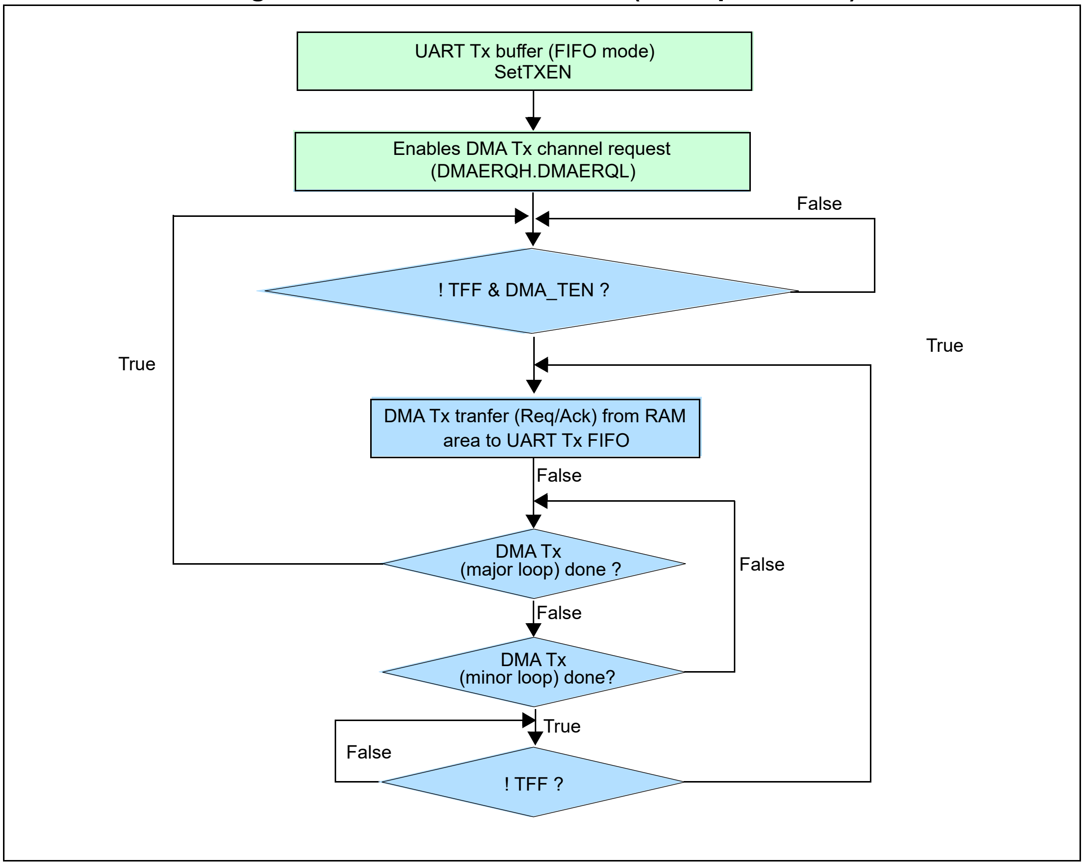
The concept FSM to control the DMA Tx interface is given in *Figure 968*. DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in *Table 1022*. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 1022. TCD setting: UART - Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	-M	-M × 2	—
DADDR[31:0][1]	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

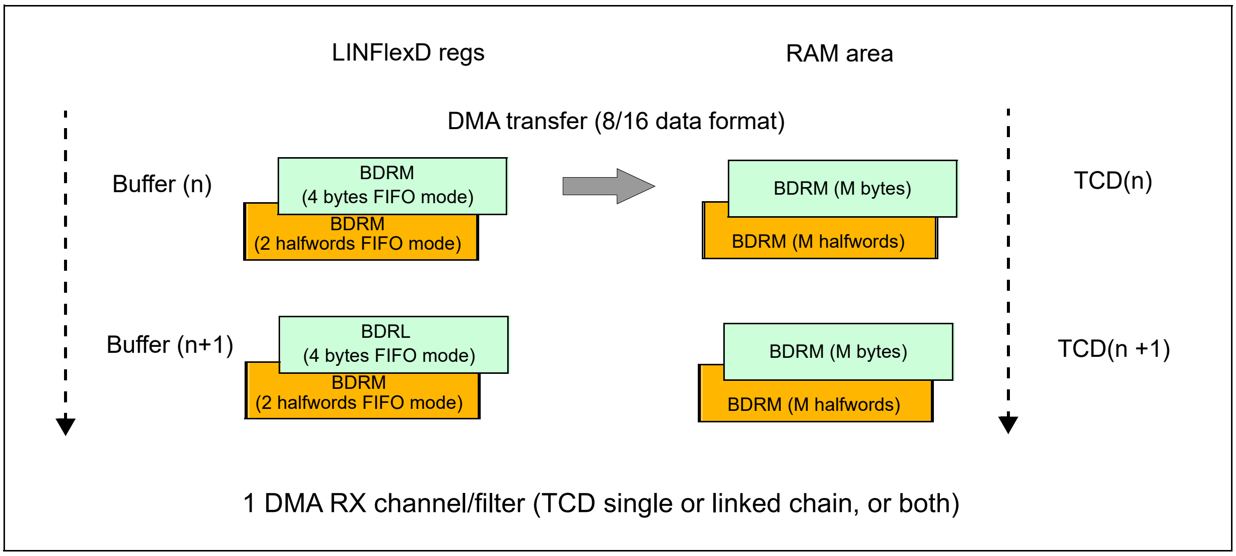
Figure 968. UART: DMA Tx FSM (concept scheme)



50.3.5.8 UART: RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Table 1023*.

Figure 969. UART: RX memory map



The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

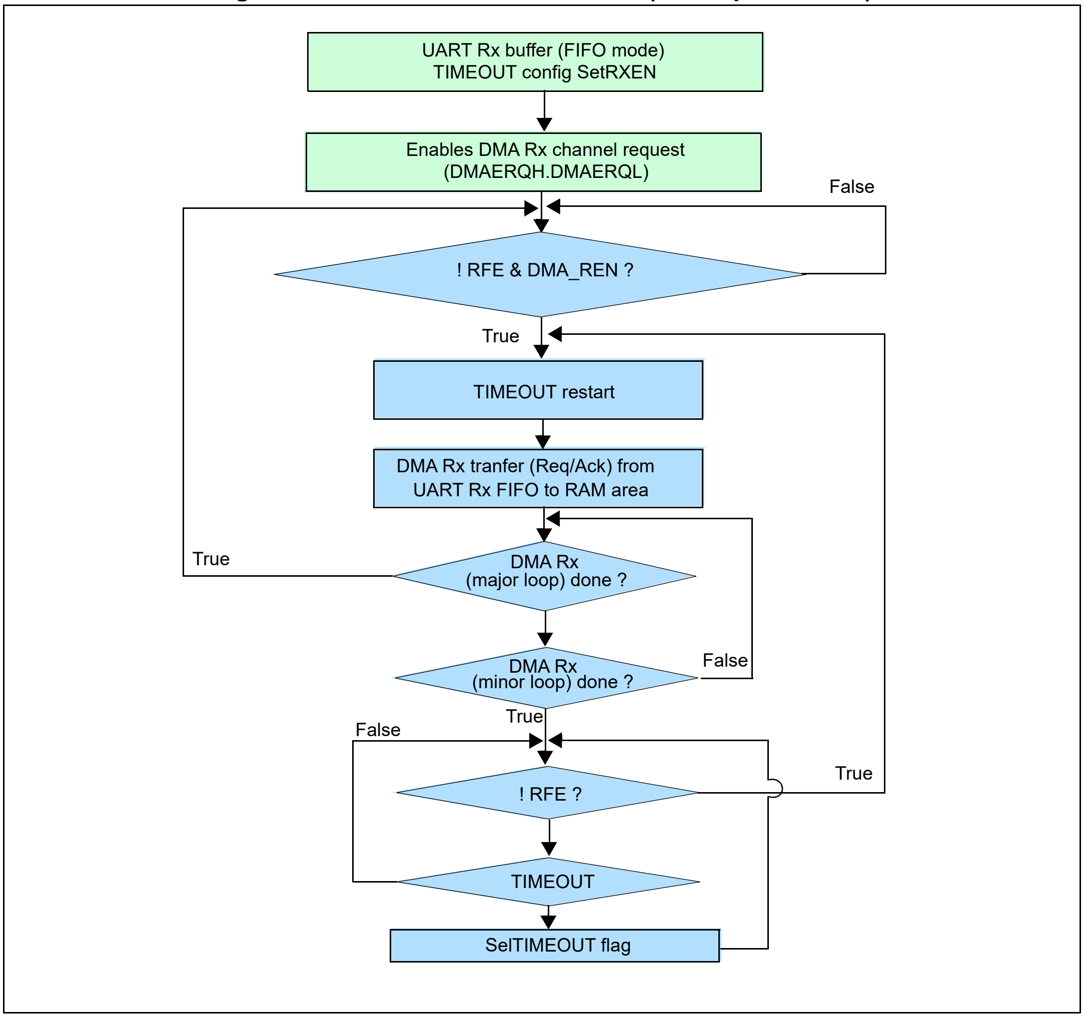
The concept FSM to control the DMA Rx interface is given in *Figure 970*. DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 1023. TCD setting: UART - Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0](1)	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	-M	-M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 970. UART — DMA Rx FSM (concept scheme)



50.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- ipd_req
  - DMA peripheral request, asserted until the DMA transfer has been completed.
- dma_done_lw
  - DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected.
- dma_ipd_complete
  - DMA major loop finished. It is asserted for one cycle after the data phase of the last write.
- dma_ipd_ack, dma_ipd_done
  - Unused in this implementation.

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 971. DMA interface (major loop — single iteration)

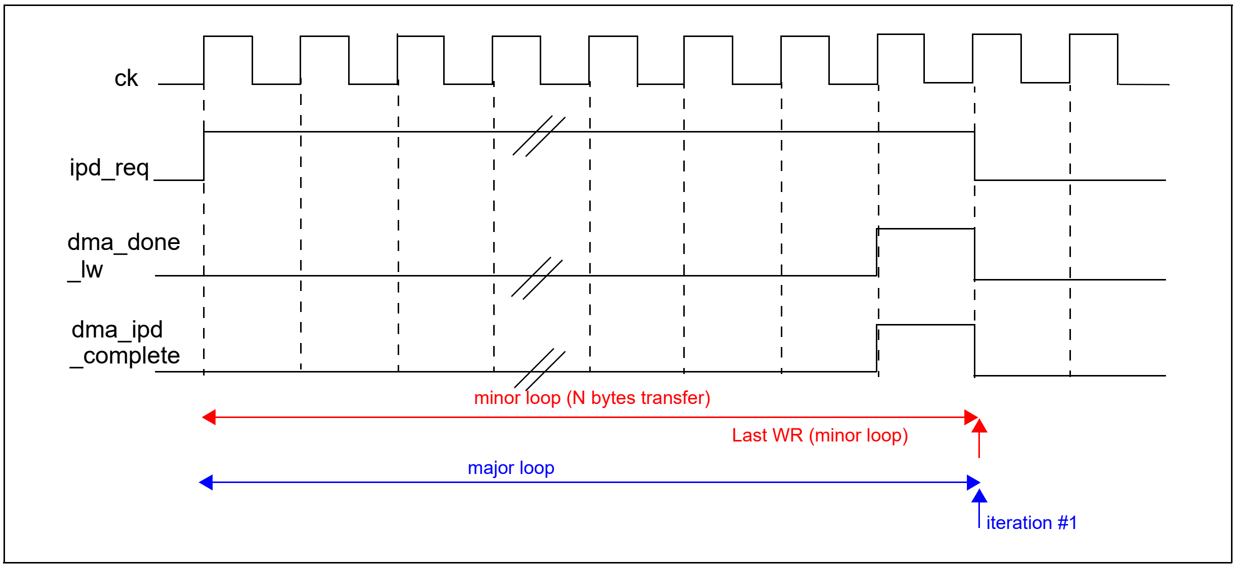


Figure 972. DMA interface (major loop — N iteration)

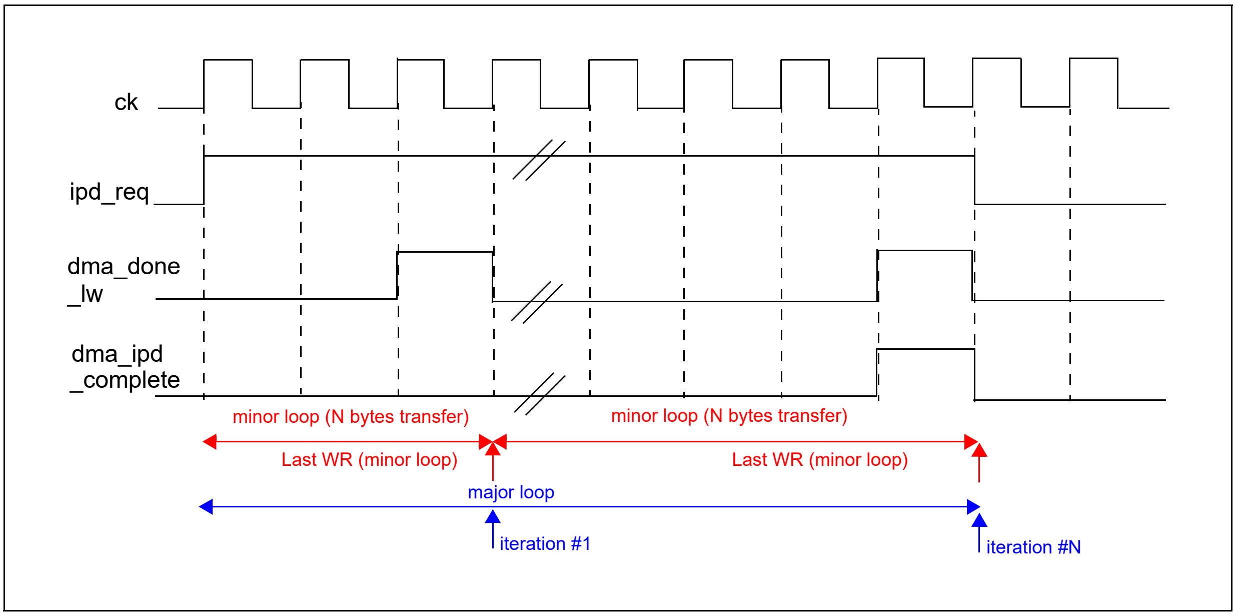

50.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

50.4 Memory map and register description

Note: Refer to the LINFlexD configuration section of the Device Configuration chapter for registers implementation per LINFlexD instance.

50.4.1 Memory map

Table 1024 shows the LINFlexD memory map.

Note: In Master mode, the registers IFCR0–IFCR15 are not present.

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in bus transfer error.

50.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format.
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

50.4.2.1 LIN Control Register 1 (LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

Address: 0x0000 Access: User read/write

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1(2)	0	0	1	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When slave = 0, this field reads ‘1’ and cannot be programmed.

Figure 973. LIN Control Register 1 (LINCR1)

Table 1025. LINCR1 field descriptions

Field	Description
16 CCD	Calculation disable 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read-only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).

Table 1025. LINCR1 field descriptions (continued)

Field	Description
19 AUTOWU	Auto Wakeup 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.
20:23 MBL[3:0]	Master Break Length These bits choose the length of the Sync break to be generated by the master. 0x0 10-bit break length 0x1 11-bit break length 0x2 12-bit break length 0x3 13-bit break length 0x4 14-bit break length 0x5 15-bit break length 0x6 16-bit break length 0x7 17-bit break length 0x8 18-bit break length 0x9 19-bit break length 0xA 20-bit break length 0xB 21-bit break length 0xC 22-bit break length 0xD 23-bit break length 0xE 36-bit (cooling) break length 0xF 50-bit break length These bits can be programmed in Initialization mode only. They are read-only in Normal mode.
24 BF	By-pass filter 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter This bit can be programmed during Initialization mode only. Note: If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.
25	Reserved
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to *Section 50.3.2.2*. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. If generic *slave* = 0, then this bit will read a ‘1’ always, and cannot be programmed.

Table 1025. LINCR1 field descriptions (continued)

Field	Description
28 SSBL	Slave Mode Sync Break Length 0 11-bit break length 1 10-bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

50.4.2.2 LIN Interrupt enable register (LINIER)

Figure 974. LIN Interrupt enable register (LINIER)

Table 1026. LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **Note:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.

Table 1026. LINIER field descriptions (continued)

Field	Description
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE_TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

50.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0x0008 Access: User read/write

Figure 975. LIN Status Register (LINSR)

Table 1027. LINSR field descriptions

Field	Description
12 AUTOSYNC_COMP	Autosynchronization Completed This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers should be read in autosynchronization mode.
13:15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 1027. LINSR field descriptions (continued)

Field	Description
16:19 LINS	LIN state 0x0 Sleep mode LINFlexD is in Sleep mode to save power consumption. 0x1 Init 0x2 Idle This mode is entered when: SLEEP bit and INIT bit are reset by software, Wakeup pulse has been received on RX pin (AUTOWU set), Previous frame transmission/reception has been completed/aborted. 0x3 Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0x4 Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0x5 Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0x6 Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0x7 Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 0x8 Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 0x9 Checksum Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXBUSY	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.

Table 1027. LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **Note:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin and when: The slave is in Sleep mode The master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next eight bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: All filters are inactive and Bypass filter (BF) bit is set No match in any filter and Bypass filter (BF) bit is set TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

50.4.2.4 LIN Error Status Register (LINESR)

Address: 0x000C Access: User read/write

Figure 976. LIN error status register (LINESR)

Refer to *Section 50.3.2.5: Errors* for detailed description of all errors.

Table 1028. LINESR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

Table 1028. LINESR field descriptions (continued)

Field	Description
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **Note:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

50.4.2.5 UART Mode Control Register (UARTCR)

Address: 0x0010 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R/W	MIS(1)	CSP(1)			OSR(1)				ROSE(1)	NEF(1)(2)			DTU_PCETX(1)	SBUR(1)		WLS(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R/W	TDFL_TFC(2)			RDFL_RFC(3)			RFBM(1)	TFBM(1)	WL1(1)	PC1(1)	RXEN	TXEN	PC0(1)	PCE(1)	WL0(1)	UART(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When TFBM = 0, the field is read/write; when TFBM = 1, the field is read-only.
3. When RFBM = 0, the field is read/write; when RFBM = 1, the field is read-only.

Figure 977. UART Mode Control Register (UARTCR)

Table 1029. UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 1 UARTCTO monitors the idle state of the reception line. 0 UARTCTO monitors the number of bits to be received. The default value of this bit is 0.
1:3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: – OSR 4: CSP 2, 3 – OSR 5: CSP 2, 3, 4 – OSR 6: CSP 3, 4, 5 – OSR 8: CSP NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received (num_of_frames). When num_of_frames equals NEF, Disable Timeout is set and num_of_frames gets reset to zero, restarting the timer and enabling the timeout again.
13:14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.

Table 1029. UARTCR field descriptions (continued)

Field	Description
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.
16:18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL_TFC defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL_TFC is a read/write field. TDFL_TFC[2] is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL_TFC = x01 or TDFL_TFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes TDFL_TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TDFL_TFCx is a read-only field available for debug purposes. 000 empty 001 1-byte 010 2-bytes 011 3-bytes 100 4-bytes Others: Reserved **Note:** TDFL_TFC can be programmed and are significative only when the UART bit is set.
19:21 RDFL_RFC	Reception Data Field Length/RX FIFO Counter RDFL_RFC defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL_RFC is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL_RFC = x01 or RDFL_RFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes RDFL_RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RDFL_RFCx is a read-only field available for debug purposes. 000 Empty 001 1-byte 010 2-bytes/1.5 byte in case of WLS bit setting 011 3-bytes 100 4-bytes/2×1.5 byte in case of WLS bit setting Others: Reserved RDFL_RFC can be programmed and are significative only when the UART bit is set. **Note:** In buffer mode, RDFL_RFC should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.

Table 1029. UARTCR field descriptions (continued)

Field	Description
22 RFBM	RFBM Rx FIFO/Buffer mode 0 Rx Buffer mode enabled 1 Rx FIFO mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx FIFO/Buffer mode 0 Tx Buffer mode enabled 1 Tx FIFO mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
26 RXEN	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TXEN	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
29 PCE	Parity Control Enable 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.

Table 1029. UARTCR field descriptions (continued)

Field	Description
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

50.4.2.6 UART Mode Status Register (UARTSR)

Address: 0x0014 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	SZF	OCF	PE				RMB	FEF	BOF	RDI	WUF	RFNE	TO	DRF_RFE(1)	DTF_TFF(2)	NF
W	w1c	w1c	w1c				w1c	w1c	w1c	w1c	w1c		w1c			w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. When RFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when RFBM = 1, the field is read-only.
2. When TFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when TFBM = 1, the field is read-only.

Figure 978. UART Mode Status Register (UARTSR)

Table 1030. UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. For Baud rate above 1 Mbit/s, this flag is not usable.
18:21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. PE[i] (where i = 0,1,2 or 3) can be equal to: 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **Note:** Parity is checked only after a complete frame is received. When WL bits = 10 or 11, either PE[0] or PE[2] is only set. – When PE[0] is set, it indicates Parity error in either first or second byte received. – When PE[2] is set, it indicates Parity error in either third or fourth byte received.
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table 1030. UARTSR field descriptions (continued)

Field	Description
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software.The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF_RFE	Data Reception Completed Flag/Rx FIFO Empty Flag DRF_RFE is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF_RFE should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF_RFE bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF_RFE is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DRF_RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. DRF_RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF_TFF	Data Transmission Completed Flag/TX FIFO Full Flag DTF_TFF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF_TFF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DTF_TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. DTF_TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

50.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Address: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	MODE(1)	IOT(1)	TOCE	CNT							
W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.

Figure 979. LIN Time-Out Control Status Register (LINTCSR)

Table 1031. LINTCSR field descriptions

Field	Description
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event This feature is applicable only when MODE bit in LINTCSR is cleared.
23 TOCE	Time-out counter enable 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24:31 CNT	Counter Value These bits reflect the value of a free-running counter used for timeout. **Note:** For proper functionality of this counter, LINIBRR should be greater than or equal to 5. This counter increments once in every bit duration, as per the programmed bit rate. The counter starts as soon as the IP comes out of reset and increments based on the slowest baud rate possible (LINIBRR = FFFFFh), until the user programs LINIBRR and LINFBRR with the desired values.

50.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the count value in LINTOCR register. This register is writable by software only in Output Compare Mode.

Address: 0x001C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	1	1	1	0	0	0	0[1]/1	1[1]/0	1	1	0	0

1. This reset value is valid only in Master mode (slave = 0).

Figure 981. LIN Time-Out Control Register (LINTOCR)

Table 1033. LINTOCR field descriptions

Field	Description
20:23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0xE = 14, corresponding to $T_{Response\_Maximum} = 1.4 * T_{Response\_Nominal}$
25:31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is 0x2C = 45, corresponding to $T_{Header\_Maximum}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 0x1C = 28 (1.4 × 10 bits of sync + 1.4 × 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

50.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0x0024 Access: User read/write

1. This field can be read in any modes and written only in Initialization mode.
2. This field can be read/set by software.
3. When slave = 0, reset value is '0' and the this field cannot be programmed.

Figure 985. LIN Control Register 2 (LINCR2)

Table 1037. LINCR2 field descriptions

Field	Description
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **Note:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.

50.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0x0034 Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 986. Buffer Identifier Register (BIDR)

Table 1038. BIDR field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1 **Note:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copies them in the BDRs 1 LINFlexD transmits the data from the BDRs
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = ‘1’).

50.4.2.15 Buffer Data Register Least Significant (BDRL)

This register is a part of an 8-byte data buffer.

2. This field is read 0 by software.

Figure 994. Global Control Register (GCR)

Table 1046. GCR field descriptions

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. 0 The first bit of received data is LSB – in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB – in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. 0 Received data is not inverted 1 Received data is inverted

Table 1046. GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. The following register fields are reset by SR: LINSR: All fields except RXbusy and AUTOSYNC_COMP LINESR: All fields LINTCSR: Only CNT[0:7] UARTSR: All fields except RFE and TFFt UARTCR: Only TFC and RFC UARTCTO: All fields

50.4.2.23 UART Preset Timeout Register (UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

Address: 0x8C + 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

Figure 995. UART Preset Timeout Register (UARTPTO)

Table 1047. UARTPTO field descriptions

Field	Description
20:31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A value of 0, 1 or 2 is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer to the UARTCTO register.

50.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (refer to *Section 50.4.2.23*) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

*Note: Due to this synchronisation, UARTCTO reflects the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) which was present on it, before 4 to 6 clock cycles of PBRIDGEx_CLK.*

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO-1
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

Address: 0x8C + 0x08 Access: User read

50.5 Programming considerations

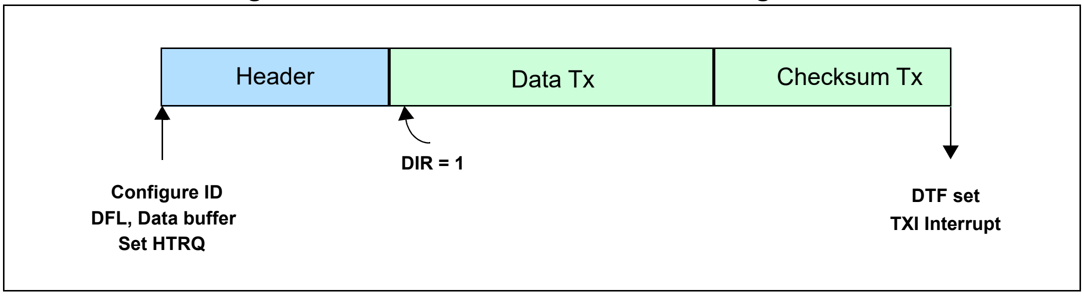
The next subsections describe the various configurations in which the LINFlexD module can be used.

50.5.1 Master node

LINFlexD acts as Master when the MME bit is set.

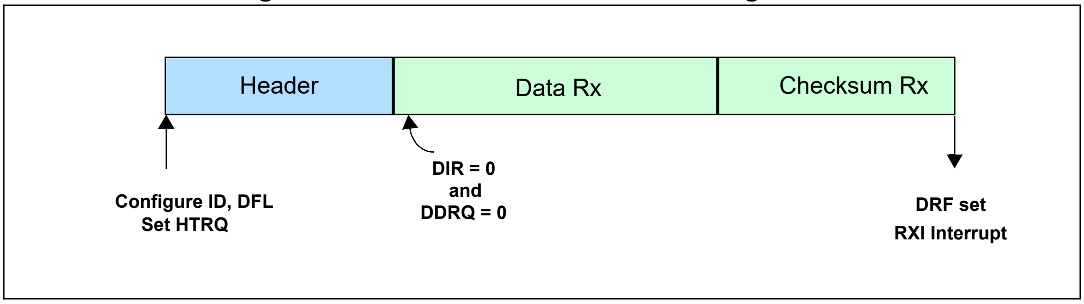
50.5.1.1 Transmitter

Figure 999. Master node: transmitter configuration



50.5.1.2 Receiver

Figure 1000. Master node: receiver configuration



50.5.1.3 Transmitter, Bit Error

Figure 1001. Master node: transmitter, bit error configuration

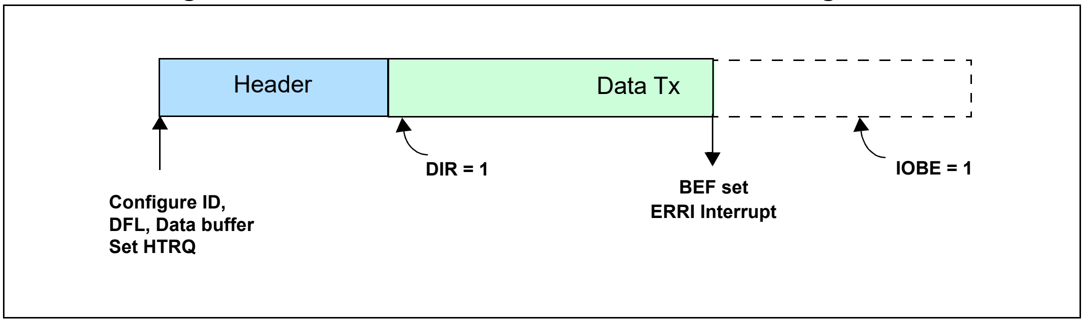


Figure 1002. Master node: transmitter, checksum error configuration

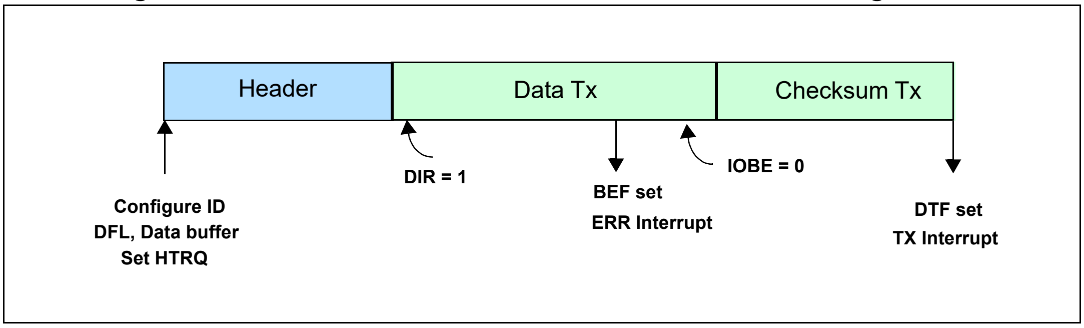
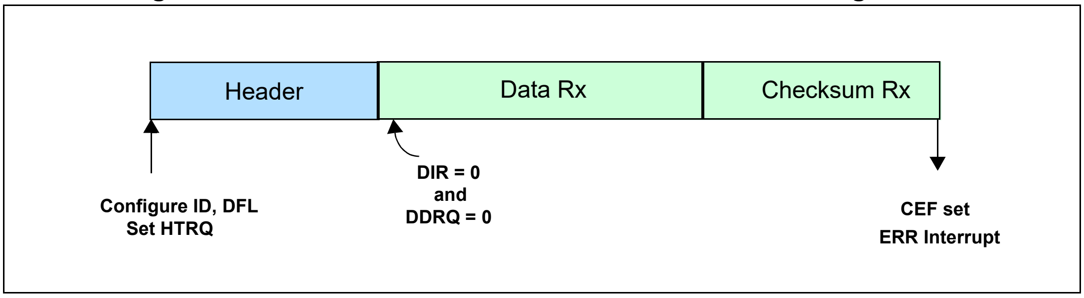


50.5.1.4 Receiver, Checksum Error

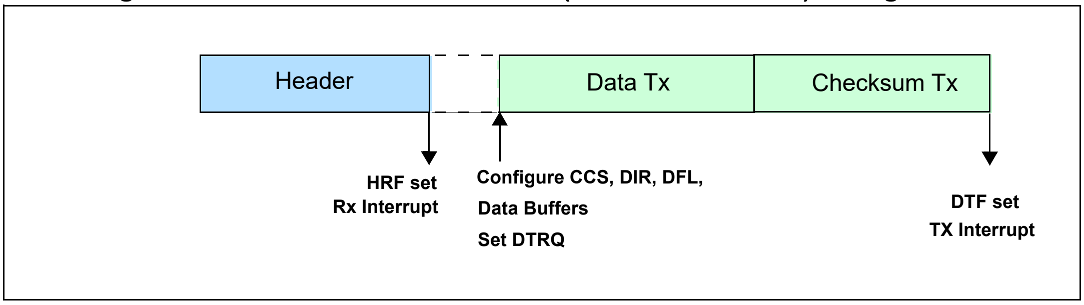
Figure 1003. Master node: receiver, checksum error configuration



50.5.2 Slave node

50.5.2.1 Transmitter (no identifier filters)

Figure 1004. Slave node: transmitter (no identifier filters) configuration



50.5.2.2 Receiver (no identifier filters)

Figure 1005. Slave node: receiver (no identifier filters) configuration

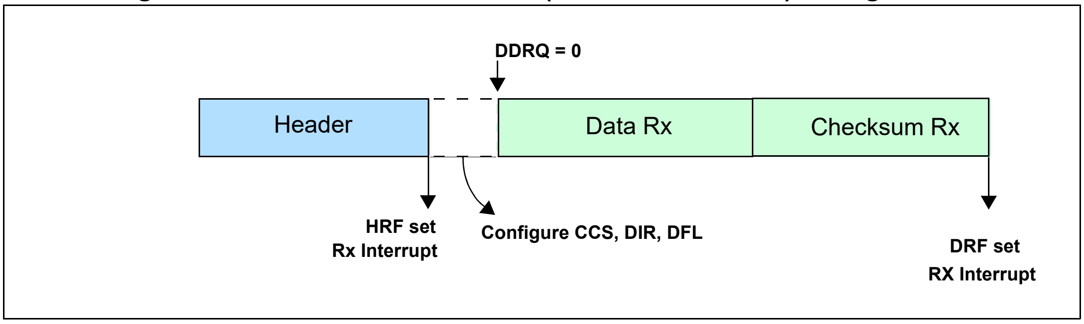


Figure 1006. Slave node: receiver (no identifier filters) configuration

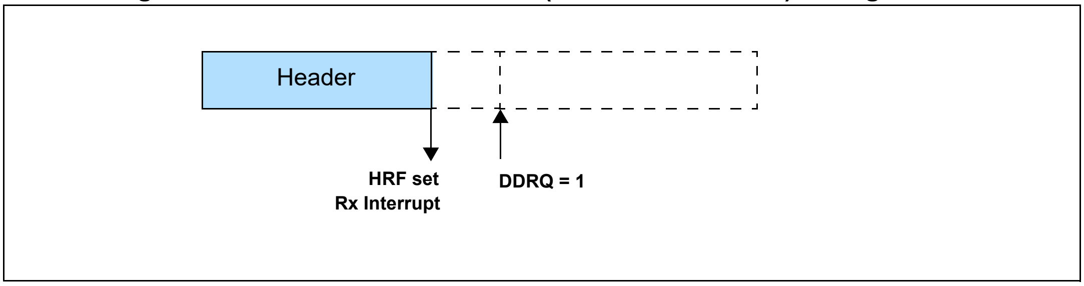
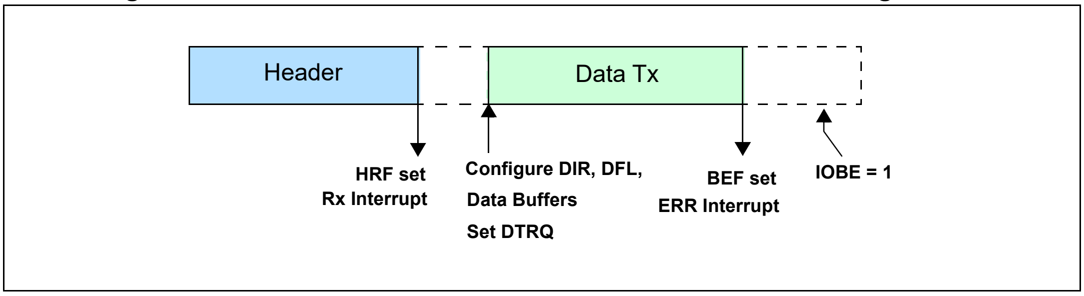


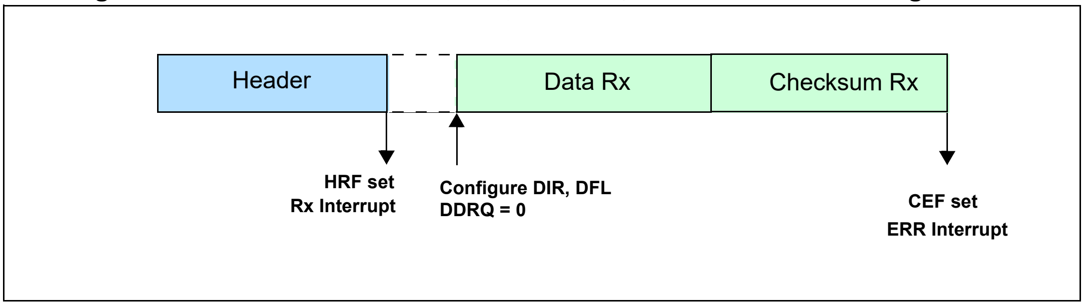
50.5.2.3 No filters, transmitter, bit error

Figure 1007. Slave node: No filters, transmitter, bit error configuration



50.5.2.4 No filters, receiver, checksum error

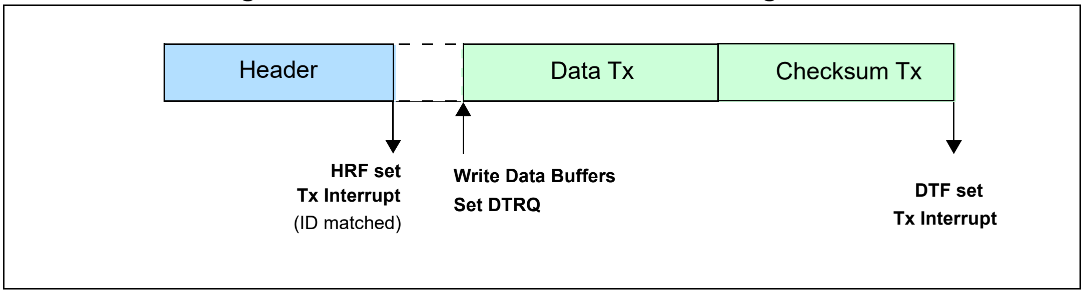
Figure 1008. Slave node: No filters, receiver, checksum error configuration



50.5.2.5 At least one TX filter, BF is reset, ID matches filter

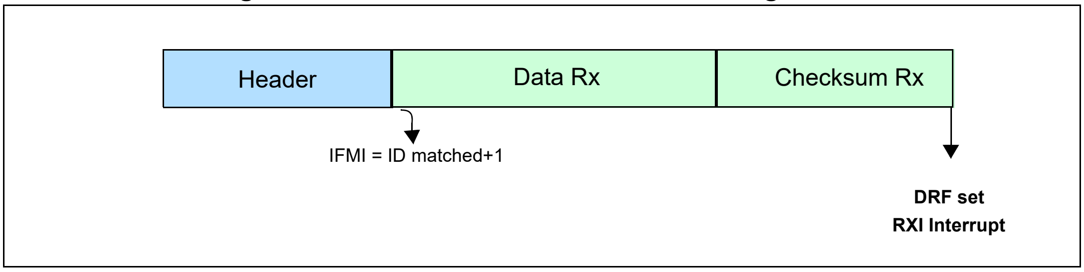
This configuration can be used in case slave never receives data, for example, sensor.

Figure 1009. Slave node: one TX filter configuration



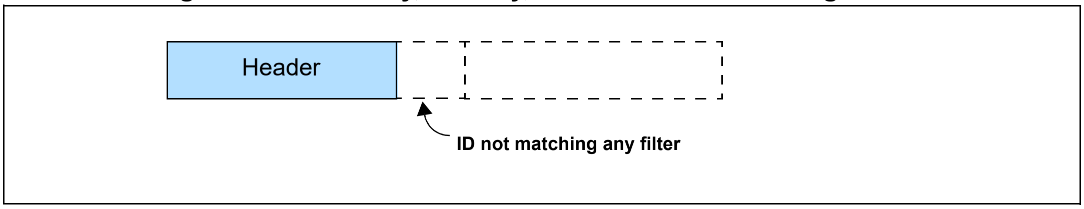
50.5.2.6 At least one RX filter, BF reset, ID matches filter

Figure 1010. Slave node: one RX filter configuration



50.5.2.7 RX only, TX only, RX and TX filters, ID not matching filter, BF reset

Figure 1011. RX only, TX only, RX and TX filters configuration



50.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

Figure 1012. TX filter, BF is set configuration: ID has matched

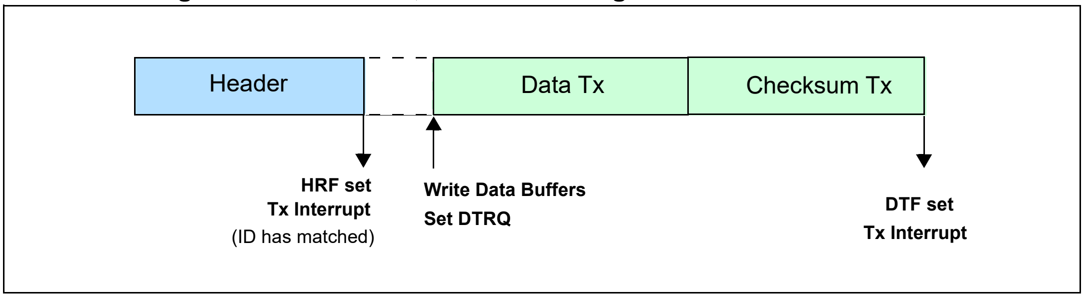


Figure 1013. TX filter, BF is set configuration: ID not matched

51 Reset Generation Module (MC_RGM)

51.1 Introduction

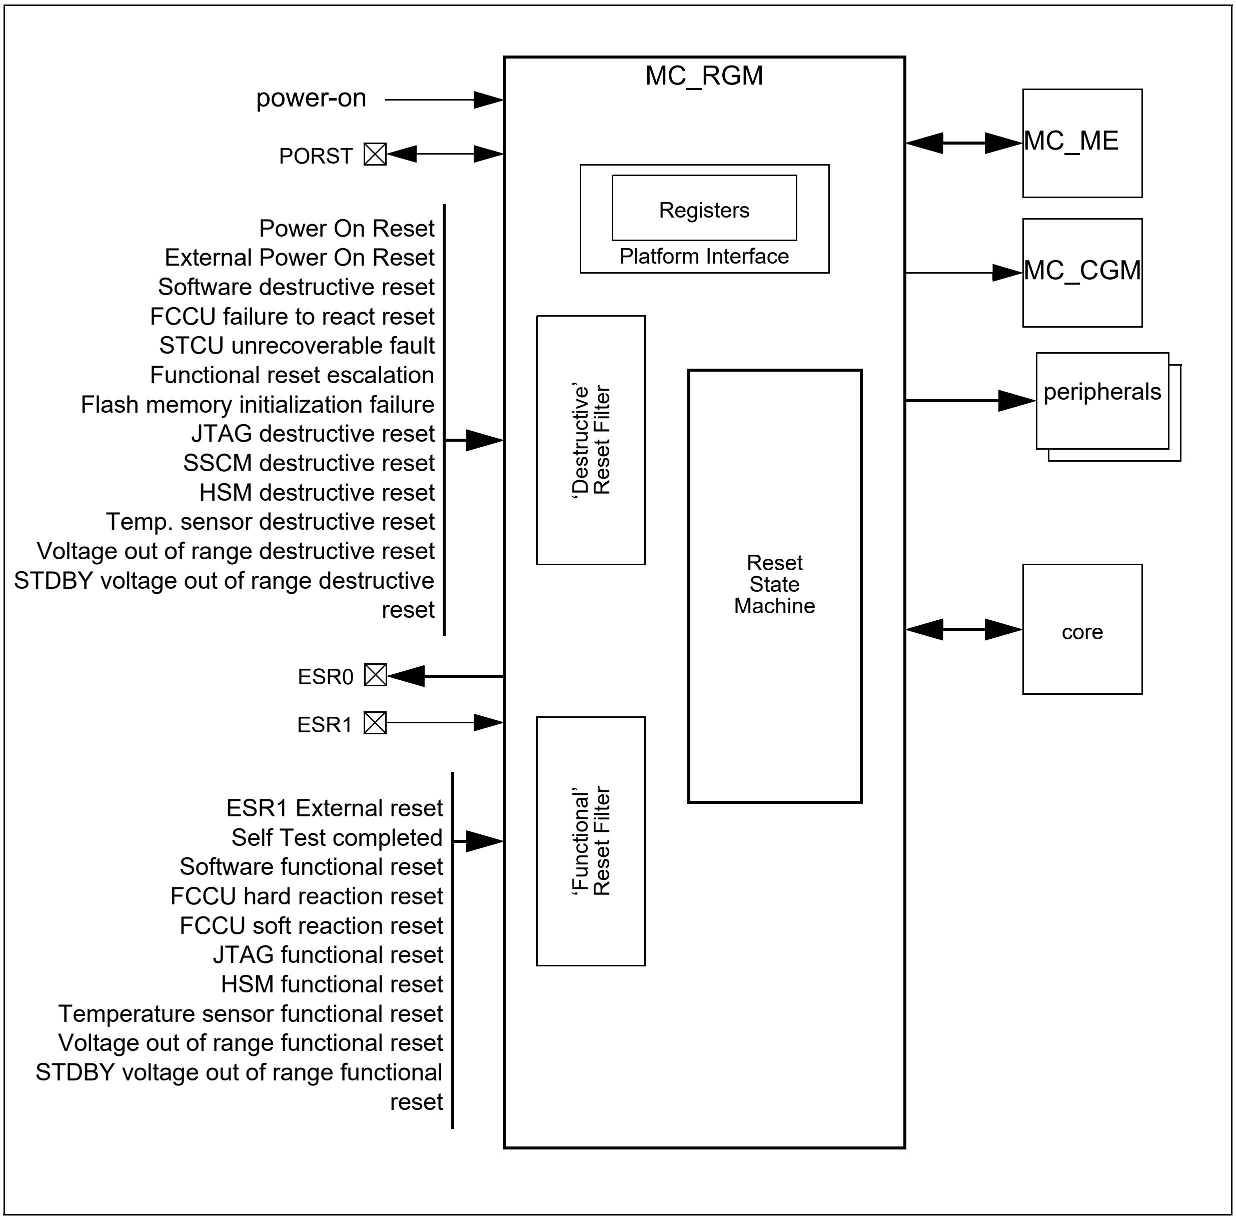
This chapter describes the MC_RGM module.

51.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

Figure 1026 shows the MC_RGM block diagram.

Figure 1026. MC_RGM block diagram



51.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to SAFE mode or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration

51.1.3 Reset sources

The different reset sources are organized into two families: ‘destructive’ and ‘functional’.

- A ‘destructive’ reset source is associated with an event related to a critical (usually hardware) error or dysfunction. When a ‘destructive’ reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown .
  ‘Destructive’ resets are:
  - Power On Reset
  - External Power On Reset
  - Software destructive reset
  - FCCU failure to react reset
  - STCU unrecoverable fault
  - Functional reset escalation
  - Flash memory initialization failure
  - JTAG destructive reset
  - SSCM destructive reset
  - HSM destructive reset
  - Temperature sensor destructive reset
  - Voltage out of range destructive reset
  - STDBY voltage out of range destructive reset
- A ‘functional’ reset source is associated with an event related to a less-critical (usually non-hardware) error or dysfunction. When a ‘functional’ reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example, debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets.
  ‘Functional’ resets are:
  - ESR1 External reset
  - Self Test completed
  - Software functional reset
  - FCCU hard reaction reset
  - FCCU soft reaction reset
  - JTAG functional reset
  - HSM functional reset
  - Temperature sensor functional reset
  - Voltage out of range functional reset
  - STDBY voltage out of range functional reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (that is PHASE*n* states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (refer to *Section 51.3.1.2: 'Destructive' Event Reset Disable Register (RGM_DERD)* and *Section 51.3.1.3: 'Destructive' Event Alternate Request Register (RGM_DEAR)* for 'destructive' resets and *Section 51.3.1.6: 'Functional' Event Reset Disable Register (RGM_FERD)* and *Section 51.3.1.7: 'Functional' Event Alternate Request Register (RGM_FEAR)* for 'functional' resets).

51.2 External signal description

The MC_RGM interfaces to the output reset pin ESR0.

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error.*

51.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

51.3.1.1 'Destructive' Event Status Register (RGM_DES)

This register contains the status of the 'destructive' reset sources, including those configured not to generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing '1'.

This register is reset only on power-on.

Address: 0x000 Access: User read, Supervisor read/write, Test read/write

Table 1053. RGM_DES field descriptions

Field	Description
6 F_VOR_STDBY	Flag for voltage out of range from LVDs or HVDs, or both, during standby mode 'destructive' reset 0 No voltage out of range 'destructive' reset event has occurred since the last clear 1 A voltage out of range 'destructive' reset event has occurred **Note:** for LVD100_SB it is not allowed to enable destructive reset, only functional reset is supported.
7 F_VOR_DEST	Flag for voltage out of range 'destructive' reset 0 No voltage out of range 'destructive' reset event has occurred since the last clear 1 A voltage out of range 'destructive' reset event has occurred
8 F_TSR_DEST	Flag for temperature sensor 'destructive' reset 0 No temperature sensor 'destructive' reset event has occurred since the last clear 1 A temperature sensor 'destructive' reset event has occurred
16 F_HSM_DEST	Flag for HSM 'destructive' reset request 0 No HSM 'destructive' reset request event has occurred since the last clear 1 A HSM 'destructive' reset request event has occurred
17 F_SSCM_DEST	Flag for SSCM 'destructive' reset request 0 No SSCM 'destructive' reset request event has occurred since the last clear 1 A SSCM 'destructive' reset request event has occurred

Table 1053. RGM_DES field descriptions (continued)

Field	Description
21 F_JTAG_DEST	Flag for JTAG 'destructive' reset request 0 No JTAG 'destructive' reset request event has occurred since the last clear 1 A JTAG 'destructive' reset request event has occurred
22 F_FIF	Flag for flash memory initialization failure 0 No flash memory initialization failure event has occurred since the last clear 1 A flash memory initialization failure event has occurred
23 F_EDR	Flag for ‘functional’ reset escalation 0 No ‘functional’ reset escalation event has occurred since the last clear 1 A ‘functional’ reset escalation event has occurred
26 F_SUF	Flag for STCU2 unrecoverable fault 0 No STCU2 unrecoverable fault event has occurred since the last clear 1 A STCU2 unrecoverable fault event has occurred
27 F_FFRR	Flag for FCCU failure to react reset 0 No FCCU failure to react reset event has occurred since the last clear 1 A FCCU failure to react reset event has occurred
28 F_SOFT_DEST	Flag for software ‘destructive’ reset 0 No software ‘destructive’ reset event has occurred since the last clear 1 A software ‘destructive’ reset event has occurred
30 F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred **Note:** F_PORST will not be set if an external PORST is asserted during standby mode. Rather MC_RGM.FES.F_JTAG_FUNC will be set.
31 F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

51.3.1.2 ‘Destructive’ Event Reset Disable Register (RGM_DERD)

This register provides dedicated bits to disable particular ‘destructive’ reset sources. When a ‘destructive’ reset source is disabled, the associated ‘destructive’ event will trigger either a SAFE mode request or an interrupt request (refer to *Section 51.3.1.3: ‘Destructive’ Event Alternate Request Register (RGM_DEAR)*). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a ‘destructive’ or power-on reset.

This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x010 Access: User read, Supervisor read/write, Test read/write

31 D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

51.3.1.3 'Destructive' Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a 'destructive' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0x020 Access: User read, Supervisor read/write, Test read/write

6 BE_VOR_STDBY	Reset Enable for voltage out of range from LVDs or HVDs, or both, during standby mode ‘destructive’ reset 0 ESR0 is asserted on a voltage out of range ‘destructive’ reset event
7 BE_VOR_DEST	Reset Enable for voltage out of range ‘destructive’ reset 0 ESR0 is asserted on a voltage out of range ‘destructive’ reset event
8 BE_TSR_DEST	Reset Enable for temperature sensor 'destructive' reset 0 ESR0 is asserted on a temperature sensor 'destructive' reset event if the reset is enabled
16 BE_HSM_DEST	Reset Enable for HSM 'destructive' reset request 0 ESR0 is asserted on a HSM 'destructive' reset request event
17 BE_SSCM_DEST	Reset Enable for SSCM 'destructive' reset request 0 ESR0 is asserted on a SSCM 'destructive' reset request event
21 BE_JTAG_DEST	Reset Enable for JTAG 'destructive' reset request 0 ESR0 is asserted on a JTAG 'destructive' reset request event 1 ESR0 is not asserted on a JTAG 'destructive' reset request event
22 BE_FIF	Reset Enable for flash memory initialization failure 0 ESR0 is asserted on a flash memory initialization failure event
23 BE_EDR	Reset Enable for ‘functional’ reset escalation 0 ESR0 is asserted on a ‘functional’ reset escalation event

Table 1056. RGM_DBRE field descriptions (continued)

Field	Description
26 BE_SUF	Reset Enable for STCU2 unrecoverable fault 0 ESR0 is asserted on a STCU2 unrecoverable fault event
27 BE_FFRR	Reset Enable for FCCU failure to react reset 0 ESR0 is asserted on a FCCU failure to react reset event
28 BE_SOFT_DEST	Reset Enable for software ‘destructive’ reset 0 ESR0 is asserted on a software ‘destructive’ reset event
30 BE_PORST	Reset Enable for external power-on reset 0 ESR0 is asserted on an external power-on reset event if the reset is enabled
31 BE_POR	Reset Enable for power-on reset 0 ESR0 is asserted on a power-on reset event

Note: For more details about ESR0, refer to Section 51.4.3.2: ESR0 Output External reset.

51.3.1.5 ‘Functional’ Event Status Register (RGM_FES)

This register contains the status of the ‘functional’ reset sources, including those configured not to generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing ‘1’ if the triggering event has already been cleared at the source.

This register is reset only on power-on.

Note: If a ‘functional’ reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.

Table 1057. RGM_FES field descriptions

Field	Description
6 F_VOR_FUNC_STDBY	Flag for voltage out of range from LVDs or HVDs, or both, during standby ‘functional’ reset 0 No voltage out of range ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion 1 A voltage out of range ‘functional’ reset event has occurred
7 F_VOR_FUNC	Flag for voltage out of range ‘functional’ reset 0 No voltage out of range ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion 1 A voltage out of range ‘functional’ reset event has occurred
8 F_TSR_FUNC	Flag for temperature sensor ‘functional’ reset 0 No temperature sensor 'functional' reset event has occurred since either the last clear or the last power-on reset assertion 1 A temperature sensor 'functional' reset event has occurred
16 F_HSM_FUNC	Flag for HSM ‘functional’ reset request 0 No HSM 'functional' reset request event has occurred since either the last clear or the last power-on reset assertion 1 A HSM 'functional' reset request event has occurred

Table 1057. RGM_FES field descriptions (continued)

Field	Description
21 F_JTAG_FUNC	Flag for JTAG ‘functional’ reset or stand-by exit 0 No JTAG ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion, or no exit from stand-by 1 A JTAG ‘functional’ reset event has occurred, or a PORST functional reset during the stand-by mode occurred
25 F_FCCU_SOFT	Flag for FCCU soft reaction 0 No FCCU soft reaction event has occurred since either the last clear or the last power-on reset assertion 1 A FCCU soft reaction event has occurred
26 F_FCCU_HARD	Flag for FCCU hard reaction reset 0 No FCCU hard reaction reset event has occurred since either the last clear or the last power-on reset assertion 1 A FCCU hard reaction reset event has occurred
28 F_SOFT_FUNC	Flag for software ‘functional’ reset 0 No software ‘functional’ reset event has occurred since either the last clear or the last power-on reset assertion 1 A software ‘functional’ reset event has occurred
29 F_ST_DONE	Flag for self test completed 0 No self test completed event has occurred since either the last clear or the last power-on reset assertion 1 A self test completed event has occurred
30 F_ESR1	Flag for ESR1 External Reset 0 No ESR1 external reset event has occurred since either the last clear or the last power-on reset assertion 1 An ESR1 external reset event has occurred

51.3.1.6 ‘Functional’ Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable ‘functional’ reset sources.When a ‘functional’ reset source is disabled, the associated ‘functional’ event will trigger either a SAFE mode request or an interrupt request (refer to *Section 51.3.1.7: ‘Functional’ Event Alternate Request Register (RGM_FEAR)*). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any ‘destructive’ reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

30 D_ESR1	Disable ESR1 External Reset 0 An ESR1 external reset event triggers a reset sequence 1 An ESR1 external reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_FEAR.AR_ESR1

51.3.1.7 ‘Functional’ Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a ‘functional’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x320 Access: User read, Supervisor read/write, Test read/write

Field	Description
6 AR_VOR_FUNC_STDBY	Alternate Request for LVDs or HVDs, or both, during standby voltage out of range 'functional' reset 0 Generate a SAFE mode request on a voltage out of range 'functional' reset event if the reset is disabled 1 Generate an interrupt request on a voltage out of range 'functional' reset event if the reset is disabled
7 AR_VOR_FUNC	Alternate Request for voltage out of range 'functional' reset 0 Generate a SAFE mode request on a voltage out of range 'functional' reset event if the reset is disabled 1 Generate an interrupt request on a voltage out of range 'functional' reset event if the reset is disabled
8 AR_TSR_FUNC	Alternate Request for temperature sensor 'functional' reset 0 Generate a SAFE mode request on a temperature sensor 'functional' reset event if the reset is disabled 1 Generate an interrupt request on a temperature sensor 'functional' reset event if the reset is disabled
30 AR_ESR1	Alternate Request for ESR1 External Reset 0 Generate a SAFE mode request on a ESR1 external reset event if the reset is disabled 1 Generate an interrupt request on a ESR1 external reset event if the reset is disabled

51.3.1.8 'Functional' Reset Enable Register (RGM_FBRE)

This register enables the generation of an external reset on 'functional' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0x330 Access: User read, Supervisor read/write, Test read/write

29 BE_ST_DONE	Reset Enable for self test completed 0 ESR0 is asserted on a self test completed event
30 BE_ESR1	Reset Enable for ESR1 External Reset 0 ESR0 is asserted on an ESR1 external reset event if the reset is enabled 1 ESR0 is not asserted on an ESR1 external reset event

Note: For more details about ESR0, refer to Section 51.4.3.2: ESR0 Output External reset.

51.3.1.9 ‘Functional’ Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence will be done when a ‘functional’ reset sequence is triggered. The ‘functional’ reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

Note: This could be useful for fast reset sequence, for example to skip flash memory reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x340 Access: User read, Supervisor read/write, Test read/write

51.3.1.10 ‘Functional’ Reset Escalation Threshold Register (RGM_FRET)

This register sets the threshold for ‘functional’ reset escalation to a ‘destructive’ reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the ‘functional’ reset escalation function. Writing any value to this register will reset the ‘functional’ reset counter. Refer to *Section 51.4.6: ‘Functional’ reset escalation* for details on the ‘functional’ reset escalation function.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0x604 Access: User read, Supervisor read/write, Test read/write

51.3.1.11 'Destructive' Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for 'destructive' reset escalation keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the 'destructive' reset software escalation function. Writing any value to this register will reset the 'destructive' reset counter. Refer to *Section 51.4.7: 'Destructive' reset escalation*, for details on the 'destructive' reset escalation function.

This register is reset only on power-on.

5 LINFLEXD_4_RST	LINFLEXD_4 reset Writing a ‘1’ to this bit resets the LINFLEXD_4 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1066. RGM_PRST2 register field descriptions (continued)

Field	Description
6 LINFLEXD_6_RST	LINFLEXD_6 reset Writing a ‘1’ to this bit resets the LINFLEXD_6 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_6 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
7 LINFLEXD_8_RST	LINFLEXD_8 reset Writing a ‘1’ to this bit resets the LINFLEXD_8 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_8 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 LINFLEXD_10_RST	LINFLEXD_10 reset Writing a ‘1’ to this bit resets the LINFLEXD_10 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_10 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
9 LINFLEXD_12_RST	LINFLEXD_12 reset Writing a ‘1’ to this bit resets the LINFLEXD_12 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_12 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_0_CTR_RST	CAN_RAM_SUB_0_CTR reset Writing a ‘1’ to this bit resets the CAN_RAM_SUB_0_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_0_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** RGM is able to reset CAN RAM controller and not CAN RAM content. In other words, it is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_0_CTR_RST bit.
23 M_CAN_0_SUB_0_RST	M_CAN_0_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_0_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_0_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1066. RGM_PRST2 register field descriptions (continued)

Field	Description
26 M_CAN_1_SUB_0_RST	M_CAN_1_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 M_CAN_2_SUB_0_RST	M_CAN_2_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_2_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 M_CAN_3_SUB_0_RST	M_CAN_3_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_3_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_3_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

51.3.1.15 Peripheral Reset Register 3 (RGM_PRST3)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1067* for details.

Address: 0x61C Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SAR_ADC_12BIT_0_RST	0	0	0	0	0	0	0	0	0	0	0	0	SAR_ADC_10BIT_STDBY_RST	0	SAR_ADC_12BIT_B_RST
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1041. Peripheral Reset Register 3 (RGM_PRST3)

Table 1067. RGM_PRST3 register field descriptions

Field	Description
0 SAR_ADC_12BIT_0_RST	SAR_ADC_12BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 SAR_ADC_10BIT_ STDBY_RST	SAR_ADC_10BIT_STDBY reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_STDBY peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_STDBY peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 SAR_ADC_12BIT_B_RST	SAR_ADC_12BIT_B reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_B peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_B peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** In case BCTU_0 is used to trigger SAR_ADC_12BIT_B conversions, force the reset of BCTU_0 before setting SAR_ADC_12BIT_B_RST to 1'b1 by RGM_PRST7[BODY_CTU_0_RST] bit. De-assert BCTU_0 reset (clearing BODY_CTU_0_RST to 1’b0) only after SAR_ADC_12BIT_B is out of reset (clearing SAR_ADC_12BIT_B_RST to 1'b0).
26 IIC_0_RST	IIC_0 reset Writing a ‘1’ to this bit resets the IIC_0 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_0_RST	DSPI_0 reset Writing a ‘1’ to this bit resets the DSPI_0 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_2_RST	DSPI_2 reset Writing a ‘1’ to this bit resets the DSPI_2 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1067. RGM_PRST3 register field descriptions (continued)

Field	Description
30 DSPI_4_RST	DSPI_4 reset Writing a ‘1’ to this bit resets the DSPI_4 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 DSPI_6_RST	DSPI_6 reset Writing a ‘1’ to this bit resets the DSPI_6 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_6 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

51.3.1.16 Peripheral Reset Register 4 (RGM_PRST4)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1068* for details.

Address: 0x620 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1042. Peripheral Reset Register 4 (RGM_PRST4)

Table 1068. RGM_PRST4 register field descriptions

Field	Description
1 PIT_1_RST	PIT_1 reset Writing a '1' to this bit resets the PIT_1 peripheral. Writing a '0' to this bit releases the reset to the PIT_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 SAR_ADC_12BIT_0_SEQ _RST	SAR_ADC_12BIT_0_SEQ reset Writing a '1' to this bit resets the SAR_ADC_12BIT_0_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_12BIT_0_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
18 SAR_ADC_12BIT_1_SEQ _RST	SAR_ADC_12BIT_1_SEQ reset Writing a '1' to this bit resets the SAR_ADC_12BIT_1_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_12BIT_1_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 SAR_ADC_10BIT_STDBY _SEQ_RST	SAR_ADC_10BIT_STDBY_SEQ reset Writing a '1' to this bit resets the SAR_ADC_10BIT_STDBY_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_10BIT_STDBY_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 SAR_ADC_12BIT_B _SEQ_RST	SAR_ADC_12BIT_B_SEQ reset Writing a '1' to this bit resets the SAR_ADC_12BIT_B_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_12BIT_B_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

51.3.1.17 Peripheral Reset Register 5 (RGM_PRST5)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1069* for details.

Address: 0x624 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
22 FCCU_RST	FCCU reset Writing a ‘1’ to this bit resets the FCCU peripheral. Writing a ‘0’ to this bit releases the reset to the FCCU peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
25 CRC_1_RST	CRC_1 reset Writing a ‘1’ to this bit resets the CRC_1 peripheral. Writing a ‘0’ to this bit releases the reset to the CRC_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 DMAMUX_1_RST	DMAMUX_1 reset Writing a ‘1’ to this bit resets the DMAMUX_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DMAMUX_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

51.3.1.18 Peripheral Reset Register 6 (RGM_PRST6)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1070* for details.

Address: 0x628 Access: User read, Supervisor read/write, Test read/write

Figure 1044. Peripheral Reset Register 6 (RGM_PRST6)

Table 1070. RGM_PRST6 register field descriptions

Field	Description
3 LINFLEXD_1_RST	LINFLEXD_1 reset Writing a ‘1’ to this bit resets the LINFLEXD_1 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 LINFLEXD_3_RST	LINFLEXD_3 reset Writing a ‘1’ to this bit resets the LINFLEXD_3 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
5 LINFLEXD_5_RST	LINFLEXD_5 reset Writing a ‘1’ to this bit resets the LINFLEXD_5 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1070. RGM_PRST6 register field descriptions (continued)

Field	Description
6 LINFLEXD_7_RST	LINFLEXD_7 reset Writing a ‘1’ to this bit resets the LINFLEXD_7 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_7 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
7 LINFLEXD_9_RST	LINFLEXD_9 reset Writing a ‘1’ to this bit resets the LINFLEXD_9 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_9 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 LINFLEXD_11_RST	LINFLEXD_11 reset Writing a ‘1’ to this bit resets the LINFLEXD_11 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_11 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
10 LINFLEXD_15_RST	LINFLEXD_15 reset Writing a ‘1’ to this bit resets the LINFLEXD_15 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_15 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_1_ CTR_RST	CAN_RAM_SUB_1_CTR reset Writing a ‘1’ to this bit resets the CAN_RAM_SUB_1_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_1_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** RGM is able to reset CAN RAM controller and not CAN RAM content. In other words, it is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_0_CTR_RST bit.
25 M_CAN_1_SUB_1_RST	M_CAN_1_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 M_CAN_2_SUB_1_RST	M_CAN_2_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1070. RGM_PRST6 register field descriptions (continued)

Field	Description
27 M_CAN_3_SUB_1_RST	M_CAN_3_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_3_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_3_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 M_CAN_4_SUB_1_RST	M_CAN_4_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_4_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_4_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

51.3.1.19 Peripheral Reset Register 7 (RGM_PRST7)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1071* for details.

Address: 0x62C Access: User read, Supervisor read/write, Test read/write

Figure 1045. Peripheral Reset Register 7 (RGM_PRST7)

Table 1071. RGM_PRST7 register field descriptions

Field	Description
0 SAR_ADC_12BIT_1_RST	SAR_ADC_12BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
12 BODY_CTU_0_RST	BODY_CTU_0 reset Writing a ‘1’ to this bit resets the BODY_CTU_0 peripheral. Writing a ‘0’ to this bit releases the reset to the BODY_CTU_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 STDBY_CTU_0_RST	STDBY_CTU_0 reset Writing a ‘1’ to this bit resets the STDBY_CTU_0 peripheral. Writing a ‘0’ to this bit releases the reset to the STDBY_CTU_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
14 EMIOS_0_RST	EMIOS_0 reset Writing a ‘1’ to this bit resets the EMIOS_0 peripheral. Writing a ‘0’ to this bit releases the reset to the EMIOS_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 EMIOS_1_RST	EMIOS_1 reset Writing a ‘1’ to this bit resets the EMIOS_1 peripheral. Writing a ‘0’ to this bit releases the reset to the EMIOS_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 ETHERNET_0_RST	ETHERNET_0 reset Writing a ‘1’ to this bit resets the ETHERNET_0 peripheral. Writing a ‘0’ to this bit releases the reset to the ETHERNET_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_1_RST	DSPI_1 reset Writing a ‘1’ to this bit resets the DSPI_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1071. RGM_PRST7 register field descriptions (continued)

Field	Description
29 DSPI_3_RST	DSPI_3 reset Writing a ‘1’ to this bit resets the DSPI_3 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 DSPI_5_RST	DSPI_5 reset Writing a ‘1’ to this bit resets the DSPI_5 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Caution: Use the RGM_PRST*n* registers with care. Refer to *Section 51.4.8: Individual peripheral resets* for the proper sequence to prevent unexpected chip behavior.

51.3.1.20 Peripheral Reset Status Register 0 (RGM_PSTAT0)

This register provides the current reset status for various peripherals. It can be accessed in read only in all modes. Refer to *Table 1072* for details.

Address: 0x630 Access: User read/write, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

51.4 Functional description

51.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in *Table 1080*.

Table 1080. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion(1)
power-on reset	all executes a start-up self test if enabled	yes
‘destructive’ resets	all except some clock/reset management executes a start-up self test if enabled	yes
long external reset	all except some clock/reset management and debug executes a start-up self test if enabled	programmable(2)
long external and long 'functional' resets	all except some clock/reset management, STCU, FCCU, and debug	programmable(2)
shortened ‘functional’ resets(3)	flip-flops except some clock/reset management , STCU, FCCU, and debug	programmable(2)

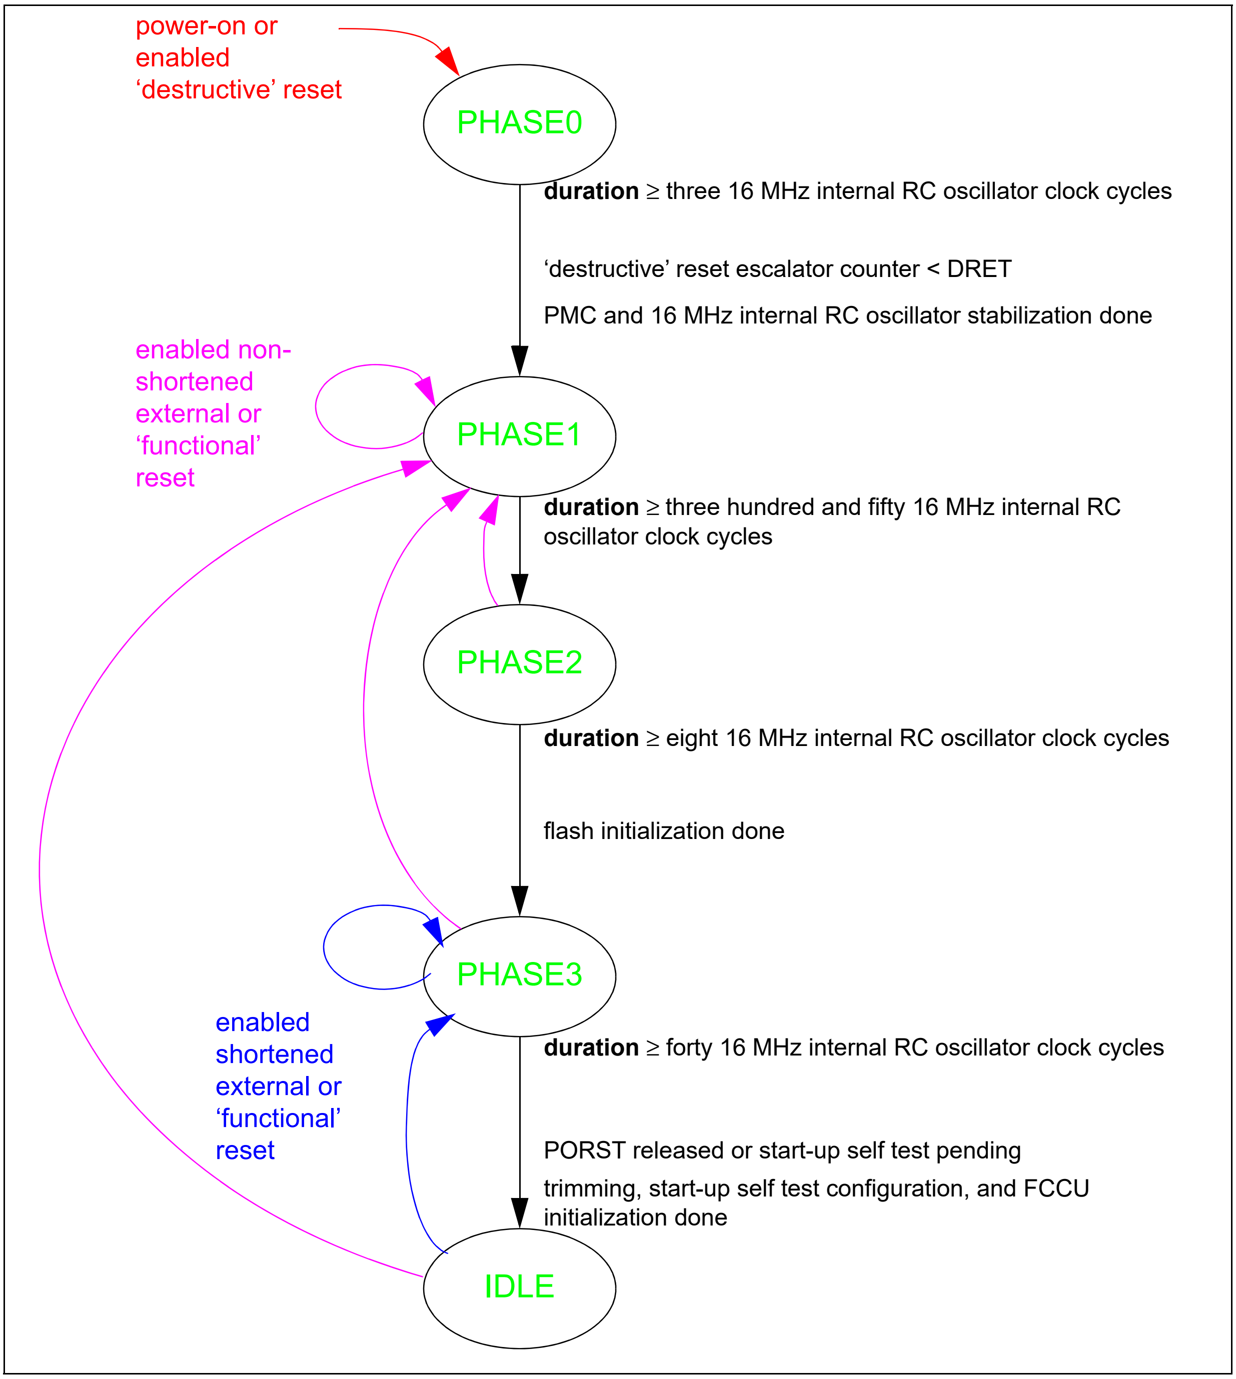
1. ‘external reset assertion’ means that the ESR0 pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3.
2. the assertion of the external reset is controlled via the RGM_FBRE register.
3. the short sequence is enabled via the RGM_FESS register.

Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in *Figure 1054*.

Figure 1054. MC_RGM state machine



51.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled ‘destructive’ reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled ‘destructive’ resets have been processed
- all processes that need to be done in PHASE0 are completed
  - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of three 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled ‘destructive’ reset event
- the ‘destructive’ reset escalator counter has not reached the value in the RGM_DRET[DRET] field

51.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or ‘functional’ reset event if it has not been configured to trigger a ‘short’ sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened ‘functional’ resets have been processed
- a minimum of three hundred and fifty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened ‘functional’ reset event

51.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
  - flash initialization
- a minimum of eight 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

51.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened ‘functional’ reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization
- a minimum of forty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened ‘functional’ reset event
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

51.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

51.4.2 'Destructive' resets

A 'destructive' reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given 'destructive' reset event (RGM_DES.F_<destructive reset> bit) is set when the 'destructive' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'destructive' reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note: The RGM_DERD register can be written only once between two 'destructive' reset events.

The chip's low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD or HVD, or both) is enabled, the supply is sufficient to have the 'destructive' event correctly propagated through the digital logic. Therefore, if a given 'destructive' reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given 'destructive' reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled 'destructive' reset will trigger a reset sequence starting from the beginning of PHASE0.

51.4.2.1 External power-on reset: PORST

The bidirectional external power-on reset pin PORST is a special case 'destructive' reset.

The detection of a falling edge on PORST will start the reset sequence.

The chip asserts PORST if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 us after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self-test on power-on, 'destructive', and external resets, this is the exit of PHASE3 after self test execution has completed.

51.4.3 External reset

51.4.3.1 ESR1 Input External reset

PA[4] can be configured as ESR1 input external reset through WKPU registers (refer to *Figure 17: NMI block diagram SPC584Bx*).

The status flag associated with the external reset falling edge event (RGM_FES.F_ESR1 bit) is set when the external reset is asserted and the power-on reset is not asserted.

Note: The RGM_FERD register can be written only once between two 'destructive' reset events.

Reset Generation Module (MC_RGM): An enabled external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_ESR1 is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the Flash memory.

51.4.3.2 ESR0 Output External reset

PC[1] can be configured as ESR0 output external reset by programming the DCF Record ESR0_CONFIG.

The MC_RGM may assert the external reset ESR0 if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an ESR1 external reset event if configured via the RGM_FBRE register to assert the external reset ESR0
- a 'functional' reset event configured via the RGM_FBRE register to assert the external reset ESR0

In this case, ESR0 is asserted until all conditions for exiting PHASE3 have been met.

51.4.4 ‘Functional’ resets

A ‘functional’ reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content are still intact.

The status flag associated with a given ‘functional’ reset event (RGM_FES.F_<functional reset> bit) is set when the ‘functional’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘functional’ reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note: The RGM_FERD register can be written only once between two power-on reset events.

An enabled ‘functional’ reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a ‘functional’ reset. When RGM_FESS.SS_<functional reset> is set, the associated ‘functional’ reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a ‘functional’ reset should not reset the flash memory module.

Refer to *Chapter 56: Mode Entry Module (MC_ME)*, for details on the STANDBY0 and DRUN modes.

51.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_DERD/FERD and RGM_DEAR/FEAR registers as shown in *Table 1081*.

Table 1081. MC_RGM alternate event selection

RGM_DERD/FERD bit value	RGM_DEAR/FEAR bit value	Generated event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (that is at the reset source that caused the alternate request) and also clearing the appropriate RGM_DES/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

If a masked 'destructive' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

If a masked 'functional' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

51.4.6 'Functional' reset escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once 'functional' reset escalation has been enabled, the MC_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (that is entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or 'destructive' reset. If the counter reaches the value in the RGM_FRET register's FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

51.4.7 'Destructive' reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset[s] which causes a reset sequence to be initiated (that is entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (that is entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

51.4.8 Individual peripheral resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRST*n* registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (Refer to the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRST*n* registers.
4. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is set.
5. Clear the bit corresponding to the peripheral in the RGM_PRST*n* registers.
6. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is cleared.

The peripheral can be kept in reset indefinitely by not executing steps *5* and *6*. After the completion of step *6*, the peripheral can be enabled again via the MC_ME.

s. Only exception is the external power-on reset pin PORST that does not affect the increase of counter.

52 Boot Assist Flash (BAF)

52.1 Introduction

The BAF code is programmed by ST. The two main tasks of BAF are to provide a serial bootloader feature and to search for the application entry point.
For details regarding how the BAF code is executed, refer to *Chapter 8: Reset and Boot*.

The BAF is executed via the IRCOSC as clock source.

The MCU is booted through a collaboration of several blocks, hardware and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the HW boot core of the device pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. When the Life Cycle is set to FAIL_ANALYSIS, the BAF code shall check the UOPS[BAF_FA] bit inside SSCM as described in *Chapter 53: System Status and Configuration Module (SSCM)*. This bit mirrors the bit 31 of the UTEST_Miscellaneous_2 DCF. It tells whether the BAF shall stay in an endless loop or not when the Life Cycle is set to FAIL_ANALYSIS. In case the DCF is not programmed, the bit shall be 0 (refer to *Figure 1055*). Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module or the M_CAN module. The package pins used by LINFlexDs are the same pins used by the M_CAN modules. Hence, the external PHY can be either LIN or CAN (refer to *Section 52.3.8* for configuration details).

52.2 Memory map

For the BAF location in flash, refer to the Embedded memories chapter. The BAF block base address is 0x0040_4000. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in *Table 1082*.

Note: The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic ‘0’ the BAF Flash block cannot be programmed.

Table 1082. BAF memory organization

BAF Component	Address
BAF image header	0x0040_4000
BAF code entry point	0x0040_4100
BAF data area and stack	0x5280_0000–0x5280_0603

52.2.1 BAF image header

BAF image contains a 256-byte header starting from address 0x0040_4000. The BAF header is explained in *Table 1083*.

Table 1083. BAF image header

Address offset	Size (bits)	Field description
0x0000	32	SSCM boot record tag
0x0004	32	BAF start address
0x0008	32	BAF version number
0x000C–0x00FF	Reserved	

52.2.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0x0040_4000. The 32-bit field is explained in *Table 1084*.

Table 1084. BAF image version

Field	Description
0:7	Major Number: This field contains the major version number for the BAF image
8:15	Minor Number: This field contains the minor version number for the BAF image
16:31	Reserved

52.3 Functional description

A functional description of the BAF modes is contained in the following sections.

52.3.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of these different boot modes.

- Application code execution

  If the internal flash contains application code with a valid boot header, the application is executed.

- Serial boot

  If no valid boot header is found and the current life cycle phase of the device is less than Infield, an attempt is made to download the application by a serial protocol using the LINFlexD modules or M_CAN modules. The downloaded code is then executed by the boot CPU.

- Static mode

  The device enters power safe mode and waits for an external reset.

52.3.2 Device initialization

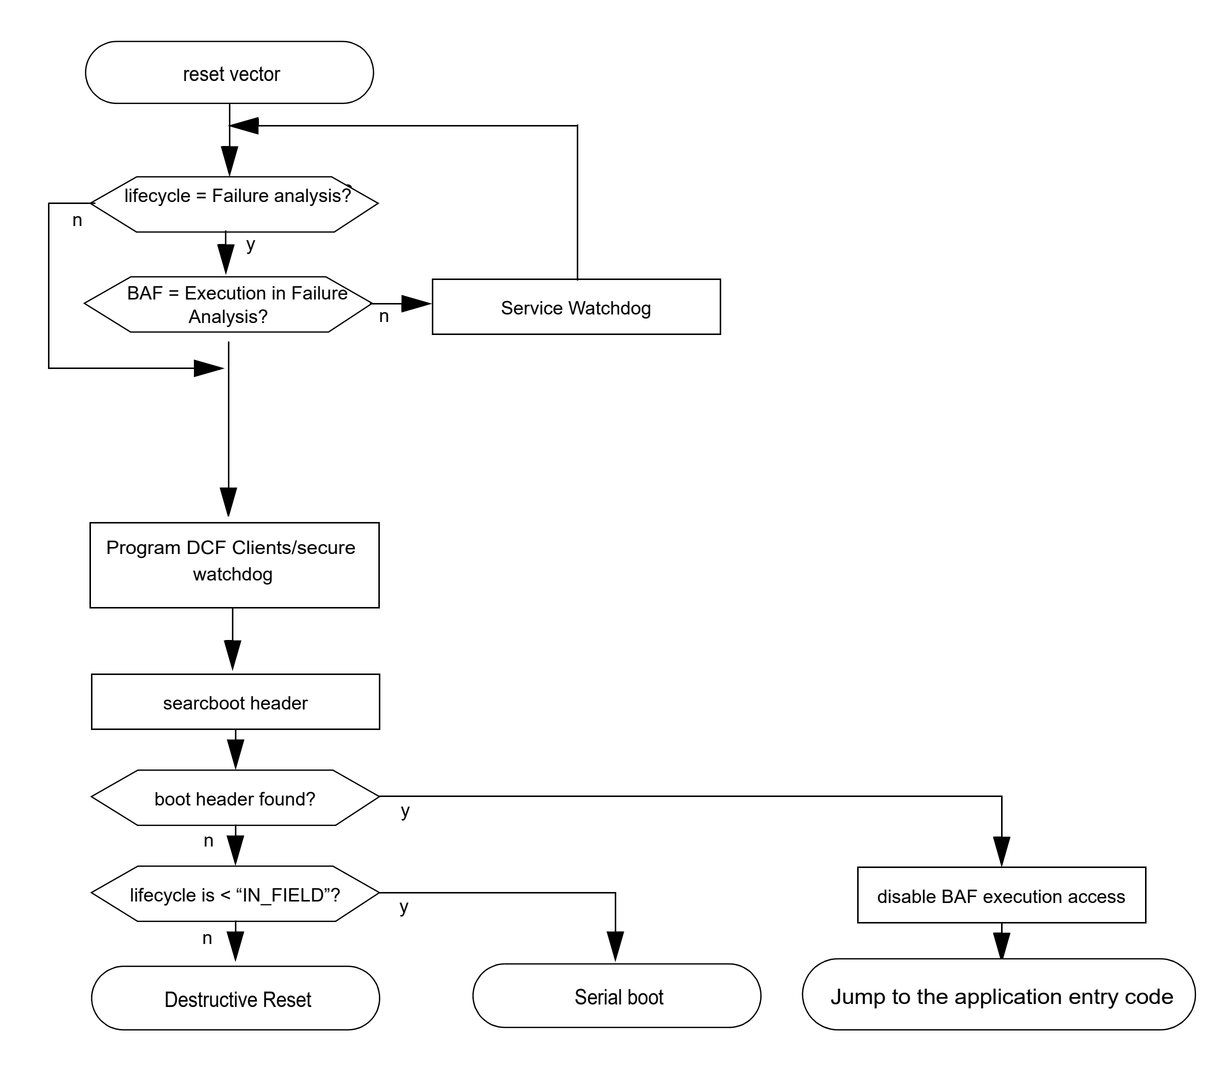
The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the Hardware Security Module (HSM) in the following way:

- HSM: If the HSM is enabled and the “wait for HSM” flag is present, then the boot core waits for the HSM to become ready.
- BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module’s MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
- BAF uses DMEM memory area of the boot CPU as in *Table 1082: BAF memory organization* for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.
- The memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration. At this point the BAF has finished its operation.

52.3.3 Flow of control

Figure 1055 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

Figure 1055. Flow of control



52.3.4 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (SSCM_UOPS[HSB = 1]). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

52.3.5 Initialization of BAF DCF clients

52.3.5.1 'Soft' DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32 bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is 0xFFFF_FFFF). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in *Table 1085*.

The DCF clients which are used for initialization of security watchdog are explained in *Section 52.3.5.2: Security watchdog configuration*.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in *Table 1085* provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside within the BAF or UTEST blocks only. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in *Section 52.3.5.6: SER_BOOT_CBACK – BAF serial boot DCF client*.

Table 1085. BAF DCF client list

Address (hex)	Name	Label	Description
0x0000	Security Watchdog Control Register	SEC_SWT_CR	Data to write to SWT Control Register
0x0001	Security watchdog Time out register	SEC_SWT_TO	Security watchdog counter value
0x0002	Security watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0x0003	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog
0x0004–0x01FF	Reserved		
0x0200	Address	ADDR	The address to which DATAX is written
0x0201	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0x0202	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0x0203	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0x0204–0x020F	Reserved		
0x0210	Callback Address	CALLBACK	The address of a callback function
0x0211	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0x0212–0x0213	Reserved		Reserved for future use.
0x0214	Reserved		Reserved for future use.
0x0215–0x7FFF	Reserved		Reserved for future use.

Note: BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

52.3.5.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then program the security watchdog registers. BAF configures only SWT2 as security watchdog for the CPU2 core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core’s IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

52.3.5.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0000 while parsing, BAF programs the DCF client “Security watchdog control register” with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

52.3.5.2.2 Security Watchdog TImeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

52.3.5.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in ‘fixed address execution service mode’. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0x0002 while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

Note: To program the core IAC8 special purpose register, the ownership of this register should be with software. If hardware has its ownership software will not be able to write to it using mtspr instruction.

52.3.5.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to BAF which CPU will use the security watchdog. BAF parses the DCF record and if it finds a record with CS14 set and address field set as 0003h, BAF programs this DCF client. This means that BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. *Figure 1056* and *Table 1086* indicate the data layout for this client in the DCF record. This client is written once during reset. Subsequent writes are ignored.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients are not written, data is configured erroneously.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). If the security watchdog is assigned to CPU2 (IOP), first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

DCF Client Address 0x0003

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				0				0			

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				0	0	SC

Table 1086. SEC_SWT_CPU field description

Field	Description
30:31 SC	These two bits select the CPU which will use the security watchdog. 00 Reserved 01 Reserved 10 CPU2 (IOP) 11 Reserved

Note: BAF programs FCCU for enabling SWT2 and SWT3 as fault source and makes them hardware recoverable. This is done to ensure that fault latched in FCCU get cleared on reset and on next SWT timeout FCCU can again trigger reset. BAF does not clear the faults latched in FCCU as they can be of interest for application.

52.3.5.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0x0200 while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

Field	Description
0:31 ADDR	32-Bit Address DCF client This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU.

52.3.5.4 BAF DCF client - DATAX

Caution: While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

52.3.5.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0201 while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

DCF Client Address 0x0201

52.3.5.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0202 while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to ‘0’ (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

52.3.5.4.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0203 while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

52.3.5.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0210 while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in Power Architecture web site and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Caution: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore, several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

52.3.5.6 SER_BOOT_CBACK – BAF serial boot DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0211 while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32 bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in over Architecture web site and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: No parameters are passed to the function invoked by the BAF.Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed (refer to *Table 1091* for details regarding return value).

Table 1091. Serial boot callback function return value definition

Return values	Description
0x00	Boot from internal flash using standard search for boot record (refer to 'Search boot header and boot options' in *Chapter 7: Device configuration*).
0x01	Serial boot using both M_CAN and LINFlexD (in UART mode) (refer to 'Search boot header and boot options' in *Chapter 7: Device configuration*). **Note:** Serial boot is conditioned by life cycle as described in *Figure 1055*

52.3.6 TDM Diary Operation

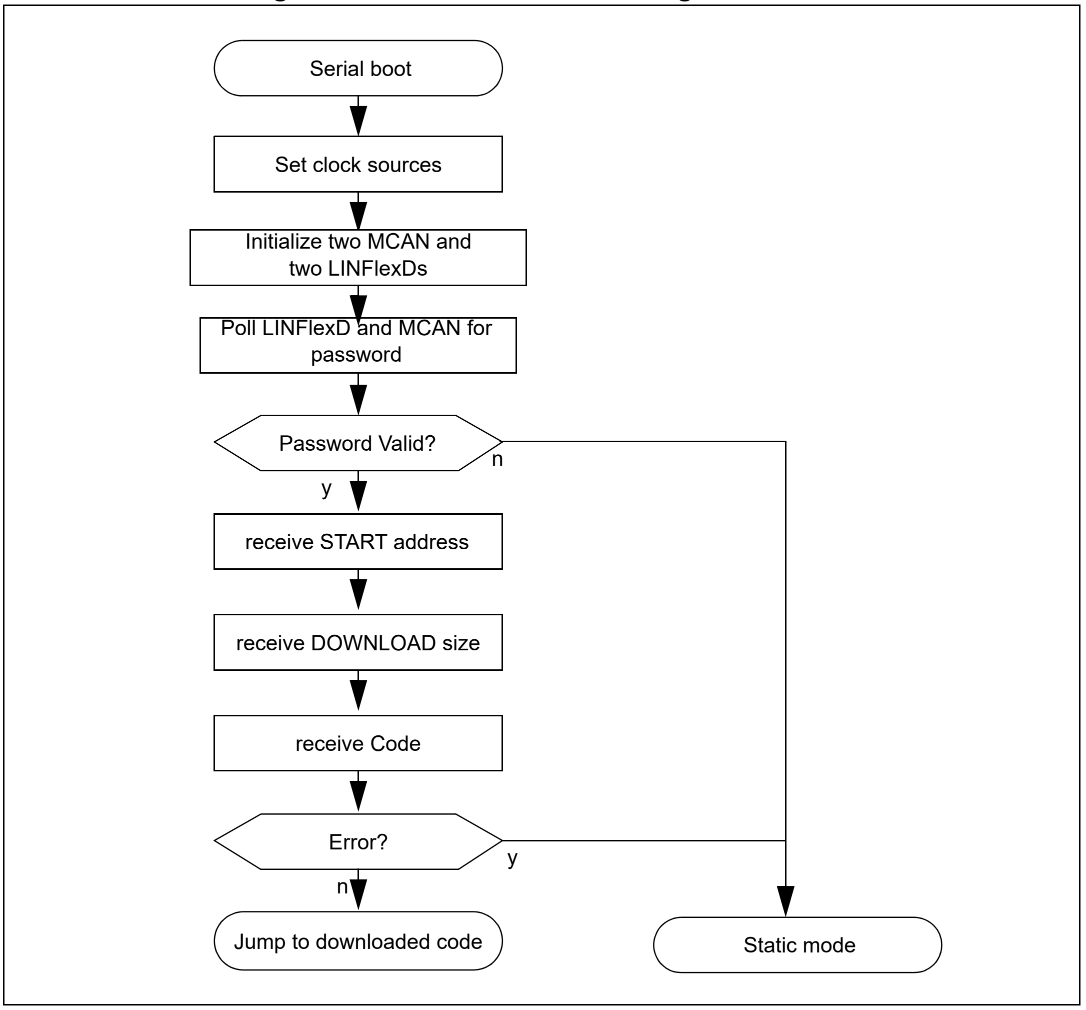
On every reset, BAF copies the first four bytes of last record of every Tamper Detect Region to corresponding Software Tamper Override Key Region Registers in TDM. BAF reads the base address of TDM Diary from DBA register in TDM. For more details on TDM refer to the corresponding section. This is done as a part of TDM Diary Override enhancement.

52.3.7 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than In Field, it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

If the customer selects serial boot using serial boot using serial boot DCF client, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than Failure Analysis, it attempts a serial boot.

Figure 1061. Flow of control during serial boot



The clock source in the MC_CGM is configured (with IRCOSC for LINFlexD and with XOSC for CAN) and the PADs are set up for two LINFlexDs and two M_CANs signals, then the code is downloaded using LINFlexD or M_CAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via LINFlexD or M_CAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At start of serial boot sequence the Rx-channels of all two serial interfaces shall be enabled and the BAF code shall take care for polling all two Rx-channels for detecting the valid serial boot message. After a successful detection of the active Rx-channel the corresponding Tx-channel shall be enabled and the inactive Rx-channel shall be disabled.

At the start of the process both LINFlexDs and M_CANs are configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and does not participate further in serial boot.

If a CAN message of 8 bytes with ID 0x11 is received on the M_CAN controller first, the BAF program

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message not containing 8 bytes or NOT with ID 0x11 is received by M_CAN controller or a M_CAN controller generates a CAN error, it is probable that the tool is sending a LINFlexD frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is 0xFE of the password. If not continue polling. The data may be a valid CAN message.
- If it is first byte of the password (0xFE) then disable the M_CAN controller and restore to its reset state.
- Configures the M_CAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

52.3.7.1 Serial boot mode protocol

From a high-level perspective, the download protocol over M_CAN and LIN interfaces follows the steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.

   NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Note: Since this device supports only VLE code and no Book E code, the VLE bit is used only for backward compatibility.

3. Host transmits a sequence of data bytes that are to be executed.
4. The boot CPU executes code from start address provided in step 2.

Each step must be completed before the next step starts.

The exact protocol between LINFlexD and M_CAN are slightly different.

52.3.7.2 LINFlexD download protocol

The communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   – If the data is correct, the host can send the next byte of data.
   – If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. *x* bytes of code that is downloaded to SRAM and executed (*x* must match the value specified in step 3.).

52.3.7.3 M_CAN download protocol

The M_CAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by M_CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 0x11 as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 0x1.
2. A message with 0x12 as the ID and 8-byte length to send the start address, size of the code and VLE mode bit.The MCU transmits back the same data but with an ID of 0x2.
3. A message with 0x13 as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 0x3.

52.3.7.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password 0xFEED_FACE_CAFE_BEEF.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

52.3.7.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in *Figure 1062* and *Figure 1063*.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

CODE_LENGTH															

Figure 1063. VLE bit, NO_ECHO bit and code size

52.3.7.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero’s and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0x0000_0000_0000_0000) to the next address location. This is written to avoid possible ECC error during core prefetch.

52.3.7.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

52.3.8 Serial boot configuration

52.3.8.1 LINFlexD configuration

Boot using UART protocol is implemented by LINFlexD module.

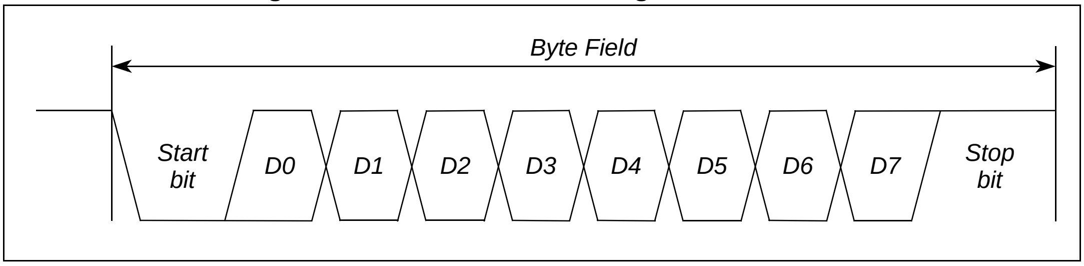
Note: Refer to the pin configuration table in Chapter 7: Device configuration for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx is configured as an input and multiplexed to the LINFlexD module. The LINFlexD_Tx remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data . The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx pin transmission.

The LINFlexD controller is configured to operate with an 8-bit data frame without parity bit and 1 stop bit.

Figure 1064. LINFlexD bit timing in UART mode

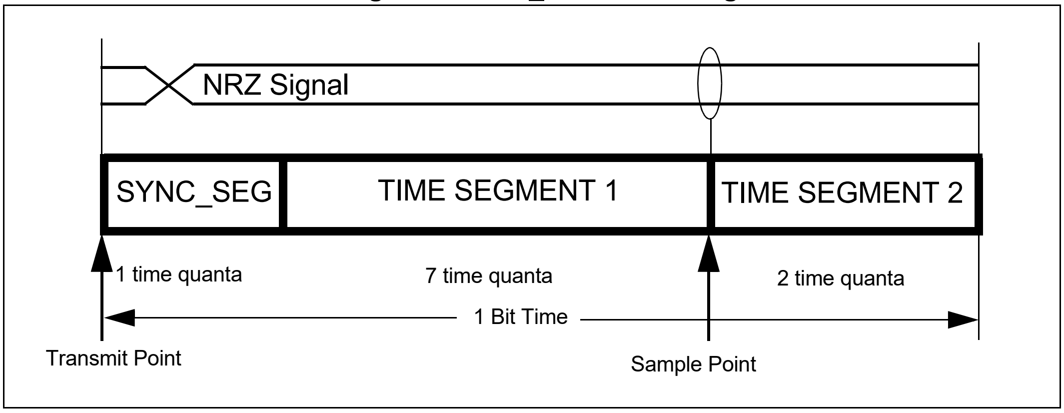


52.3.8.2 M_CAN configuration

The M_CAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0A specification (refer to *Table 1092* for baud rates).

The Bit timing is configured as shown in *Figure 1065*

Figure 1065. M_CAN Bit Timing



52.3.8.3 Baud rates

The LINFlexD baud rate is set at 250kbaud. *Table 1092* below shows some possible baud rates.

The M_CAN baud rate is set by the frequency of the external crystal/40.

Table 1092. M_CAN baud rates

Frequency	M_CAN baud rate
8 MHz	200 Kbaud
12 MHz	300 Kbaud
16 MHz	400 Kbaud
20 MHz	500 Kbaud
40 MHz	1000 Kbaud

52.3.8.4 LINFlexD and M_CAN pin configuration

Refer to *Chapter 7: Device configuration* for pin details.

52.3.8.5 Protocol summary

Table 1093 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 1093. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.

Table 1093. LINFlexD serial boot mode download protocol (continued)

Protocol steps	Host message sent	BAF response message	Action
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is not echoed, otherwise data is echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	None	None	Branch to downloaded code

Table 1094 shows the M_CAN serial boot protocol.

Table 1094. M_CAN serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	CAN ID 0x011 + 64-bit password	CAN ID 0x001 + 64-bit password	Password checked against fixed password (0xFEED_FACE_CAFE_BEEF). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 0x012 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	CAN ID 0x002 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 0x013 + 8 to 64-bits of raw binary data	VLE bit + 31 bit number of bytes (MSB first)	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	None	None	Branch to downloaded code

52.4 Resources accessed by BAF code execution

The BAF code execution uses several IPs to achieve the main functions.

- Magic carpet (clocks)

Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD and M_CAN

The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.

- PFLASH

PFLASH module is used to disable BAF execution. Remapping of the external overlay memory is configured automatically under certain conditions. The two PFLASH are used.

- Interrupts

No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.

- Security watchdog

When SWT2 is chosen as security watchdog, SWT3 is used for task monitoring purpose.

- FCCU

FCCU is used to configure Fault Reaction of SWT2 and SWT3.

- TDM

TDM for implementing TDM Diary enhancements.

- SSCM

Used to read some register bits (mirrors of DCF)

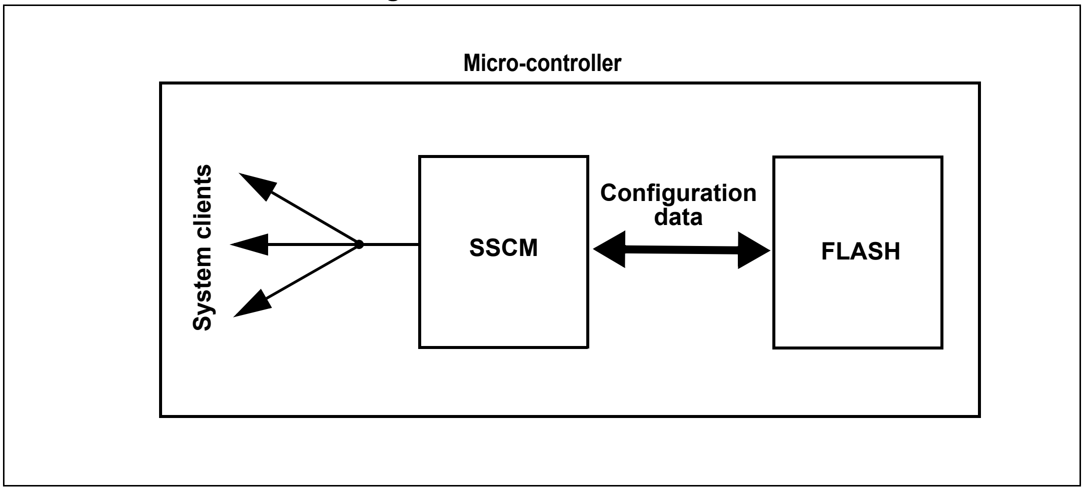
53 System Status and Configuration Module (SSCM)

53.1 Introduction

53.1.1 Overview

The System Status and Configuration Module (SSCM) is aimed at reading the system configuration from the Flash and distributing to various clients inside the micro-controller, pictured in *Figure 1066*.

Figure 1066. SSCM overview



53.1.2 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Determine HSM boot vector
  - Decodes the Device Life Cycle

53.1.3 Modes of operation

The SSCM operates identically in all system modes.

53.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

Table 1095 shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Note: All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit *boundaries. As an example, the STATUS register is accessible by a 16-bit READ/WRITE to address Base + 0x0002, but performing a 16-bit access to Base + 0x0003 is illegal.*

Table 1095. SSCM memory map

Address offset	Register	Access	Reset value	Section
0x0000	SSCM System Status (STATUS)	R/W	0xyyy0(1)	Section 53.2.1.1
0x0002	SSCM System Memory and ID Register (MEMCONFIG)	R	0xyyyy(1)	Section 53.2.1.2
0x0004–0x0005	Reserved			
0x0006	SSCM Error Configuration Register (ERROR)	R/W	0x0000	Section 53.2.1.3
0x0008–0x0009	Reserved(2)			
0x000A–0x001C	Reserved			
0x0020	SSCM HSM and User Option Status Register (UOPS)	R	0xyyyy_yyyy(1)	Section 53.2.1.4
0x0024–0x0027	Reserved			
0x0028	Processor Start Address Register (PSA)	R	0xyyyy_yyyy(1)	Section 53.2.1.5
0x002C–0x002F	Reserved			
0x0030	SSCM HSM Start Address Register (HSA)	R	0xyyyy_yyyy(1)	Section 53.2.1.6
0x0034	Life Cycle Status Register (LCSTAT)	R	0x0000_0y0y(1)	Section 53.2.1.7
0x0038–0x004F	Reserved			

1. Refer to register description for reset value details.
2. No register abort on this location.

53.2.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

53.2.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CER	0	NXEN1	NXEN	1	0	0	BMODE			VLE	0	0	0	0
W		w1c														
Reset	0	0	0	-(2)	-(2)	1	0	0	-(2)			-(1)	0	0	0	0

1. Reset value depends on the associated option bits in flash memory.
2. Reset value depends on the device status after leaving reset.

Figure 1067. System Status Register (STATUS)

Table 1096. STATUS field descriptions

Field	Description
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error while loading DCF clients (with PARITY Enabled). This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
8:10 BMODE	Device Boot Mode 000 Reserved 001 Reserved 010 Reserved 011 User Code Boot (BAF not executed) 100 Reserved 101 BAF Code Boot (BAF executed) 110 Reserved 111 Reserved This field is only updated during reset. If the device goes into standby mode and wakes up from it again, the bits retain their original value.
11 VLE	Variable Length Instruction Mode When booting in User Code Boot mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0 User Code Boot Location contains standard PPC code 1 User Code Boot Location contains VLE code

53.2.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Offset: 0x0002 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	1	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0

1. Reset value reflects the JTAG ID of the device.

Figure 1068. System memory and ID register (MEMCONFIG)

Table 1097. MEMCONFIG field descriptions

Field	Description
0:9 JPIN	JTAG Part ID Number
11:14 MREV	Minor Mask Revision

53.2.1.3 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Offset: 0x0006 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1069. Error Configuration Register (ERROR)

Table 1098. ERROR field descriptions

Field	Description
14 PAE	Peripheral Bus Abort Enable This bit enables bus aborts on: – any access to a peripheral slot that is not used on the device. – illegal accesses to off-platform peripherals. On platform peripherals cannot be controlled by SSCM peripheral abort. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
15 RAE	Register Bus Abort Enable This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception **Note:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the PBRIDGE level). In this case, the PAE and RAE register bits have no effect on the abort.

53.2.1.4 HSM and User Option Status Register (UOPS)

Offset: 0x0020 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0/1[(1)]	0	0	0	0	0	0	0	0	0	0	0	0/1[(1)]	0/1[(1)]	0/1[(1)]	0/1[(1)]

1. Values are determined by DCF record and life cycle - default is 0.

Figure 1070. HSM and User Option Status Register (UOPS)

Table 1099. UOPS field descriptions

Field	Description
16 BAF_FA	BAF execution mode when bypass mode DCF is zero and lifecycle is FA 0 BAF enters an infinite loop 1 BAF executes as normal **Note:** This bit is mirrored from bit 31 of the UTEST_Miscellaneous_2 DCF client.
17 FL_STDBY	Code flash on after standby mode, despite MC_ME programming 0 Code Flash can be switched off when exiting from STANDBY mode, if programmed in MC_ME.MC_DRUN.CFLAON 1 Code Flash cannot be switched off when exiting from STANDBY mode, even if programmed in MC_ME.MC_DRUN.CFLAON **Note:** This bit is mirrored from bit 30 of UTEST_Miscellaneous_2 DCF client. When this bit is set, writing on MC_ME.MC_DRUN.CFLAON has no effect.
18 FL_RUN	Code flash on during RUNx mode, despite MC_ME programming 0 Code Flash can be switched off in RUNx mode, if programmed in MC_ME.MC_DRUx.CFLAON 1 Code Flash can be switched off in RUNx mode, even if programmed in MC_ME.MC_RUNx.CFLAON **Note:** This bit is mirrored from bit 29 of UTEST_Miscellaneous_2 DCF client. When this bit is set, writing on MC_ME.MC_RUNx.CFLAON has no effect.
28:30 HSB	HSM Boot Configuration 001 When the device is in BAF Code Boot mode, BAF waits for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM waits for HSM ready flag before allowing application code to start. Others: When the device is in BAF Code Boot mode, BAF will not wait for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM will not wait for HSM ready flag before allowing application code to start. This field can be set via DCF record (refer to the SPC584Bx Microcontroller Security Reference Manual for the HSM details).
31 HSE	HSM Enabled This bit is set to 1 if HSM is enabled via DCF record.

53.2.1.5 Processor Start Address Register (PSA)

Offset 0x0028 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SADR[(1)]															
W																
Reset	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1

R	0	0	0	0	0	0	0	0	0	0	0	0	0	LC		
W																
Reset	0	0	0	0	0	0	0/1(1)	0/1(1)	0	0	0	0	0	0/1(2)	0/1(2)	0/1(2)

1. Reset value reflects the Test Life Cycle of the device.
2. Reset value is the Life Cycle of the device.

Figure 1073. Life Cycle Status Register (LCSTAT)

Table 1102. LCSTAT field descriptions

Field	Description
29:31 LC	Life Cycle As determined by the SSCM by reading the LC slots. The encoding is: 000 FAIL_ANALYSIS 001 Reserved 010 PROD_OEM 011 CUST_DELIV 100 Reserved 101 Reserved 110 ST_PROD 111 IN_FIELD

53.3 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

53.3.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. *Figure 1074* shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Figure 1074. DCF start record

0:31
0x05AA 55AF

0:31
0x0000 0000

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - refer to *Figure 1075*. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Figure 1075. Format of a DCF data record

0:31
WDATA[31:0]

0:14	15:29	30	31
CS[14:0]	ADDR[16:2]	PRTY	STOP

The stop record indicates that processing should stop. The general format of the stop record is shown in *Figure 1076*. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Figure 1076. DCF stop record

0:31
Reserved

0:30	31
Reserved	1

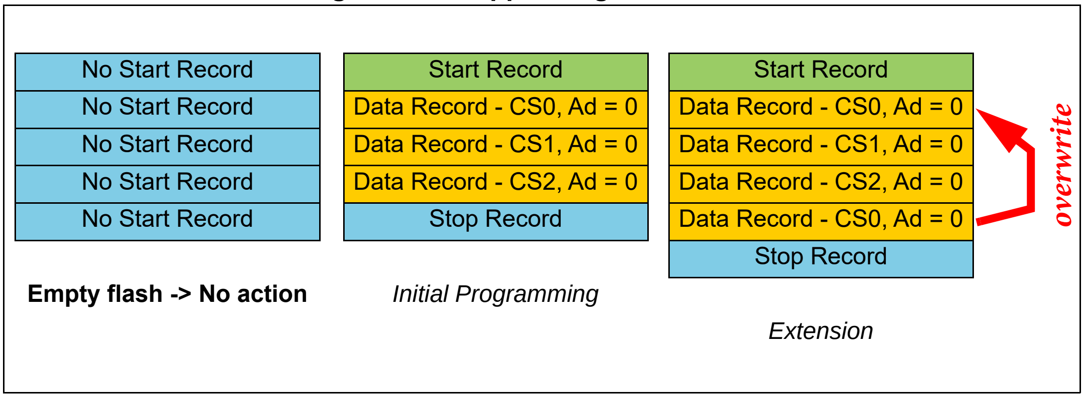
If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 1103*.

Table 1103. Series of DCF records in UTEST

ADDR offset	DATA			
0x00	0x05AA_55AF			
0x04	0x0000_0000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8n - 1 + 0x0	Reserved			
8n - 1 + 0x4	Reserved			1
8n + 0x0				
8n + 0x4				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 1077*.

Figure 1077. Appending DCF records



In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0x0000_0001 then the PRTY field needs to be set to '1', so that the total number of 1s is even).

53.3.2 ECC error monitoring

During flash memory scanning (such as Life Cycle or DCF records), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs the SSCM will request a destructive reset.

53.3.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- User Code Boot mode (SSCM): the device will boot from the first bootable section of the flash memory main array (BOOT_ID = 0x5A).
- BAF Code Boot: the device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup (BOOT_ID = 0xA5).
- Standby-Boot : after waking up from Standby Mode, the processor will execute from the Standby RAM. The flash memory will not be accessible in this mode.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location for SSCM and BAF, that is 0x5A and 0xA5 respectively) then the device will enter serial boot mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. Refer to *Section 53.3.6: HSM boot header search* for details.

53.3.4 BAF configuration

In BAF Code Boot mode the boot core will start to execute the BAF code at the location provided in the “Embedded Flash Memory” chapter (TestFlash block memory map). The BMODE field in the SSCM status register will be set to the value 0b101. Details of the BAF operation are described in the BAF chapter.

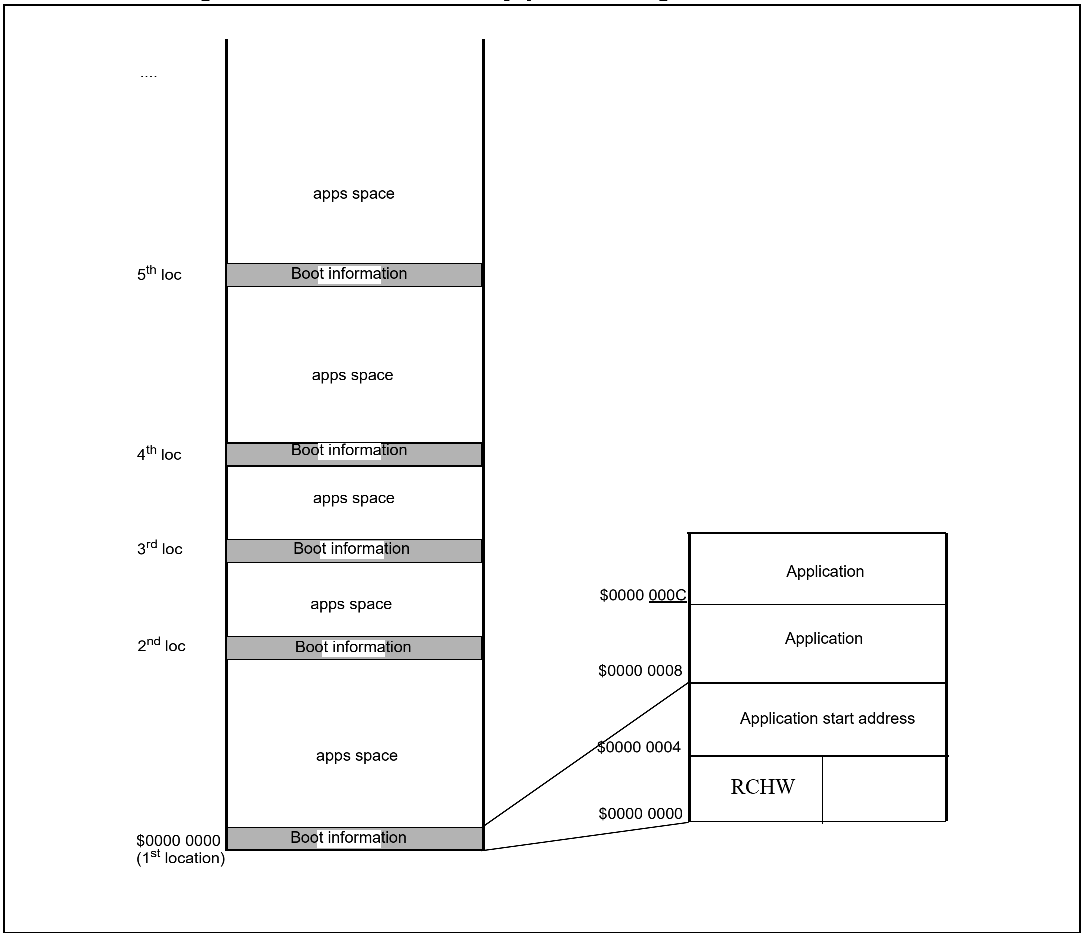
53.3.5 User code boot sector search

53.3.5.1 Potential boot sectors

As shown in *Figure 1078* in User Code Boot mode, several locations are searched for a valid boot ID. The lowest sector which starts with a valid boot ID will be used to boot the device.

The flash memory locations that are searched for boot information are shown in the “Reset and Boot” chapter (section “HW boot record search (SSCM search)”).

Figure 1078. Flash memory partitioning and RCHW search



53.3.5.2 Reset Configuration Half-Word

For each boot sector in the flash memory, SSCM checks the content of the Reset Configuration Half-Word (RCHW) at offset 0x00. If the RCHW field BOOT_ID holds the value 0x5A then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. (If a device only supports VLE code for future compatibility the flag must always be set to '1'.) All other bits are reserved.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	VLE	BOOT_ID							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Reserved

Figure 1079. Reset Configuration Half-Word

Once the device detects that it needs to boot from flash memory, and finds a valid BOOT_ID, it will boot from the application start address at offset 0x04 within the boot sector.

53.3.5.3 Standby Boot mode

In Standby Boot mode, the MCU can be configured to boot from internal flash memory (User Code Boot mode) or from Standby RAM. If the MCU boots from Standby RAM the reset sequence can be abridged - in this case the flash memory will not be available (refer to RGM block guide for mode selection).

The device security status will be stored in the SSCM Standby area, so debugging will be possible if the device is unsecured.

To enter Standby Boot mode (SBM) first the RGM needs to be configured appropriately, then low power standby mode must be entered and subsequently a wakeup interrupt must be received.

The intent of SBM is to allow quick wakeup from low power standby mode. Upon wakeup application code could perform a quick check whether the device is needed, perform a short task, then return to standby again and conserve power.

To further aid this, the device allows to boot without activating the flash memory - which significantly reduces the length of the wakeup sequence (refer to the MC_RGM chapter).

In Standby Boot mode the device will boot from Standby RAM offset 0x00. The application needs to load code to this location before going into low power standby mode. In some cases the entire code will be located here, but it is also possible to merely place a jump command at offset 0x00 and continue execution from another location (for example, the flash memory if it is activated or from the external bus).

If the device boots without enabling the flash memory, it is not possible to determine the security status again. Hence the security status is stored in the SSCM standby area, and the device will therefore have the same access restrictions as were in place before entering low power standby mode. For example, if the device was secure before entering low power standby mode, then debug will not be possible in Standby Boot mode.

Sometimes it is desirable to activate the flash memory even though it was initially bypassed in Standby Boot mode. To do this the application needs to select a run mode which enables the flash memory - the device will transition into that run mode once the flash memory reset sequence is complete.

53.3.6 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (refer to the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.

The HSM Boot Header has the format as described in *Figure 1080*.

Figure 1080. Boot header structure

0x00	Boot Header ID	
0x08	Reserved	Start Address
10x0	Reserved for Configuration Bits	

A valid Boot Header ID has the value 0xFFFF_0000_FFFF_0000.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0x0000_0000_0000_0000. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

53.3.7 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from UTEST flash memory area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- ST Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 256 bits each, at fixed locations in UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- The valid field
- The invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 status:

Table 1104. Life Cycle slots

Use case	Offset	LC slot	Valid field (128 bits)		Invalid field (128 bits)		LC slot status
1	0x00-0x10	1	Erased	Erased	Erased	Erased	Erased
2	0x00-0x10	1	Marked	Erased	Marked	Erased	Inactive
3	0x00-0x10	1	Marked	Erased	Erased	Erased	Active
4	0x00-0x10	1	Any other value				Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 0x55AA_50AF_55AA_50AF, “Erased” is detected by the bit pattern 0xFFFF_FFFF_FFFF_FFFF.

Table 1105 shows how the slots are arranged in memory.

Table 1105. Life Cycle Slots in Memory

Offset	LC Slot word
0x00 - 0x07	Valid[63:0]
0x08 - 0x0F	Don't care

The Life Cycle is determined as shown in *Table 1106*. The priority of the entries is from top to bottom, so the first row which applies determines the resulting Life Cycle.

Table 1106. Resulting Life Cycle

LC Slot 0 ST_PROD(1)	LC Slot 1 CUST_DEL(1)	LC Slot 2 OEM_PROD(1)	LC Slot 3 IN_FIELD(1)	LC Slot 4 FA(1)	Resulting LifeCycle
Active	Erased	Erased	Erased	Erased	ST Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	*Inactive*	**Active**	Erased	Erased	OEM Production
Inactive	*Inactive*	*Inactive*	**Active**	Erased	In Field
Inactive	*Inactive*	*Inactive*	*Inactive*	**Active**	FA
Any other combination				Erased	In Field
Any other combination					System Reset

1. Erased = all slot bits at ‘1’

53.4 Initialization and application information

53.4.1 Reset

The reset state of each individual bit is shown within the Register Description section (refer to *Section 53.2.1: Register descriptions*).

53.5 Additional safety measures

53.5.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the MC_RGM. In case of a spurious reset the SSCM will not interfere with the flash memory bus or overwrite configuration registers. Status internal to the SSCM will be lost, however.

54 Power management controller digital interface (PMC_Dig)

54.1 Introduction

The Control PMU manages the PMU at reset, standby entry, standby exit and during run. It checks the LVD or HVD accuracy.

The PMC analog block interfaces the digital part of the device by the PMC_Dig block.

This chapter describes the digital block of the PMU.

The PMC_Dig contains all of the registers and digital logic to generate all of the enable signals, two stage trim control bits, Power on Reset (POR) generation, standby entry/exit sequence and test mode logic for the analog block. The PMU digital logic also contains the controls for PMU analog outputs to be sensed with the ADC module.

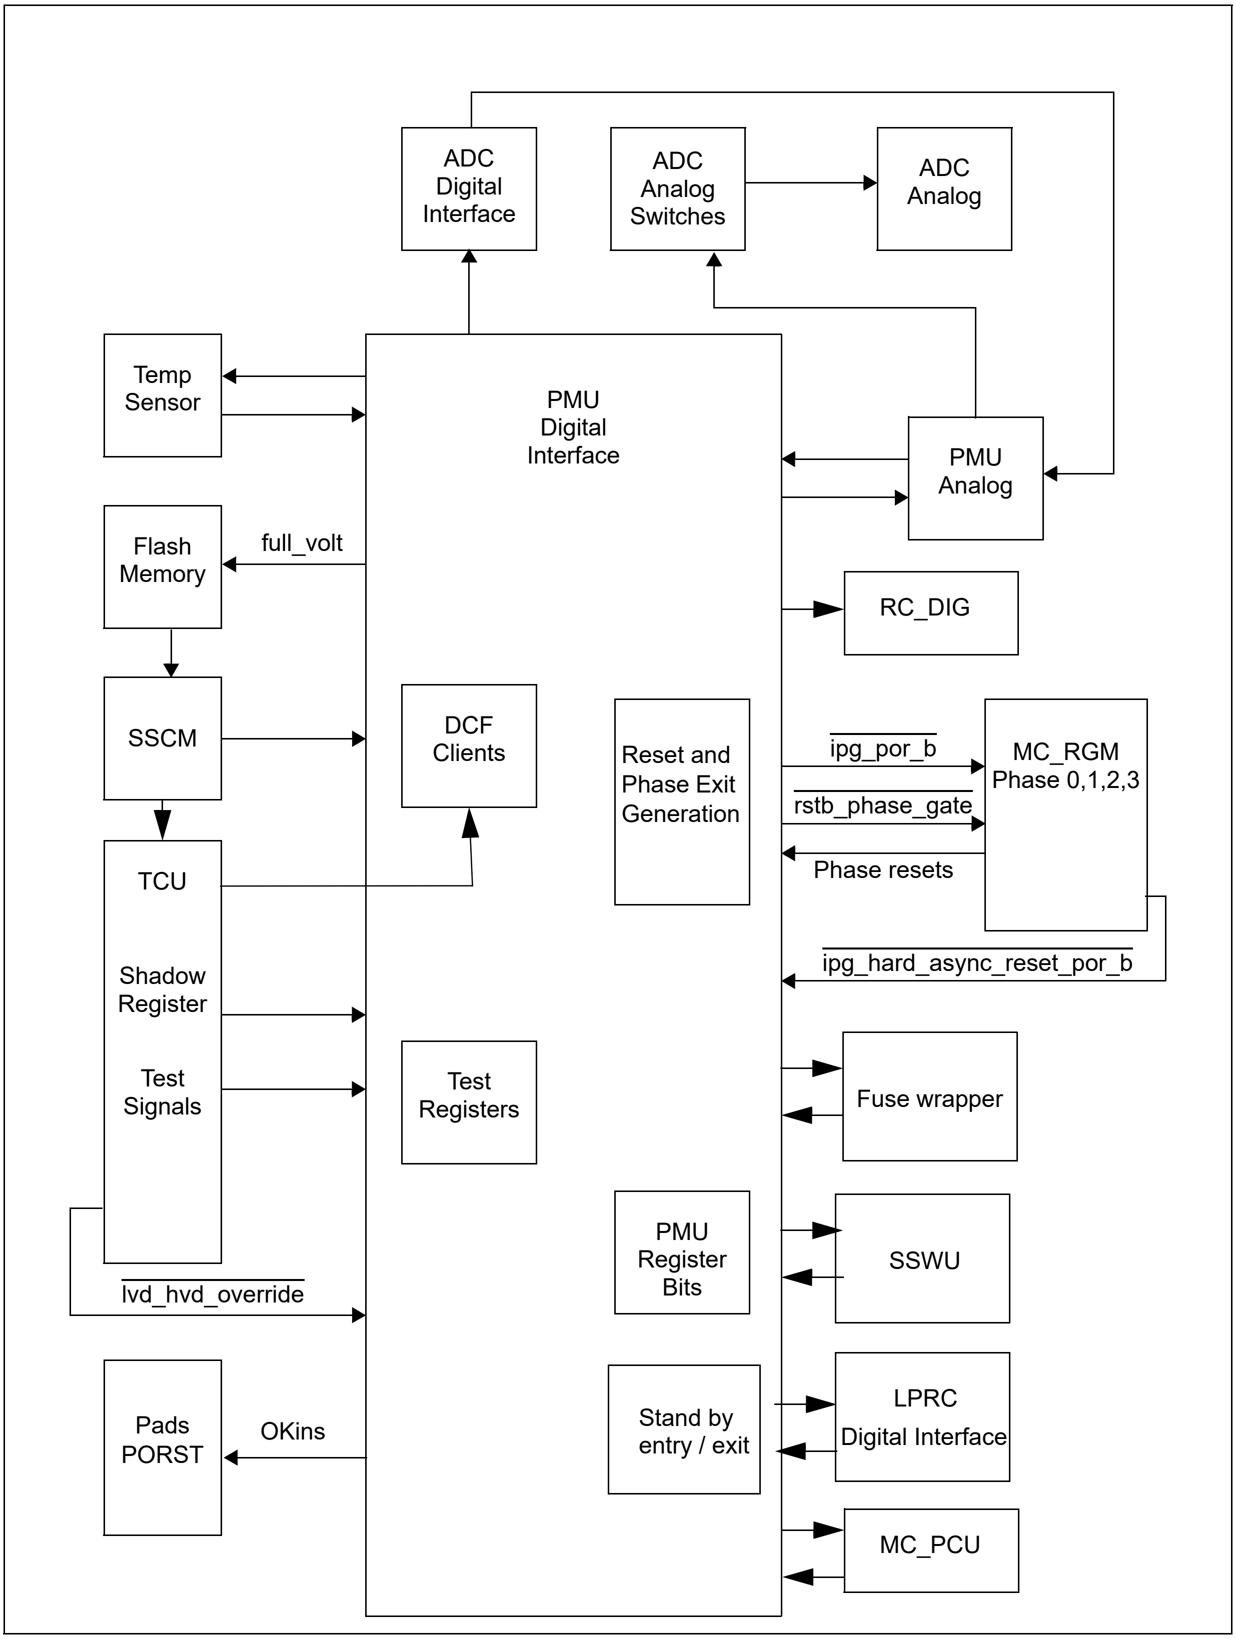
In addition, the PMU digital logic contains the enable signals, trim bits and other registers for the temperature sensor for SOC and a dedicated temperature sensor for RC regulator.

There are also several custom interfaces to various other blocks: The Reset Generation Module (MC_RGM) block receives the LVD values during POR to use for phase transition conditions and reset generation of FUSE_WRAPPER.

There are two custom interfaces, one to Flash memory via the SSCM (and DCF client blocks) that is used to load the trim values during initial POR. The other to fuse block via fuse_wrapper that is responsible for first stage trimming, that is to say, bandgap trimming of both regulator and monitor.

The PMU digital block generates a transfer error event to the system if the selected address is greater than the highest address in the PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed. *Figure 1081* shows the top level block diagram of the digital PMU and its interfaces to the device modules.

Figure 1081. Digital PMU block diagram



54.2 Main features

- PMU management at a main reset
- Resets signal generation

54.2.1 Standard features

- IPS bus interface

54.3 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers
- any other operation (free byte enables or other operations) must be avoided.

The PMC_Dig block generates a transfer error in the following cases:

- any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.

The registers of the PMC_Dig block are accessible (read/write) in each access mode: user, supervisor or test.

About the Reset used among the register:

- The POR reset is used on EPR_LVx, EPR_HVx, REE_LVx, REE_HVx, RES_LVx and RES_HVx registers
- The destructive reset generated by voltage detectors is used on REE_TD, RES_TD, FEE_LVx, FEE_HVx, BIST_x and FEE_TD registers
- The functional reset is used on IE_HVx, IE_LVx, IE_G, CTL_TD registers

54.4 Memory map/register definition

Table 1107 shows the PMU memory map. The PMU includes many registers for configuring and monitoring LVD monitors, and some other control registers.

1. Refer to *Section 54.5*.

Table 1109 shows the correspondence between VD number and VD name, where HV means a 3.3 V/5.0 V supply and LV means a 1.2 V supply.

Table 1109. VD number versus VD name table

VD Number	VD Name	VD Meaning
VD0	POR031_C	LV detector asserts when PMU supply < 0.31 V
VD1	MVD082T_C	LV detector asserts when PMU supply < 0.82 V
VD2	MVD094_C	LV detector asserts when PMU supply < 0.94 V
VD2	MVD094_FA/FB	LV detector asserts when FLASH supply < 0.94 V
VD3	LVD100_C	LV detector asserts when PMU supply < 1.0 V
VD3	LVD100_FL	LV detector asserts when FLASH supply < 1.0 V
VD3	LVD100_SB	LV detector asserts when standby supply < 1.0 V
VD6	HVD134_C	LV detector asserts when PMU supply > 1.34 V
VD7	UVD140_C	LV detector asserts when PMU supply > 1.40 V
VD7	UVD140_FL	LV detector asserts when FLASH supply > 1.40 V
VD8	POR200_C	HV detector asserts when PMU supply < 2.00 V
VD9	MVD240T_C	HV detector asserts when PMU supply < 2.40 V
VD10	MVD270_C	HV detector asserts when PMU supply < 2.70 V
VD10	MVD270_FL	HV detector asserts when FLASH supply < 2.70 V
VD11	LVD290_AS	HV detector asserts when SAR ADC supply < 2.90 V
VD11	LVD290_C	HV detector asserts when PMU supply < 2.90 V
VD11	LVD290_FL	HV detector asserts when FLASH supply < 2.90 V
VD11	LVD290_IF	HV detector asserts when IO ETHERNET supply < 2.90 V
VD13	HVD400_IF	HV detector asserts when IO ETHERNET supply > 4.00 V
VD14	LVD400_AS	HV detector asserts when SAR ADC supply < 4.00 V

Table 1109. VD number versus VD name table (continued)

VD Number	VD Name	VD Meaning
VD14	LVD400_IF	HV detector asserts when IO ETHERNET supply < 4.00 V
VD14	LVD400_IM	HV detector asserts when IO MAINS supply < 4.00 V
VD15	UVD600_FL	HV detector asserts when FLASH supply > 6.00 V
VD15	UVD600_IF	HV detector asserts when IO ETHERNET supply > 6.00 V

54.5 Registers description

54.5.1 Event Pending Register (EPR_LV0)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 0 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Offset: 0x0000 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1082. Event Pending Register (EPR_LV0)

Table 1110. EPR_LV0 field descriptions

Field	Description
3 LVD3_SB	LVD3_SB flag This bit is the low-voltage status flag associated with LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V supply always on IO ring. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 1.00 V point supply.
5 LVD3_FL	LVD3_FL flag This bit is the low-voltage status flag associated with LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 1.00 V point supply.
7 LVD3_C	LVD3_C flag This bit is the low-voltage status flag associated with LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 1.00 V point supply.

54.5.2 Reset Event Enable Register (REE_LV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Offset: 0x0004 Access: User read/write, Supervisor read/write, Test read/write

Figure 1083. Reset Event Enable Register (REE_LV0)

Table 1111. REE_LV0 field descriptions

Field	Description
3 REE3_SB	REE3_SB reset enable This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates a system reset. The RES3_SB bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
5 REE3_FL	REE3_FL reset enable This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage of 1.00 V on Flash supply, generates a system reset. The RES3_FL bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE3_C	REE3_C reset enable This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates a system reset. The RES3_C bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

54.5.3 Reset Event Select Register (RES_LV0)

This Reset Event Select Register controls, in LOW VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Offset: 0x0008 Access: User read/write, Supervisor read/write, Test read/write

Figure 1084. Reset Event Select Register (RES_LV0)

Table 1112. RES_LV0 field descriptions

Field	Description
3 RES3_SB	RES3_SB reset event select This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply of the cold point, generates a destructive reset or a functional reset. The REE3_SB bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset. **Note:** for LVD100_SB it is not allowed to enable destructive reset, only functional reset is supported.
5 RES3_FL	RES3_FL reset event select This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES3_C	RES3_C reset event select This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

54.5.4 Interrupt Enable (IE_LV0)

This configuration register contains a set of LV0 interrupt Enable bits that correspond to each of the LV0 Event Pending Registers (EPR_LV0). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_LV0 bits can be read or written at any time.

Offset: 0x000C Access: User read/write, Supervisor read/write, Test read/write

Figure 1085. Interrupt Enable Register (IE_LV0)

Table 1113. IE_LV0 field descriptions

Field	Description
3 VD3IE_SB	VD3IE_SB Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply event. 0 Interrupt disabled. 1 Interrupt enabled. **Note:** Interrupt occurrence in case of LVD happens only in normal mode (interrupt being not powered in standby mode)
5 VD3IE_FL	VD3IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply event. 0 Interrupt disabled. 1 Interrupt enabled.
7 VD3IE_C	VD3IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply event. 0 Interrupt disabled. 1 Interrupt enabled.

54.5.5 FCCU Event Enable Register (FEE_LV0)

This FCCU Event Enable Register LV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Offset: 0x0010 Access: User read/write, Supervisor read/write, Test read/write

Figure 1086. FCCU Event Enable Register (FEE_LV0)

Table 1114. FEE_LV0 field descriptions

Field	Description
3 FEE3_SB	FEE3_SB FCCU event enable This bit defines whether a VD assertion of LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the always on IO ring does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the always on IO ring causes an FCCU event. **Note:** FCCU event in case of LVD happens only in normal mode (FCCU being not powered in standby mode)
5 FEE3_FL	FEE3_FL FCCU event enable This bit defines whether a VD assertion of LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Flash causes an FCCU event.
7 FEE3_C	FEE3_C FCCU event enable This bit defines whether a VD assertion of LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Core causes an FCCU event.

54.5.6 Event Pending Register (EPR_LV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0020 Access: User read/write, Supervisor read/write, Test read/write

Field	Description
15 HVD6_C	HVD6_C flag This bit is the low-voltage status flag associated with HVD134_C VD, the voltage level detect for the low voltage Core 1.34 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 6 threshold, and clears when the supply rises above its corresponding HVD6 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 1.34 V point supply.

54.5.7 Reset Event Enable Register (REE_LV1)

This Reset Event Enable Register controls, in LOW VOLTAGE 1 range, whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Offset: 0x0024 Access: User read/write, Supervisor read/write, Test read/write

Table 1116. REE_LV1 field descriptions

Field	Description
15 REE6_C	REE6_C reset enable This bit defines whether a HVD134_C VD, the voltage level detect for the low voltage Core 1.34 V supply of the cold point, generates a system reset. RES_LV1[RES6_C] determines whether the reset is functional or destructive. 0Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

54.5.8 Reset Event Select Register (RES_LV1)

This Reset Event Select Register controls, in LOW VOLTAGE 1 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Field	Description
15 RES6_C	RES6_C event select This bit defines whether a HVD134_C VD, the voltage level detect for the low voltage Core 1.34 V supply of the cold point, generates a destructive reset or a functional reset. REE_LV1[REE6_C] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

54.5.9 Interrupt Enable (IE_LV1)

This configuration register contains a set of LV1 interrupt Enable bits that correspond to each of the LV1 Event Pending Registers (EPR_LV1). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_LV1 bits can be read or written at any time.

Offset: 0x002C Access: User read/write, Supervisor read/write, Test read/write

Figure 1092. Event Pending Register (EPR_HV0)

Table 1120. EPR_HV0 field descriptions

Field	Description
2 LVD11_AS	LVD11_AS flag This bit is the high-voltage status flag associated with LVD290_AS, the voltage level detect for the low voltage SAR ADC 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 2.90 V point supply.
3 LVD11_IF	LVD11_IF flag This bit is the high-voltage status flag associated with LVD290_IF, the voltage level detect for the low voltage IO Ethernet 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 2.90 V point supply.
6 LVD11_FL	LVD11_FL flag This bit is the high-voltage status flag associated with LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 2.90 V point supply.
7 LVD11_C	LVD11_C flag This bit is the high-voltage status flag associated with LVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the low voltage 2.90 V point supply.

54.5.12 Reset Event Enable Register (REE_HV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Figure 1093. Reset Event Enable Register (REE_HV0)

Table 1121. REE_HV0 field descriptions

Field	Description
2 REE11_AS	LVD11_AS reset enable This bit defines whether LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply generates a system reset. The RES11_AS bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
3 REE11_IF	LVD11_IF reset enable This bit defines whether LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO /Ethernet 2.90 V supply generates a system reset. The RES11_IF bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
6 REE11_FL	LVD11_FL reset enable This bit defines whether LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply of the cold point generates a system reset. The RES11_FL bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE11_C	LVD11_C reset enable This bit defines whether LVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply, of the cold point generates a system reset. The RES11_C bit determines whether a system reset is enabled or not. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

54.5.13 Reset Event Select Register (RES_HV0)

This Reset Event Select Register controls, in HIGH VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Field	Description
2 RES11_AS	RES11_AS reset event select This bit defines whether an LVD assertion on the SAR ADC 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_AS bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
3 RES11_IF	RES11_IF reset event select This bit defines whether an LVD assertion on the IO Ethernet 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_IF bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

Table 1122. RES_HV0 field descriptions (continued)

Field	Description
6 RES11_FL	RES11_FL reset event select This bit defines whether an LVD assertion on the Flash 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES11_C	RES11_C reset event select This bit defines whether an LVD assertion on the Core 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

54.5.14 Interrupt Enable (IE_HV0)

This configuration register contains a set of HV0 interrupt Enable bits that correspond to each of the HV0 Event Pending Registers (EPR_HV0). These bits indicate whether an interrupt enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_HV0 bits can be read or written at any time.

Field	Description
2 LVD11IE_AS	LVD11IE_AS Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
3 LVD11IE_IF	LVD11IE_IF Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO Ethernet 2.90 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
6 LVD11IE_FL	LVD11IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
7 LVD11IE_C	LVD11IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the lVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

54.5.15 FCCU Event Enable Register (FEE_HV0)

This FCCU Event Enable Register HV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Figure 1096. FCCU Event Enable Register (FEE_HV0)

Table 1124. FEE_HV0 field descriptions

Field	Description
2 FEE11_AS	FEE11_AS FCCU event enable This bit defines whether a LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the ADC does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the ADC causes an FCCU event.
3 FEE11_IF	FEE11_IF FCCU event enable This bit defines whether a LVD290_IF VD, the voltage level detect for the high voltage assertion on the IO Ethernet 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the IO Ethernet does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the IO Ethernet causes an FCCU event.
6 FEE11_FL	FEE11_FL FCCU event enable This bit defines whether a LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Flash causes an FCCU event.
7 FEE11_C	FEE11_C FCCU event enable This bit defines whether a LVD290_C VD, the voltage level detect for the high voltage assertion on the Core 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Core causes an FCCU event.

54.5.16 Event Pending Register (EPR_HV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in HIGH VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Offset: 0x0060 Access: User read/write, Supervisor read/write, Test read/write

Figure 1097. Event Pending Register (EPR_HV1)

Table 1125. EPR_HV1 field descriptions

Field	Description
10 LVD14_AS	LVD14_AS flag This bit is the High voltage status flag associated with LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_AS threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
12 LVD14_IF	LVD14_IF flag This bit is the High voltage status flag associated with LVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IF threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

Table 1125. EPR_HV1 field descriptions (continued)

Field	Description
14 LVD14_IM	LVD14_IM flag This bit is the High voltage status flag associated with LVD400_IM VD, the VD for the high voltage IO main 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IM threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
21 HVD13_IF	HVD13_IF flag This bit is the High Voltage status flag associated with HVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply falls below its corresponding HVD13_IF threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

54.5.17 Reset Event Enable Register (REE_HV1)

This Reset Event Enable Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Figure 1098. Reset Event Enable Register (REE_HV1)

Table 1126. REE_LV1 field descriptions

Field	Description
10 REE14_AS	REE14_AS reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_AS bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
12 REE14_IF	REE14_IF reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_IF bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
14 REE14_IM	REE14_IM reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_IM bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
21 REE13_IF	REE13_IF reset enable This bit defines whether HVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply generates a system reset. The RES13_IF bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

54.5.18 Reset Event Select Register (RES_HV1)

This Reset Event Select Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Table 1127. RES_HV1 field descriptions

Field	Description
10 RES14_AS	RES14_AS reset event select This bit defines whether a LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply generates a destructive reset or a functional reset by LVD14_AS bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
12 RES14_IF	RES14_IF reset event select This bit defines whether a LVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply generates a destructive reset or a functional reset by LVD14_IF bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
14 RES14_IM	RES14_IM reset event select This bit defines whether a LVD400_IM VD, the VD for the high voltage IO mains 4.00 V supply generates a destructive reset or a functional reset by LVD14_IM bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
21 RES13_IF	RES13_IF reset event select This bit defines whether a HVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply generates a destructive reset or a functional reset by HVD13_IF bit. 0 Destructive Reset Generated. HVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the cold point causes a functional system reset.

54.5.19 Interrupt Enable Register (IE_HV1)

This configuration register contains a set of HV1 interrupt Enable bits that correspond to each of the HV1 Event Pending Registers (EPR_HV1). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0088h. The IE_HV1 bits can be read or written at any time.

21 HVDIE13_IF	HVDIE13_IF Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_IF VD, the VD for the high voltage IO Ethernet 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

54.5.20 FCCU Event Enable Register (FEE_HV1)

This FCCU Event Enable Register HV1 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Figure 1102. Supply Gauge Status Register (*GR_S*)

Table 1130. *GR_S* field descriptions

Field	Description
1 TEMP_2	TEMP_2 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
2 TEMP_1	TEMP_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (135 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
3 TEMP_0	TEMP_0 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (-40 °C). It is asserted when the temperature falls below its corresponding threshold, and clears when the temperature is above its corresponding threshold. 0 Currently no occurrence. 1 Temperature occurrence detected.
8 VD14_AS	VD14_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_AS for the high voltage 4.00 V SAR ADC supply. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 4.00 V supplies.
9 VD14_IF	VD14_IF low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_IF for the high voltage 4.00 V IO Ethernet supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 4.00 V supplies.
11 VD14_IM	VD14_IM low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_IM for the high voltage 4.00 V IO main supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies fall below the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 4.00 V supplies.

Table 1130. *GR_S* field descriptions (continued)

Field	Description
13 VD13_IF	VD13_IF high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_IF for the high voltage 4.00 V IO Ethernet supply. It is asserted when the IO supply rises above its corresponding HVD threshold, and clears when the supply rises above its corresponding HVD threshold. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 4.00 V supply.
21 VD11_AS	VD11_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_AS for the high voltage 2.90 V SAR ADC supplies. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.90 V supplies.
22 VD11_IF	VD11_IF low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_IF for the high voltage 2.90 V IO Ethernet supplies. It is asserted when any of the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.90 V supplies.
24 VD11_FL	VD11_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_FL for the high voltage 2.90 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.90 V supplies.
25 VD11_C	VD11_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_C for the high voltage 2.90 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.90 V supplies.
27 VD6_C	VD6_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD134_C for the high voltage 1.34 V Core supplies. It is asserted when any of the Core supplies rises above the corresponding HVD threshold, and clears when all the Core supplies fall below the corresponding HVD threshold. All the 1.34 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 1.34 V supply.

Table 1130. *GR_S* field descriptions (continued)

Field	Description
29 VD3_SB	VD3_SB low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_SB for the low voltage 1.00 V always on supplies. It is asserted when any of the always on ring supplies falls below the corresponding LVD threshold, and clears when the always on supply rises above the corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 1.00 V supplies.
30 VD3_FL	VD3_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_FL for the high voltage 1.00 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 1.00 V supplies.
31 VD3_C	VD3_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_C for the low voltage 1.00 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 1.00 V supplies.

54.5.22 Pending Gauge Status Register (GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

54.5.23 Interrupt Enable Pending Register (IE_G)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt is enabled. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are enabled via a write of ‘1’ to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

Field	Description
25:31 SSWU_PRESCALER	Prescaler value for SSWU. **Note:** The resulting TU prescaler will be SSWU_PRESCALER + 1. Refer to *Section 11.6.6: TU*

54.5.29 Event Pending Register (EPR_TD)

This Event Pending Register indicates the present and past state of the temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0300 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1110. Event Pending Register (EPR_TD)

Table 1138. EPR_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a ‘1’ is written to this bit location. *If the IETD_2 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_2] is also asserted, a system reset is generated, *which clears IETD_2 and negate the interrupt request*. If REE_TD[TEMP_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
30 TEMP_1	TEMP_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (135 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a ‘1’ is written to this bit location. *If the IETD_1 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_1] is also asserted, a system reset is generated, *which clears IETD_1 and negate the interrupt request*. If REE_TD[TEMP_1] is asserted and a destructive reset is selected (via RES_TD[TEMP_1] being 0), then a destructive reset is generated. If RES_TD[TEMP_1] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
31 TEMP_0	TEMP_0 flag This bit is the temperature status flag associated with the temperature for the *cold* temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a ‘1’ is written to this bit location. *If the IETD_0 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_0] is also asserted, a system reset is generated, *which clears IETD_0 and negate the interrupt request*. If REE_TD[TEMP_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.

54.5.30 Reset Event Enable Register (REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Offset: 0x0304 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1111. Reset Event Enable Register (REE_TD)

Table 1139. REE_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset enable This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset
30 TEMP_1	TEMP_1 reset enable This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset 1 Enabled. Temperature Sensor detect causes system reset
31 TEMP_0	TEMP_0 reset enable This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.

54.5.31 Reset Event Select Register (RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Offset: 0x0308 Access: User read/write, Supervisor read/write, Test read/write

Figure 1112. Reset Event Select Register (RES_TD)

Table 1140. RES_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset event select This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_2] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
30 TEMP_1	TEMP_1 reset event select This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_1] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
31 TEMP_0	TEMP_0 reset event select This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.

54.5.32 Temperature Sensor Configuration Register (CTL_TD)

The Temperature Sensor Configuration Registers (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to be operable. It also includes two 5-bit signed trim adjustment register fields that are used to modify both TS trim values (one bus for over temperature and one bus for under temperature).

Offset: 0x030C Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1113. Temperature Sensor Configuration Register (CTL_TD)

Table 1141. CTL_TD field descriptions

Field	Description
11 PMC_AOUT_EN	Temperature Sensor Enable for PMU Refer to the Temperature Sensor chapter for details.
12:15 TRIM_ADJ_OVER1	TRIM_ADJ_OVER1[3:0] Customer adjustable over trim register for PMU These bits are a signed binary number that is added to the over temperature trim (NT_TD1) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
16 TS2IE	Temperature Sensor input 2 Interrupt Enable This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
17 TS1IE	Temperature Sensor input 1 Interrupt Enable This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.

Table 1141. CTL_TD field descriptions (continued)

Field	Description
18 TS0IE	Temperature Sensor input 0 Interrupt Enable This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs
20:23 TRIM_ADJ_OVER	TRIM_ADJ_OVER[3:0] Customer adjustable over trim register for ADC These bits are a signed binary number that is added to the over temperature trim (NT_TD2) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
26:29 TRIM_ADJ_UNDER	TRIM_ADJ_UNDER[3:0] Customer adjustable under trim register These bits are a signed binary number that is added to the Under temperature trim value (NT_TD0). The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
30 AMUX_CTAT_TS_CTRL	Analog mux enable Refer to the Temperature Sensor chapter for details.
31 ADC_AOUT_EN	Temperature Sensor Enable for ADC Refer to the Temperature Sensor chapter for details.

54.5.33 Temperature Sensor FCCU Event Enable Register (FEE_TD)

This Temperature Sensor FCCU Event Enable Register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

Offset: 0x0318 Access: User read/write, Supervisor read/write, Test read/write

Figure 1119. DigItal Regulator Delay Status Register (DREG_DELAY_STATUS)

Table 1147. DREG_DELAY_STATUS field description

Field	Description
22 DELAY2_SEL	The delay2_sel is used for selection between fix delay and self-detection mechanism for digital controller settling. 0 no self detection mechanism, there will be fixed delay corresponding to delay2 provided for DREG settling 1 self detection mechanism for settling of DREG controller
23:27 DELAY2	The delay2 is used for programming time from 2 µs to 80 µs for DREG controller settling in steps of 2.5 µs. Default value corresponds to 25 µs.
28:31 DELAY1	The delay1 is used for programming time 0.15625 µs to 2.34375 µs for DREG analog settling in steps of 0.15625 µs. Default value corresponds to 0 µs.

54.5.39 Digital Controller Slope0 (DREG_SLOPE0)

All the slope register (DREG_SLOPE0–10) combines to provide gain of digital ballast regulation loop.

Figure 1133. User BIST Control Register (BIST_CTRL)

Table 1161. BIST_CTRL field descriptions

Field	Description
11 IRQST	IRQST is the InteRrupt reQuest pending STatus bit to generate a User BIST Interrupt. It is a R/W0 register. That means set by HW and cleared by SW. The destructive reset resets this bit. 0 No interrupt occurred. 1 An interrupt occurred.
15 IRQEN	IRQEN is the InteRrupt reQuest ENable bit to permit a User BIST Interrupt. It is a R/W register. The destructive reset resets this bit. 0 Interrupt is disabled. 1 Interrupt enabled.
19 NCFST	NCFST is the Not Critical Fault bit. The assertion of this bit will generate FCCU event once user BIST fails. It is set by HW and cleared by SW. The destructive reset resets this bit. 0 No User BIST NCF occurred. 1 A User BIST NCF occurred.
23 NCFEN	NCFEN is the Not Critical Fault ENable bit to permit a User BIST Not Critical Fault and Fault indication is sent to FCCU. It is a R/W register. The destructive reset resets these bits. 0 No User BIST NCF enabled. 1 A User BIST NCF enabled.
25:27 STATUS	STATUS Register are three read-only bits, that according to the value has a own meaning. 000 BIST_IDLE 001 BIST_RUN 010 BIST_PASSED 011 BIST_FAILED 100 BIST_ABORT 101 Reserved 110 Reserved 111 Reserved
31 START	START User BIST bit If set by SW a 1 is present in the START bit for a System clock cycle only, then the START bit register is clear by HW. The destructive reset resets this bit. 0 No start pulse. 1 A start pulse occurs of a 1 system clock cycle duration

54.5.53 User BIST Time1 and Time0 Register (BIST_TIME10)

The User BIST Time1 and Time0 Register (BIST_TIME10) contains two time numbers Time1 and Time0 giving the System clock cycles number required by the User BIST timer1 and timer0.

Offset: 0x03D8 Access: User read/write, Supervisor read/write, Test read/write

Field	Description
4:15 TIME_6	TIME_6 is the system clock cycles number required by the TIMER 6 in the User BIST management. The destructive reset resets these bits.
20:31 TIME_5	TIME_5 is the system clock cycles number required by the TIMER 5 in the User BIST management. The destructive reset resets these bits.

54.5.56 User BIST VD Under Test Monitor Register (BIST_DEBUG)

This VD Under Test Monitor register contains a monitor of the Voltage Detector Under Test of the USER BIST sub-block.

Note: The BIST_DEBUG register can only be read while BIST is running. Once BIST is finished the status can be obtained by checking the BIST_FLAGS_PHASE1 and BIST_FLAGS_PHASE2 registers.

Offset: 0x03E4 Access: User read/write, Supervisor read/write, Test read/write

Table 1165. BIST_DEBUG field description

Field	Description
26:31 VD_MON	The six read only bits of field VD_MON give the current VD Under Test of the User BIST unit among the following VDs: 0x1F LVD100_SB 0x1E MVD094_C 0x1D MVD094_FA 0x1C MVD094_FB 0x1B LVD100_C 0x1A LVD100_FL 0x15 MVD270_C 0x16 MVD270_SB 0x14 MVD270_FL 0x13 LVD290_C 0x12 LVD290_FL 0x10 LVD290_AS 0x0E LVD290_IF 0x09 LVD400_AS 0x08 LVD400_IM 0x06 LVD400_IF 0x19 HVD134_C 0x18 UVD140_C 0x17 UVD140_FL 0x0B HVD400_IF 0x04 UVD600_FL 0x02 UVD600_IF 0x00 No VD under Test

54.6 Standby entry/exit

Standby entry is an application initiated mode.The standby entry process starts once the application configures [MC_ME_MCTL] register for target mode as standby. For detailed description of entry/exit, please refer to MC_PCU.

54.7 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of an analog enable, a set of mode registers, and an over-temperature threshold select control.

For more information regarding the Temperature Sensor function, please refer to the *Chapter 40: Temperature Sensor*.

54.8 Power On Reset (MC_RGM Phase Gates)

The PMU digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMU and Temperature Sensor Analog blocks.

There are two signals for both the PMU and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMU digital logic also indicates when the RGM allows transition to the next POR phase.

The digital PMU also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMU digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled LVDs and HVDs have become deasserted and the time from the LVD circuits to adjust to new trim values has elapsed, then the signal is sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

54.9 Flash interface (DCF client usage)

The PMU digital is updated during POR from the Flash block via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMU, Temperature Sensor, and ADC Bandgap).

These trim bits that are loaded from the Flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

A DCF client is used to interface to the Flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES bits. Refer to *Section 54.5.30: Reset Event Enable Register (REE_TD)* for more information regarding the REE/RES bits load from Flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (thus to allow the bits to be rewritable) and same is the reset value of the REE register.

The monitors for which reactions are enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “1” (reset enabled) and in the Reset Event Select (RES_XX) register as “0” (destructive reset selected).

The monitors for which reactions are not enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “0” (reset disabled) and in the Reset Event Select (RES_XX) register as “1” (functional reset selected).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the POR reset signal.

For more information regarding the DCF records, please refer to the DCF Records chapter.

The trim data is read out of the Flash’s differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the Flash indicates this to the PMU digital via the SSCM module.

Once the PMU trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the Flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD signals must indicate that a valid voltage has been reached before the voltage indication is sent to the Flash.

54.10 Voltage monitor BIST programming

The application has to program the BIST_TIMExx registers according to the following timings, respect to the configured PBRIDGE_CLK:

- BIST_TIME10[Time_0] = 40 µs.
- BIST_TIME10[Time_1] = 50 µs.
- BIST_TIME32[Time_2] = 50 µs.
- BIST_TIME32[Time_3] = 50 µs.
- BIST_TIME65[Time_5] = 200 ns.
- BIST_TIME65[Time_6] = 200 ns.

In case that aforementioned timings are not applied, some voltage monitor BIST could trigger fake faults.

The user can run a BIST mode by setting the BIST_CTRL[START] register bit. The following voltage detectors are then serially tested:

- LVD100_SB
- MVD094_C
- MVD094_FA
- MVD094_FB
- LVD100_C
- LVD100_FL
- MVD270_C_MAIN
- MVD270_C_STBY
- MVD270_FL
- LVD290_C
- LVD290_FL
- LVD290_AS
- LVD290_IF
- LVD400_AS
- LVD400_IM
- LVD400_IF
- HVD134_C
- UVD140_C
- UVD140_FL
- HVD400_IF
- UVD600_FL
- UVD600_IF

Interrupt can be enabled by programming BIST_CTRL[IRQEN] and interrupt status is checked with BIST_CTRL[IRQST] on completion of BIST sequence.

FCCU event can be enabled by programming BIST_CTRL[NCFEN]. The BIST_CTRL[NCFST] status indicates BIST Fail on completion of BIST sequence.

BIST_DEBUG[VD_MON] register bits allow to know which voltage detector is under test.

The overall status of BIST is provided by the BIST_CTRL[STATUS] register bits.

The status of individual monitors is checked in flag registers BIST_FLAGS_PHASE1 (pass is all zero) and BIST_FLAGS_PHASE2 (pass is all one).

Note: When the SOC supply is 3.3V, the LVD400_xx monitors are not lifted but when we run BIST all the monitors are masked (during this time the event is seen in PMC_DIG_EPR_HV1 register). When the SOC supply is 5V, the HVD400_xx monitors are not lifted but when we run BIST, the event is seen in PMC_DIG_EPR_HV1 register.

55 Power Control Unit (MC_PCU)

55.1 Introduction

55.1.1 Overview

The power control unit (MC_PCU) is used to control the overall microcontroller power consumption. There are 4 power domains controlled by the MC_PCU which physically disconnects power to the domains when the specific operating mode allows this.

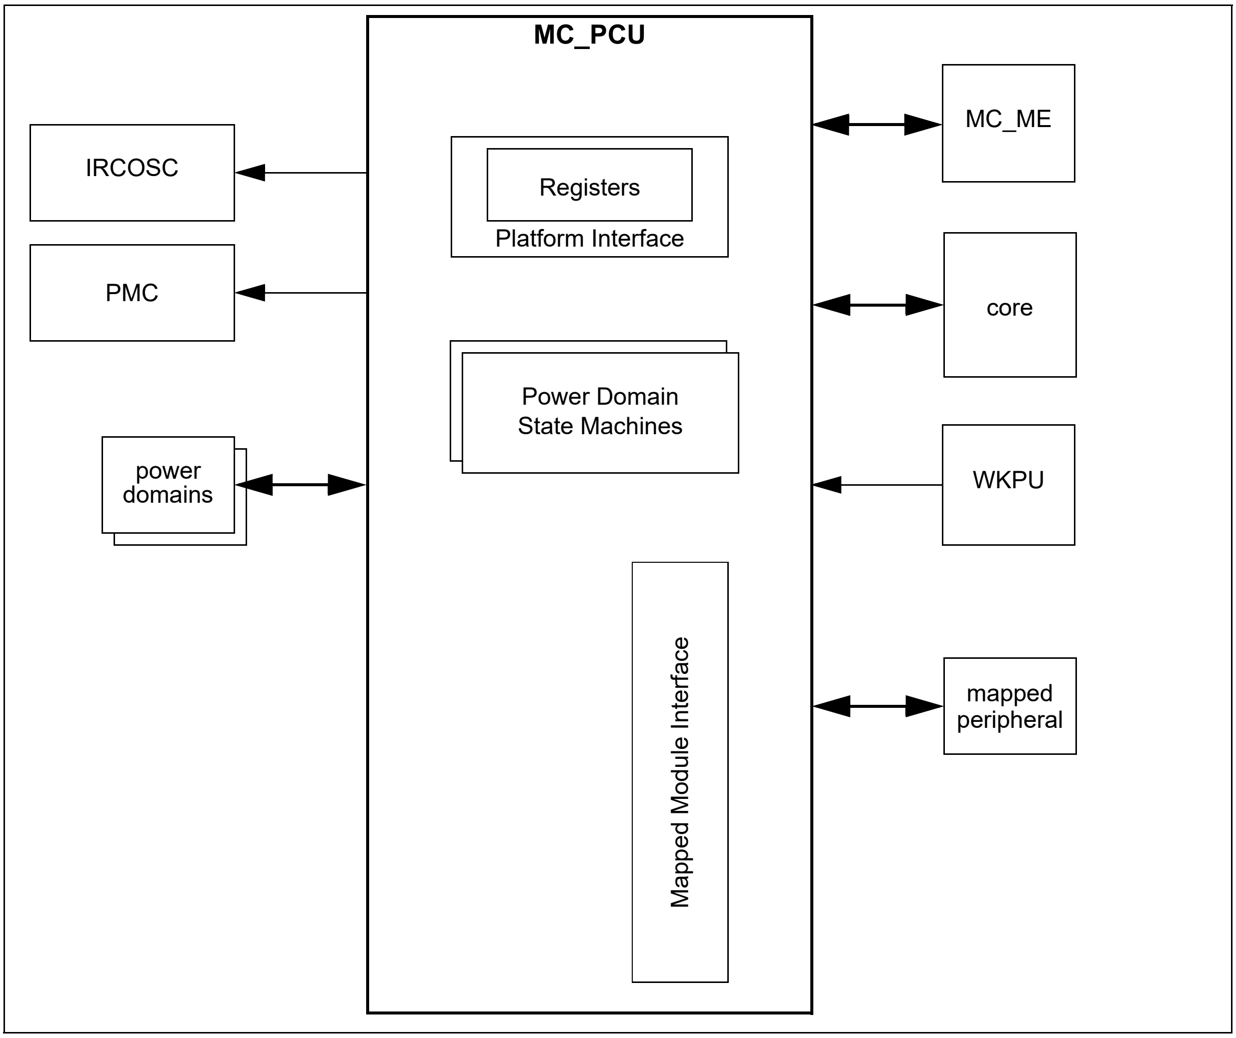
When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information of such a power domain is lost. When re-connecting a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage.

For each mode, software can configure whether a power domain is connected to the supply voltage (power-up state) or disconnected (power-down state). Maximum power saving is reached by entering the STANDBY mode.

On each mode change request, the MC_PCU evaluates the power domain settings in the power domain configuration registers and initiates a power-down or a power-up sequence for each individual power domain. The power-up/down sequences are handled by finite state machines to ensure a smooth and safe transition from one power state to the other.

Figure 1138 depicts the MC_PCU block diagram.

Figure 1138. MC_PCU block diagram



55.1.2 Features

The MC_PCU includes:

- Support for 4 power domains
- Support for chip modes RESET, DRUN, SAFE, TEST, RUN0…3, HALT, STOP and STANDBY (for further mode details, refer to the MC_ME chapter)
- Power states updating on each mode change and on system wakeup
- A handshake mechanism for power state changes thus guaranteeing operable voltage

55.2 External Signal Description

The MC_PCU has no connections to any external pins.

55.3 Memory Map and Register Definition

55.3.1 Memory Map

Table 1166. MC_PCU Register Description

Address offset	Register name	Location
0x0000	Power Domain #0 Configuration (PCU_PCONF0)	*Section 55.3.2.1*
0x0004	Power Domain #1 Configuration (PCU_PCONF1)	*Section 55.3.2.2*
0x0008	Power Domain #2 Configuration (PCU_PCONF2)	*Section 55.3.2.3*
0x000C	Power Domain #3 Configuration (PCU_PCONF3)	*Section 55.3.2.4*
0x0010–0x003F	Reserved	
0x0040	Power Domain Status Register (PCU_PSTAT)	*Section 55.3.2.5*

Note: Any access to unused registers as well as write accesses to read-only registers will not change register content and will cause a transfer error

55.3.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at address offset 0x0040, as a half-word at address offset 0x0042, or as a byte at address offset 0x0043.

55.3.2.1 Power Domain #0 Configuration Register (PCU_PCONF0)

Offset: 0x0000 Access: User read, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	1	0	1	1	1	1	1	1	1	1	1

Figure 1140. Power Domain #1 Configuration Register (PCU_PCONF1)

This register defines for power domain #1 whether it is on or off in each chip mode. The bit field description is the same as in *Table 1167*. As the platform, clock generation, and mode control reside in power domain #1, this power domain is only powered down during the STANDBY mode. Therefore, none of the bits are programmable. This register is available for completeness reasons.

The difference between PCU_PCONF0 and PCU_PCONF1 is the reset value of the STBY0 bit: during the STANDBY mode, power domain #1 is disconnected from the power supply, and therefore PCU_PCONF1.STBY0 is always ‘0’. Power domain #0 is always on, and therefore PCU_PCONF0.STBY0 is ‘1’.

For further details about STANDBY mode, refer to *Section 55.4.4.1: STANDBY Mode transition*. NO_FEATURE

55.3.2.3 Power Domain #2 Configuration Register (PCU_PCONF2)

Offset: 0x0008 Access: User read, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

Figure 1143. Power Domain Status Register (PCU_PSTAT)

This register reflects the power status of all available power domains.

Table 1168. PCU_PSTAT field descriptions

Field	Description
31 PD0	Power status for power domain #0 0 Power domain is inoperable. 1 Power domain is operable.

55.4 Functional description

55.4.1 General

The MC_PCU controls all available power domains on a chip mode basis. The PCU_PCONF*n* registers specify during which system/user modes a power domain is powered up. The power state for each individual power domain is reflected by the bits in the PCU_PSTAT register.

On a mode change, the MC_PCU evaluates which power domain(s) must change power state. The power state is controlled by a state machine (FSM) for each individual power domain which ensures a clean and safe state transition.

55.4.2 Reset / Power-On Reset

After any reset, the chip will transition to the RESET mode during which all power domains are powered up (refer to the MC_ME chapter). Once the reset sequence has been completed, the DRUN mode is entered and software can begin the MC_PCU configuration.

55.4.3 MC_PCU configuration

By default, all power domains are powered in all modes other than STANDBY. Software can change the configuration for each power domain on a mode basis by programming the PCU_PCONF*n* registers.

Each power domain which is powered down is held in a reset state. Read/write accesses to peripherals in those power domains will result in a transfer error.

55.4.4 Mode transitions

On a mode change requested by the MC_ME, the MC_PCU evaluates the power configurations for all power domains. It compares the settings in the PCU_PCONF*n* registers for the new mode with the settings for the current mode. If the configuration for a power domain differs between the modes, a power state change request is generated. These requests are handled by a finite state machine to ensure a smooth and safe transition from one power state to another.

55.4.4.1 STANDBY Mode transition

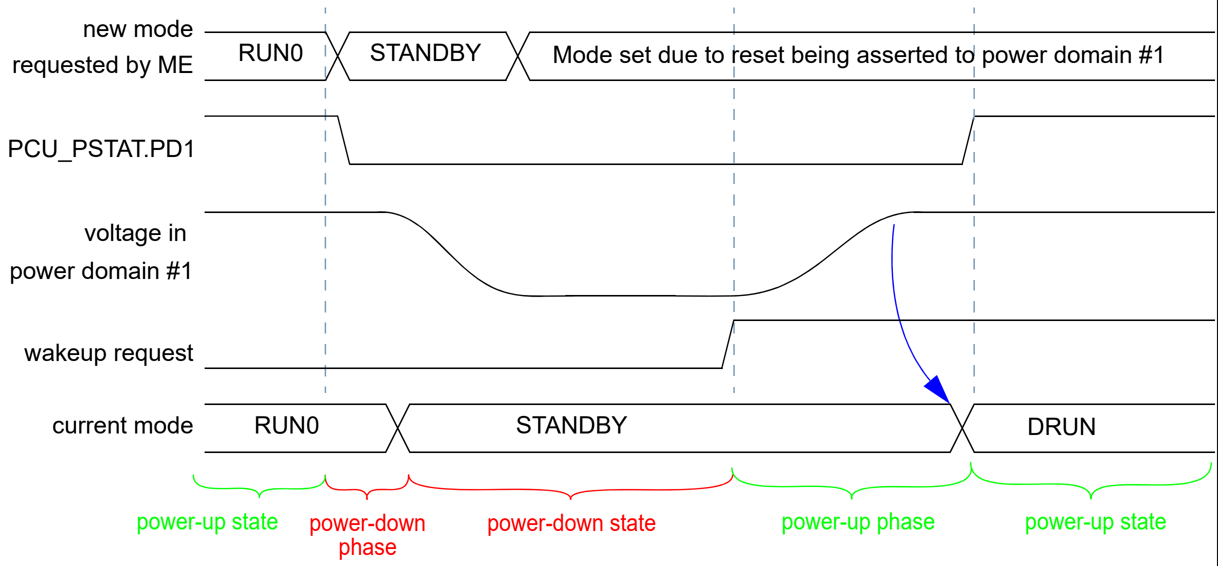
STANDBY offers the maximum power saving. The level of power saving is software-controllable via the settings in the PCU_PCONF*n* registers for power domain #2 onwards. Power domain #0 stays connected to the power supply while power domain #1 is disconnected from the power supply. Amongst others power domain #1 contains the platform and the MC_ME. Therefore this mode differs from all other user/system modes.

Once STANDBY is entered it can only be left via a system wakeup. On exiting the STANDBY mode, all power domains are powered up according to the settings in the PCU_PCONF*n* registers, and the DRUN mode is entered. In DRUN mode, both domains #0 and #1 are powered.

Figure 1144 shows an example for a mode transition from RUN0 to STANDBY to DRUN. All power domains which have PCU_PCONF*n*.STBY cleared will enter power-down phase. In this example power domain #1 will be disabled during STANDBY mode.

When the MC_PCU receives the mode change request to STANDBY mode it starts the power down phase for power domain #1. During the power down phase, clocks are disabled and reset is asserted resulting in a loss of all information for this power domain. Then the power domain is disconnected from the power supply (power-down state).

Figure 1144. MC_PCU Events During Power Sequences (STANDBY mode)



Notes:

Not drawn to scale; PCONF1.RUN0 = 1; PCONF1.STBY0 = 0

When the MC_PCU receives a system wakeup request, it starts the power-up phase. The power domain is re-connected to the power supply and the voltage in power domain #1 will increase slowly. Once the voltage is in an operable range, clocks are enabled and the reset is be deasserted (power-up state).

Prior to standby entry, PCTL for WKPU should be disabled.

Note: It is possible that due to a wakeup request, power-up is requested before a power domain completed its power-down sequence. In this case, the information in that power domain is lost.

Exiting the STANDBY mode can only be done via a system wakeup event from:

- API/SSWU module (mapped on WKUP0 line),
- RTC timer (mapped on WKUP1 line),
- external wakeup pads (WKUPx line, where x>1).

Refer to the wakeup vector mapping table in the Device Configuration chapter for complete wakeup lines list and to SPC584Bx IO_Definition document for pad/wakeup lines mapping.

55.4.4.2 Power Saving for Memories During STANDBY Mode

All memories which are not powered down during STANDBY mode automatically enter a power saving state. No software configuration is required to enable this power saving state. While a memory is residing in this state an increased power saving is achieved. Data in the memories is retained.

55.5 Application information

55.5.1 STANDBY mode considerations

STANDBY offers maximum power saving possibility. But power is only saved during the time a power domain is disconnected from the supply. Increased power is required when a power domain is re-connected to the power supply. Additional power is required during restoring the information (for example in the platform). Care should be taken that the time during which the chip is operating in STANDBY mode is significantly longer than the required time for restoring the information.

56 Mode Entry Module (MC_ME)

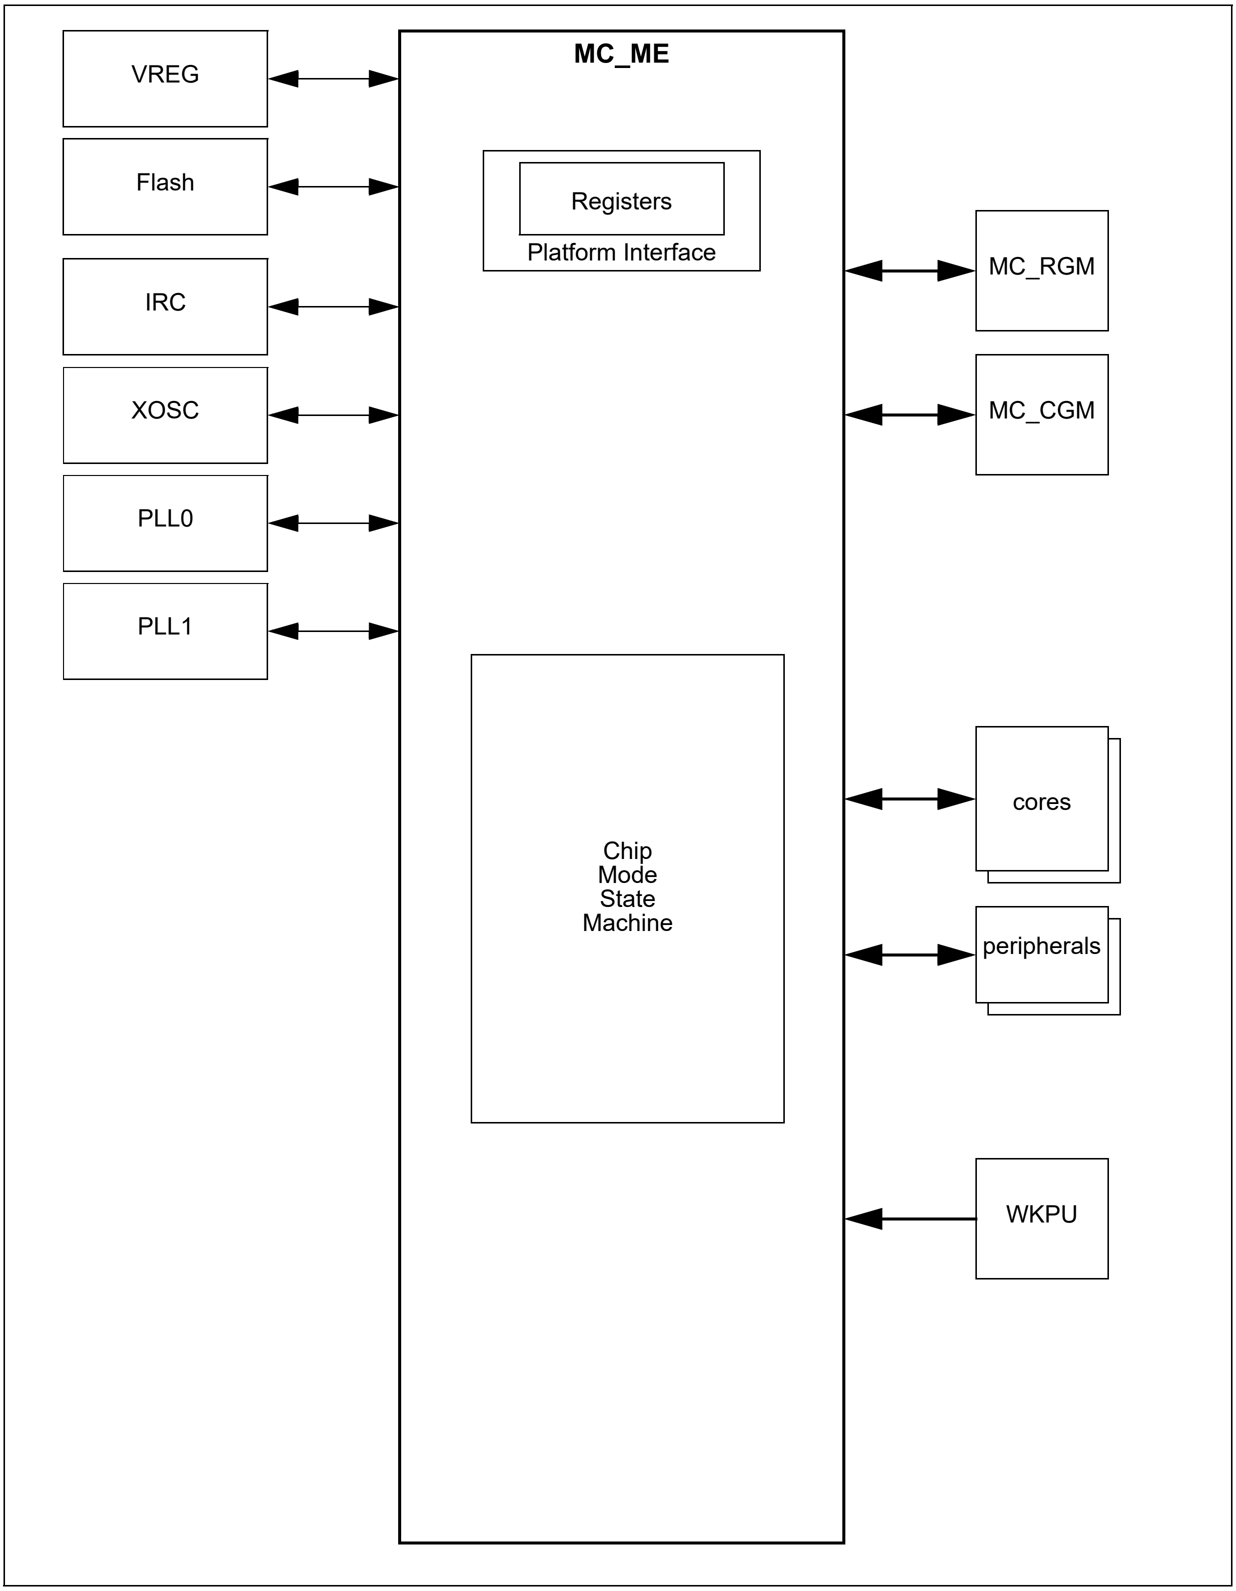
56.1 Introduction

56.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

Figure 1145 shows the MC_ME block diagram.

Figure 1145. MC_ME block diagram



56.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers
- additional core clock gating and boot address control based on the ME_CCTL*n* and ME_CADDR*n* registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

56.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as: RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as: RUN0–3, HALT0, STOP0, and STANDBY0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0–3 are the chip software running modes.

Table 1169 describes the MC_ME modes.

Table 1169. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and Flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAF, when present, is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0–3, wakeup request from STANDBY0	system reset assertion, RUN0–3, TEST, STANDBY0 via software, SAFE via software or hardware failure.

Table 1169. MC_ME mode descriptions (continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0–3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0–3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0–3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0–3 modes, HALT0, STOP0, STANDBY0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals such as: clock sources, Flash, main regulator, for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event or wakeup event
STANDBY0	This is a reduced-leakage low-power mode during which power supply is cut off from most of the chip. Wakeup from this mode takes a relatively long time, and content is lost or must be restored from backup.	software request from RUN0–3, DRUN modes	system reset assertion, DRUN on wakeup event

56.2 External signal description

The MC_ME has no connections to any external pins.

56.3 Memory map and register definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

56.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

56.3.2.1 Global Status Register (ME_GS)

This register contains global mode status.

Offset : 0x000 Access: User read, Supervisor read, Test read

Table 1171. ME_GS field descriptions

Field	Description
0:3 S_CURRENT_MODE	Current chip mode status 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 reserved
4 S_MTRANS	Mode transition status 0 Mode transition process is not active 1 Mode transition is ongoing
8 S_PDO	Output power-down status This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In STOP0 mode, the slew rate control mechanism of the output pads is disabled to reduce power consumption, but the state of the output remains functional.
11 S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
14:15 S_FLA	Flash availability status 00 Flash is not available 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode and available for use
24 S_PLL1	secondary PLL status 0 secondary PLL is not stable 1 secondary PLL is providing a stable clock
25 S_PLL0	primary PLL status 0 primary PLL is not stable 1 primary PLL is providing a stable clock
26 S_XOSC	external crystal oscillator status 0 external crystal oscillator is not stable 1 external crystal oscillator is providing a stable clock

Table 1171. ME_GS field descriptions (continued)

Field	Description
27 S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28:31 S_SYSCLK	System clock switch status These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

56.3.2.2 Mode Control Register (ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

Note: Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Offset: 0x004 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1147. Mode Control Register (ME_MCTL)

Table 1172. ME_MCTL field descriptions

Field	Description
0:3 TARGET_MODE	Target chip mode These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0–3 mode value. 0000 RESET (triggers a ‘functional’ reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 RESET (triggers a ‘destructive’ reset event)
16:31 KEY	Control key These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101 1010 1111 0000 (0x5AF0) INVERTED KEY: 1010 0101 0000 1111 (0xA50F)

56.3.2.3 Mode Enable Register (ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET, SAFE, DRUN, and RUN0 modes are always enabled.

Offset: 0x008 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W											w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1149. Interrupt Status Register (ME_IS)

Table 1174. ME_IS field descriptions

Field	Description
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) This bit is set if a write access to one of the ME_CCTLn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending

Table 1174. ME_IS field descriptions (continued)

Field	Description
28 I_ICONF	Invalid mode configuration interrupt This bit is set whenever a write operation to ME_<*mode*>_MC registers with invalid mode configuration is attempted. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt This bit is set whenever an invalid mode transition is requested. It is cleared by writing a ‘1’ to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a ‘1’ to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a ‘1’ to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, STOP0, or STANDBY0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

56.3.2.5 Interrupt Mask Register (ME_IM)

This register controls whether an event generates an interrupt or not.

Offset: 0x010 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1151. Invalid Mode Transition Status Register (ME_IMTS)

Table 1176. ME_IMTS field descriptions

Field	Description
26 S_MRIG	Mode Request Ignored status This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress, a transition to STOP0 mode is requested while a wakeup or interrupt request is active, a transition to HALT0 mode is requested while an interrupt request is active, or a transition to STANDBY mode is requested while a wakeup request is active. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not ignored 1 Mode transition requested is ignored
27 S_MTI	Mode Transition Illegal status This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is ‘1’). Please see *Section 56.4.5: Mode Transition Interrupts*, for the exceptions to this behavior. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	**Non-existing Mode Access status** This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a ‘1’ to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

56.3.2.7 Debug Mode Transition Status Register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Figure 1152. Debug Mode Transition Status Register (ME_DMTS)

Table 1177. ME_DMTS field descriptions

Field	Description
0:3 PREVIOUS_MODE	Previous chip mode These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 reserved
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has responded. 0 Handshake is not busy 1 Handshake is busy

Table 1177. ME_DMTS field descriptions (continued)

Field	Description
11 PMC_PROG	MC_PCU Mode Change in Progress indicator This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
16 CDP_PRPH_0_255	Clock Disable Process Pending status for Peripherals 0–255(1) This bit is set when any peripheral appearing has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table 1177. ME_DMTS field descriptions (continued)

Field	Description
19 IRC_SC	IRC State Change during mode transition indicator This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A secondary clock source is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status 0 No system clock source switching is pending 1 A system clock source switching is pending
23 FLASH_SC	FLASH State Change during mode transition indicator This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224–255(1) This bit is set when any peripheral appearing in ME_PS7 has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
25 CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192–223 This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_160_191	Clock Disable Process Pending status for Peripherals 160–191 This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1177. ME_DMTS field descriptions (continued)

Field	Description
27 CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128–159 This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96–127 This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64–95 This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32–63 This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0–31 This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTLn register. Please refer to *Table 1170* for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

56.3.2.8 RESET Mode Configuration Register (ME_RESET_MC)

This register configures system behavior during RESET mode. See *Table 1178* for details.

Note: The following configuration values are set according to the chip configuration:

XOSCON

Offset: 0x020 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1160. STANDBY0 Mode Configuration Register (ME_STANDBY0_MC)

Table 1178. ME_<*mode*>_MC Field Descriptions

Field	Description
1:3 PWRLVL	Power level This bit indicates the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled. **Note:** For ME_RESET_MC, ME_HALT0_MC, ME_STOP0_MC and ME_STANDBY0_MC registers this bit field is read-only and always 0.
8 PDO	I/O output power-down control This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, internal weak pull-ups of outputs are enabled and pads power sequence driver is disabled The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional. In STANDBY0 mode, power sequence driver and all pads except those mapped on wakeup lines are not powered and therefore high impedance. Wakeup line configuration remains unchanged
11 MVRON	Main voltage regulator control This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
14:15 FLAON	Flash power-down control This bit specifies the operating mode of the Flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
24 PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on
26 XOSCON	external crystal oscillator control 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on

Table 1178. ME_<*mode*>_MC Field Descriptions (continued)

Field	Description
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28:31 SYSCLK	System clock switch control These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

56.3.2.16 Peripheral Status Register 0 (ME_PS0)

14 TEST	Core control during TEST 0 the HSM is frozen with clock gated 1 the HSM is running
15 RESET	Core control during RESET the HSM is always disabled during RESET.

56.3.2.30 Core Address Register 0 (ME_CADDR0)

This register gives the boot address for peripheral core_2 and a bit for controlling whether peripheral core_2 is to be reset on the next mode change that has peripheral core_2 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (that is while ME_GS[S_MTRANS] = 1). A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted.

Note: The reset value of the ME_CADDR0[ADDR] field is determined by the chip configuration and boot mode.

Offset: 0x1E0 Access: User read, Supervisor read/write, Test read/write

56.4 Functional description

56.4.1 Mode transition request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

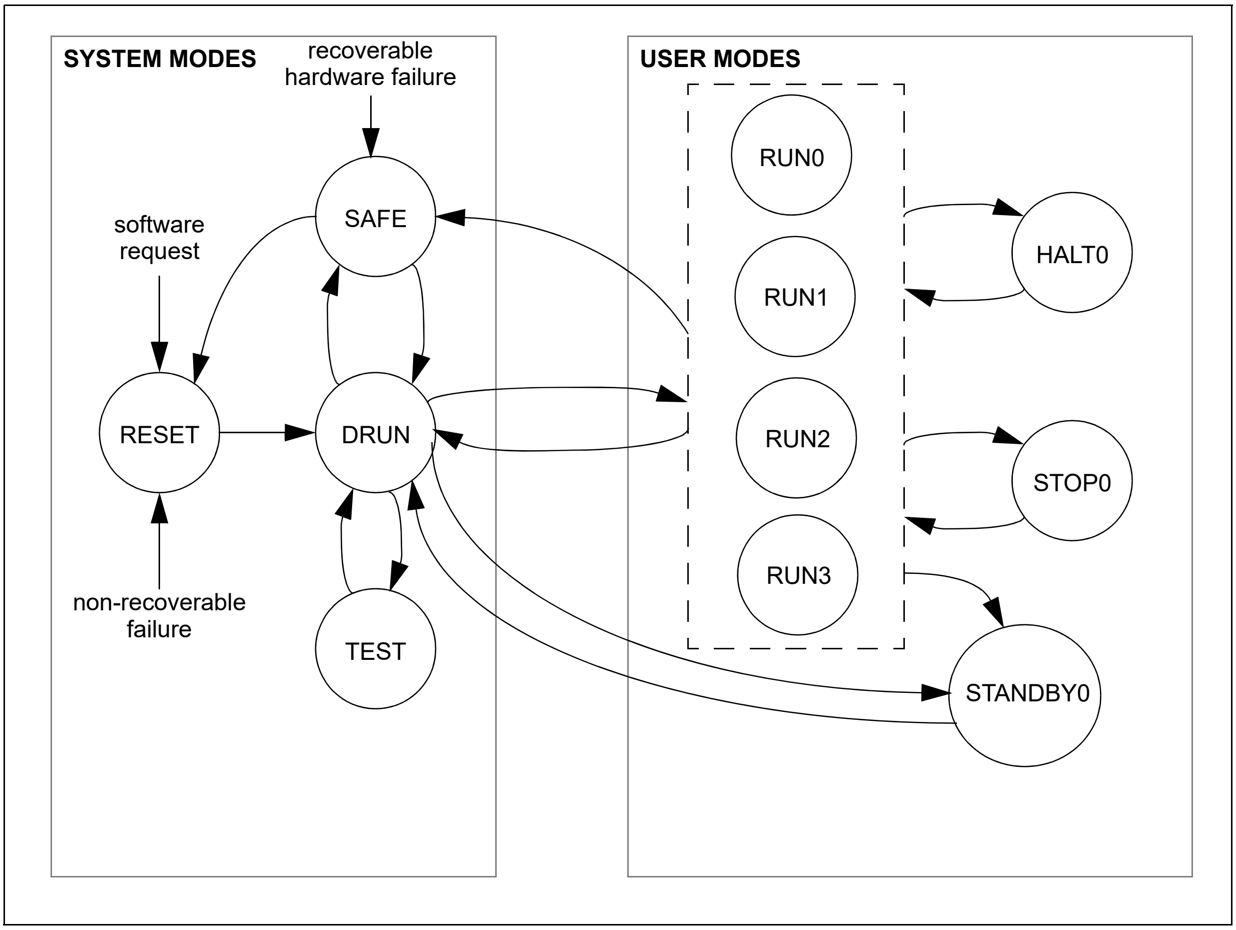
Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register.The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please see *Section 56.4.5: Mode Transition Interrupts*.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as: RUN0–3 → RUN0–3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0, STOP0, or STANDBY0 modes.

If CMU reveals a loss of PLL/XOSC clock before a transition request, such transition is not completed. If failure removal and CMU flags are reset, then transition is executed correctly.

Figure 1177. MC_ME Mode Diagram



56.4.2 Modes details

56.4.2.1 RESET mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0–3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either “0000” for a ‘functional’ reset or “1111” for a ‘destructive’ reset.
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details).

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

56.4.2.2 DRUN mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0–3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0011”
- from the STANDBY0 mode after an external wakeup event or internal wakeup alarm

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the Flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in Flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs
- to execute small routines in a ‘ping-pong’ with the STANDBY0 mode

When this mode is entered from STANDBY0 after a wakeup event, the ME_DRUN_MC register content is restored to its pre-STANDBY0 values, and the mode starts in that configuration.

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

56.4.2.3 SAFE mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with “0010”
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see *Chapter 51: Reset Generation Module (MC_RGM)*, for details)

Note: If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by hardware, a SAFE mode interrupt is generated. See *Section 56.4.5.3* for details.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note: If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

Internal weak pull-ups of outputs are enabled upon entering this mode, in case that the PDO bit of the ME_SAFE_MC register is set. The input levels remain unchanged.

56.4.2.4 TEST mode

The chip enters this mode on the following event:

From the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0001”

As soon as the above event has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to “1111”, and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

56.4.2.5 RUN0–3 modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0–3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0100–0111”
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0–3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0–3_MC registers. In these modes, the Flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

56.4.2.6 HALT0 mode

The chip enters this mode on the following event:

From one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1000”.

As soon as the above event has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The Flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen
- the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (that is within a few system clock cycles of an interrupt event)

The normal exit of the HALT0 mode is from an interrupt event. Wakeup events will not cause HALT0 mode exit.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

56.4.2.7 STOP0 mode

The chip enters this mode on the following event:

From one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1010”.

As soon as the above event has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the primary PLL
- the secondary PLL

The Flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (for example, allow for system clock source to be re-started)

The normal exit from the STOP0 mode is by an interrupt or a wakeup event.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

56.4.2.8 STANDBY0 Mode

The chip enters this mode on the following event:

From the DRUN or one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1101”.

As soon as the above event occurs, a STANDBY0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STANDBY0_MC register. In this mode, the power supply is turned off for most of the chip. The only parts of the chip that are still powered during this mode are pads mapped on wakeup lines and power domain #0 which contains the MC_RGM, MC_PCU, WKPU, PASS, OSC32k, RTC, LPROSC, SSWU, ADC-STDBY, PMC_DIG. The IRC can be optionally switched off. This is the lowest power consumption mode possible on the chip.

This mode is intended as an extreme low-power mode with

- the cores, the Flashes, and almost all peripherals and memories powered down and to be used by software
- to wait until it is required to do something with no need to react quickly (such as, allow for system power-up and system clock source to be re-started)

The exit sequence of this mode is similar to the reset sequence, and the resets to all but power domain #0 are asserted with timing that is the same as reset PHASE1 through PHASE3. Device will boot from the address specified on ME_CADDR0 register. In case that boot from RAM is requested, ME_CADDR0 will address standby RAM (see *Table 6: System and stand-by RAM memory map*). In this case, it is also possible to keep Flash in power-down by writing ‘01’ to FLAON field in the ME_DRUN_MC register.

If there is a STANDBY0 mode request while any wakeup event is active, the chip mode does not change.

The IO pins in STANDBY mode can be divided in 2 types:

- Not Low Power pin (NLP)
  They are not active in STANDBY and when STANDBY is entered, both input and output buffers inside the pins are disabled. Thus also internal pull-up/down are disabled.

Floating state will not affect the power consumption because of isolation within the pad is automatically applied.

- Low Power pin (LP)
  The LP pins are active during STANDBY. They are configured in CMOS level logic and this configuration cannot be changed. Moreover, when the device enters the STANDBY mode, the pad-keeper feature is activated for LP pins. It means that:
  - if the pad voltage level is above the pad keeper high threshold (PK_h), a weak pull-up resistor is automatically enabled;
  - if the pad voltage level is below the pad keeper low threshold (PK_l), a weak pull-down resistor is automatically enabled.

For the pad-keeper high/low thresholds please refer to the device datasheet. Regarding the pad-keeper weak pull-up/down, these are the same as the ones configurable through SIUL2_MSCR register in running mode, and their values (Rwpu/Rwpd) are showed in the datasheet.

Refer to the SPC584Bx pinout Microsoft Excel file (package sheets) for the list of LP pins.

56.4.3 Mode transition process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the XOSC is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL’s lock status bit.

56.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. See *Section 56.4.5*, for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

56.4.3.2 Target mode configuration loading

On completion of the *Target mode request* step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (such as voltage sources, clock sources, Flash, pads) control process.

An overview of resource control possibilities for each mode is shown in *Table 1188*. A ‘X’ indicates that a given resource is configurable for a given mode.

Table 1188. MC_ME Resource Control Overview

Resource	Mode							
	RESET	**TEST**	**SAFE**	**DRUN**	**RUN0–3**	**HALT0**	**STOP0**	**STANDBY0**
IRC	on	X on	on	on	on	on	on	X on
XOSC	off	X off	off	X off	X off	X off	X off	off
PLL0	off	X off	off	X off	X off	X off	off	off
PLL1	off	X off	off	X off	X off	X off	off	off
FLASH	normal	X normal	normal	X normal	X normal	X low-power	X power-down	power-down
MVREG	on	on	on	on	on	on	on	off
PDO	off	X off	X on	off	off	off	X off	on

56.4.3.3 Peripheral clocks disable

On completion of the *Target mode request* step and the system clock frequency ramp-down of the *System clock switching* step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0–7 and ME_LP_PC0–7, and the peripheral control registers ME_PCTLn

Note: The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is *good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.*

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please see *Section 56.4.6: Peripheral Clock Gating*, for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

56.4.3.4 Processor low-power mode entry

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the HALT0 mode, the MC_ME requests the processor to enter its halted state. The processor acknowledges its halt state request after completing all outstanding bus transactions.

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the STOP0 or STANDBY0 mode, the MC_ME requests the processor to enter its stopped state. The processor acknowledges its stop state request after completing all outstanding bus transactions.

56.4.3.5 Processor clocks disable

If, on completion of the *Processor low-power mode entry* step, and all processors which are configured in the ME_CCTLn registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

Caution: Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

56.4.3.6 System clock disable

If, on completion of the *Processor clocks disable* step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

56.4.3.7 Clock sources (Main Voltage Regulator Independent) switch-on

On completion of the *Processor low-power mode entry* step, the MC_ME switches on all clock sources, which do not need the main voltage regulator to be on, based on the

<clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator: in HALT0 mode; in STOP0 mode; in STANDBY0 mode depending on ME_STANDBY0_MC.IRCON bit setting
- the external crystal oscillator: in HALT0 mode and STOP0 mode, depending on ME_HALT0_MC.XOSCON bit and ME_STOP0_MC.XOSCON bit setting correspondingly
- the primary PLL
- the secondary PLL

Note: Clock sources which need the main voltage regulator to be stable are not controlled by this step.

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order not to disturb the system clock which might require one of these clocks before switching to a different target clock.

56.4.3.8 Main Voltage Regulator Switch-On

On completion of the *Target mode request* step, if the main voltage regulator needs to be switched on from its off state based on the MVRON bit of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the MC_PCU to power-up the regulator and waits for the output voltage stable status in order to update the S_MVR bit of the ME_GS register.

This step is required only during the exit of the low-power modes HALT0 and STOP0. In this step, the 16 MHz internal RC oscillator is switched on regardless of the target mode configuration, as the main voltage regulator requires the 16 MHz int. RC osc. during power-up in order to generate the voltage status.

During the STANDBY0 exit sequence, the MC_PCU alone manages the power-up of the main voltage regulator, and the MC_ME is kept in RESET or shut off (depending on the power domain #1 status).

56.4.3.9 Flash memory module switch-on

On completion of the *Main Voltage Regulator Switch-On* step, if the Flash memory needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the Flash memory to exit from its low-power/power-down mode. When the Flash memory is available for access, the S_FLA bit field of the ME_GS register is updated to “11” by hardware.

Caution: It is illegal to switch the FLASH or the DFLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

56.4.3.10 Clock Sources (Main Voltage Regulator Dependent) Switch-On

On completion of the *Clock sources (Main Voltage Regulator Independent) switch-on* and *Main Voltage Regulator Switch-On*, the MC_ME controls all clock sources, which need the main voltage regulator to be on, based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the primary PLL depending on ME_<target mode>_MC.PLL0ON bit
- the secondary PLL depending on ME_<target mode>_MC.PLL1ON bit

56.4.3.11 Pad outputs-on

On completion of the *Main Voltage Regulator Switch-On* step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- slew rate control mechanism is switched on

56.4.3.12 Peripheral clocks enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0–7, ME_LP_PC0–7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. If the value of the PWRLVL field of the ME_<target mode>_MC register is less than that of the ME_<current mode>_MC register's, this step is executed only after the *System clock switching* process is completed.

56.4.3.13 System and processor clocks enable

On completion of the *Flash memory module switch-on* step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTLn registers to be running in the target mode and which have their RMC bits in the ME_CADDRn registers set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the MW_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the *System clock switching* process is completed.

56.4.3.14 Processor low-power mode exit

On completion of the *System and processor clocks enable* step, the MC_ME requests all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode by deasserting the corresponding core_stop bits.

56.4.3.15 System clock switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the external crystal osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (that is the external crystal oscillator has stabilized).
- The target clock configuration for the secondary PLL takes effect only after the S_PLL0 bit of the ME_GS register is set by hardware (that is the primary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with “1111”. This is possible only in the TEST mode. In the STANDBY0 mode, the clock configuration is fixed, and the system clock is automatically forced to ‘0’. .

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the *Clock sources (Main Voltage Regulator Independent) switch-on* process has completed if the target system clock source is one of the following:
  - the 16 MHz internal RC oscillator
  - the external crystal oscillator
  - the primary PLL
- the *Peripheral clocks disable* process has completed in order not to change the system clock frequency before peripherals close their internal activities
- the *Peripheral clocks enable* process has completed

An overview of system clock source selection possibilities for each mode is shown in *Table 1189*. A ‘X’ indicates that a given clock source is selectable for a given mode.

Table 1189. MC_ME System Clock Selection Overview

System Clock Source	Mode							
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0	STANDBY0
16 MHz int. RC osc.		X (default)		X (default)	X (default)	X (default)		
external crystal osc.		X		X	X	X		
primary PLL (PHI)		X		X	X	X		

Table 1189. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode							
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0	STANDBY0
secondary PLL		X		X	X	X		
system clock is disabled		X(1)						

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

56.4.3.16 Pad switch-off

If the PDO bit of the ME_<target mode>_MC register is ‘1’ then

- Internal weak pull-ups of outputs are enabled if the target mode is SAFE or TEST.

In STANDBY0 mode, the power sequence driver and all pads except the external reset and those mapped on wakeup or SSWU lines are not powered and therefore high impedance. The wakeup and SSWU line configuration remains unchanged.

This step is executed only after the *Peripheral clocks disable* process has completed.

56.4.3.17 Clock sources switch-off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to ‘0’. The following clock sources switched off at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the *System clock switching* process has completed.

56.4.3.18 Flash memory switch-off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the Flash is to be put in its low-power or power-down mode, the MC_ME requests the Flash to enter the corresponding power mode and waits for the Flash to acknowledge. The exact power mode status of the Flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the *Processor clocks disable* and *System clock disable* processes have completed.

56.4.3.19 Main Voltage Regulator Switch-Off

Based on the MVRON bit of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the main voltage regulator is to be switched off, the MC_ME requests it to power down and clears the availability status bit S_MVR of the ME_GS register.

This step is executed only after completing the following processes:

- *Clock sources switch-off*
- *Flash memory switch-off*

If the target mode is STANDBY0, the main voltage regulator is not switched off by the MC_ME and the STANDBY0 request is asserted after the above processes have completed upon which the MC_PCU takes control of the main regulator. As the MC_PCU needs the 16 MHz int. RC osc., the 16 MHz internal RC oscillator remains active until all the STANDBY0 steps are executed by the MC_PCU after which it may be switched off depending on the IRCON bit of the ME_STANDBY0_MC register.

56.4.3.20 Current mode update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :

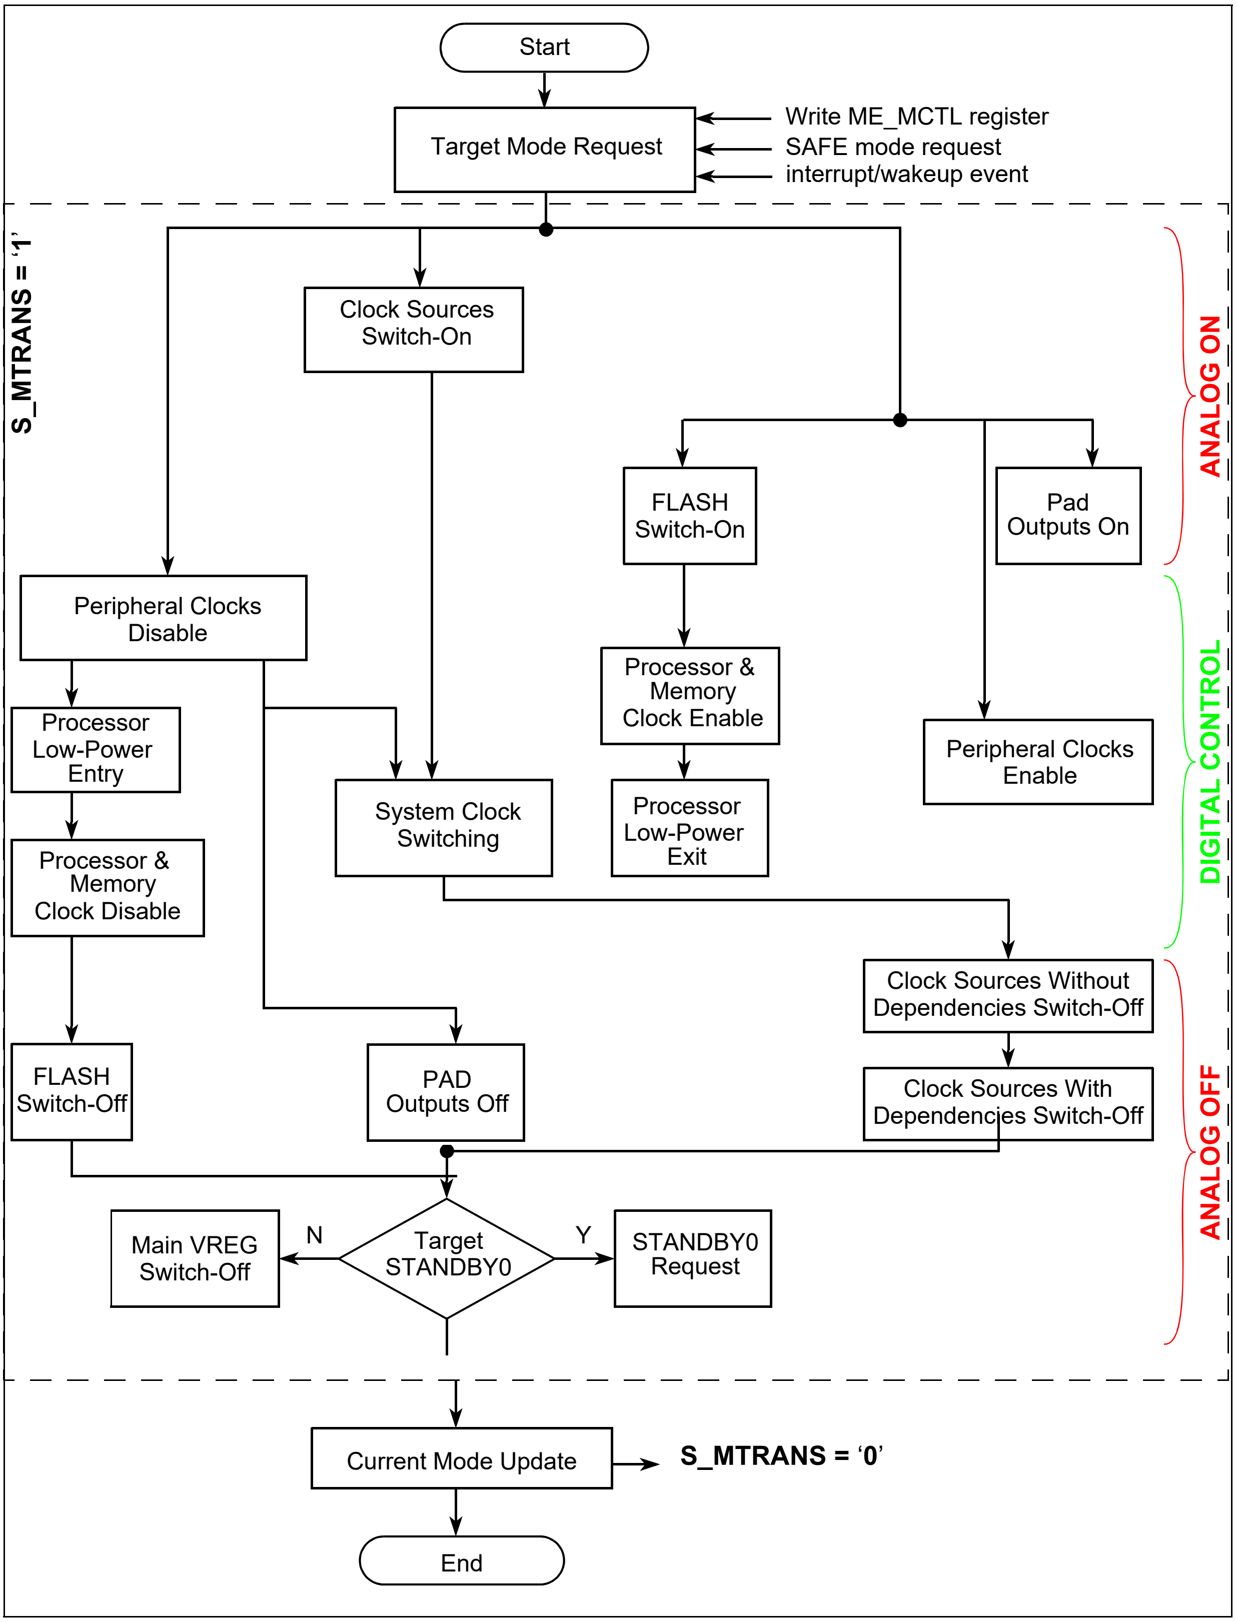
- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register.
- power sequences are done.
- clock disable/enable process is finished.
- processor low-power mode (stop) entry and exit processes are finished.

Note: SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

Figure 1178. MC_ME Transition Diagram



56.4.4 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz int. RC osc. is selected as the system clock, IRC must be on.
- If the external crystal osc. clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration “00” for the FLAON bit field is reserved.
- System clock configurations marked as ‘reserved’ may not be selected.
- Configuration “1111” for the SYSCLK bit field is allowed for the TEST mode and STANDBY mode, and only in this case may all system clock sources be turned off.

Caution: If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

56.4.5 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

56.4.5.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the **ME_<mode>_MC** registers violating the protection rules mentioned in *Section 56.4.4*, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is ‘1’.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0–7/ME_LP_PC0–7 and ME_PCTLn registers, the interrupt pending bit I_ICONF_CU of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CU of the ME_IM register is ‘1’.

If an attempt to write to one of the ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is ‘1’.

56.4.5.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.

- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (that is a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a HALT0 mode request occurs while an interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a STOP0 mode request occurs while a wakeup or interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note: As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0–3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined ‘reasonable’ amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

Warning: Depending on the cause of the mode transition not completing, aborting via a request back to the parent mode may not be able to recover. In this case, software should request a change to either SAFE or RESET mode, since the cause of the hang-up is most likely due to a hardware fault.

- Self-transition requests (for example, RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (that is S_MTRANS is ‘1’). During the low-power mode exit process, if the system is not able to enter the respective RUN0–3 mode properly (that is all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is ‘1’.

56.4.5.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is ‘1’.

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (by programming the ME_MCTL register).

56.4.5.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (that is the S_MTRANS bit of ME_GS register transits from ‘1’ to ‘0’), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is ‘1’. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

56.4.6 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0–7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0–3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTLn registers.

The low-power peripheral configuration registers ME_LP_PC0–7 are chosen only during the low-power modes HALT0, STOP0, and STANDBY0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTLn registers.

Any modifications to the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.

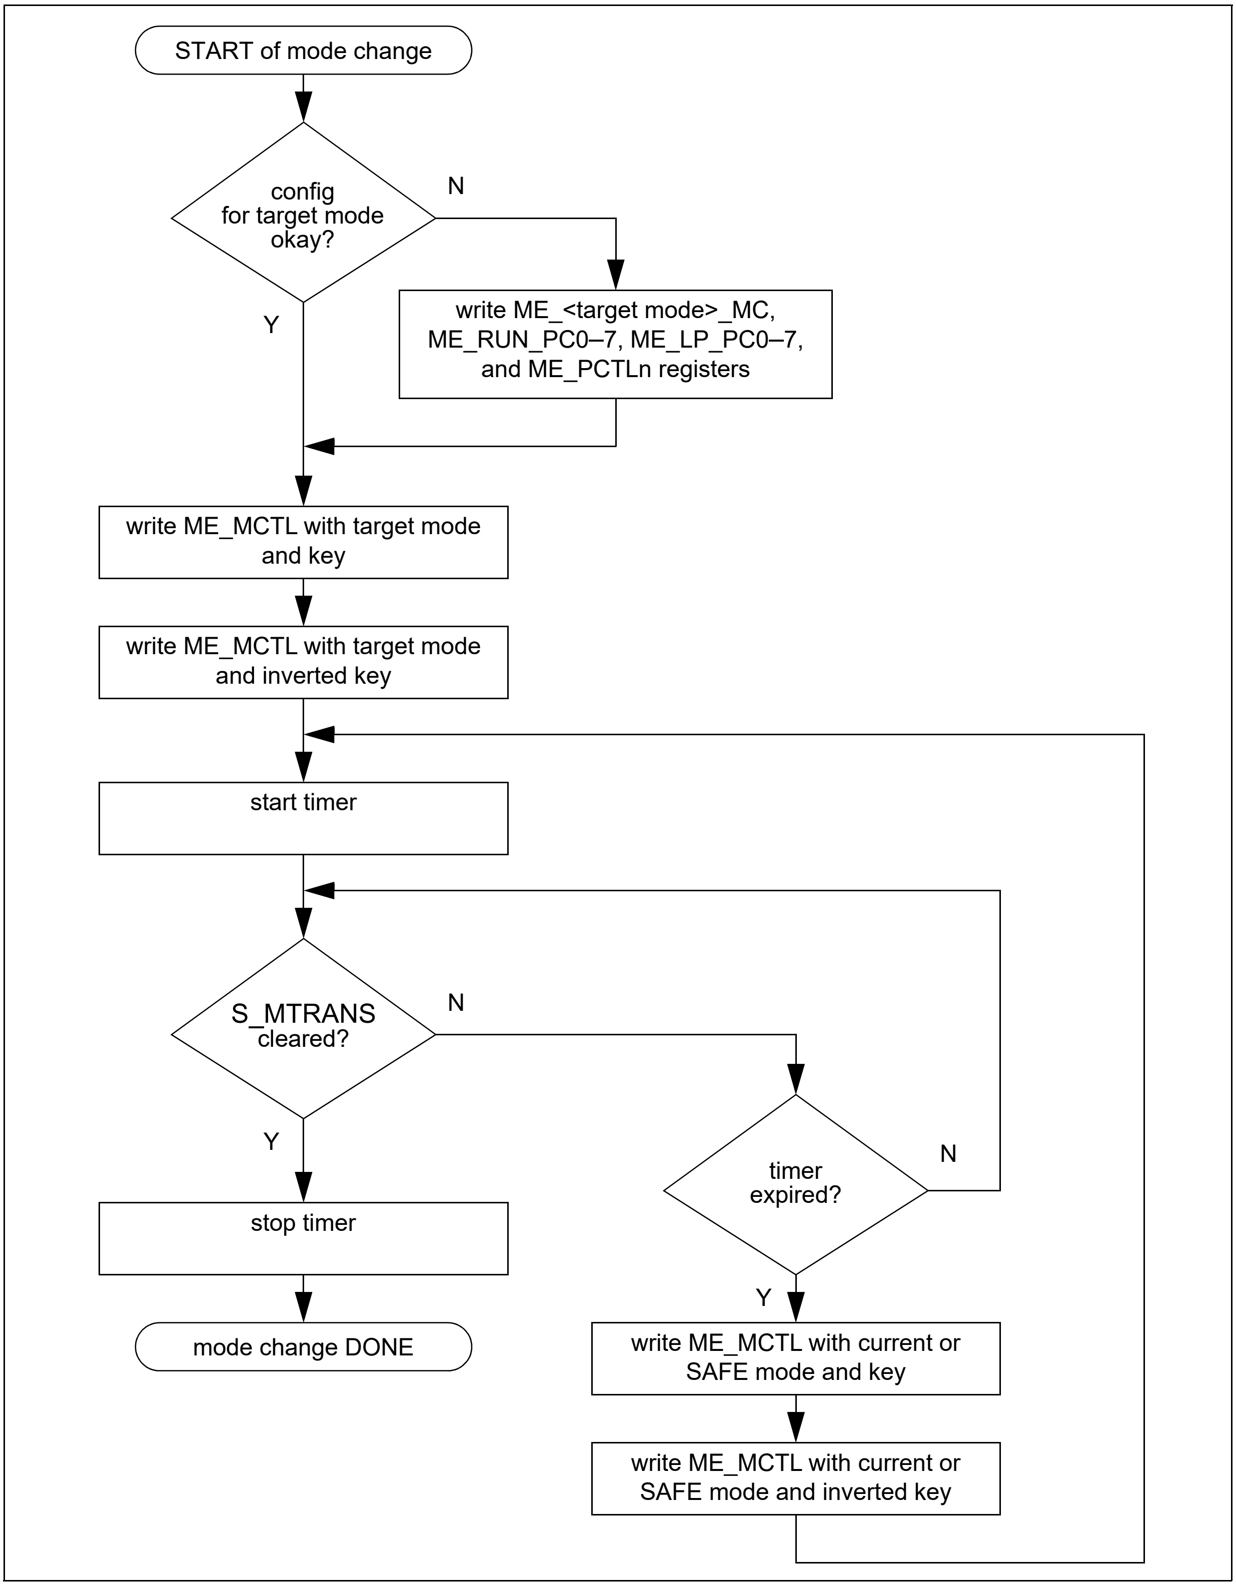
Whenever the processor enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTLn register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits. Any further modifications of the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTLn registers during a debug session will take effect immediately without requiring any new mode request.

56.4.7 Application Example

Figure 1179 shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

Figure 1179. MC_ME Application Example Flow Diagram



57 e200z420n3 Core Debug Support

This chapter describes the debug features of the e200z420n3 core.

57.1 Overview

Internal debug support in the e200z420n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z420n3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z420n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

57.1.1 Software debug facilities

e200z420n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

57.1.1.1 *PowerISA 2.06* compatibility

The e200z420n3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

57.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z420n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger (Refer to *Section 57.1.4, Sharing debug resources by software/hardware*). A data trace port is also provided.

57.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z420n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (that is the normal setting). Refer to the “Data Trace Control Register (DTC)” section in the Core (e200z420n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

57.1.3 Hardware debug facilities

The e200z420n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z420n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in *Section 57.3, Debug registers* are reserved for use by the external debugger. The same events described in *Section 57.2, Software debug events and exceptions* are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via

EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

57.1.4 Sharing debug resources by software/hardware

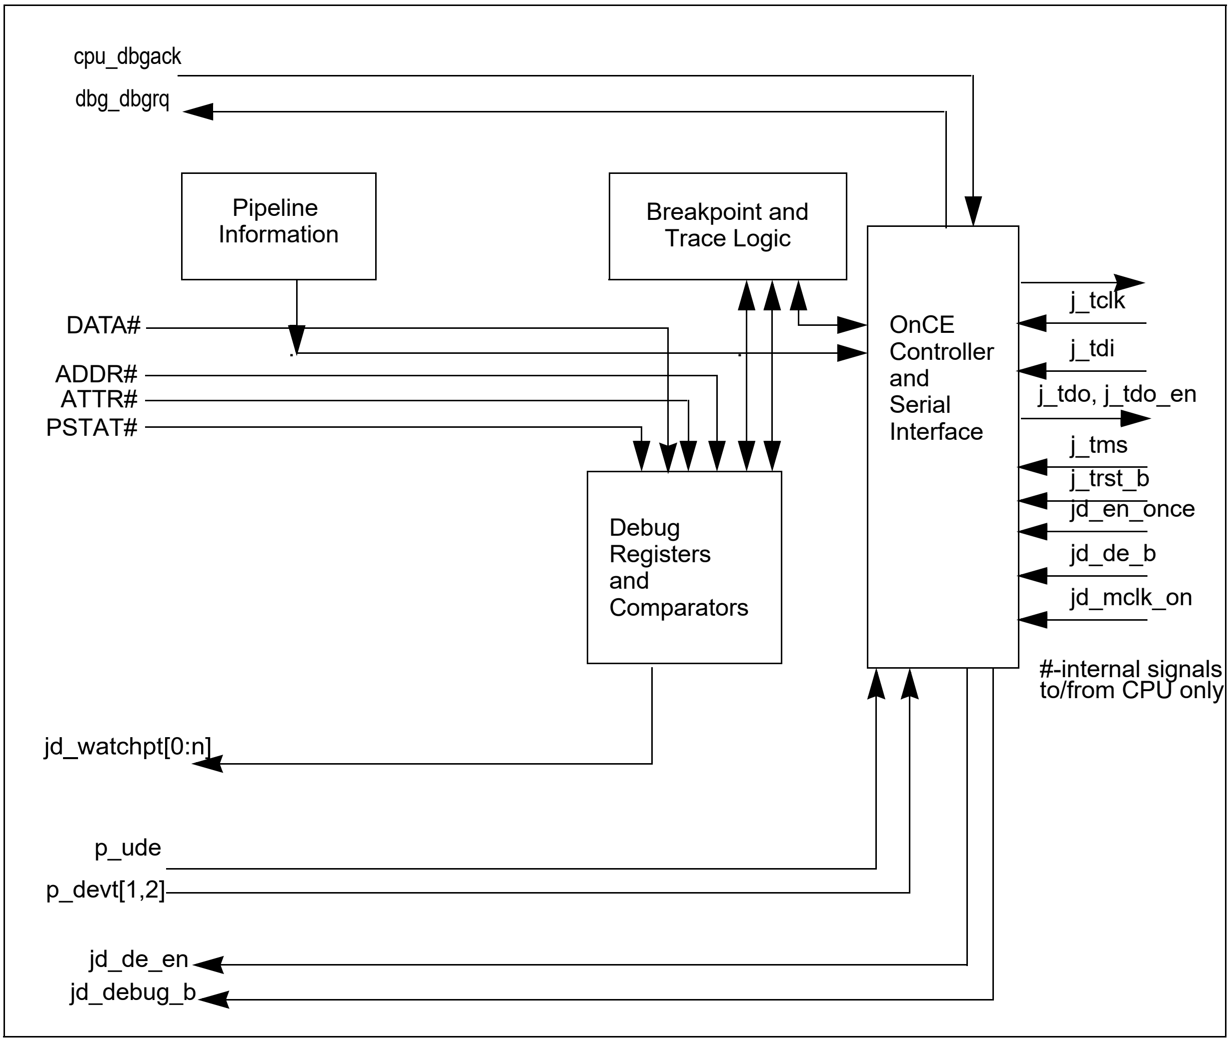
Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

57.1.4.1 Simultaneous hardware and software debug event handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1180 shows the e200z420n3 debug resources.

Figure 1180. e200z420n3 debug resources



57.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to ‘1’.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z420n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in *Section 57.2.11, External debug event*.
- The Performance Monitor Interrupt event PMI, which is described in *Section 57.2.13, Performance Monitor Interrupt debug event*.

The e200z420n3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported.

A brief description of each of the event types follows.

57.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

57.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z420n3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC\_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, that is no data comparisons are performed since these instructions do not have associated data values.

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.*

57.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC\_OFST}$ field when the DVC DAC status is recorded.

Table 1190 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in *Table 1190*, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 1190. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.

Table 1190. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.

Table 1190. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3’b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.

Table 1191 through *Table 1194* show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 1191. DAC events and resultant updates, dual-issue case 1

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3’b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)

Table 1191. DAC events and resultant updates, dual-issue case 1 (continued)

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	**Event(s)**	**Result**
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b100. No ESR update. DSRR0 points to instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.

Table 1192. DAC events and resultant updates, dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	**Event(s)**	**Result**
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3’b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3’b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3’b101. DSRR0 points to instruction (7). No ESR update. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.

Table 1192. DAC events and resultant updates, dual-issue case 2 (continued)

No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

57.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

57.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

57.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ cannot be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

57.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to ‘1’ while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to ‘1’ while MSR_{DE}=1.

57.2.7 Interrupt Taken debug event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

57.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

57.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (that is before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

57.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (that is before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

57.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to ‘1’ to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

57.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to ‘1’ to record the debug exception. This debug event is an asynchronous event.

57.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to ‘1’ to record the debug exception. This debug event is an asynchronous event.

57.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not “owned” by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not “owned” by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not “owned” by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers are performed.

57.3.1 Debug Address and Value registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 1181*) corresponds to the byte data value transferred to/from memory byte offset such as 0, 8, and the least significant byte of the register (labeled B7 in *Figure 1181*) corresponds to byte offset such as 7, F. When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z420n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

B0	B1	B2	B3

SPR 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset: Unaffected

Figure 1181. DVC1, DVC2 registers

57.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z420n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

57.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z420n3 adds some implementation specific bits to this register, as seen in *Figure 1182*.

0	1	2–3	4	5	6	7	8	9	10	11	12–13	14–15	16	17	18	19	20	21	22	23–24	25	26	27–31

SPR - 308; Read/Write; Reset(1) - 0x0

Figure 1182. Debug Control Register 0 (DBCR0) register

1. DBCR0$_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if DBCR0$_{EDM}$=0, as well as unconditionally by **m_por**. If DBCR0$_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the DBCR0$_{RST}$ field will be reset by **p_reset_b**. The DBCR0$_{RST}$ field will always be reset by **p_reset_b** regardless of the value of DBCR0$_{EDM}$.

Table 1195 provides bit definitions for Debug Control Register 0.

Table 1195. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0.
		Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to ‘1’ before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to ‘1’, all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR$_{DE}$=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR$_{DE}$ was cleared, will cause a Debug interrupt.

Figure 1184. DBCR2 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1197 provides bit definitions for Debug Control Register 2.

Table 1197. DBCR2 field descriptions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table 1197. DBCR2 field descriptions (continued)

Bit	Name	Description
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.

Table 1197. DBCR2 field descriptions (continued)

Bit	Name	Description
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

57.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 1185*.

SPR - 563; Read/Write; Reset(1) - 0x0

Figure 1185. DBCR4 register

1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1198 provides bit definitions for Debug Control Register 4.

Table 1198. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits

Table 1198. DBCR4 field descriptions (continued)

Bit	Name	Description
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1198. DBCR4 field descriptions (continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01*xx* Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01*xx* Reserved 1*xxx* Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

57.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 1186*

0–1	2–3	4–5	6–7	8–9	10–15	16–17	18–19	20–21	22–23	24–25	26–31

Table 1202. DBCR8 field descriptions (continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

57.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A ‘1’ causes the bit to be cleared, and a ‘0’ has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 1190*.

IDE	UDE	MRR		ICMP	BRT	IRPT	TRAP	IAC	0			DACR	DACW	0	DNI	RET	0				DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST			0

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 1190. Debug Status Register (DBSR)

Table 1203 provides bit definitions for the Debug Status Register.

Table 1203. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to ‘1’ if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred

Table 1203. DBSR field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

57.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is updated by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 1191*.

Data Effective Address
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 600; Read/Write; Reset - unaffected

Figure 1191. Debug Data Effective Address Register (DDEAR)

57.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

The EDBRAC0 register is shown in *Figure 1192*.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28–31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b**, reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 1192. External Debug Resource Allocation Control (EDBRAC0) register

Table 1204 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 1204. EDBRAC0 field descriptions

Bit	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored. 0 Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable.
2	RST	Reset Field Control 0 $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 Event owned by hardware debug. 1 Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 Event owned by software debug. $DBCR0_{TRAP}$ is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 Event owned by software debug. IAC1 control fields are software readable/writable.

Table 1204. EDBRAC0 field descriptions (continued)

Bit	Name	Description
9	IAC2	Instruction Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 Event owned by software debug. DAC1 control fields are software readable/writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1204. EDBRAC0 field descriptions (continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable. **Note:** This bit is reset to ‘1’.
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors that have the DEBUG control bit set to ‘1’ or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** This bit is reset to ‘1’.
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored. 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in *Table 1205* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

57.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a ‘1’ to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. Refer to the “Data Acquisition ID Tag Field” section in the Core (e200z420n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 1193*.

DQTAG								0																DEVNT							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 975; Reset(1): 0x0

Figure 1193. Debug Event Select register (DEVENT) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.** Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

Table 1206 provides bit definitions for the Debug Event Register.

Table 1206. DEVENT field descriptions

Bit	Name	Description

8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 No signal is asserted *xxxxxxx*1 **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock *xxxxxx*1*x* **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock *xxxxx*1*xx* **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock *xxxx*1*xxx* **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock *xxx*1*xxxx* **p_devnt_out[4]** is asserted for one clock *xx*1*xxxxx* **p_devnt_out[5]** is asserted for one clock *x*1*xxxxxx* **p_devnt_out[6]** is asserted for one clock 1*xxxxxxx* **p_devnt_out[7]** is asserted for one clock

57.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. Refer to the “Data Acquisition Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 1194*.

DDAM
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 576; Reset[1]: 0x0

Figure 1194. Debug Data Acquisition Message (DDAM) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1207 provides bit definitions for the Debug Data Acquisition Message Register.

Table 1207. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

57.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 1198*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to ‘1000’ or the $DBCR8_{DAC3CFG}$ field to ‘1000’ (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to ‘1000’ with $DBCR2_{DAC1US}$ set to ‘00’ or ‘10’, or the $DBCR7_{DAC3CFG}$ field is set to ‘1000’ with $DBCR8_{DAC3US}$ set to ‘00’ or ‘10’, or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to ‘1000’ with $DBCR2_{DAC1US}$ set to ‘00’ or ‘01’, or the $DBCR7_{DAC3CFG}$ field is set to ‘1000’ with $DBCR8_{DAC3US}$ set to ‘00’ or ‘01’, or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 1198* and *Table 1201* in *Section 57.3.2, Debug Control and Status registers*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

57.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to ‘1’ through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 57.2, Software debug events and exceptions* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to ‘1’, other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to ‘1’. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

*It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

57.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

57.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 1195*.

0	1	2–6	7	8–31
EDM	DNH_EN	0	DNI_CTL	0

Reset[1]: 0x0

Figure 1195. External Debug Control Register 0 (EDBCR0)

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 1208 provides bit definitions for External Debug Control Register 0.

Table 1208. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	**dnh** Instruction Enable 0 Execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 Execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE}=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. **Note:** This control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1.
8:31	—	Reserved

57.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 1196*.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0			DACR	DACW	0	DNI	RET	0				DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST			0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Read/Write; Reset(1) - 0x0000_0000

Figure 1196. External Debug Status Register 0 (EDBSR0)

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$=0.

Table 1209 provides bit definitions for External Debug Status Register 0.

Table 1209. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred

Table 1209. EDBSR0 field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

57.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A ‘1’ stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 1197*.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

22:31	—	Reserved

57.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 1198*.

Data Effective Address
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31
Read/Write; Reset: unaffected

Figure 1198. External Debug Data Effective Address Register (EDDEAR)

57.5.2 OnCE introduction

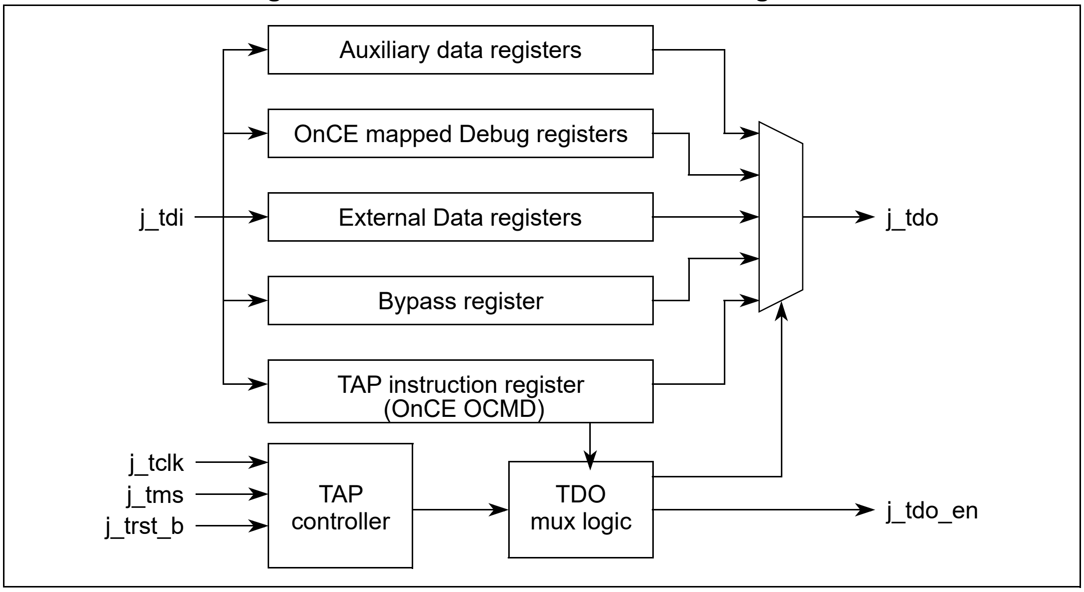
The e200z420n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z420n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

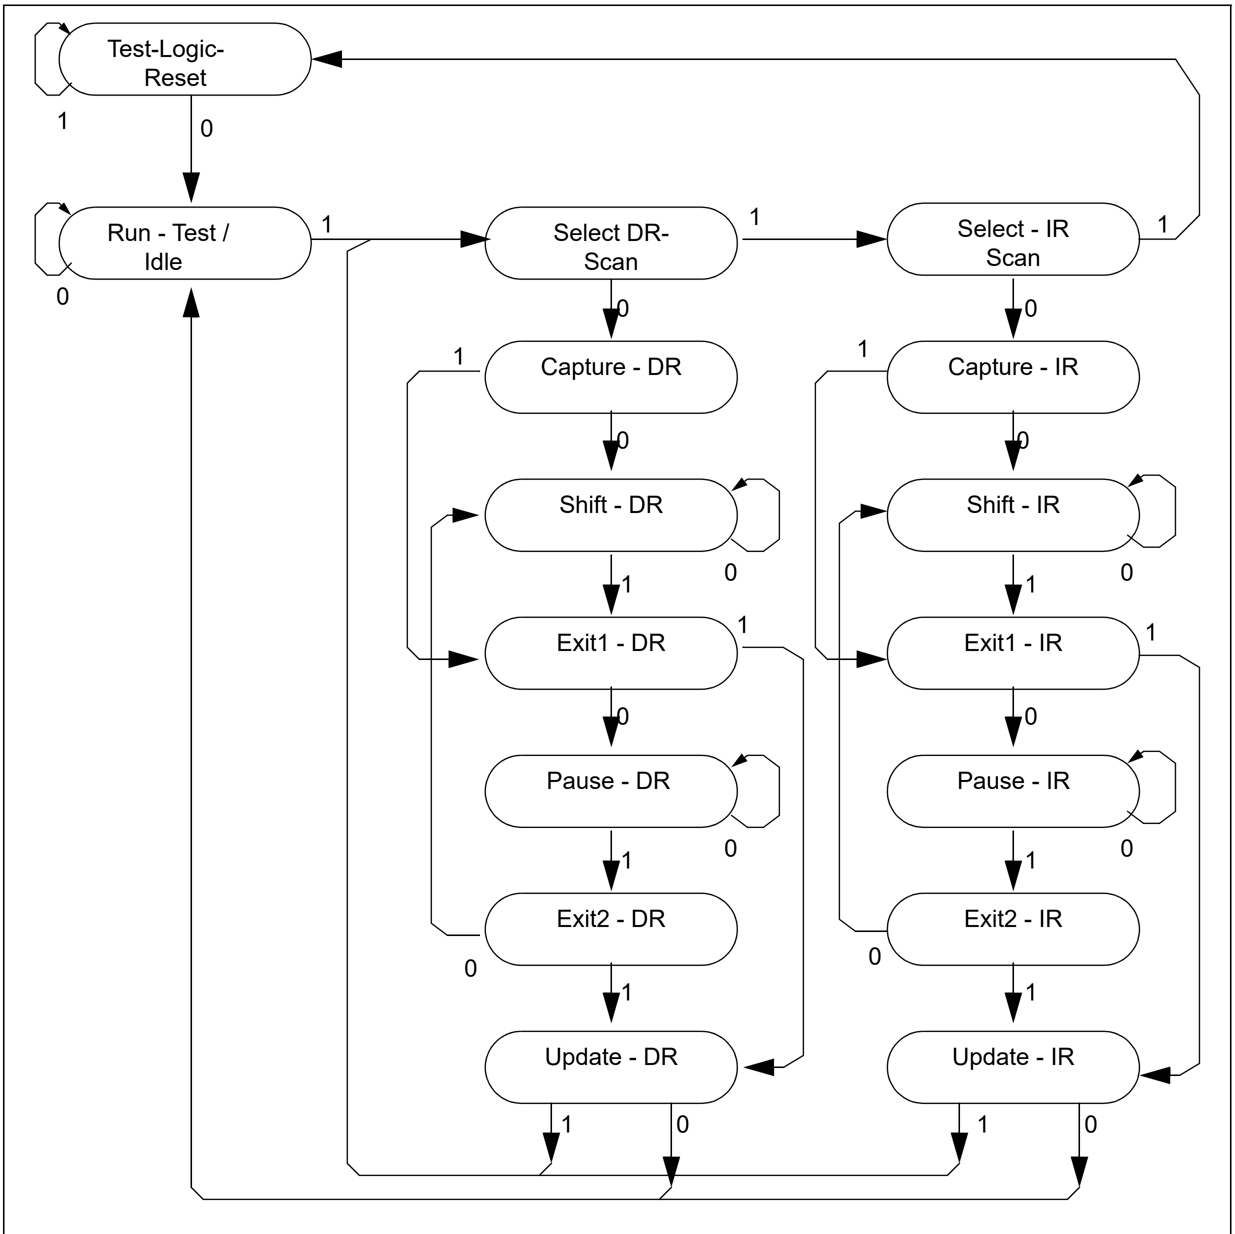
The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1199. OnCE TAP controller and registers



The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1200. OnCE controller implementation



Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 57.5.6.1, OnCE Status register*) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (refer to *Section 57.5.6.2, OnCE Command (OCMD) register*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

57.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

Table 1211 details the primary JTAG/OnCE interface signals.

Table 1211. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z420n3) Core Complex Overview.

57.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

57.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

57.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

57.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

57.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

57.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

57.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take effect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

57.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z420n3 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

57.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. Refer to *Section 57.5.6.2, OnCE Command (OCMD) register* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

57.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z420n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

57.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 1218* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

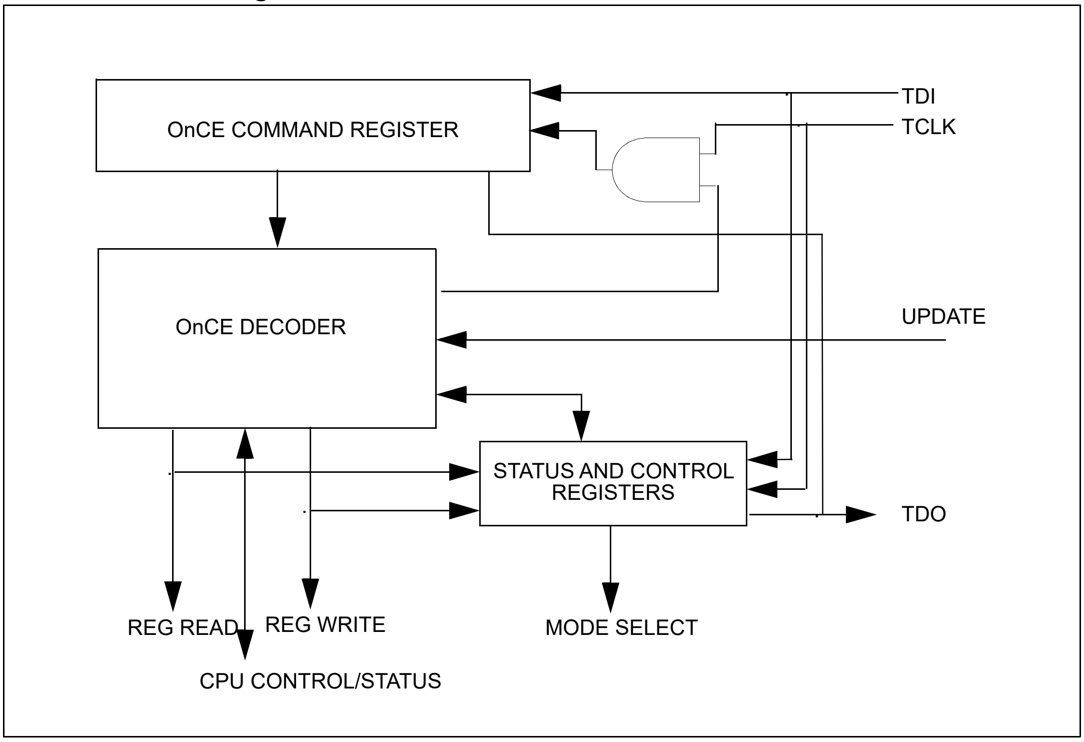
57.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

57.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 1201* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1201. OnCE Controller and Serial Interface



57.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 1202. OnCE Status register

Table 1212 provides bit definitions for the OnCE Status register.

Table 1212. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including such as External, Critical, machine check, Storage, Alignment, Program) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

57.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 1203*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step or exit functionality, or both, to be performed, even though the command appears to have no data resource requirement associated with it.

R/W	GO	EX	RS[0:6]

Figure 1203. OnCE Command (OCMD) register

Table 1213 provides bit definitions for the OCMD.

Table 1213. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 57.5.9.6, Exiting Debug mode and interrupt blocking*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1213. OCMD field descriptions (continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. **Note:** If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 57.5.9.6, Exiting Debug mode and interrupt blocking*.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 1214* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 1214 indicates the OnCE register addresses.

111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (such as interrupts, machine checks, bus error conditions) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

57.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z420n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (refer to *Section 57.7, MPU operation during debug*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 1204*.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset - 0xo000_0000 on **m_por**, **j_trst_b**, or entering Test_logic_Reset state

Figure 1204. OnCE Control Register (OCR)

Table 1215 provides bit definitions for the OnCE Control Register.

Table 1215. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug ‘G’ Attribute Bit This bit is used to provide the ‘G’ attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.

Table 1215. OCR field descriptions (continued)

Bit	Name	Description
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo-instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. **Note:** This bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

57.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z420n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z420n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z420n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (such as DBSR) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 1216 provides a list of access requirements for OnCE registers.

Table 1216. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*(1)

PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	

Table 1216. OnCE register access requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	—	—	—	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

57.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input. Refer to *Section 57.5.5.1, OnCE Enable (jd_en_once)* for details.

57.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z420n3 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z420n3 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

57.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

57.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

57.5.8.4 Debug request during Waiting, Halted, or Stopped state

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

57.5.8.5 Software request during normal activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z420n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.

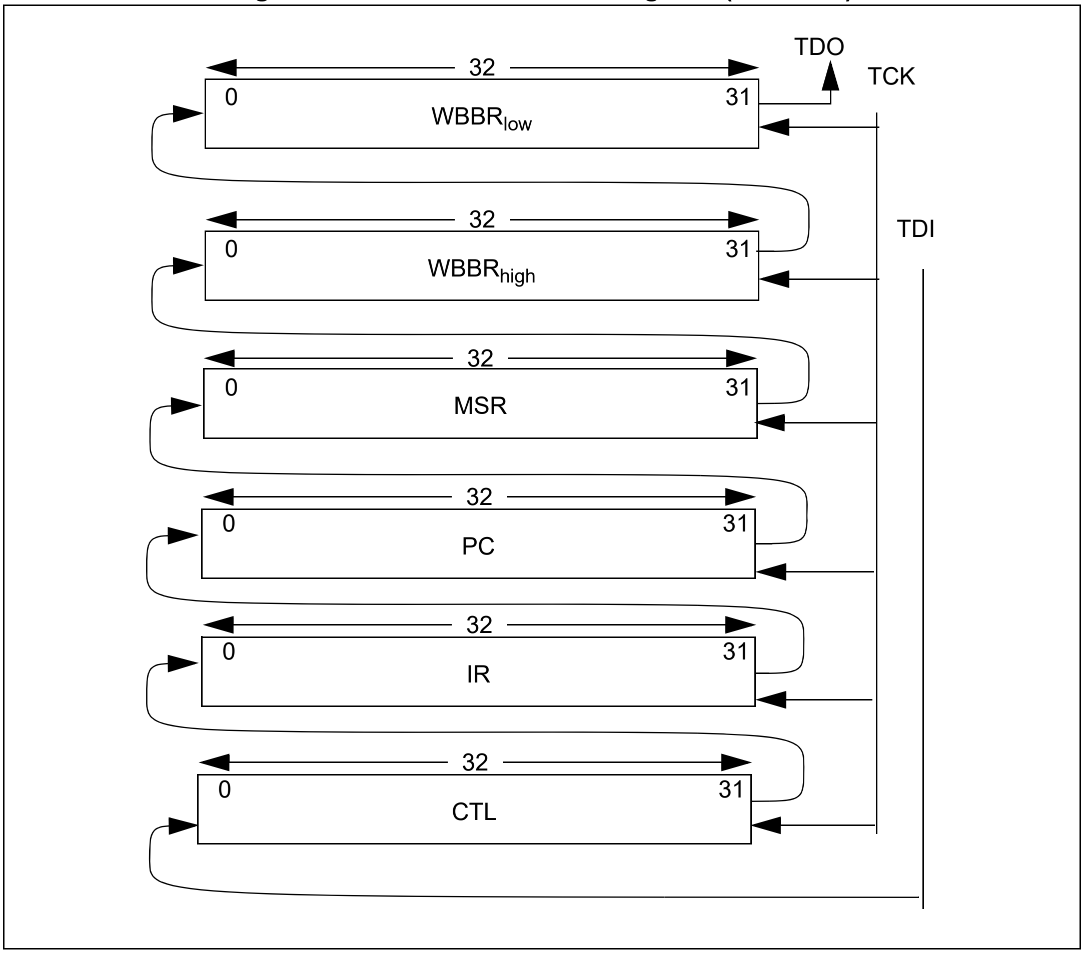
57.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH\_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z420n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

57.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 1205* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1205. CPU Scan Chain Register (CPUSCR)



57.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

57.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

Bits	0–9	10	11	12	13	14	15	16–19	20	21	22	23	24	25	26	27	28	29	30	31
Field	*	IRSTAT14	IRSTAT13	IRSTAT12	IRSTAT11	IRSTAT10	WAITING	PCOFST	PCINV	FFRA	IRSTAT0	IRSTAT1	IRSTAT2	IRSTAT3	IRSTAT4	IRSTAT5	IRSTAT6	IRSTAT7	IRSTAT8	IRSTAT9

Figure 1206. Control State Register (CTL)

Table 1217. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. Refer to *Section 57.5.5.3, OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered

Table 1217. CTL field descriptions (continued)

Bit	Name	Description
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (Refer to PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of $WBBR_{lo}$ used as operand value.
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.

Table 1217. CTL field descriptions (continued)

Bit	Name	Description
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bits set to ‘0’, and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to ‘0’s if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to ‘0’ to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

57.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

57.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 57.5.9.2, Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

57.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

57.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

57.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device or system damage, or both, these registers should not be accessed.

57.6 Watchpoint support

e200z420n3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes (refer to the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter).

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1218 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1218. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]

Table 1218. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a ‘0’ to a ‘1’ while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.

Table 1218. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

57.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR *Section 57.5.6.3, OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 57.5.6.3, OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

57.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

57.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to ‘1’. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 57.5.9.2, Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with “no-register selected”, Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 57.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 57.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

58 Debug and Calibration Interface (DCI)

58.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

58.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

58.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST’s 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as SPU. The DCI also provides the Event Out (EVTO) signal to the debug tool in case of the occurrence of any internal debug event.

Figure 1207 shows the DCI block diagram.

Figure 1207. DCI block diagram

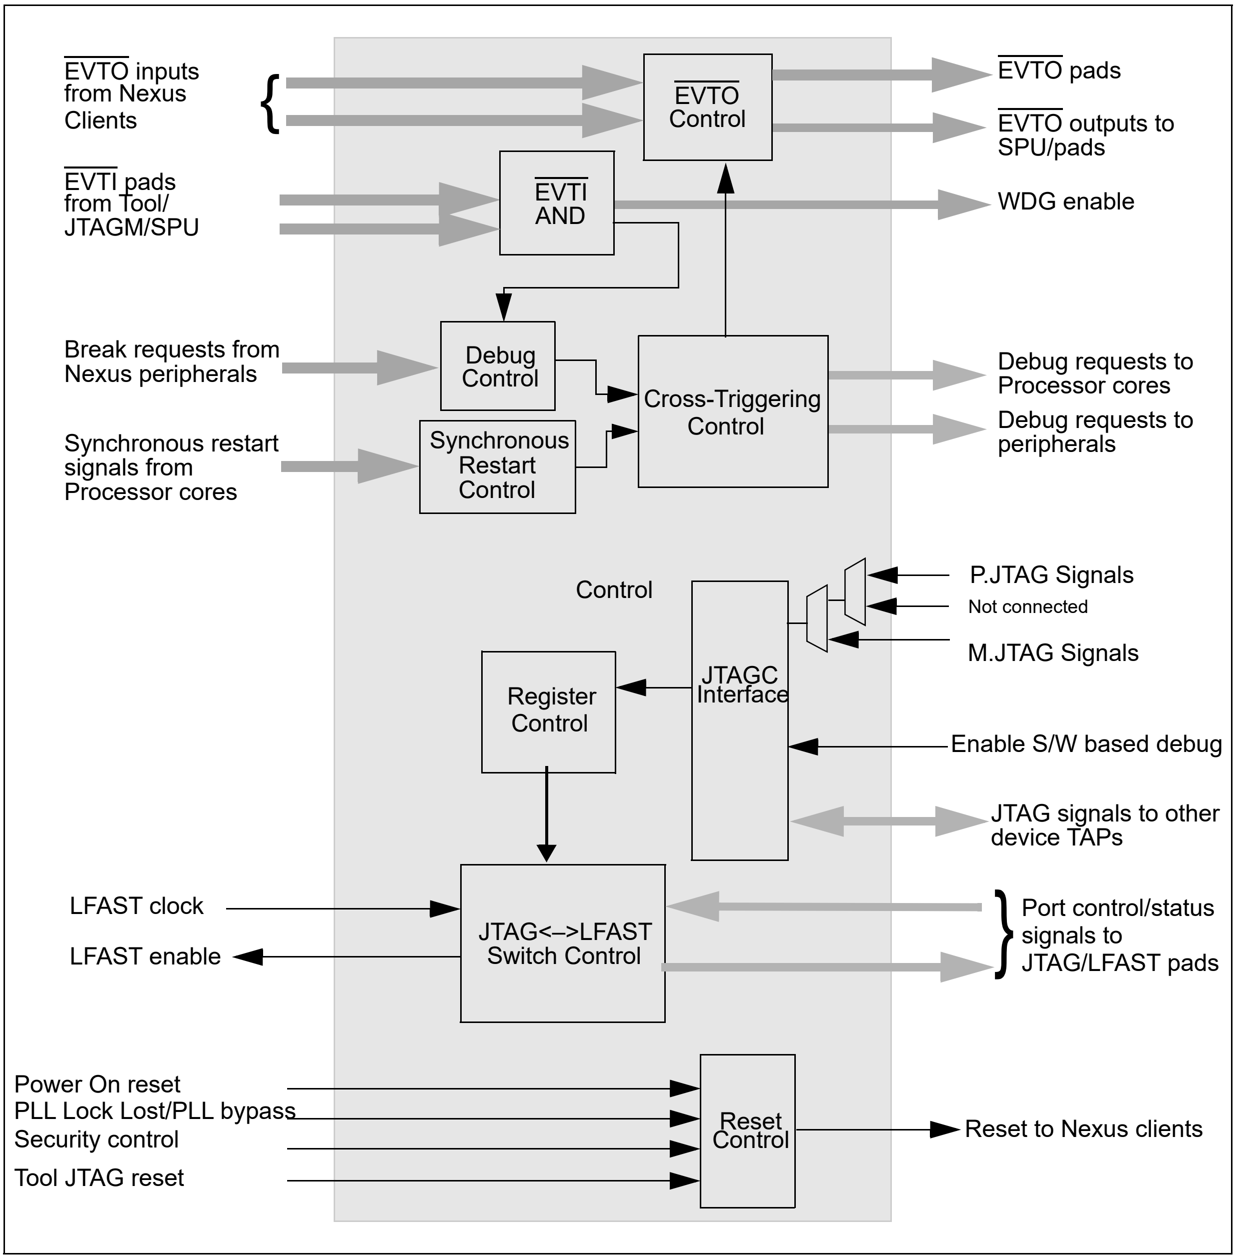


Figure 1208 shows the DCI configuration for the standard production package.

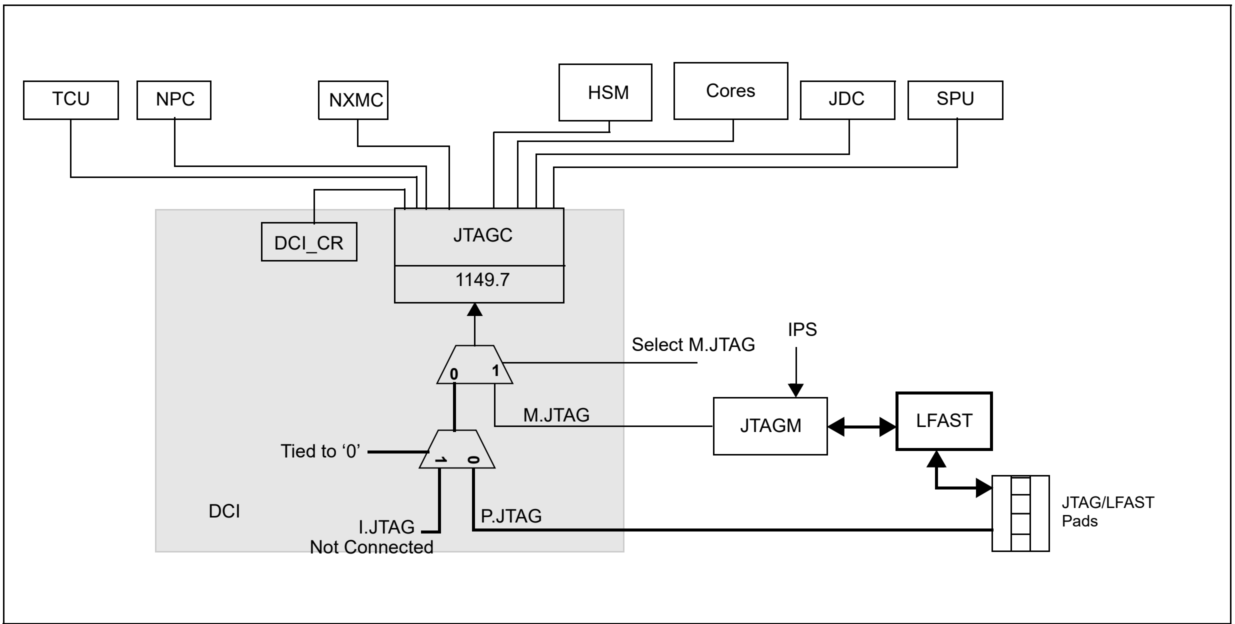
Figure 1208. DCI in a standard configuration



58.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 1219 shows a summary of the configuration options.

Table 1219. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the

JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 58.1.3.1: Port sharing between JTAG and LFAST modes on page 1951*. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 1220* shows the port mapping.

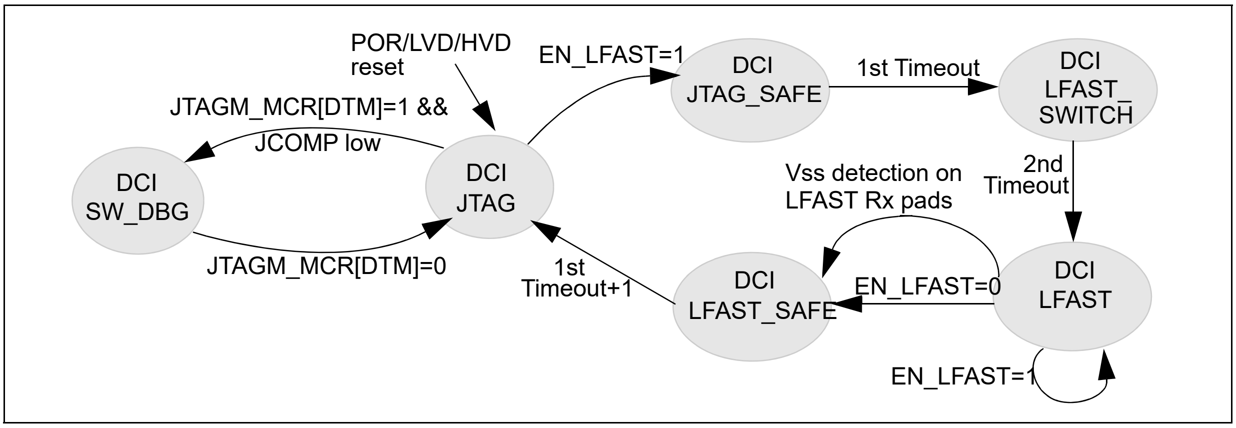
When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1220. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

Figure 1209 shows the DCI mode switching operation.

Figure 1209. DCI operating modes state diagram



Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

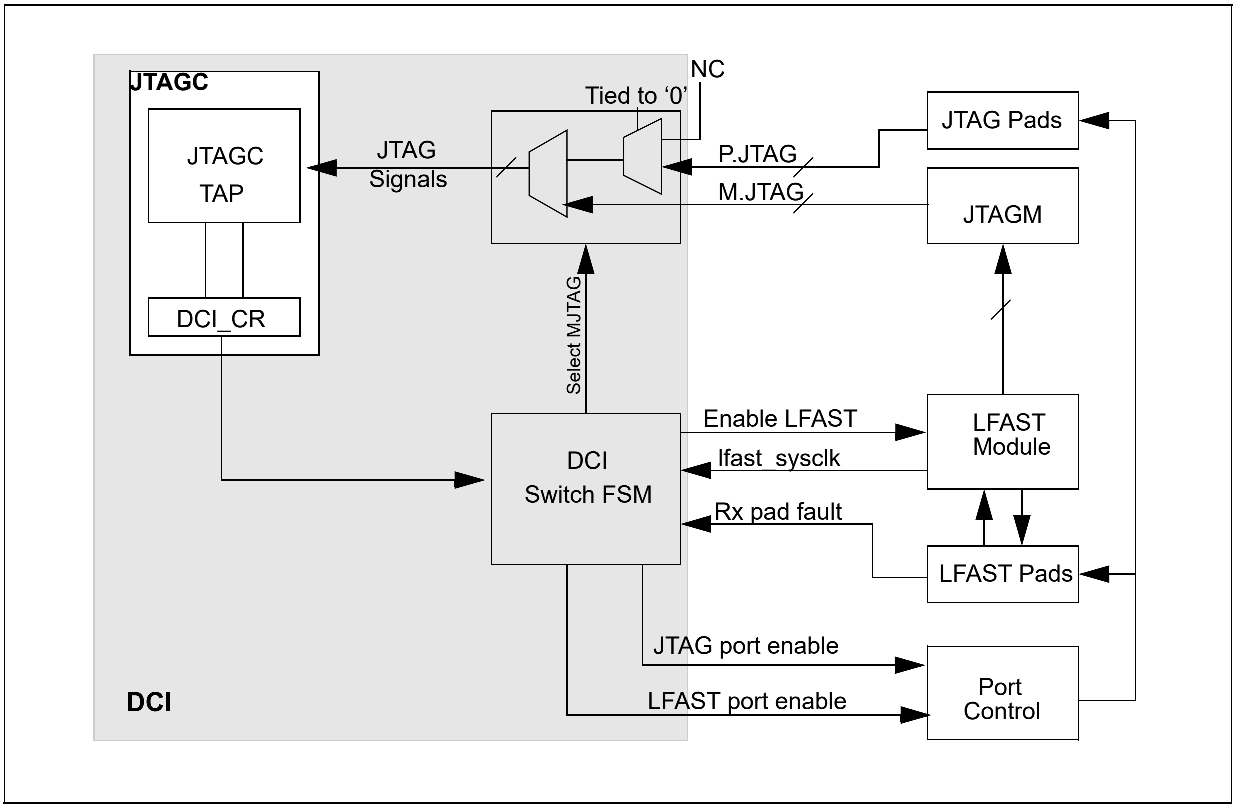
Table 1221 contains the operating mode descriptions.

Table 1221. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

Figure 1210 shows a block diagram of the JTAG/LFAST connections.

Figure 1210. DCI JTAG/LFAST switch integration



58.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

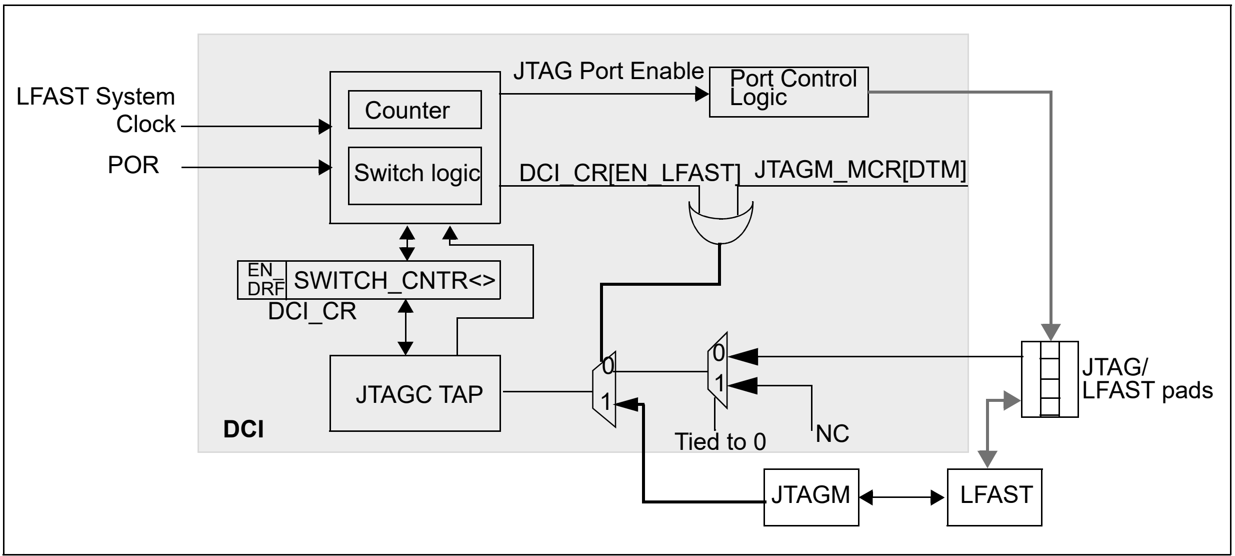
- EN_LFAST – Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2 – Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 1211*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 1211. DCI switching between JTAG and LFAST modes



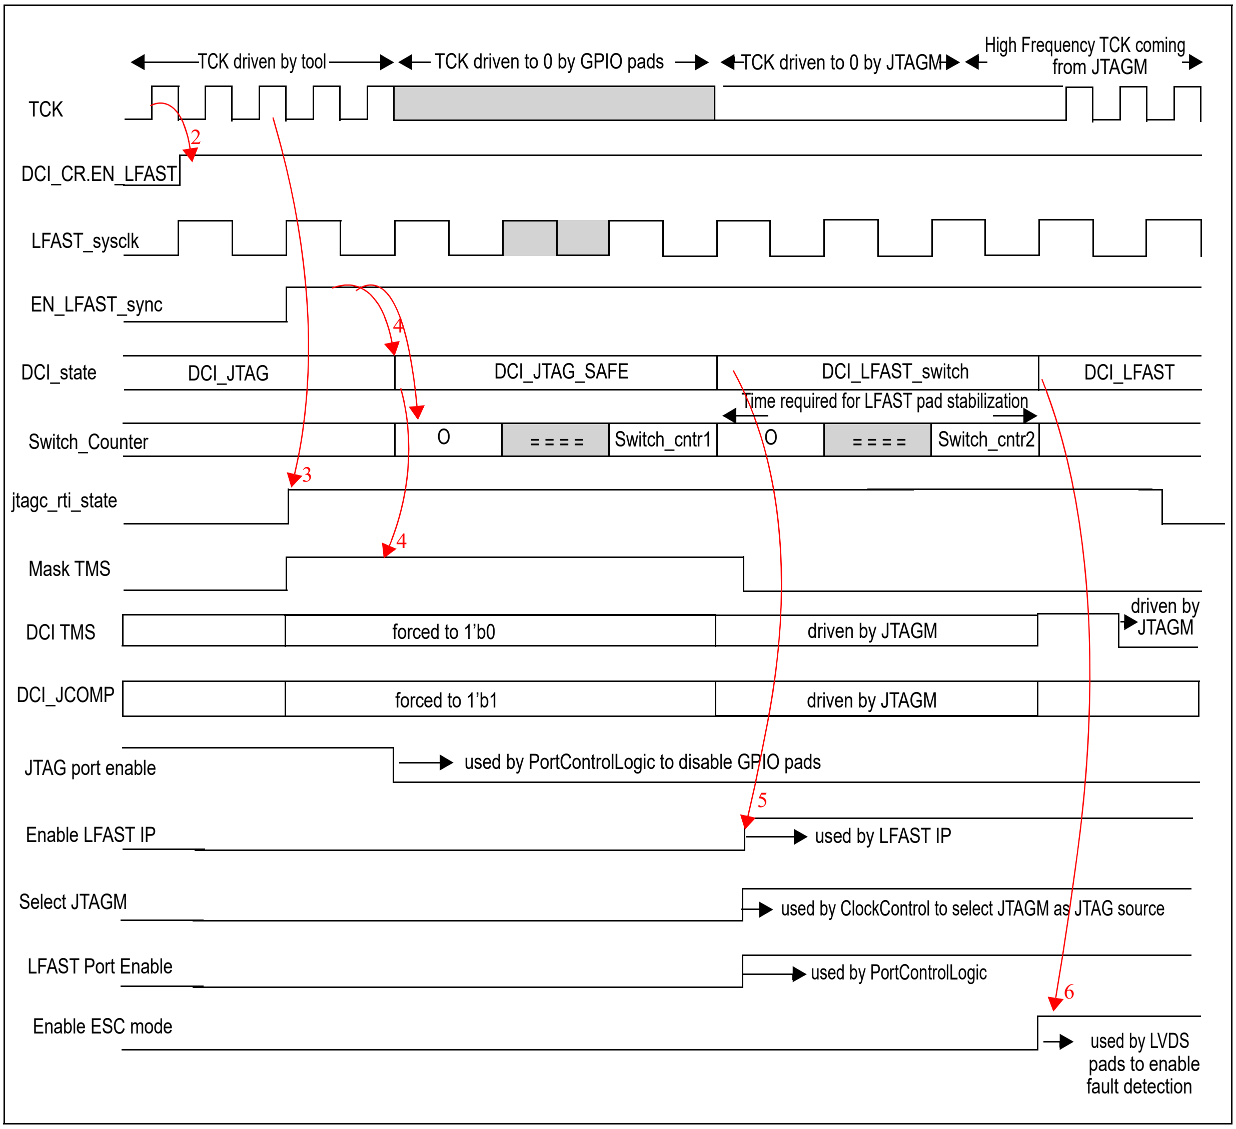
58.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 1212 shows the timing sequence.

Figure 1212. DCI JTAG to LFAST switching diagram



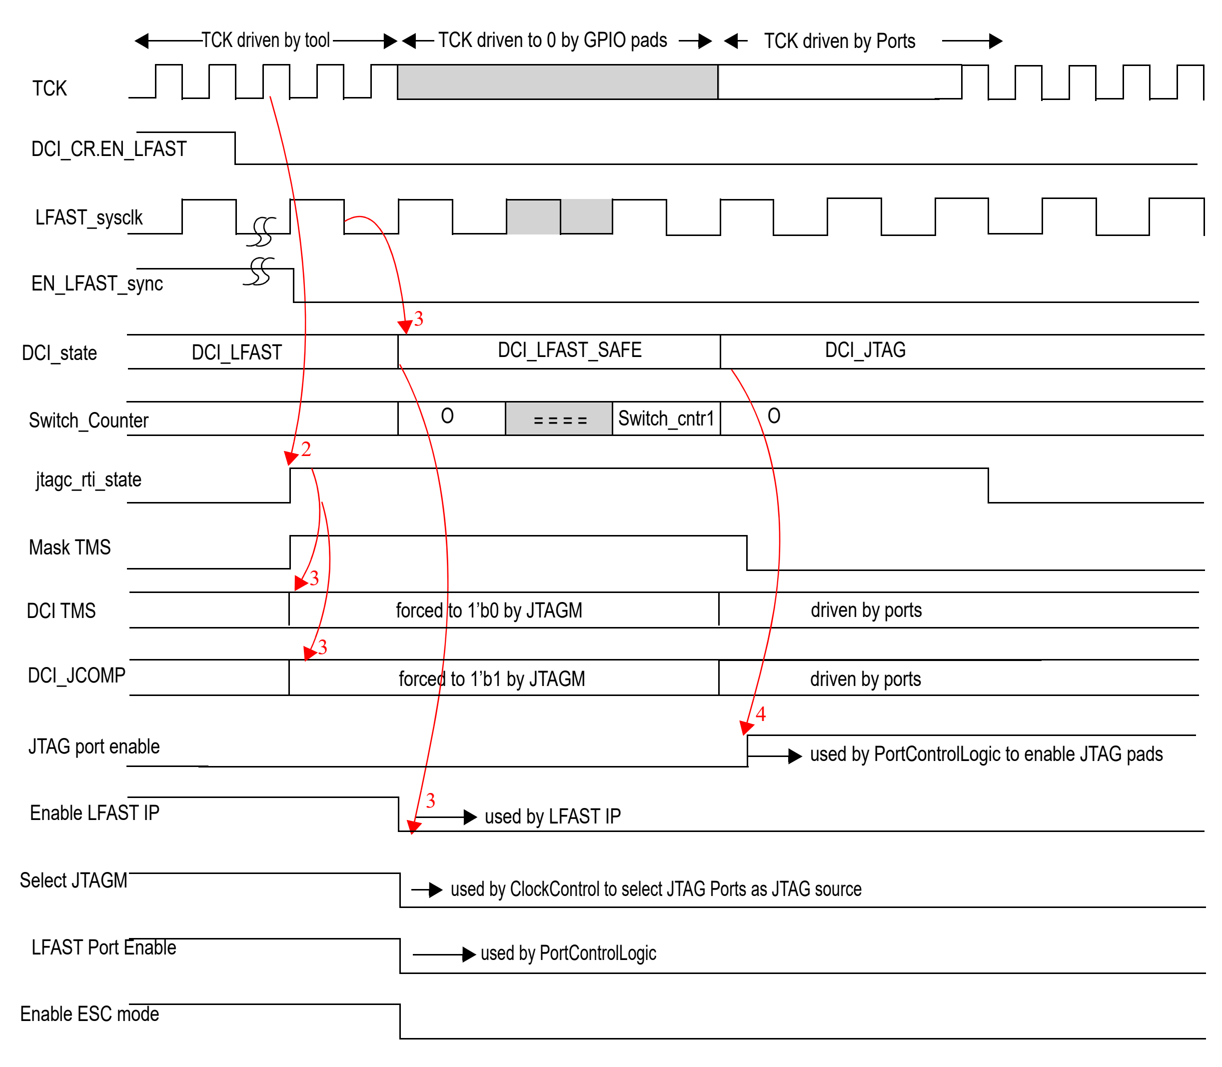
58.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 1225 and *Table 1227* summarize the MCU and tool behaviors. *Figure 1213* shows the timing sequence.

Figure 1213. DCI LFAST to JTAG switching diagram



58.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

58.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

58.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1222. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

58.1.3.5 SWT control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

Note: Debugger should check the SWT counter to confirm if SWT has actually stopped or not, otherwise repeat the sequence mentioned above to disable the SWT.

58.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as DMA, Watchdog and other peripherals.

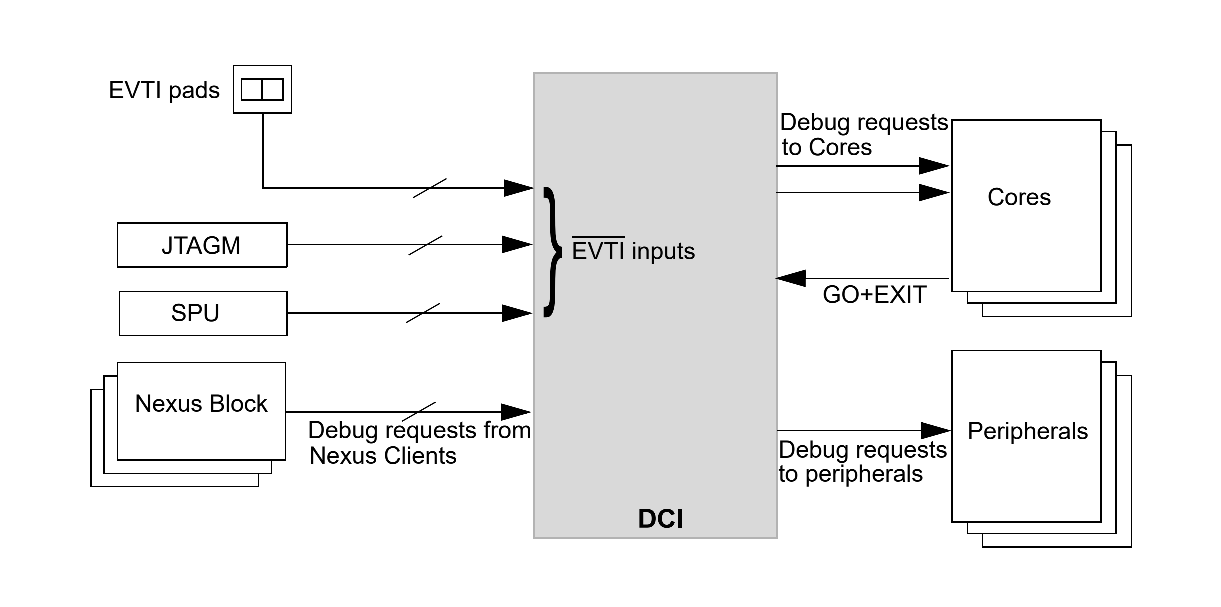
There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[0] signal from EVTI pad
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1214. DCI debug control mechanism



The various sources of EVTI inputs are synchronized and logically ANDed in the DCI to generate the following:

- debug requests for each processor core
- external debug requests for each processor core
- debug request for all non-CPU peripherals

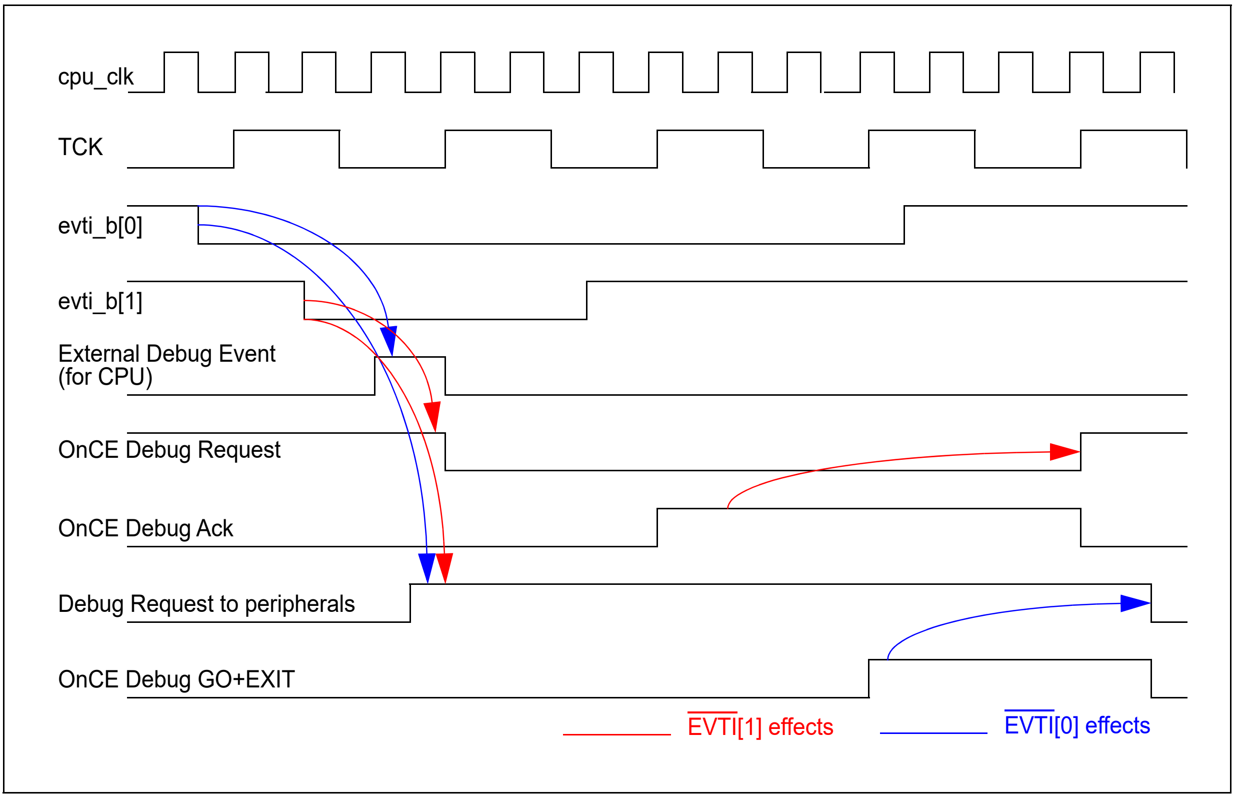
The EVTI[0] from the EVTI pads, SPU and JTAGM are used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The EVTI[1] from the SPU and JTAGM, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The EVTI[0] signal coming from the pad is enabled for debug control using DCI_CR[4] bit.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 1215 shows the timing sequence.

Figure 1215. DCI debug signal generation



58.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

58.1.3.8 Synchronous restart control

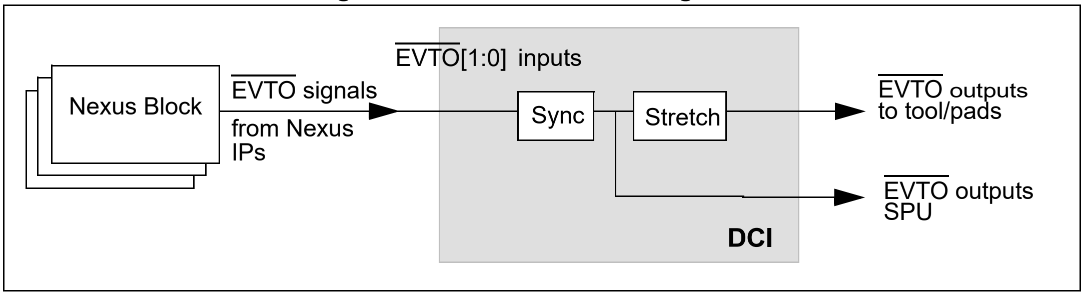
The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (that is set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

58.1.3.9 EVTO management

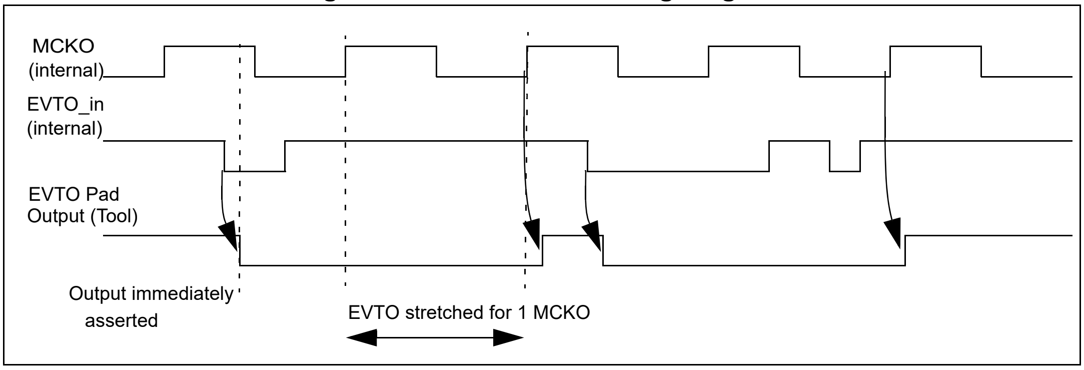
The EVTO management block diagram is presented in *Figure 1216*.

Figure 1216. DCI EVTO management



The DCI module controls distribution of the EVTO output from all Nexus Clients including the cores that produce EVTO[0] signals. The DCI uses a high frequency clock to sample EVTO signal coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[0] signals from any Nexus client, the DCI immediately asserts EVTO[0] outputs and stretches it for a minimum of one output clock period for the output to the tool(*Figure 1217*). The DCI also generates EVTO output in other device clock domains so that other Nexus clients can receive EVTO input without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

Figure 1217. DCI EVTO timing diagram



58.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

58.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

58.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

58.3 Register description

The DCI module contains one registers, DCI_CR, which is present inside the JTAGC module. This register is only controlled using the JTAGC TAP and no memory-mapped registers are present.

58.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 1218* shows the format of the DCI_CR.

	31	30	29	28	27	26	25	24

Figure 1218. DCI control register (DCI_CR) (continued)

The DCI_CR is described in *Table 1223*.

Table 1223. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2 Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1 Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset

Table 1223. DCI_CR field descriptions (continued)

Field	Description
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
4 EVTI0_PAD_EN(1)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled
1 EN_ESC_MODE	Enable Escape Mode Fault detect feature enable for LFAST Rx pads. 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(1)	Enable for LFAST-based tool selection This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

58.4 Functional description

58.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 1224* and *Table 1225* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 1226* and *Table 1227* contain the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1224. MCU operation (JTAG to LFAST switching)

TCK	Logic Input	Logic Input	Logic Output	Logic Output

58.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 1228* and *Table 1229* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 1228. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input

59 JTAG Controller (JTAGC)

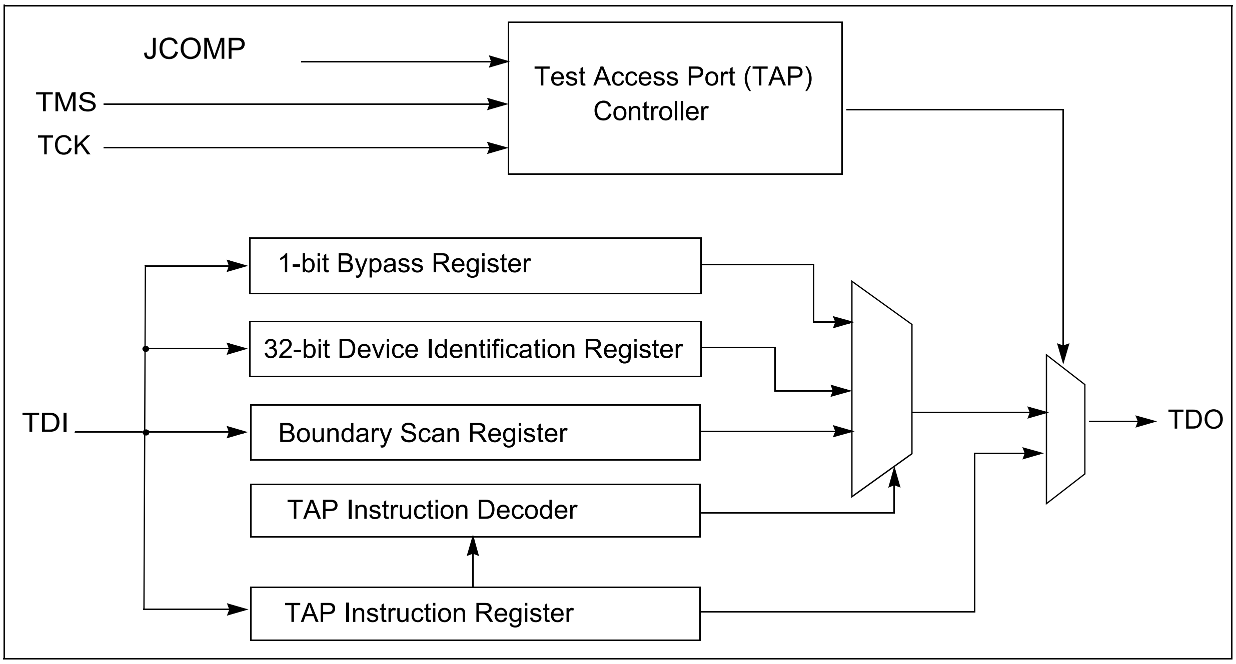
59.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

59.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1219. JTAG (IEEE 1149.1) block diagram



59.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1233* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

59.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

59.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

59.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 59.4.4*.

59.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

59.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1230. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

59.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

59.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

59.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 59.4.3*.

59.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

59.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

59.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

59.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 1220. 6-bit instruction register

59.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

59.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

Figure 1221. Device identification register

The following table describes the device identification register functions.

Table 1231. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 01 40nm
12:14 Application Family	Application Family These bits indicate the device application family 010 SPC58 - Body 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 0010 SPC584B70
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

59.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256’b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

	0	1	2	...	256
R W	JTAG_PASSWORD				
Reset:	*(1)	*	*	*	*

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1222. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1232. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

59.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 59.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

59.4 Functional description

This section explains the JTAGC functional description.

59.4.1 JTAGC reset configuration

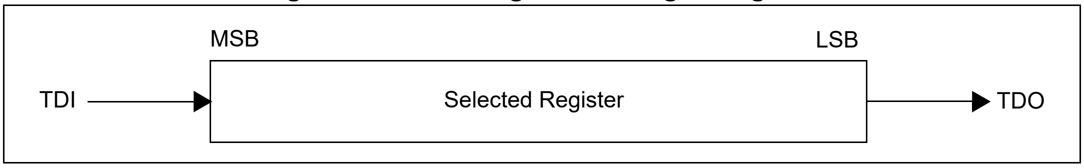
While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

59.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 59.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

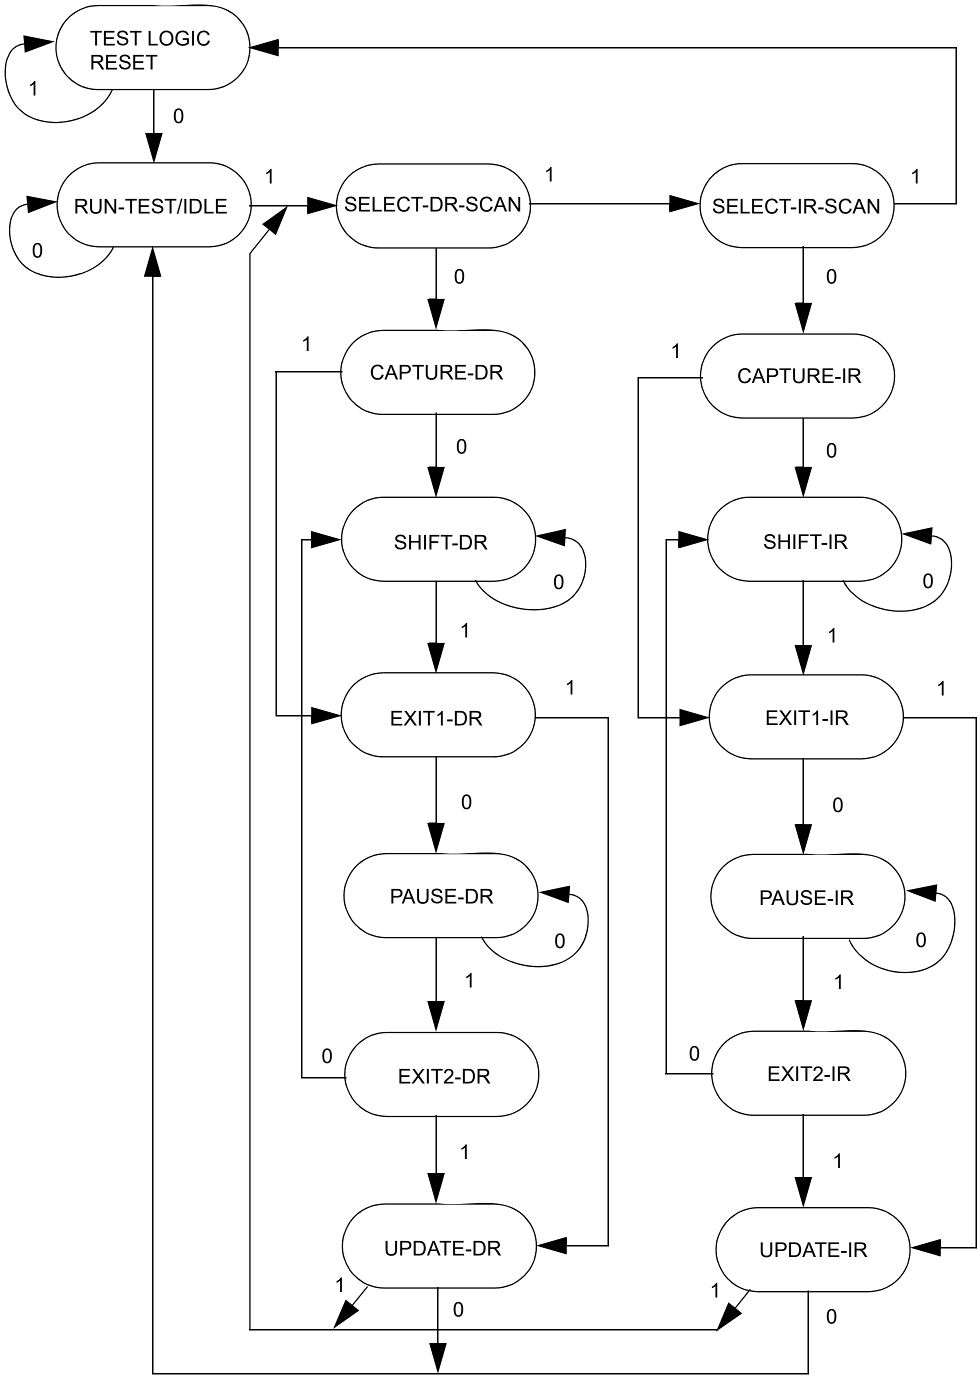
Figure 1223. Shifting data through a register



59.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine’s states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 1224. IEEE 1149.1-2001 TAP controller finite state machine



Note:

1. The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

59.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

59.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

59.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1233. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NPC_PD	100001	Enables access to the NPC TAP controller on production device
Reserved	100001	Reserved

Table 1233. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100010	Reserved
Reserved	100011	Reserved
Reserved	100100	Reserved
Reserved	100101	Reserved
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller, to access the HSM challenge and response registers
ACCESS_AUX_HSM	100111	Enables access to the HSM core TAP controller
Reserved	101001	Reserved
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101010	Reserved
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
Reserved	110011	Reserved
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
ACCESS_AUX_BUS_MON_2	110110	Enables access to NXMC Client 2 TAP controller
Reserved	110111	Reserved
Reserved	111000	Reserved
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
Reserved	111100	Reserved
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

59.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

59.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

59.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

59.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

59.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

59.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (for example high impedance).

HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

59.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

59.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

59.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

59.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

59.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, must be loaded the appropriate instruction for the test or action to be performed.

60 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

60.1 References

- IEEE Std 1149.1-2001 (R2008), Standard Test Access Port and Boundary-Scan Architecture
- IEEE Std 1149.7, Standard for Reduced-Pin and Enhanced-Functionality Test Access Port and Boundary-Scan Architecture

60.2 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backward compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

60.2.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- Compliant
  – Compliant with the IEEE 1149.1 standard
  – Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  – More than one TAPC may be associated with the TAP (once made visible by private instructions)
- Extended
  – Compatible with the IEEE 1149.1 standard
  – Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  – Additional test/debug functions
- Advanced
  – Two-pin operation using the “Advanced Protocol” – signaling where TCK(C) and TMS(C) signals transfer control/data information
  – The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

60.2.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

60.2.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in *Table 1234*. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC, and nTRST pins.

Table 1234. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4

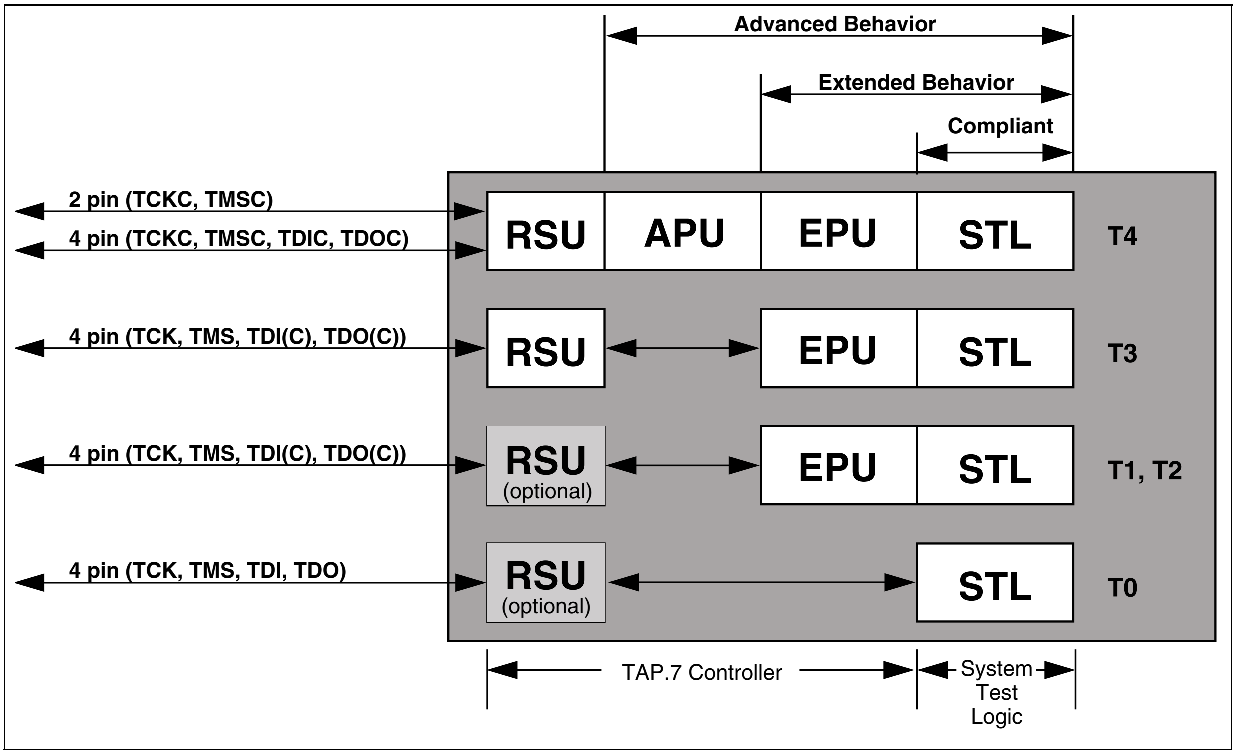
60.2.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in *Figure 1225*. It is described with the hardware layers listed below:

- **STL System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

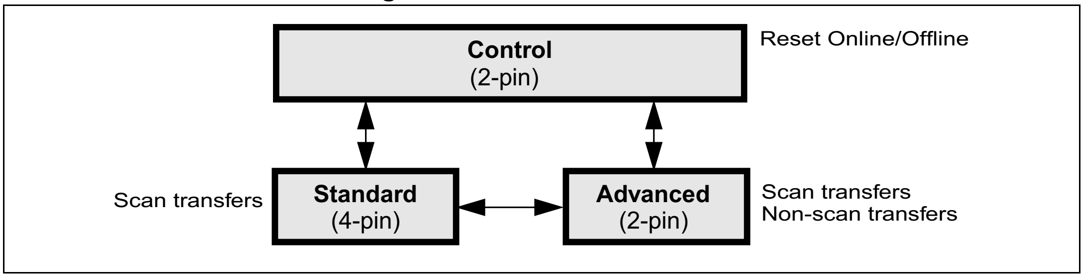
Figure 1225. TAP.7 Controller Architecture



60.2.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in *Figure 1226*.

Figure 1226. TAP.7 Behaviors



The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in *Table 1235*.

Table 1235. Class/protocol relationship

Class	Protocol		
	Standard	**Control**	**Advanced**
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

60.2.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

60.2.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

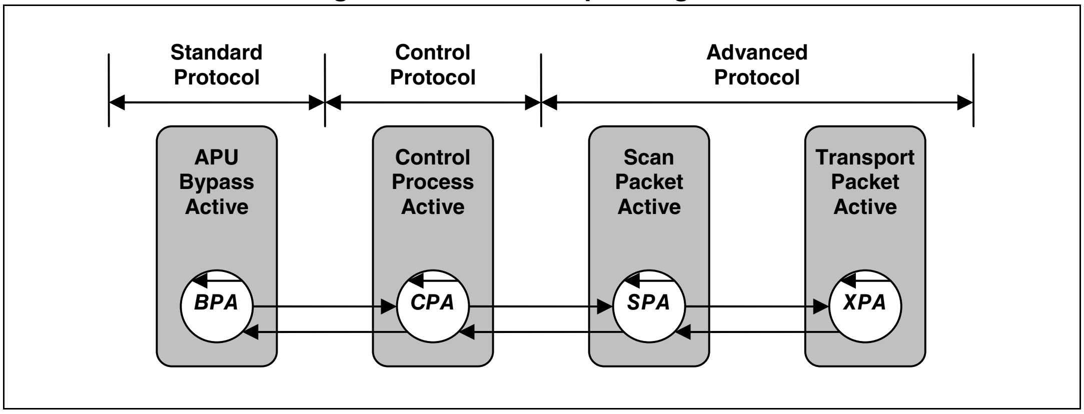
60.2.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

60.3 Operating models

Figure 1227 illustrates a simplified view of the CJTAG operating model.

Figure 1227. CJTAG operating model



60.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

60.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

60.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

60.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

60.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

60.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

60.5 Ancillary services

60.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine

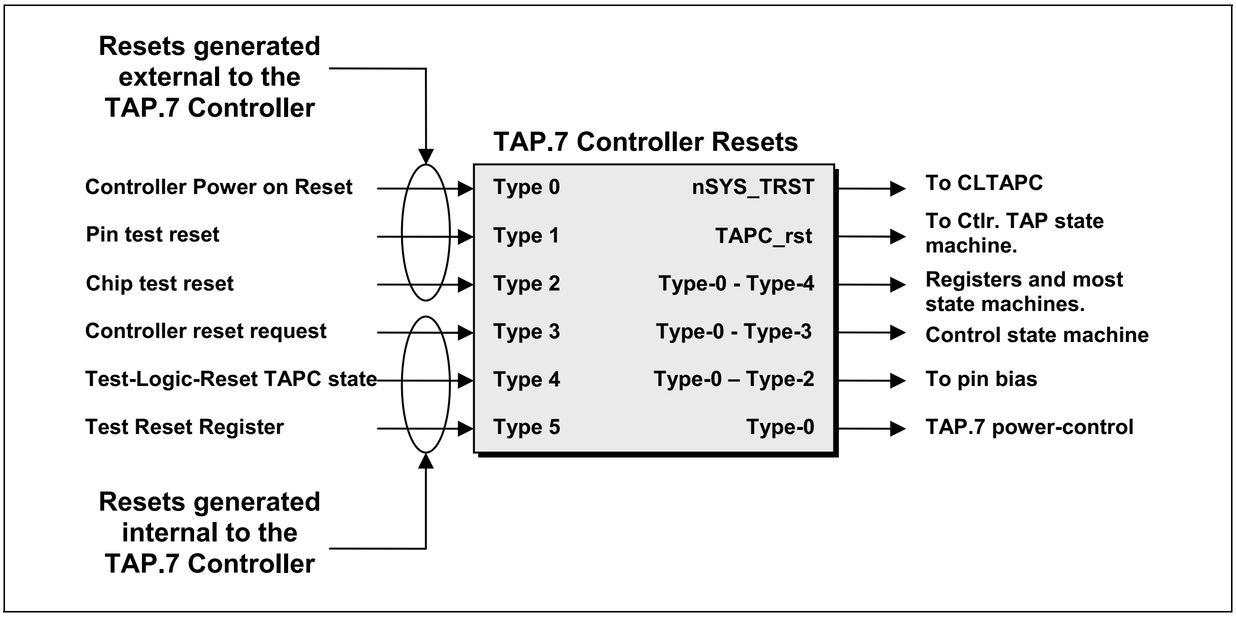
60.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 1228. Conceptual view of the EPU reset logic and state machines



60.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

60.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

60.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

60.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

60.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

60.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

60.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 1229. Reset state machine

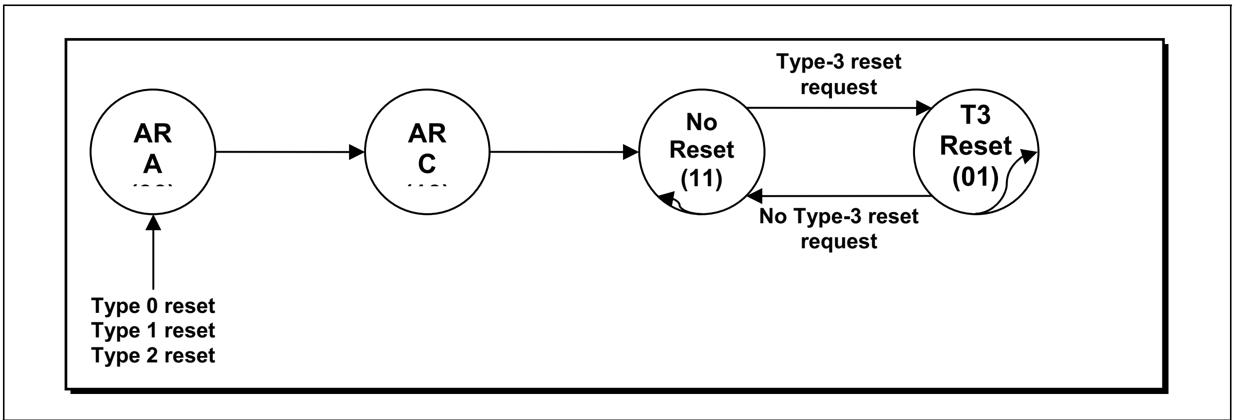


Table 1236. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in *Table 1237*.

Table 1237. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

60.5.3 Start-up Options

60.5.3.1 Overview

The TAP.7 start-up options are shown in *Table 1238*. The only startup option currently supported by the CJTAG module is 1149.1 compliant.

Table 1238. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

60.5.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine
- The TDIC and TDOC pins are present and provide the TDI and TDO function
- The CLTAPC is coupled at start-up

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 1239. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

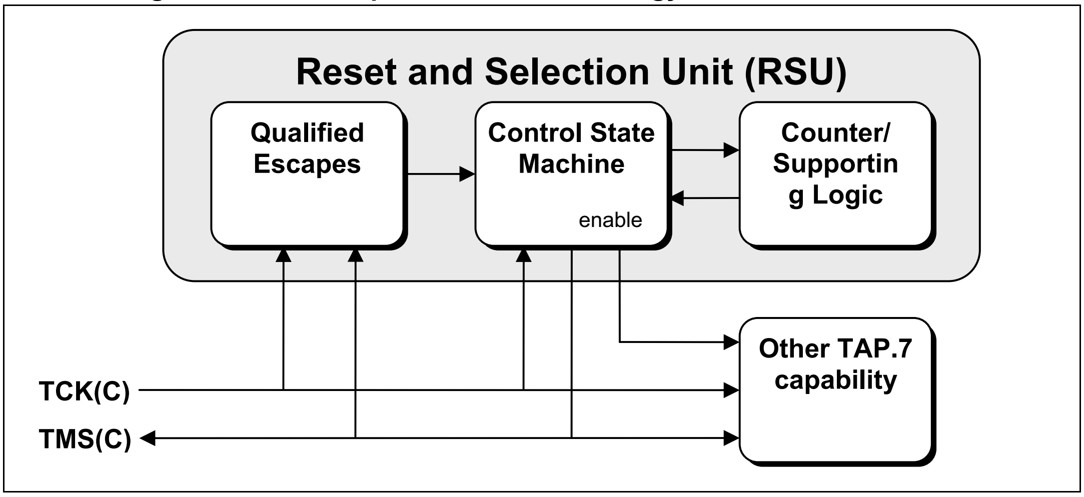
60.5.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

60.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in *Figure 1230*.

Figure 1230. Conceptual view of technology selection mechanism



60.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

60.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset).

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

60.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

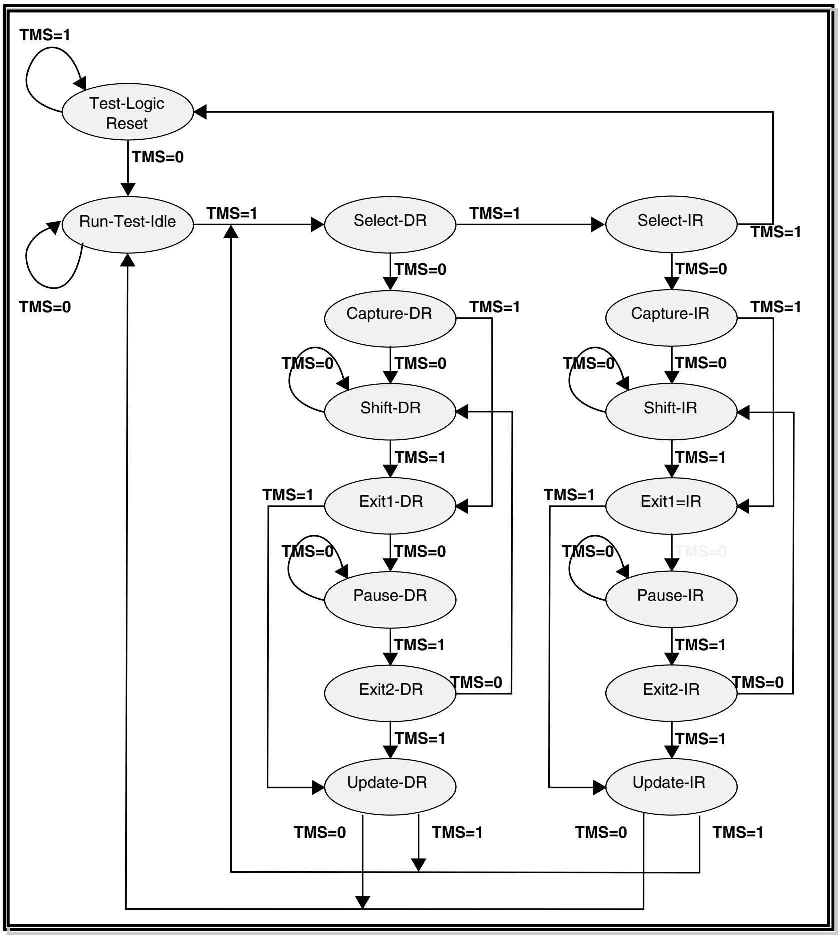
60.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occurs with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

60.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 1231. Falling edge TAP controller state machine



60.6 EPU (Extended Protocol Unit) Operation

60.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

60.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

60.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

60.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

60.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

60.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

60.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

60.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called “***TAP.7 ZBSs***”. ZBSs that are intended for other uses are henceforth called “***Other ZBSs***”. Two TAP.7 registers enable the STL’s use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created.
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

60.6.2 EPU Registers

60.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose.

These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

60.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back.

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 1240. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
		1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Options Select	Local Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge

Table 1240. TAP.7 controller register list (managed with commands) (continued)

Register type	Global/ local	Width	Register mnemonic	Name
		32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
Read-only	Local	M = Mandatory register O = Optional register		

60.6.2.3 Registers

60.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

60.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the “System Path” (STL) is used.

- **1** – Suspend use of control levels. Enables “System Path.”
- **0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

60.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- **1** – Inhibit ZBS detection.
- **0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

60.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 1241. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state

Table 1241. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

60.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

60.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the “Global Register.”

60.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

60.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

60.6.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0x** – TDI and TDO have JTAG function.
- **1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

60.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

60.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

60.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0.

60.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 1242. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format

	32	CNFG0	Configuration Register 0				

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

60.6.3 EPU Commands

There are two command types:

- Two-Part Commands
- Three-Part Commands

Any number of two-part and three-part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

60.6.3.1 Two-Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two).

The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

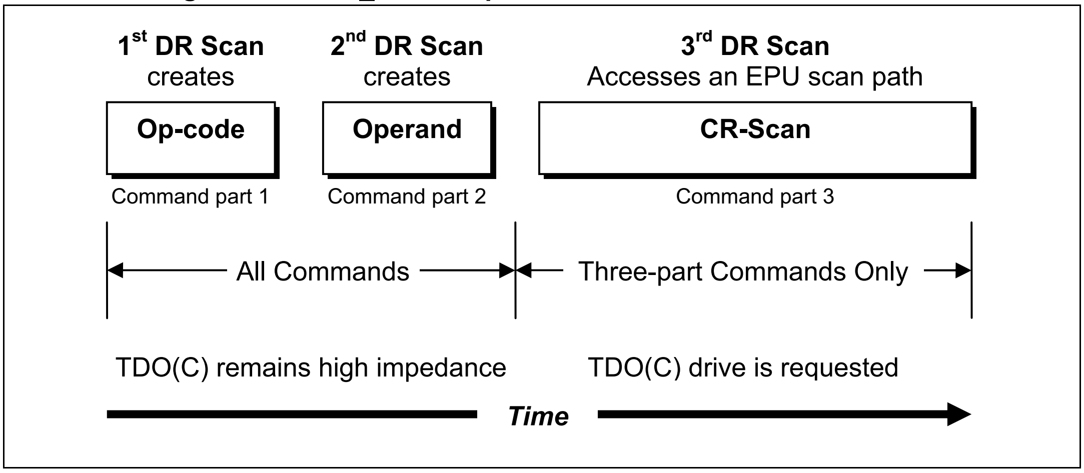
60.6.3.2 Three-Part Commands

Some commands are used to send or receive, or both, data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

60.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in *Figure 1232*.

Figure 1232. DR_Scan sequence used for command creation



The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two-part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two-part commands, but only 3 three-part commands, each having a special purpose.

60.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in *Table 1245*.

Table 1245. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate(1)	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

60.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

60.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller’s CID is valid, and are treated as no operations otherwise.

60.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

60.6.3.5 Command Definitions

60.6.3.5.1 Store Commands

60.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 1246. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	—	SGC = y
				1	—	CGM = y
		010	RdyCtl	-	—	RDYC = xy
		011	DlyCtl	-	—	DLYC = xy
		100	ScnFunc	0	—	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	—	—	Reserved
		110		—	—	
		111		—	—	

60.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 1247. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	**Operand**	**c**	**bbb**	**CAPE**	**Description**
00001	c bbb v	0	000	—	SREDGE = v
			001	—	Reserved
			010	—	TRESET = v
			011 – 111	—	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

60.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 1248. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	**Operand**	**c**	**bb**	**CAPE**	**Description**
00010	c bb vv	0	00	—	Reserved
			01	—	STCKDC = vv
			10	—	APFC = vv
			11	—	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

60.6.3.5.1.4 Store Scan Format (STFMT)

Table 1249. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	**Operand**	
00011	nnnnn	SCNFMT = nnnnn

60.6.3.5.2 Select Commands

60.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 1250. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

60.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 1251. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

60.6.3.5.3 Scan Commands

60.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 1252. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

60.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

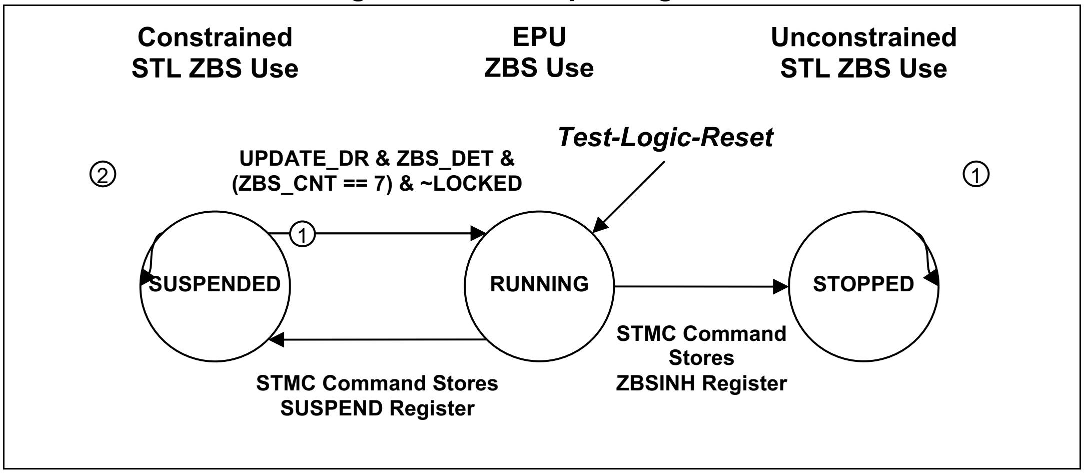
Table 1253. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

60.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in *Figure 1233*.

Figure 1233. EPU operating states



The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in *Table 1254*. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 1254. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

60.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path.
- **Bit** – Supports set and test bit operations (a 1-bit shift register).
- **String** – Support 32-bit reads or 32-bit writes.
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s.
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

60.7 APU (Advanced Protocol Unit) Operation

60.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (that is, ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU’s existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called “offline”. A TAP.7 controller that is not offline is henceforth called “online”. While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

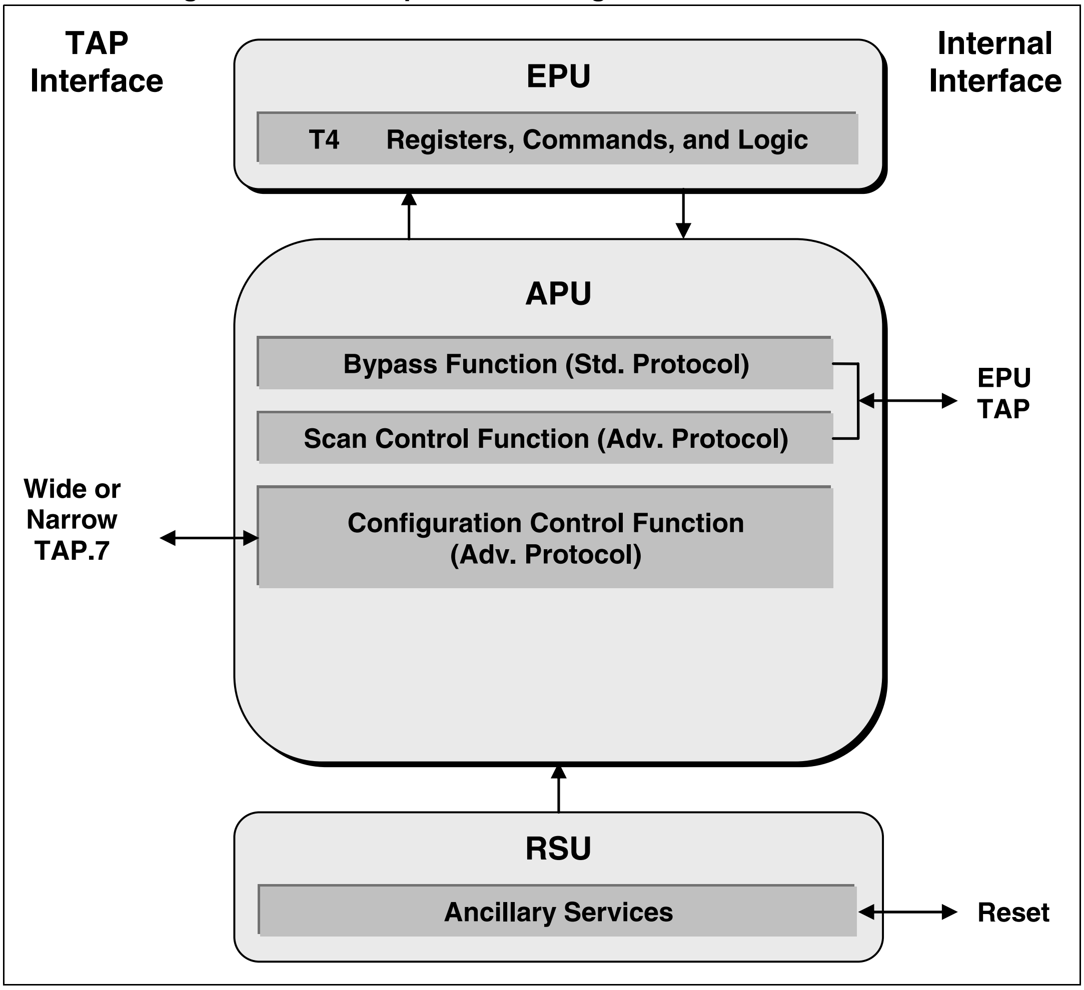
The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 1234. Conceptual block diagram of the APU functions



The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

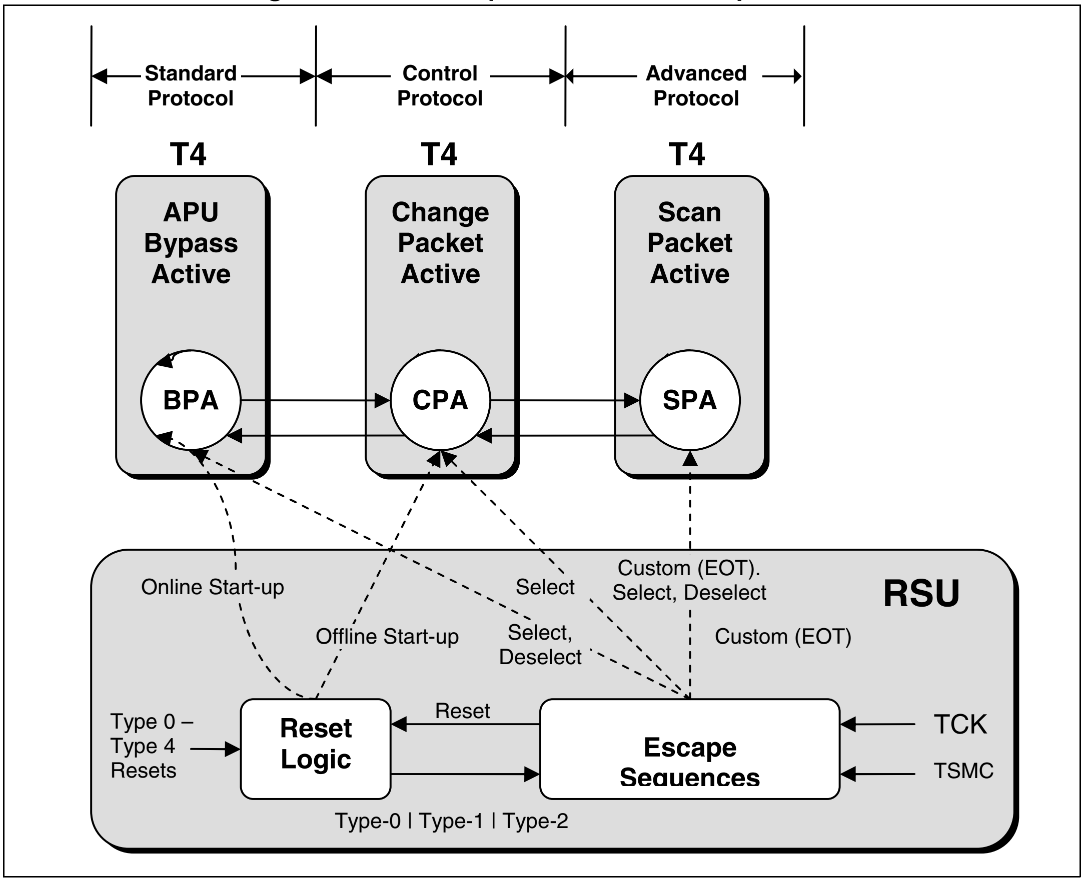
When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

60.7.2 Operation

The conceptual view of the APU operation is shown in *Figure 1235*.

Figure 1235. Conceptual view of APU operation



The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

60.7.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

60.7.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

60.7.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

60.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

60.7.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

- An input when the Standard Protocol is used
- Bidirectional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

60.7.5 APU Functions

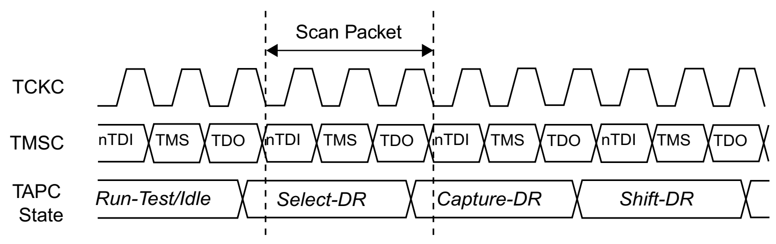
60.7.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (for example, a narrow TAP.7, or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

60.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in *Figure 1236*. There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 1236. Scan Packet sequence

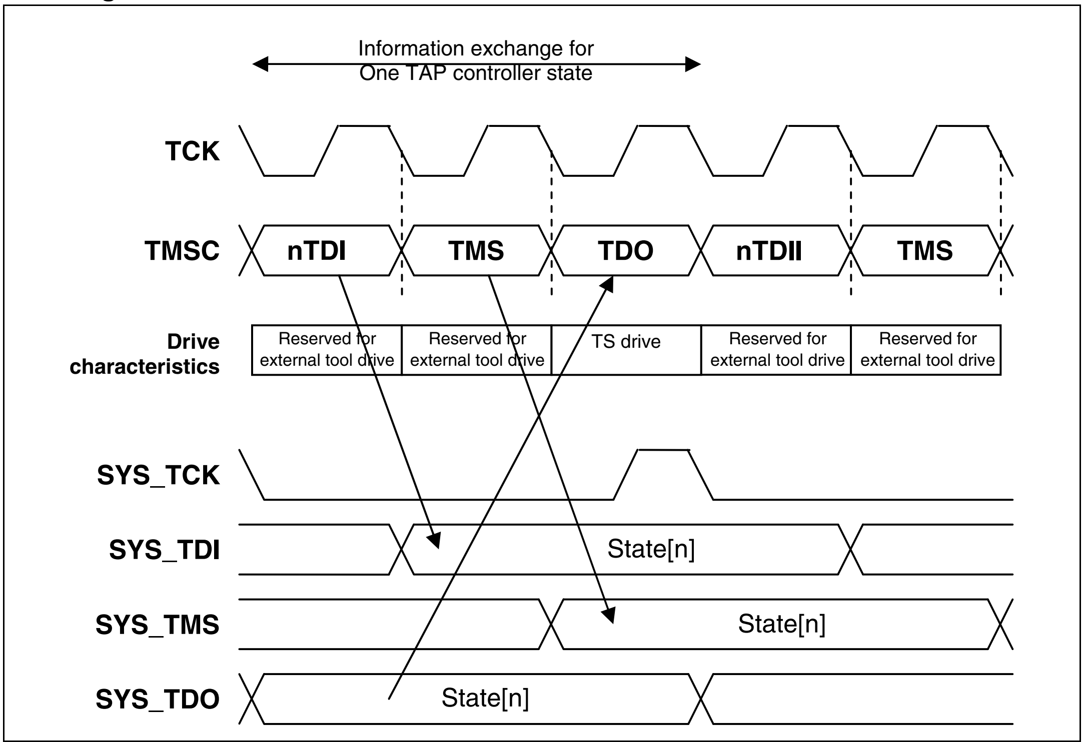


A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 1237. Serialization and De-serialization of Scan Packet Information



In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats).

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

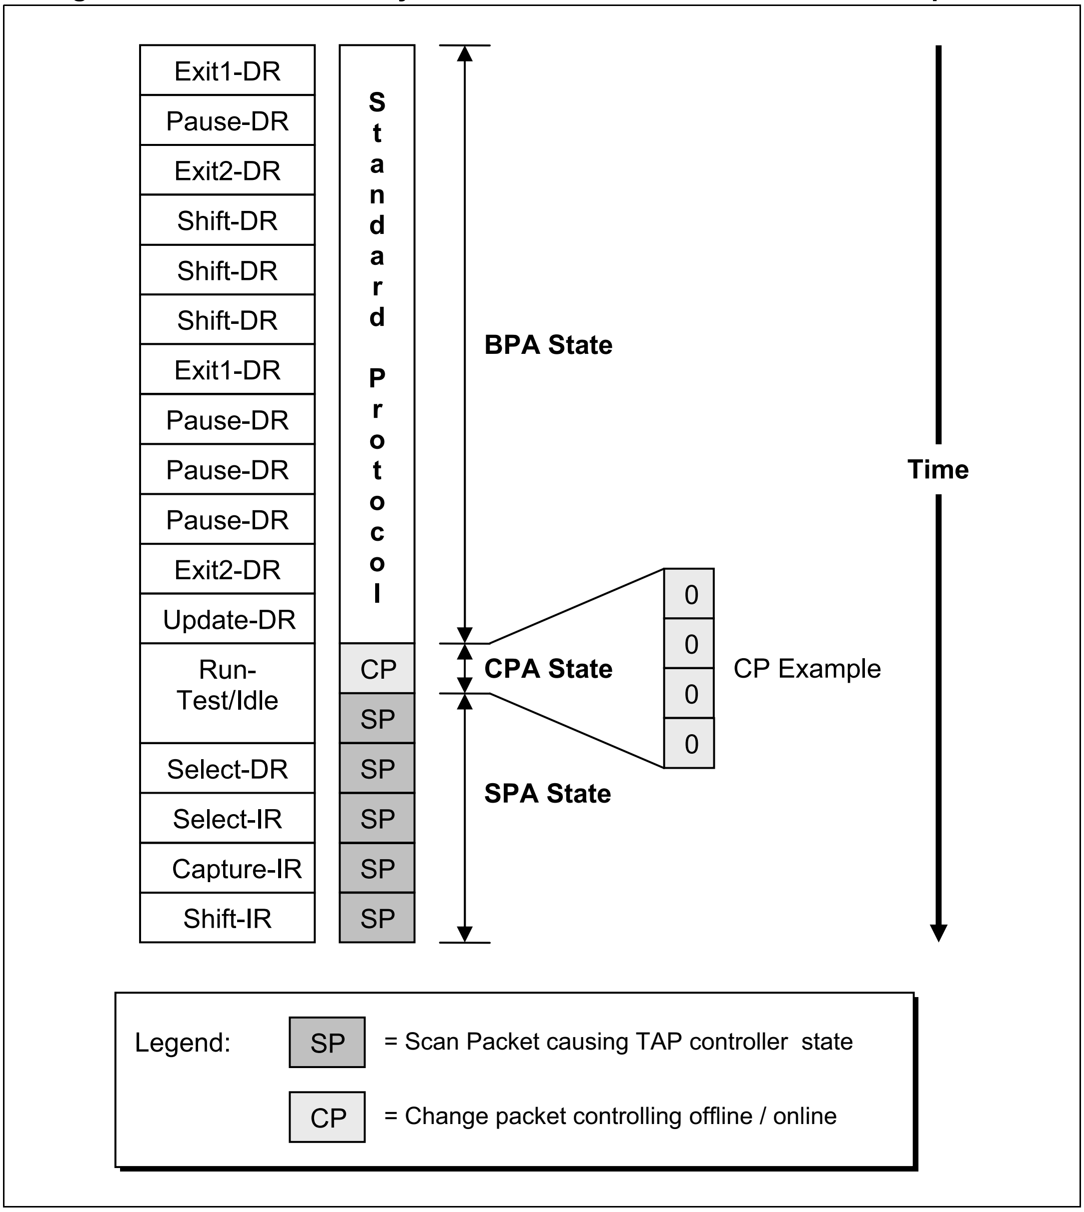
With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

60.7.5.3 Control Process Active (CPA) Function

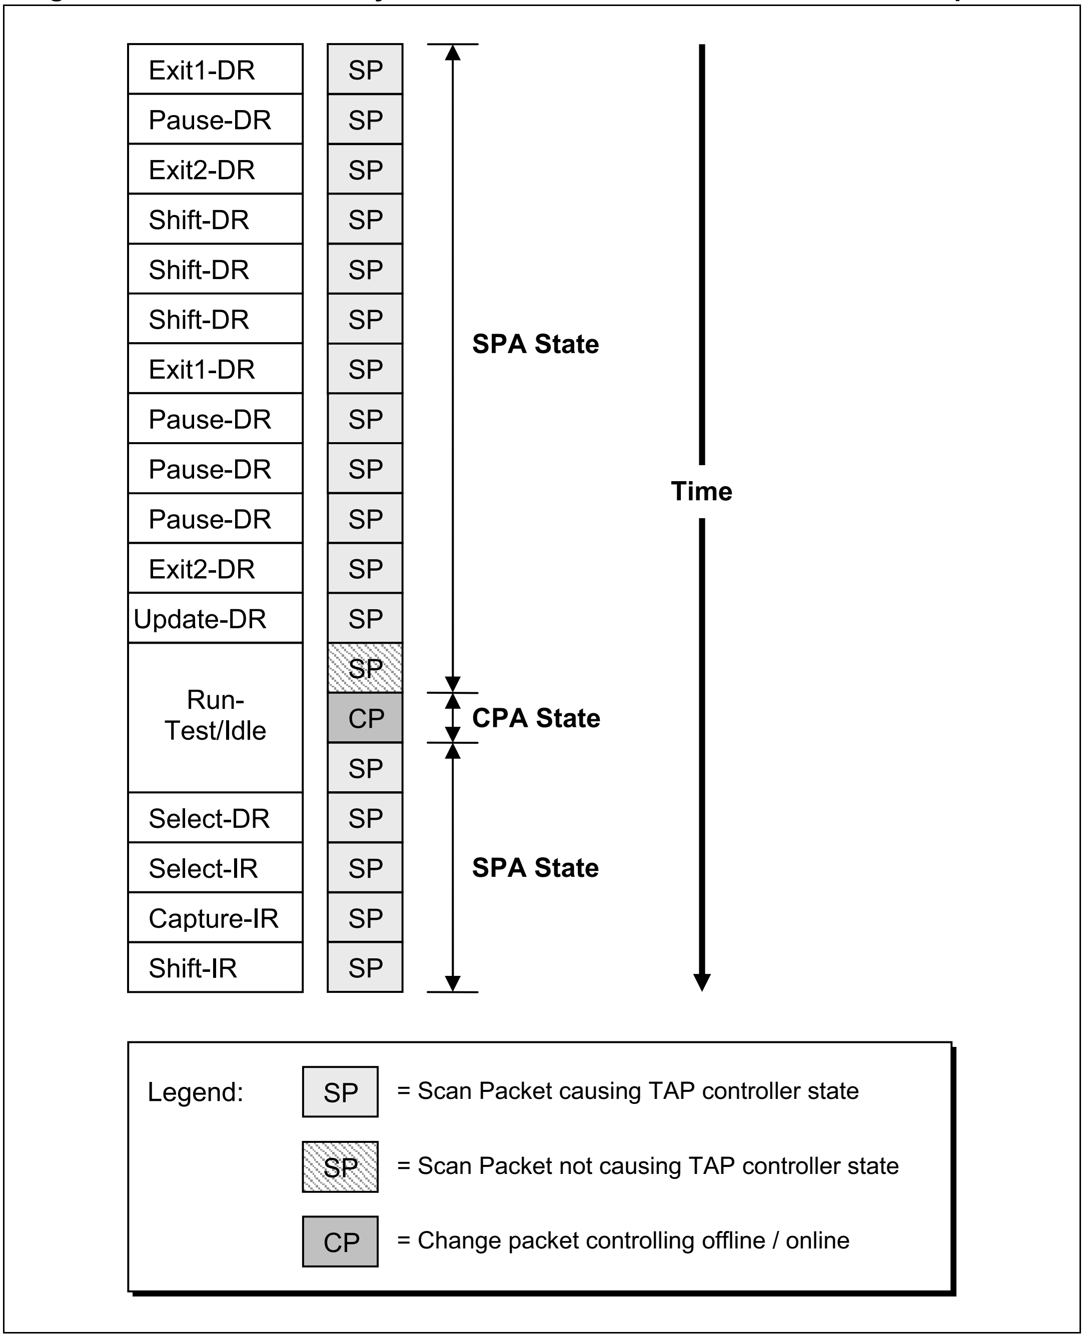
While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

Figure 1238. CPA State Entry from BPA State with Continued Online Operation



An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 1239. CPA State Entry from the SPA State with Continued Online Operation



When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 1240. CPA State Entry from the BPA State with Offline Operation

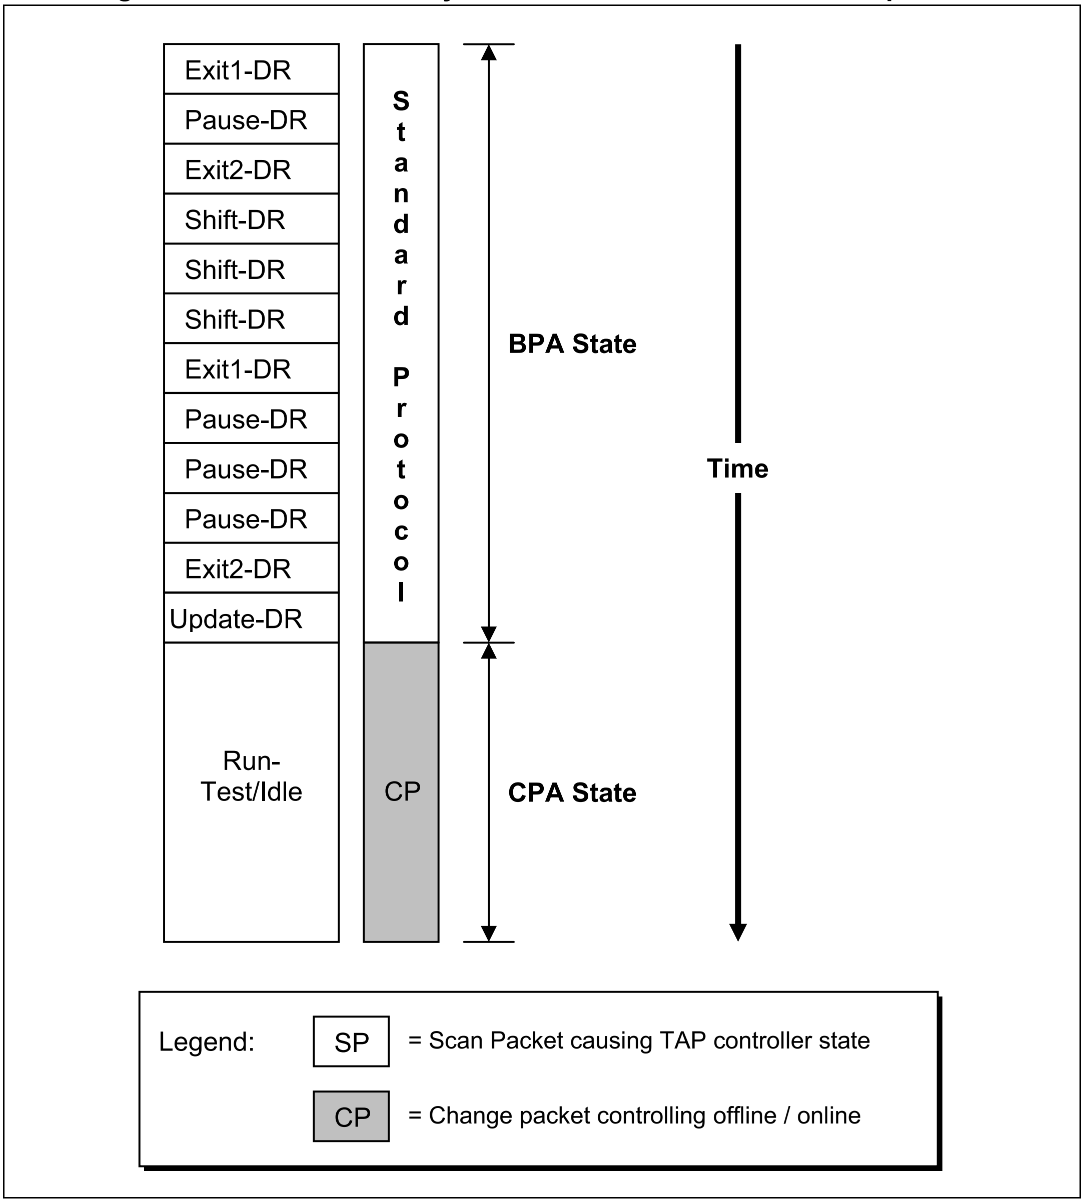


Figure 1241. CPA State Entry from the SPA State with Offline Operation

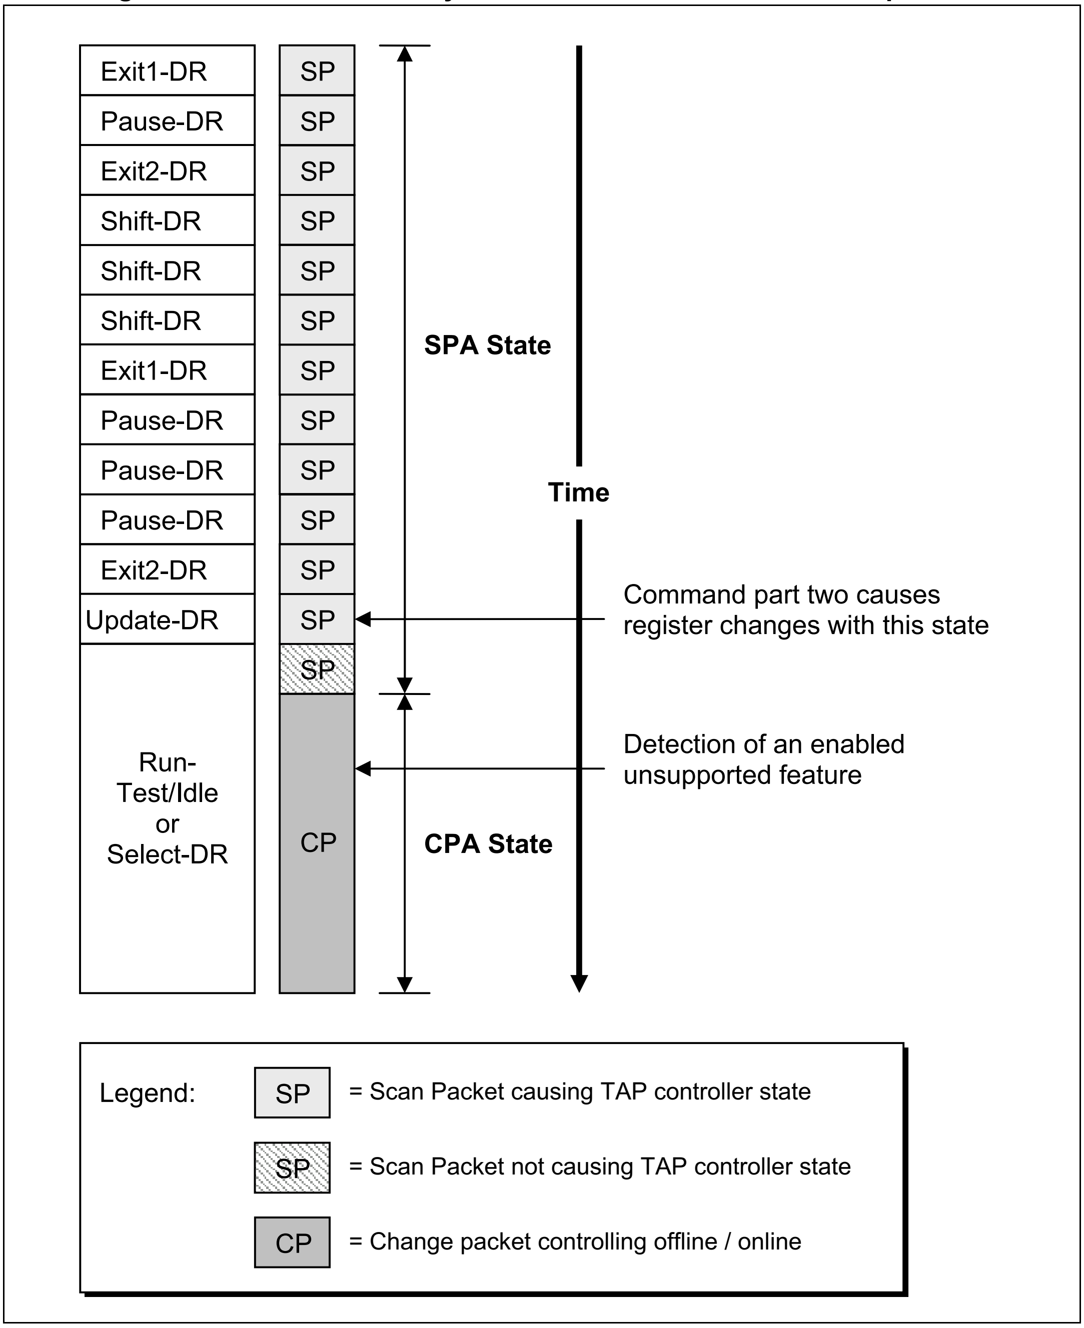


A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

60.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives:
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit)
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

60.7.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof).
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

60.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

60.7.8.1 Payload Element Content

60.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

60.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in *Table 1255*.

Table 1255. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

60.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

60.7.8.3 Scan Formats

60.7.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in *Table 1256* and *Table 1258*, respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

60.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

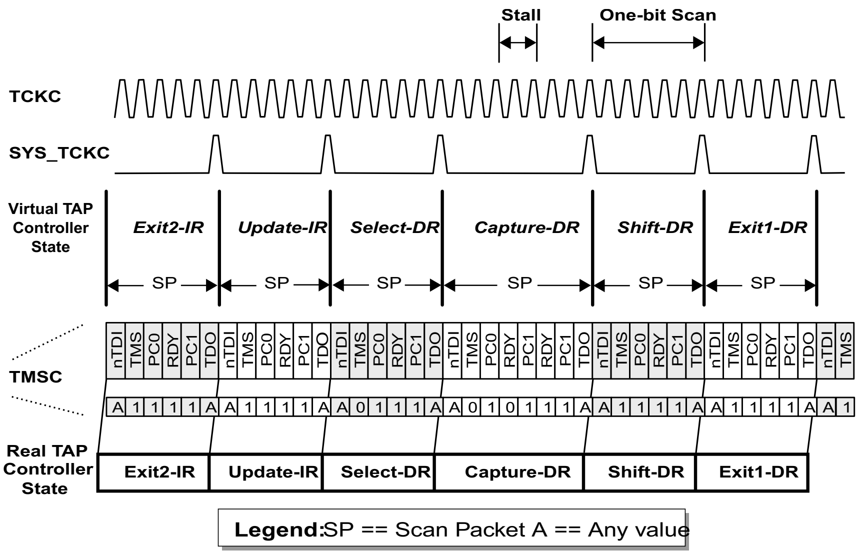
Table 1256. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 1257. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

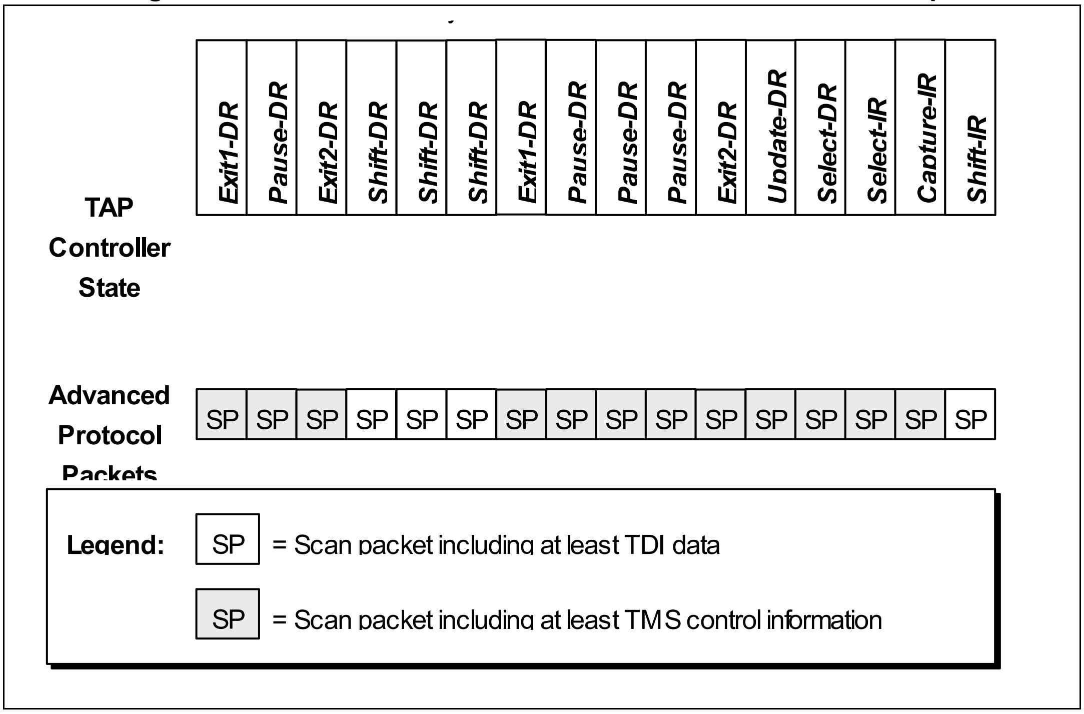
Figure 1242. MScan Transaction



60.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 1243. OScan Scan Packet content/TAPC state relationships



OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in *Table 1258*.

Table 1258. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

60.8 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

60.8.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in *Section 60.6.1.4: Control levels*.

After the control level is set to control level 2, TAP.7 commands can be executed as described in *Section 60.6.3: EPU Commands*. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in *Section 60.7.5.3: Control Process Active (CPA) Function* and *Section 60.7.6: Configuration Change Packets (CP)*. Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in *Section 60.6.3.5.1.3: Store Conditional 2-bit (STC2)*.

61 JTAG Data Communication (JDC)

61.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

61.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

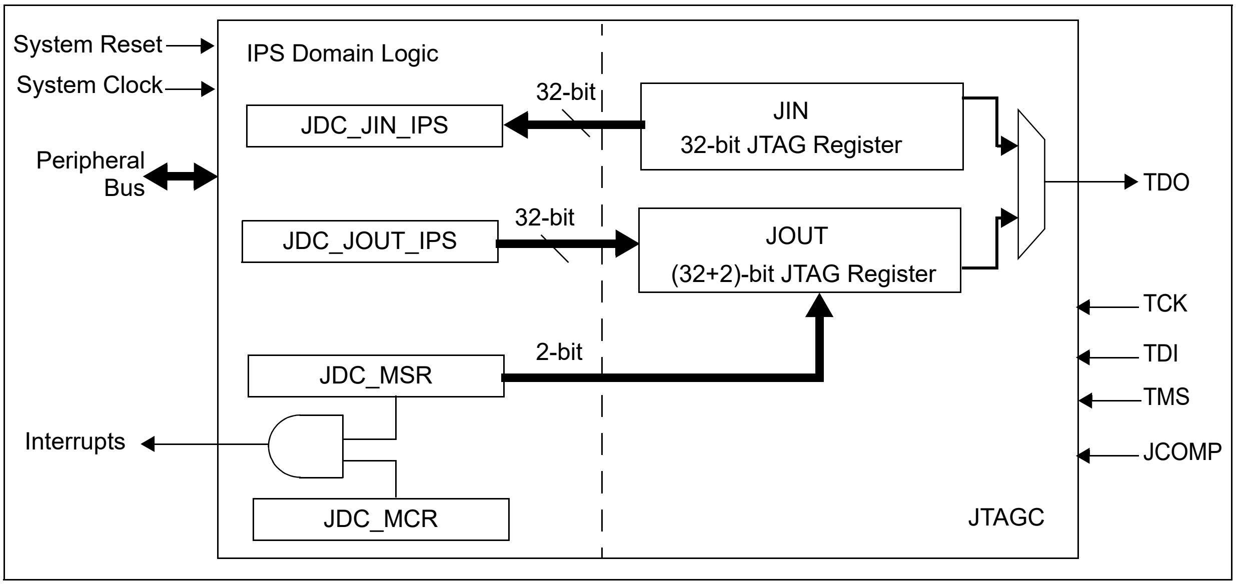
The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 1244*.

Figure 1244. JDC block diagram



61.3 Register definition

Table 1260 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1260. JDC memory map

Address offset	Register	Access	Reset value	Location

Figure 1248. JDC_JIN_IPS register

The JDC_JIN_IPS register is described in *Table 1264*.

Table 1264. JDC_JIN_IPS register field descriptions

Field	Description
0:31 DATA	Contains JIN_IPS data.

61.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

61.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JDC_JIN_RDY and JDC_JOUT_RDY status bits. *Figure 1249* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

Figure 1249. JOUT JTAG register

	33	…	2	1	0
R W	JOUT_IPS Data			JIN_RDY	JOUT_RDY
Reset	*(1)	*(1)	*(1)	*(1)	*(1)

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in *Table 1265*.

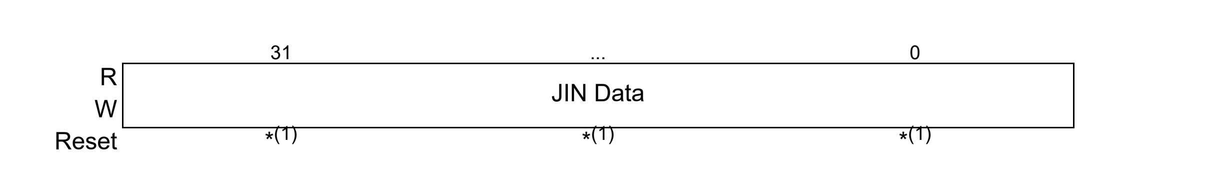
Table 1265. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

61.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 1250* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

Figure 1250. JIN JTAG Register



1. The reset value of the JIN register is 32'b0.

The JIN register is described in *Table 1266*.

Table 1266. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JDC_JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

61.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data

is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

61.4.1 IPS register access

IPS access is available to the registers described in *Section 61.3.1*.

61.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

61.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 1267*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1267. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

61.5 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The JDC_MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate

the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the JDC_MCR[JOUT_IEN] is set.

7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

62 Sequence Processing Unit (SPU)

62.1 Introduction

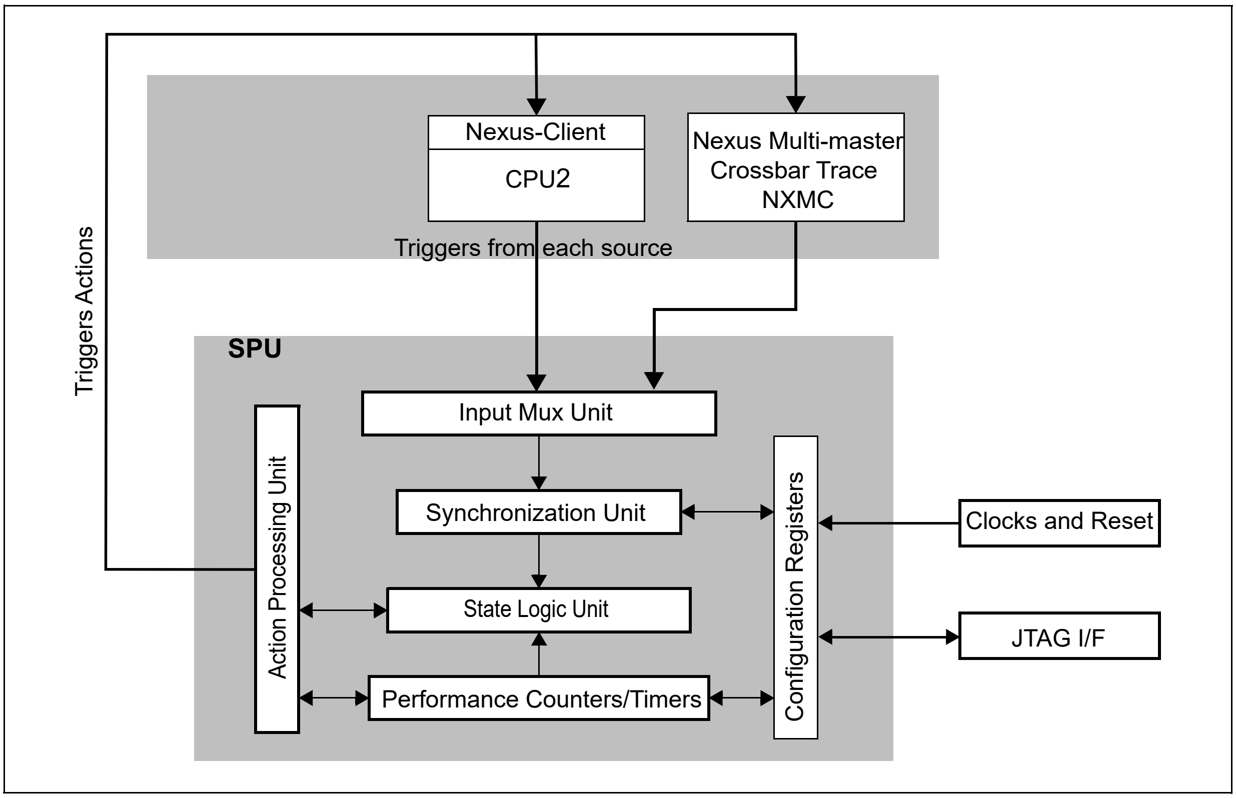
The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

62.1.1 SPU block diagram

Figure 1251 shows a top-level block diagram of the SPU.

Figure 1251. SPU block diagram



62.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 1286*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 1287*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 1288* and *Figure 1289*. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU writes to VariableB. If CPU writes a value to VariableB which is 0x100, then enable trace for the halt CPU.

The SPU consists of the following sub-blocks:

- Input Mux Unit: receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 1286*.
- State Logic Units (SLU): responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan’s law, allows for generalized signal combinations. This is shown in *Figure 1287*.
- Action Processing Unit: takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers: the SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

62.1.3 Features

The features of the SPU are as follows:

- clients:
  - CPU
  - 1 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics
  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action

- Access to timer/counter values via JTAG
- Prescaler for timer mode only
  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces
  - CPU
  - System bus
  - DCI
- Configuration registers: 32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions: SPU block triggers various actions based on the derived events, these actions are defined in *Section 62.2*

62.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Halt1: single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Single interrupt for INTC to interrupt a CPU: de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin: output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source: Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals): four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

62.3 Operation mode

62.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:

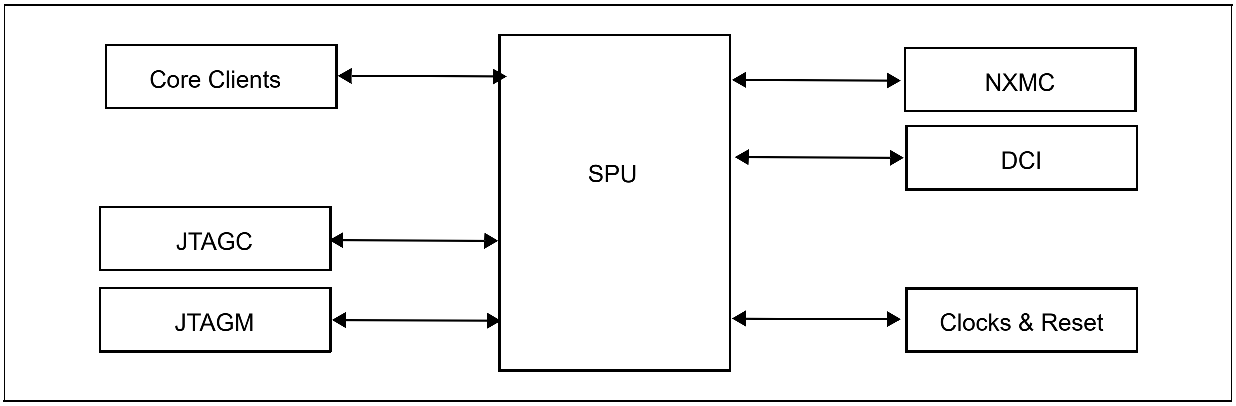
- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

62.4 SPU module interface

The SPU is connected to many clients such as the cores, system bus and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 1252*.

Figure 1252. SPU module interface



62.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 1268 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x01–0x49) registers is 4'h3.
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x01–0x72) is 4'h2.

62.5.1 Registers description

62.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 1286*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

62.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 1253 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see Calibration and Debug (or Debug and Trace) chapter that describes how the modules are configured.

62.5.1.1.11 CPU2 processor exception vector prefix (C2PEVP)

The SPU captures the exception vector from CPU2 when the exception enable signal is asserted. The exception vector decoding is defined in *Table 1294*. The SPU compares this captured vector with the value in the C2PEVP register. *Figure 1263* shows the format of the C2PEVP register.

Table 1271. C2PEVP register field descriptions

Field	Description
0:15 CPU2	CPU2 processor exception vector Program this field with one of the vector values from *Table 1294* to select the corresponding processor exception. **Note:** This field must use the byte swapped values in the CnPEVP register CPUn field value column in *Table 1294*.

62.5.1.1.12 CPU2 interrupt priority selection (C2PIS)

Figure 1264 shows the format of the C2PIS register. The SPU compares the input CPR vector from CPU2 with the value programmed to the C2PIS register and generates a match signal if necessary. The typical use case would be for posedge detection on match (to detect when the priority level is set to the compare value) or high detection while match remains.

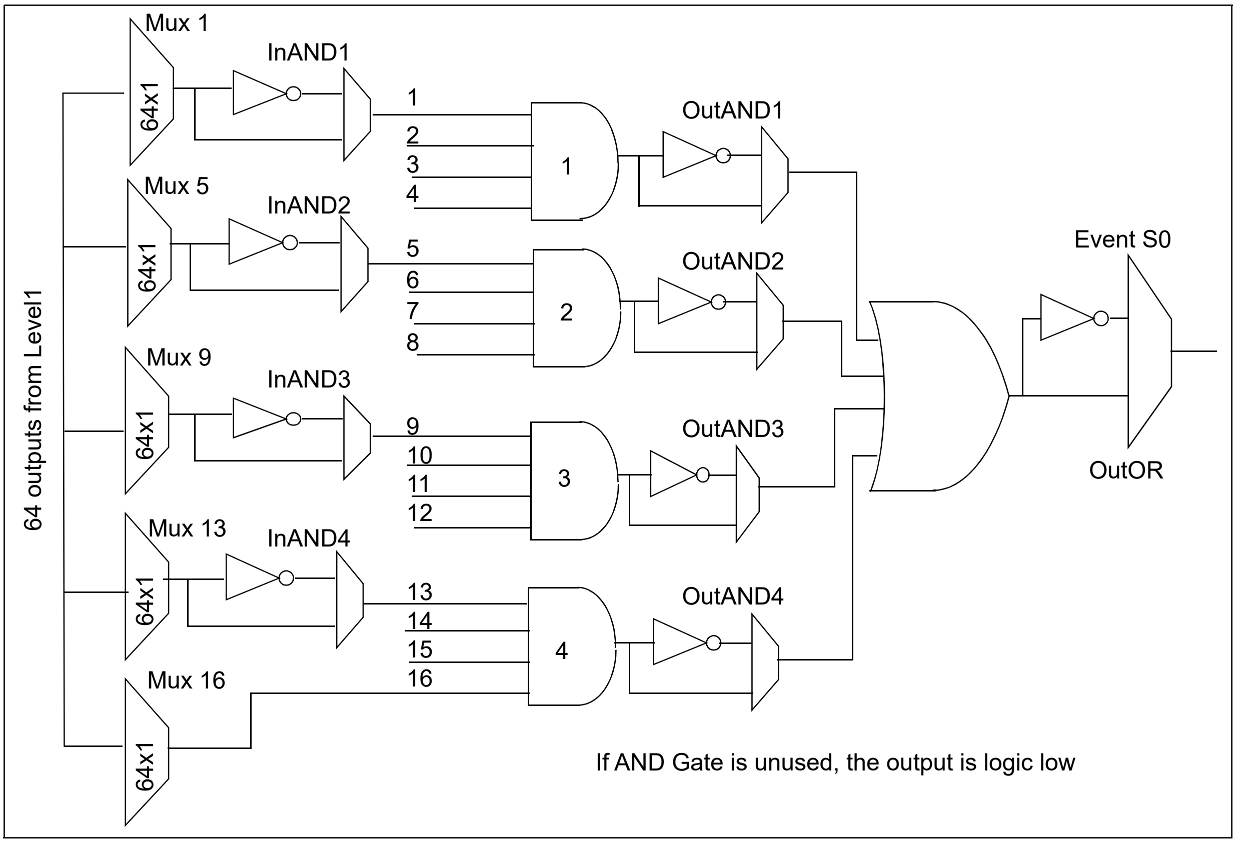
62.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 62.5.1.1: Level1 input Mux configurations registers*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 1286* for State0. Similar logic is provided for States 1 to 7.

Figure 1265. Level2 Mux AND gates input pin routing for State0



Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

62.5.1.3 Sequence unit registers

62.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 1270* shows the format of the IOICn register where the state number, n = 0 to 7.

Offset: 0x37 n*0x1 (n=0 to 7) Access: Read/Write

62.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 1271* shows the format of the SCTRL register.

31 S1ST0	Sequence1 Enable/Disable(2) Once enabled, this bit is disabled at the end of the Sequence 1. 0 Sequence 1 is disabled 1 Sequence 1 is enabled

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.
2. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.

62.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 1272 shows the format of the SnGC register where the state number, n = 0 to 7.

Offset: 0x40 +n*0x1 (n= 0 to 7) Access: Read/Write

Figure 1274. SPU enable register (SE)

The SE register fields are described in *Table 1281*.

Table 1281. SE register field descriptions

Field	Description
30 DIV	Div Option Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required
31 SED	SPU Enable/Disable This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled

Note: Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

62.5.1.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

62.5.1.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example, if there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

62.5.1.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in *Section 62.2*.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in *Section 62.2*, becomes redundant with Div4 option.

62.5.1.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 62.2*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 1282* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 1282. SPU action decoder

Figure 1277. State n false action 0 (SnFA0)

The SnFA0 register fields are described in *Table 1285*.

Table 1285. SnFA0 register field descriptions

Field	Description
4:15 ACTION2	Action 2 to be performed for State n false condition The decoding of these bits is defined in *Table 1282*.
20:31 ACTION1	Action 1 to be performed for State n false condition The decoding of these bits is defined in *Table 1282*.

62.5.1.7.4 State n false action 1 (SnFA1)

The SPU can be programmed to enable up to four different actions against a false condition of every state. All the possible actions and their encoding are listed in *Table 1282*. A total of 12 bits are needed to code every action. The first two actions for false condition are defined in SnFA0 and the next two actions are defined in SnFA1. *Figure 1278* shows the format of the SnFA1 register where the state number, n = 0 to 7.

Offset: 0x12 + n*0x2 (n=0 to 7) Access: Read/Write

20:31 ACTION3	Action 3 to be performed for State n false condition The decoding of these bits is defined in *Table 1282*.

62.5.1.7.5 Trace group configuration registers (DTMTGC, PTMTGC, OTMTGC, WTMTGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace: clients are configured with the DTM trace group configuration (DTMTGC) register
- PTM trace: clients are configured with the PTM trace group configuration (PTMTGC) register
- OTM trace: clients are configured with the OTM trace group configuration (OTMTGC) register
- WTM trace: clients are configured with the WTM trace group configuration (WTMTGC) register

Each of these groups is specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 1279 shows the format of the trace group configuration registers.

Offset: 0x21 (DTMTGC)

62.6 Functional description

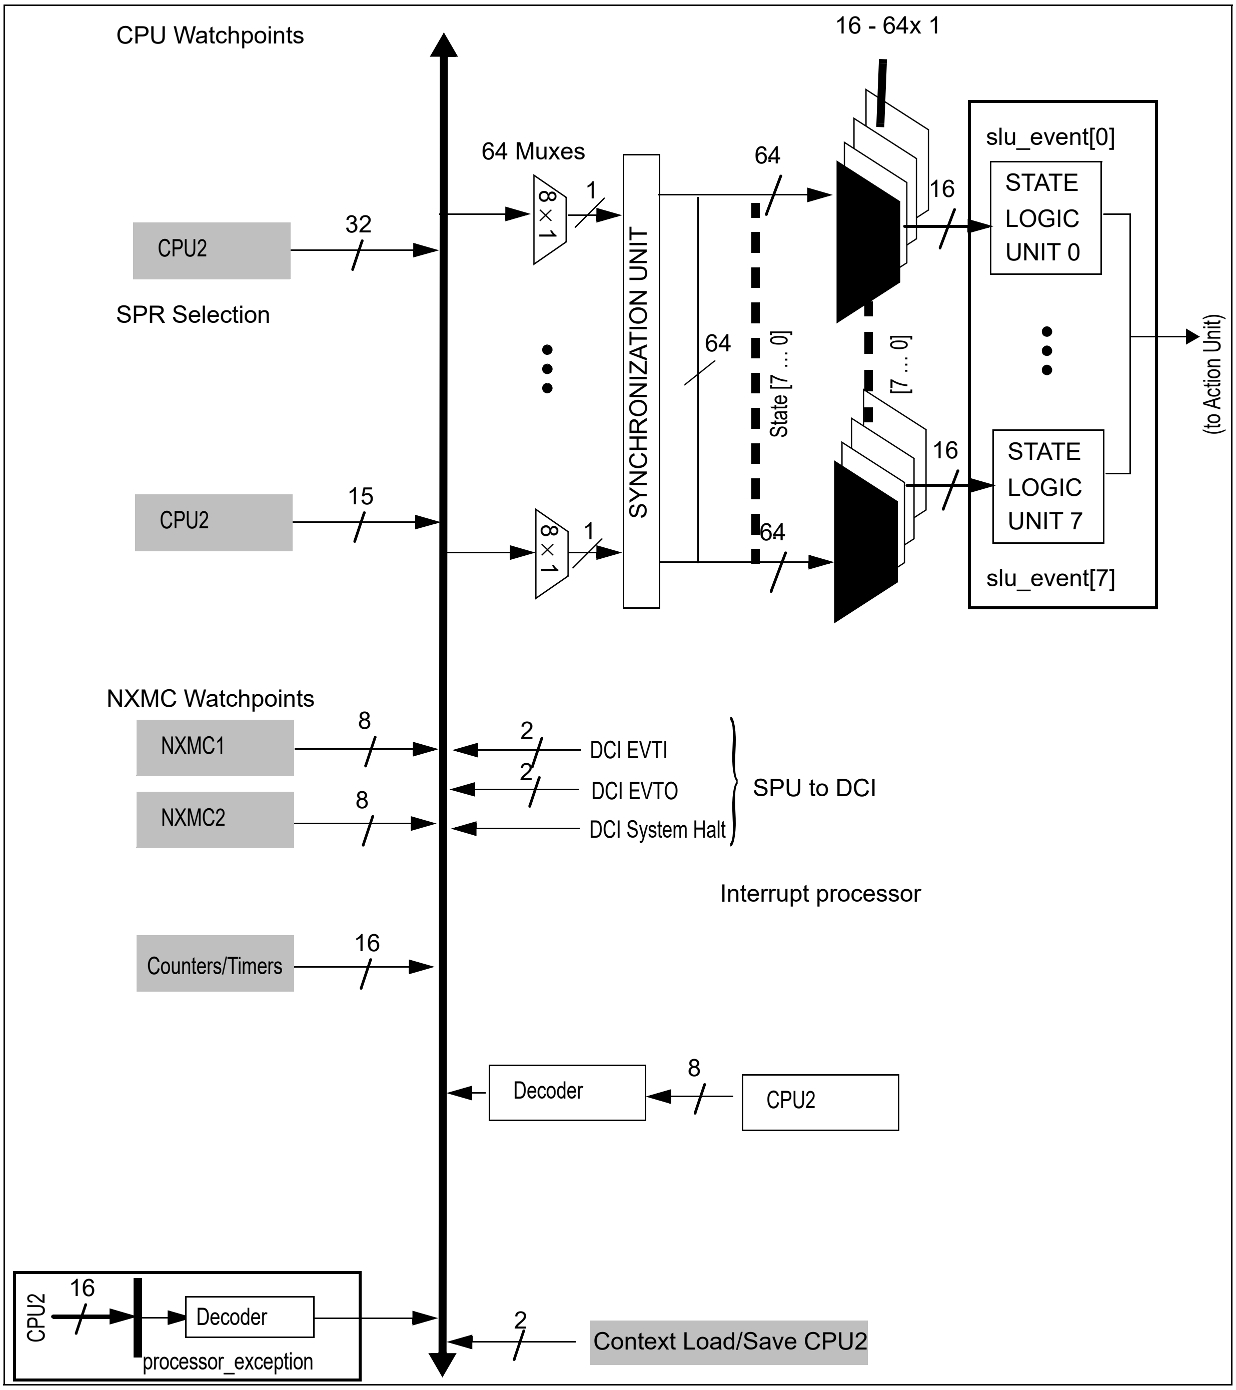
62.6.1 Input Mux unit

The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in *Figure 1286*.

- Level 1 Muxing: At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8 × 1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 1286*.
- Level 2 Muxing: At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.
  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16 × 8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 1286*.

Figure 1286. Input Mux unit block diagram



62.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input condition as shown in *Table 1294*. The CPU exception vector values from the CPU must be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0) registers as shown in *Table 1294*.

Table 1294. Processor exception processing conditions

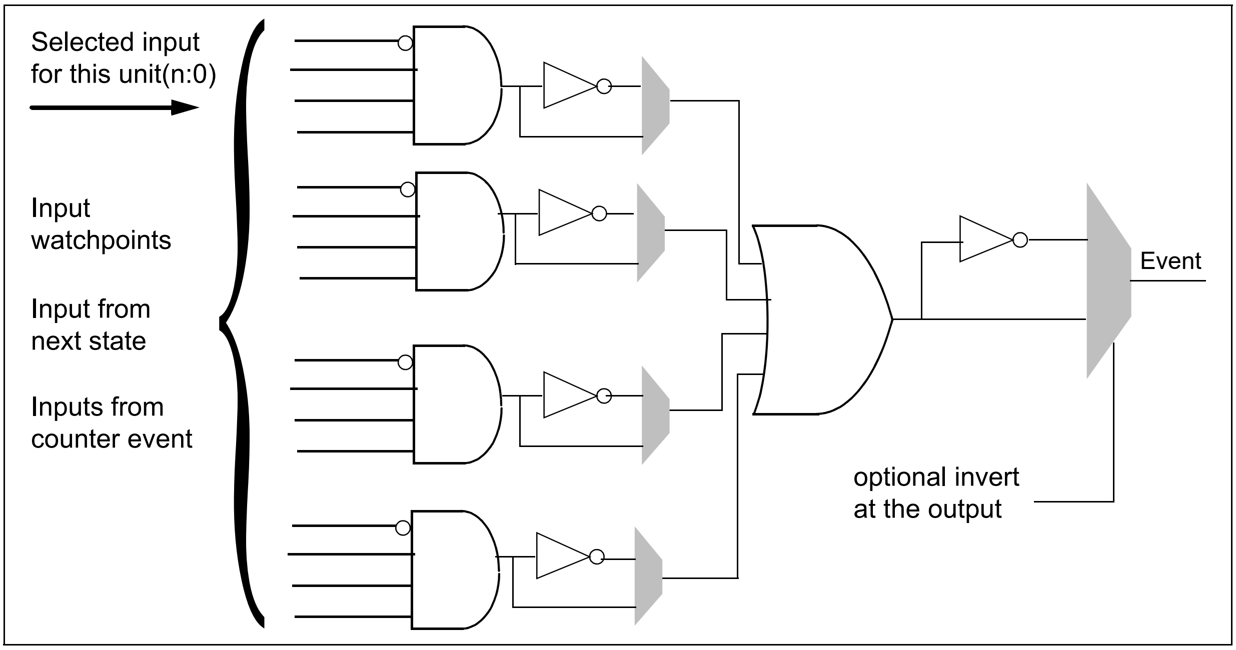
CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input: autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input: autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input: vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input: vectored

62.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 1287*.

Figure 1287. SLU block diagram



Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

62.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.

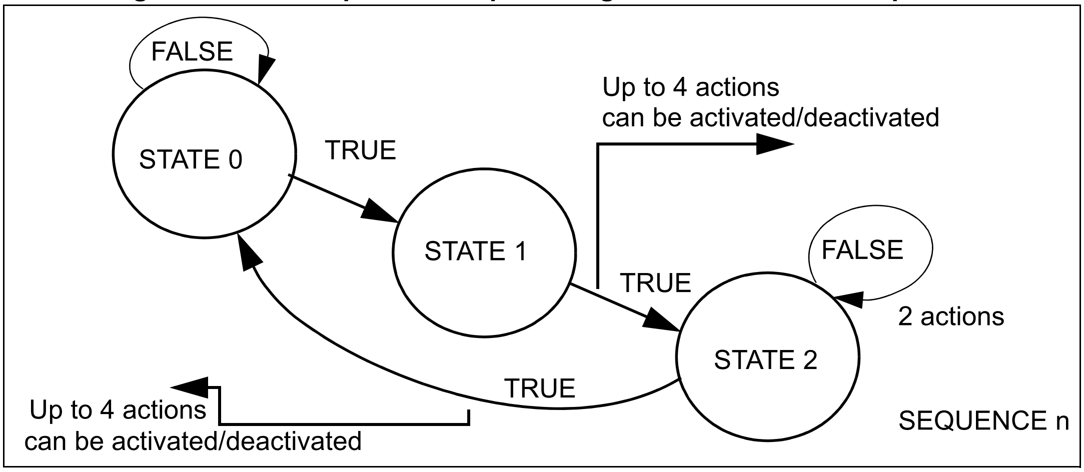
For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 1288*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic.

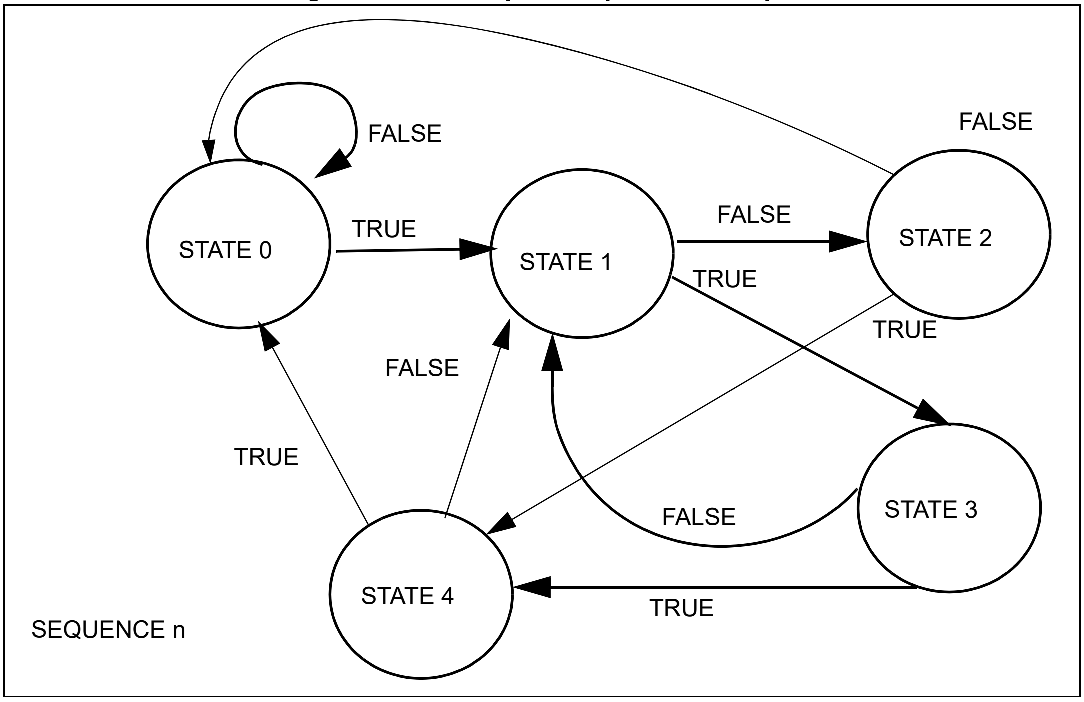
Figure 1288. Example of a simple configurable if-then-else sequence



62.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 1289*.

Figure 1289. Complex sequence example



62.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurrence of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

62.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:

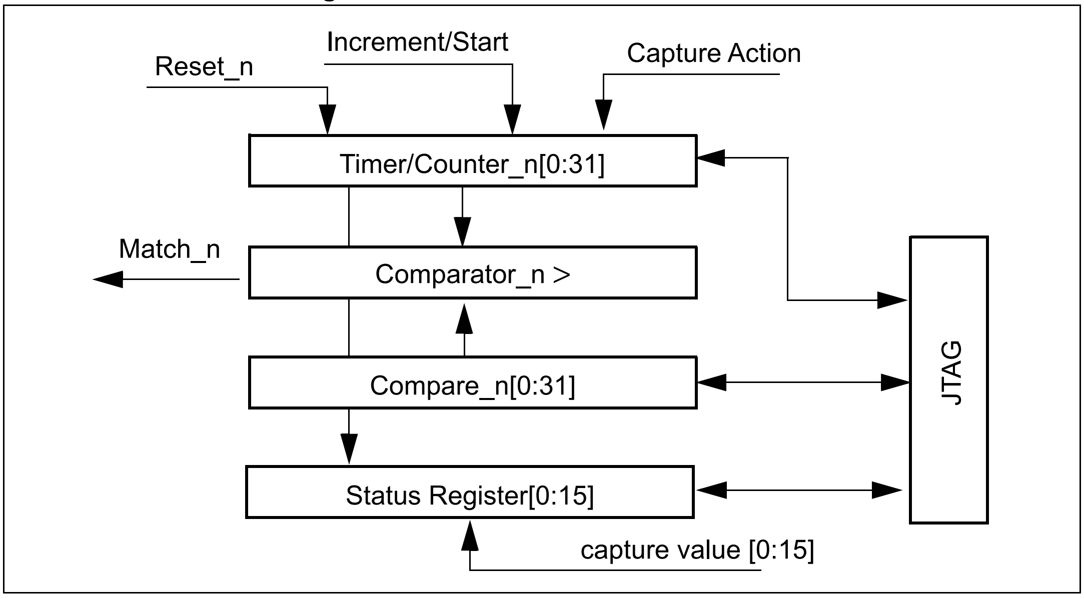
- States: each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register
- Sequence status: each sequence has a field indicating the active state of the state machine. This is a read only field

62.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 1290*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 1290. Counters/timers overview



62.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are type write 1 to clear (W1C).

There are two classes of signals, actions and events:

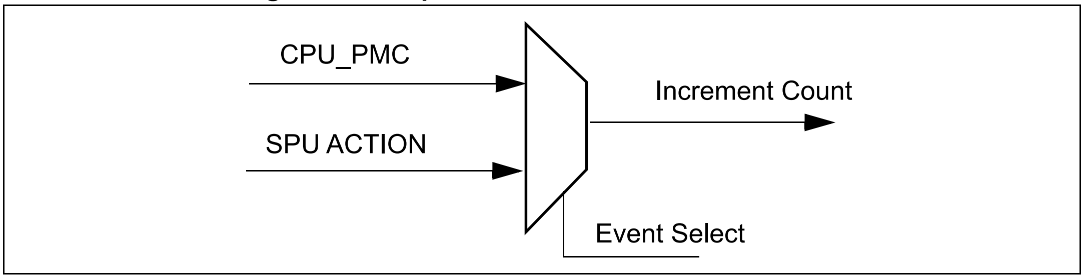
- Actions: each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.
- Event: on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

62.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 1291*. These inputs include signals from the primary SPU muxes or SPU events of counters.

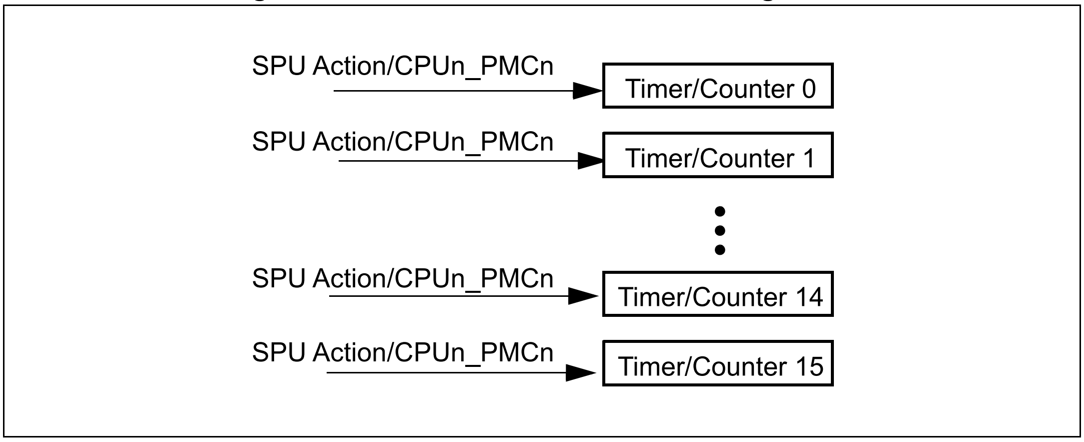
Figure 1291. nput selection for count increment



62.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 1292*.

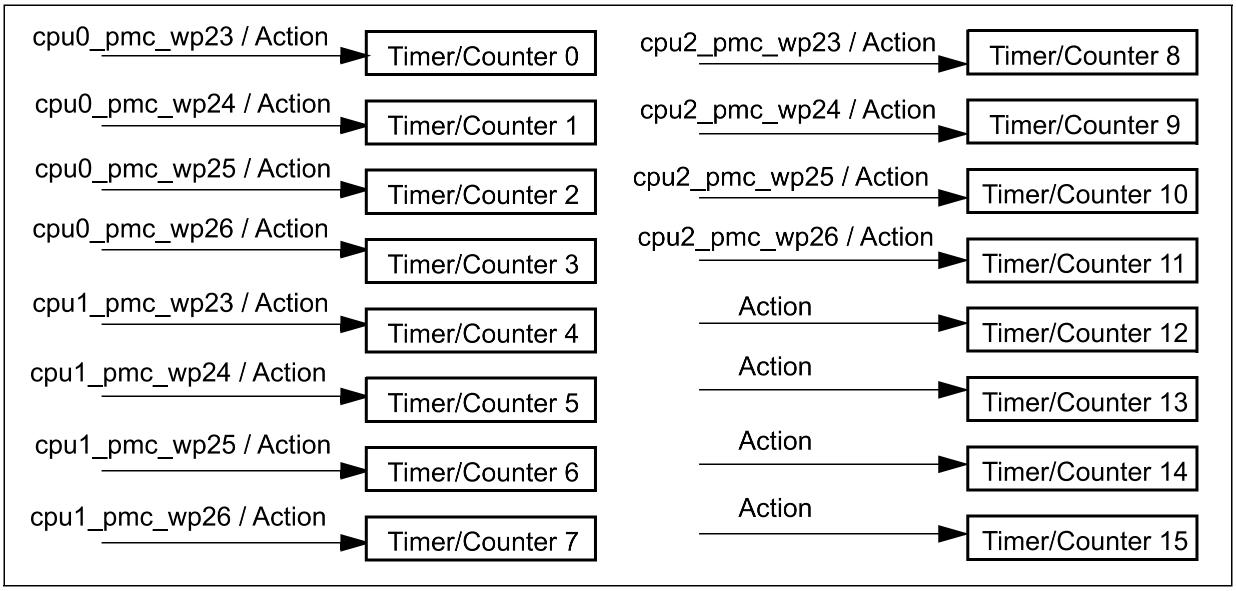
Figure 1292. SPU counters increment assignment



62.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 1293*.

Figure 1293. CPU PMC mapping inside the SPU unit



62.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 62.2*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers. Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

62.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers, defined in *Table 1287*, are available where the user can group the different traces from same or different clients.

62.6.8 Format for CKSRC & CKDATA Values

The format of the CKSRC is defined for the SPU Peripheral (as In-Circuit trace client):

Table 1295. CKSRC format

ICT CLIENTS	CKSRC Value
SPU Counter Trace Client	b00_0000
Reserved	b00_0001–b11_1111

The format for the CKDATA field for the SPU Counter trace client is:

Table 1296. CKDATA format

CKDATA	
CKDATA[CTR_Index]	CKDATA[CTR_VALUE]
4 bits	32-bits

63 JTAG Master (JTAGM)

63.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

63.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:

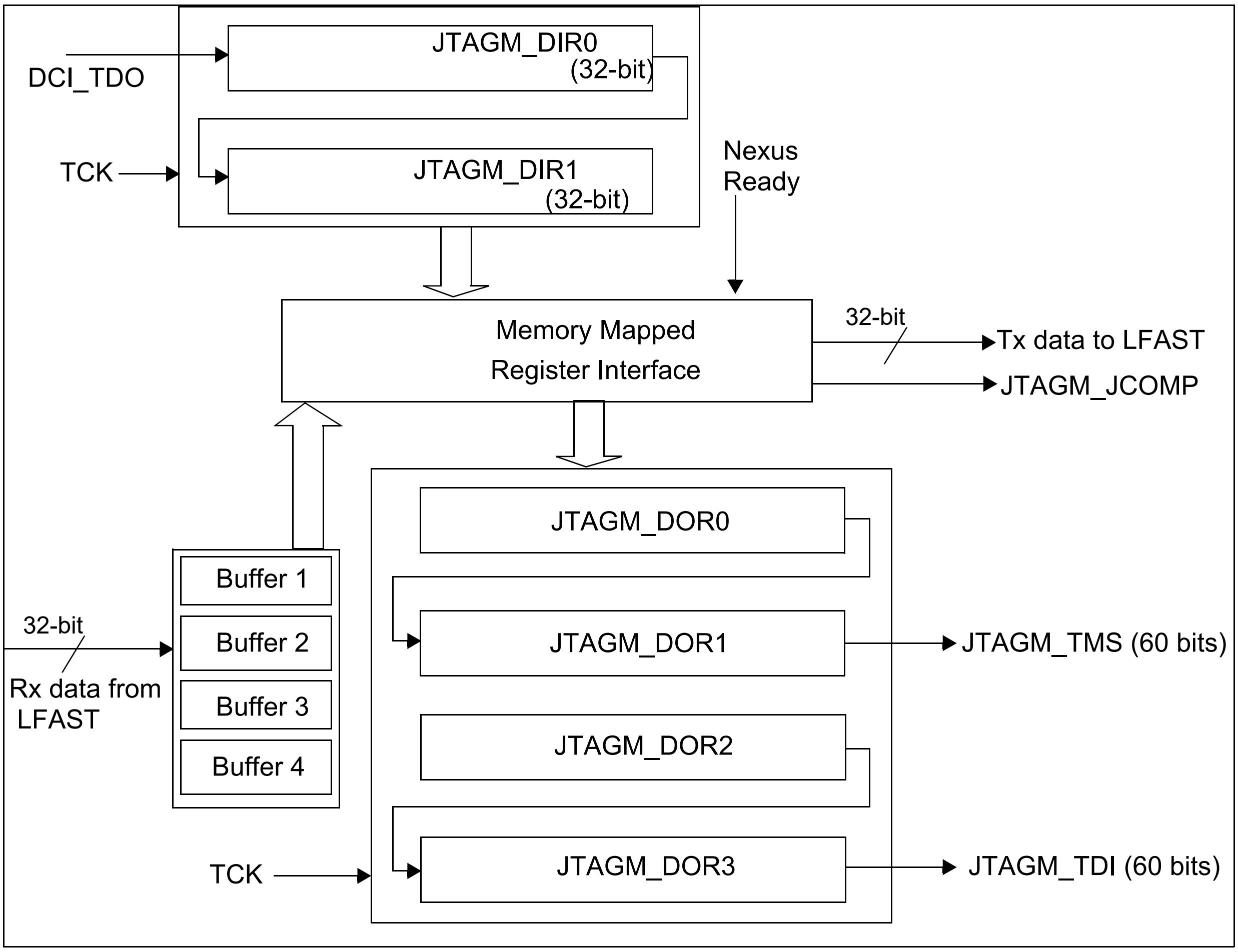
- Configuration register
- Status register
- Four data output registers
- RXCRC receive register
- Two data input registers

All these registers, described in detail in *Section 63.4*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 1294 shows the block diagram of the JTAGM.

Figure 1294. JTAGM block diagram



63.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

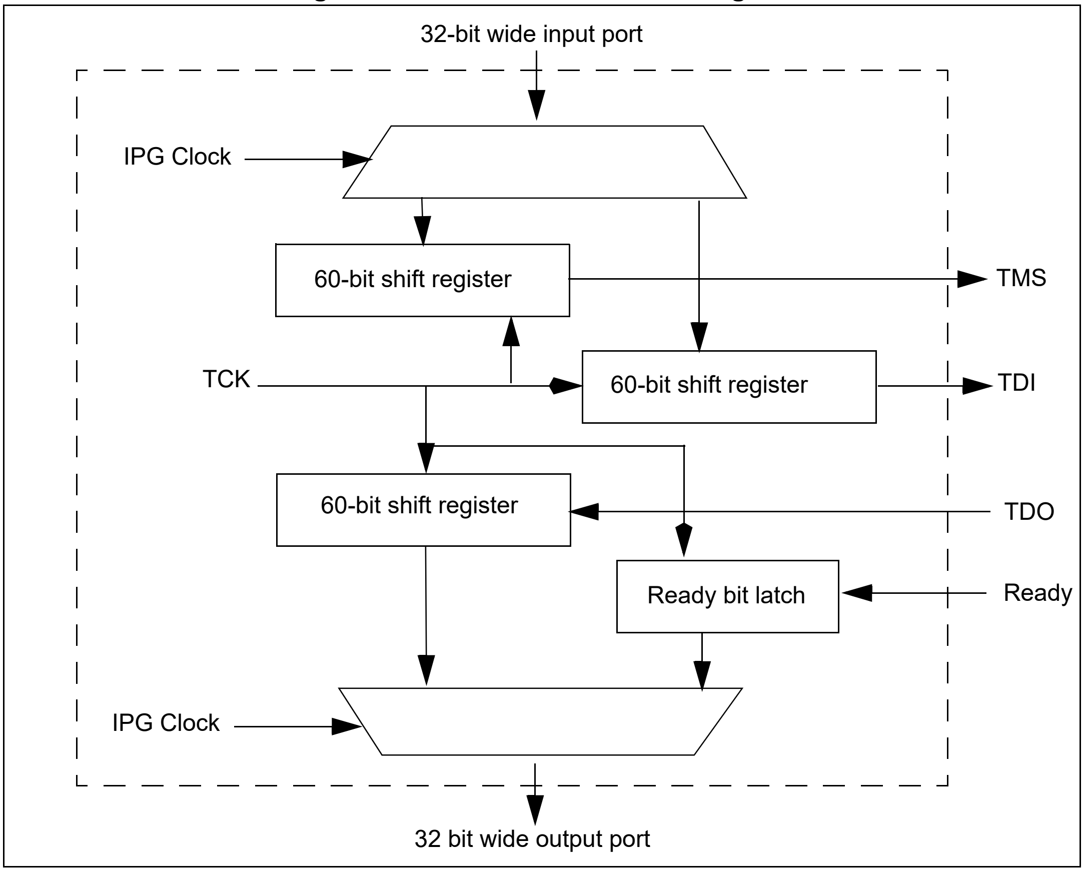
63.2 Functional description

63.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 1295 shows the flow diagram of the LFAST to DCI connection.

Figure 1295. LFAST-to-DCI flow diagram



63.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

63.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

63.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

63.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

63.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

63.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

63.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.

63.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 63.2.5.1: Status register* ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written
- 32-bit value to be written to the configuration register
- 24-bit mask of which bits within the status register should be written
- 8 bits of zero-padding
- 24 bits of data to be written to the status register
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data)

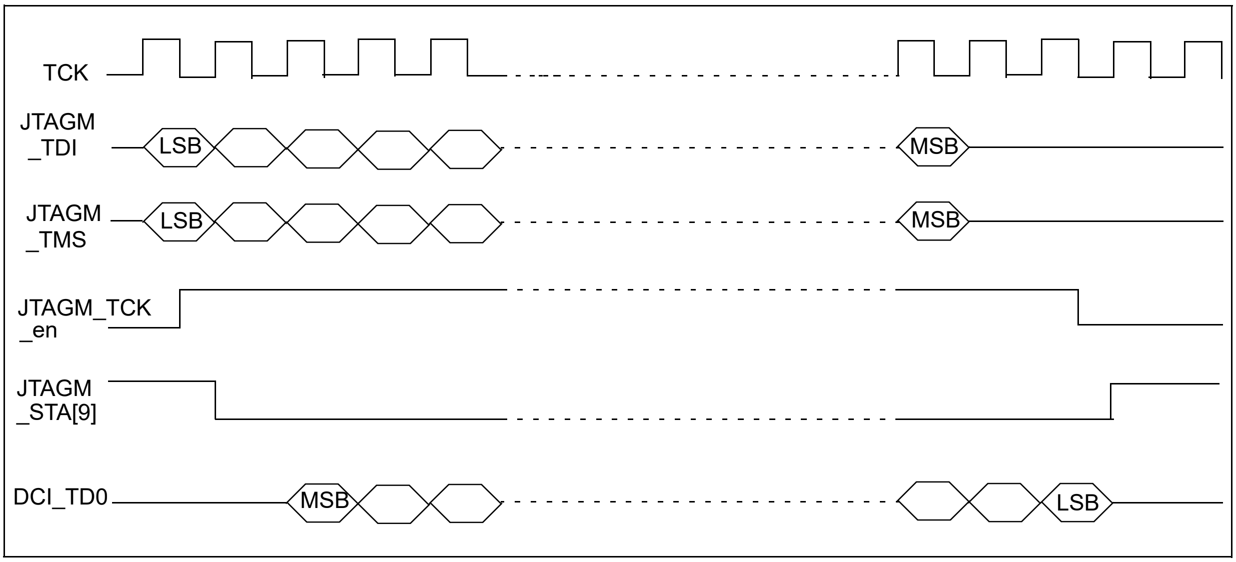
The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

63.2.8 JTAGM to DCI serial interface

Figure 1296 shows the data transfer timings between JTAGM and DCI.

Figure 1296. JTAGM to DCI serial interface diagram



63.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 1297 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 1297. Bit ordering for LFAST to JTAGM transfer

bit 127 to bit 68	bit 67 to bit 8	7	6	5	4	3	2	1	0
TMS (60 bits)	TDI (60 bits)	CRC (8 bits)							
bit 0 to bit 59	bit 0 to bit 59								
Last TMS bit transmitted by JTAGM ... First TMS bit transmitted by JTAGM	Last TDI bit transmitted by JTAGM ... First TDI bit transmitted by JTAGM								

Figure 1298 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 1298. Bit ordering for JTAGM to LFAST transfer

bit 95 to bit 36	bit 35 to bit 32	bit 31 to bit 8	7	6	5	4	3	2	1	0
TDO (60 bits)	0 pad (4 bits)	JTAGM_SR (24 bits)	CRC (8 bits)							
bit 0 to bit 59	bit 0 to bit 59	bit 31 to bit 8								
First TDO bit received by JTAGM ... Last TDO bit received by JTAGM										

The CRC calculation is described in the following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 1298*).

63.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

63.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

63.4 Memory map and register definition

Table 1297 contains the memory map of the JTAGM registers.

Table 1297. Memory map

Figure 1301. JTAGM_SR register in SW mode

The JTAGM_SR register is described in *Table 1299*.

Table 1299. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{EVTO0}$ 1 Activity defined by evto0_sense detected on $\overline{EVTO0}$

Table 1299. JTAGM_SR register field descriptions (continued)

Field	Description
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO1}}$ 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO1}}$
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to ‘1’ when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode(when DTM =0) , this bit has no effect and acts as a “dont care” . This bit should not be used by the application in the LFAST mode
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

63.4.1.3 Data out register 0 (JTAGM_DOR0)

Figure 1302 shows the format of the JTAGM_DOR0.

64 Debug Zipwire

64.1 Overview

The Debug SIPI and Debug LFAST modules work together as a single unit called Debug Zipwire. The Debug LFAST portion of the two modules allows for high speed debugging capabilities.

The Debug LFAST operates in slave mode configuration. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

64.2 Debug Zipwire Overview

Dedicated Zipwire functionality is available for debug use allowing support for increased bandwidth read/write operations to the chip memory space performed over the debug interface. This Debug Zipwire function is available on both production and ED devices. The modules used to support Debug Zipwire are the Debug SIPI module, the Debug LFAST module and the LFAST Switch.

The Debug Zipwire interface allows a connected tool to perform 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address in the microcontroller. The Zipwire architecture is fully pipelined and supports multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.The Debug Zipwire interface does not support streaming mode commands.

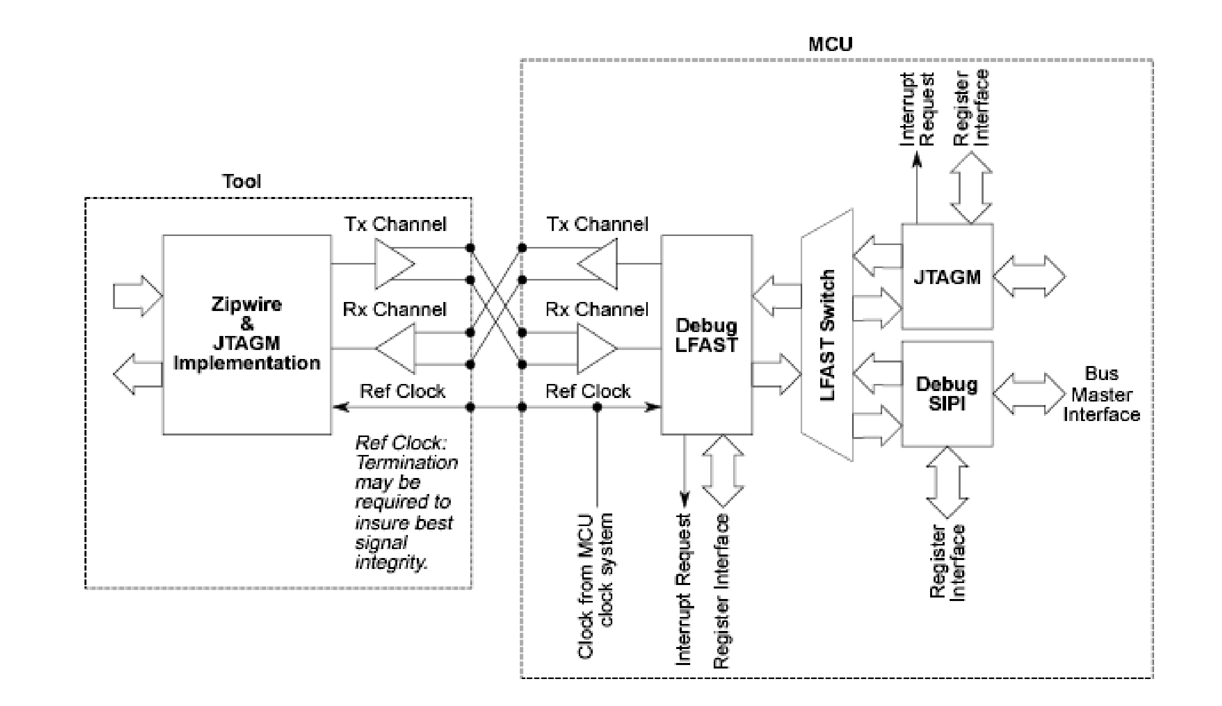
For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

64.3 Debug Zipwire Block Diagram

Figure 1309 shows a tool connected to the MCU via five wires. These five pins are shared with the standard JTAG pins, but for simplicity this is not shown in the diagram. The MCU Debug Zipwire only supports the Target mode of Zipwire. The Debug SIPI Bus Master Interface is used for all Target Mode transactions. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST Reference clock coming from the MCU clock system.

Figure 1309. Debug Zipwire connection diagram



64.4 Architecture

Debug Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200 mV swing.The pads are shared with JTAG signals.

The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). Debug SIPI runs on top of Debug LFAST and is fully encapsulated within the Debug LFAST payload. Debug SIPI uses three fixed sizes of Debug LFAST payload in Debug Zipwire:

- 32-bit
- 64-bit
- 96-bit

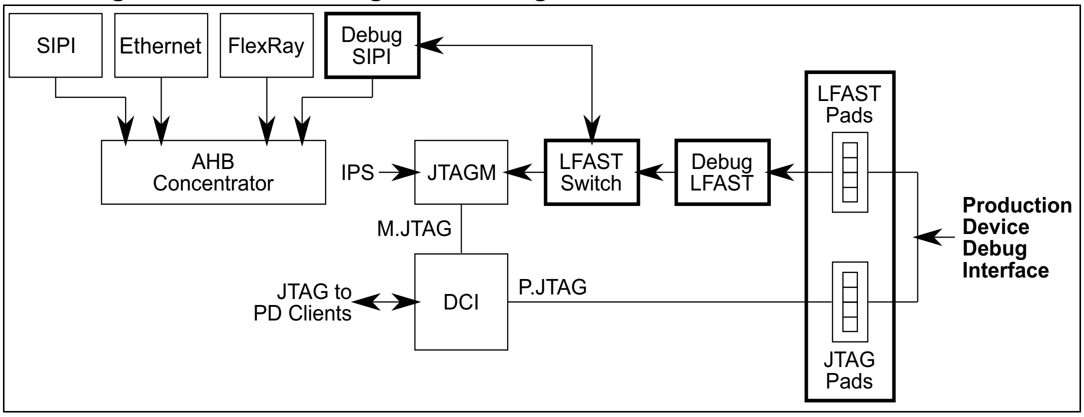
The SIPI protocol implements a suite of commands initiated by a tool, for reading and writing any 32-bit address location in a connected MCU. Only the tool can initiate commands. The MCU only responds to commands initiated by the tool and never creates any unsolicited messages.

For Debug Zipwire, a reduced version of the SIPI module called Debug SIPI is used. The Debug SIPI module implements only the recipient part of the SIPI protocol (called Target mode). The Debug SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating tool, Debug SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

64.5 Debug Zipwire implementation

Figure 1310 shows the modules on the production device which support the Debug Zipwire function, along with their interconnections to the debug interface signals.

Figure 1310. Block diagram showing connections for Production Device



Internal connections to other debug modules which are used to support other debug interface protocols such as JTAG and JTAG over LFAST are also shown. The Debug SIPI module is connected to the Debug LFAST module via an LFAST switch module, which controls routing of debug LFAST traffic to either the Debug SIPI or the JTAGM module.

64.6 LFAST clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data.

This PLL is used to support Debug Zipwire so care must be taken to ensure that any tool configuration of this resource is compatible with application usage of Interprocessor Bus Zipwire.

The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to as the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

- XOSC
- Output of PLL0 (PLL0:PHI)
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator (XOSC) from one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local

LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.

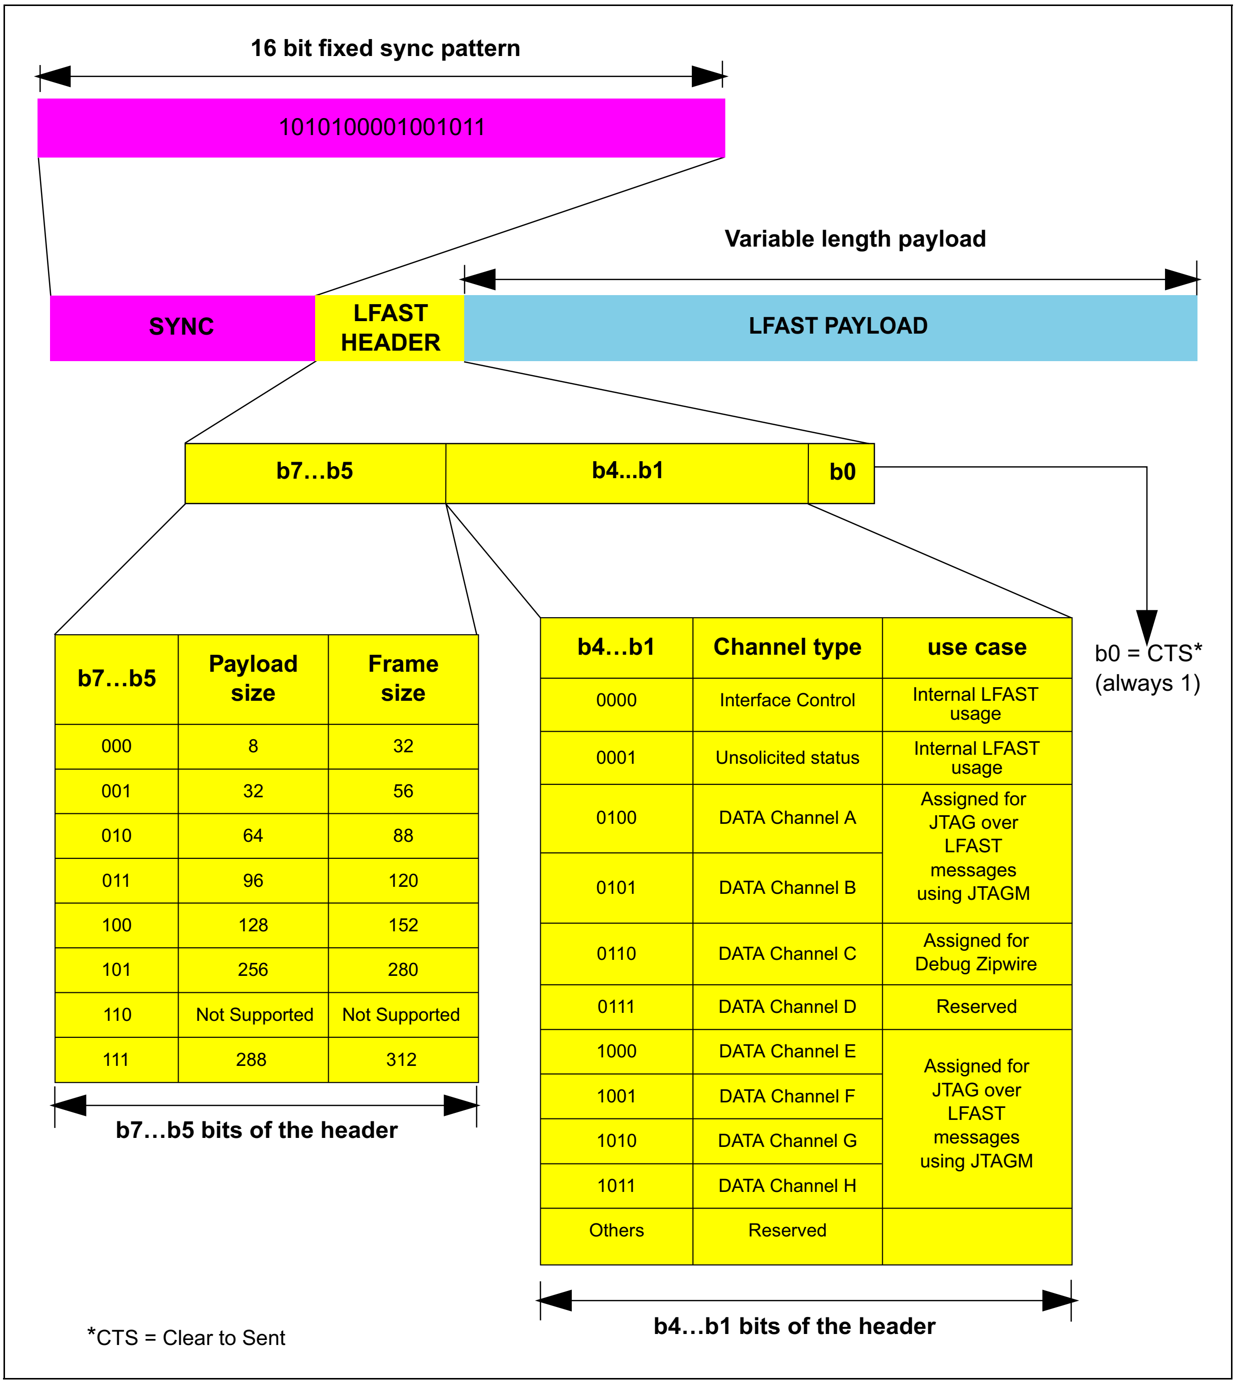
64.7 LFAST switch

Incoming messages on the Debug LFAST interface can be either for JTAG over LFAST use through the JTAGM or debug Zipwire messages. Differentiation of these messages is via use of LFAST channel number. DATA channel C is used to identify high speed Debug SIPI accesses, while JTAG over LFAST messages are supported using LFAST channels A, B, E, F, G, H as shown in *Figure 1311*

The LFAST SWITCH module is used to direct LFAST messages based on the above scheme, with JTAG over LFAST messages being routed to the JTAGM IP block and debug Zipwire messages being routed to the Debug SIPI block.

The LFAST switch has no accessible registers and requires no user configuration.

Figure 1311. LFAST channel allocation



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	Not Supported	Not Supported
111	288	312

b4…b1	Channel type	use case
0000	Interface Control	Internal LFAST usage
0001	Unsolicited status	Internal LFAST usage
0100	DATA Channel A	Assigned for JTAG over LFAST messages using JTAGM
0101	DATA Channel B	
0110	DATA Channel C	Assigned for Debug Zipwire
0111	DATA Channel D	Reserved
1000	DATA Channel E	Assigned for JTAG over LFAST messages using JTAGM
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

64.8 Debug SIPI module

The debug SIPI module is used to support high bandwidth read/write accesses over the LFAST debug interface. It is dedicated for debug use and is entirely separate from the SIPI module used to support interprocessor bus zipwire interface.

The debug SIPI characteristics are shown in the table below:

Table 1307. Debug SIPI feature set

Feature	Debug implementation
Number of channels supported	1
Initiator support	No
Target support	Yes
Block transfer support	No
Chip XBAR connection	M1 on XBAR_1

The debug SIPI module issues read and write accesses via the AHB concentrator connected to physical master port 2 on XBAR_1, which is shared with the Ethernet and Zipwire SIPI bus masters.

The debug SIPI memory mapped registers are accessible via PBRIDGE_0 (off platform - slot 10) with base address FFFD_4000h.

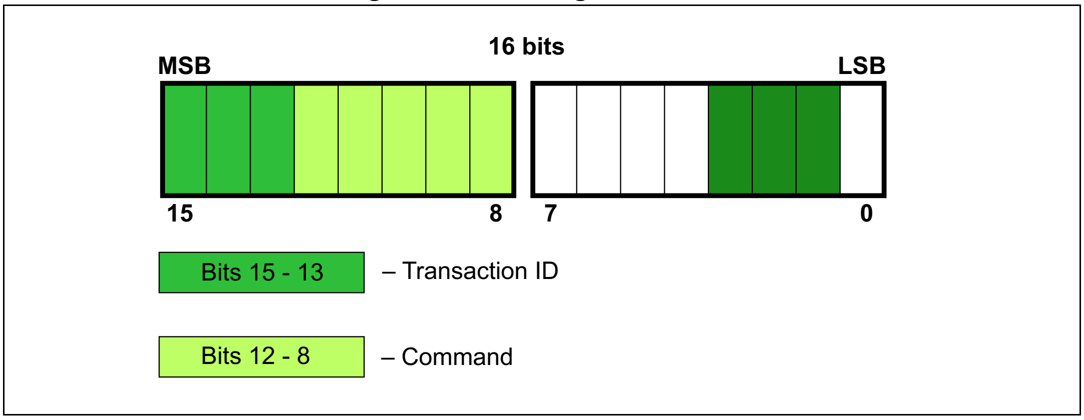
The debug SIPI has Logical Bus Master Assignment of 6 for SMPU0 and SMPU1, an NXMC trace source ID (SRC) of 1101b and a trace master ID (MASTER) = 1011b.

The debug SIPI supports only target mode SIPI operations on a single channel with a reduced command set. Commands supported include read (8/16/32 bits) and write (8/16/32 bits) along with the appropriate responses. Other SIPI commands are unimplemented as noted in *Table 1308*.

The debug SIPI will be capable of:

- receiving a 64-bit command on LFAST channel C and responding with either a 64-bit response or 32-bit error response on LFAST channel C.
- receiving a 96-bit command on LFAST channel C and responding with either a 32-bit acknowledge or 32-bit error response on LFAST channel C.

Figure 1312. Debug SIPI header



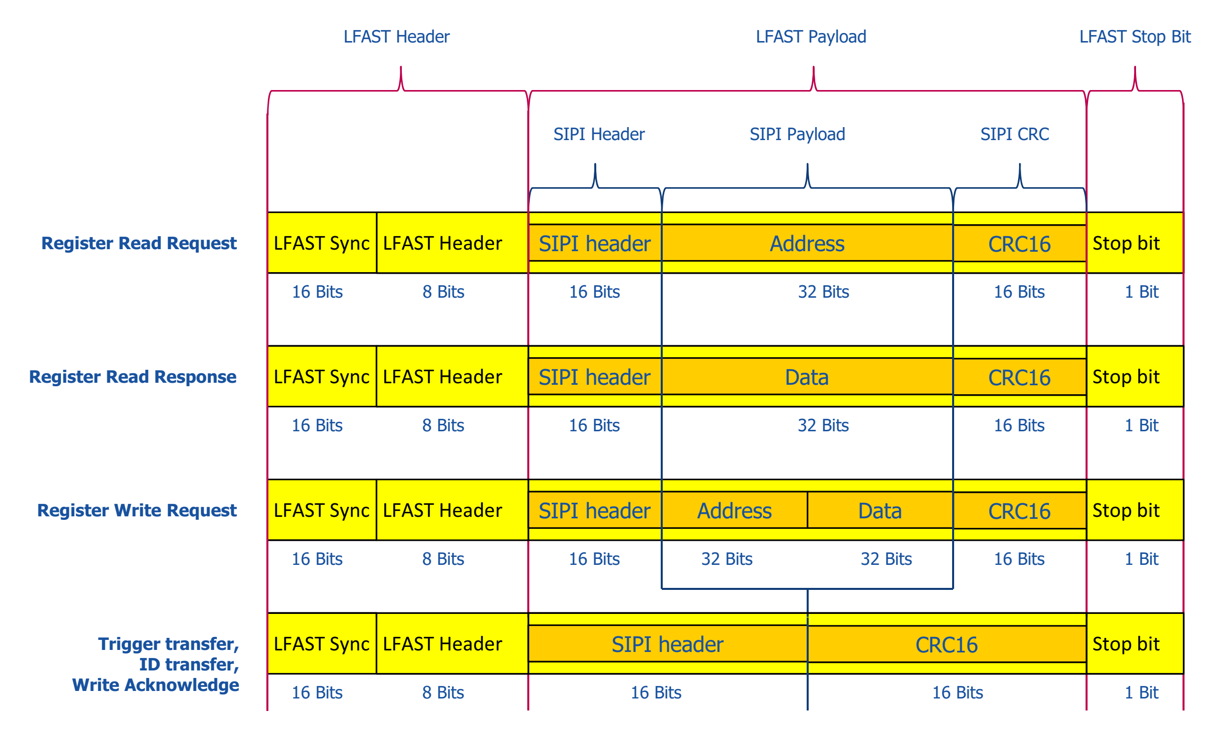
Note: See Figure 1311 for the description of bits[7:0]

Table 1308. SIPI header command coding

Bits[12:8] (hex)	Command	Payload Size	Message Direction at chip (SIPI Target)
00	Read 8 bits (Received by SIPI from LFAST)	64	Rx
01	Read 16 bits (Received by SIPI from LFAST)	64	Rx
02	Read 32 Bits (Received by SIPI from LFAST)	64	Rx
03	Reserved	—	—
04	Write 8 bits with ACK (Received by SIPI from LFAST)	96	Rx
05	Write 16 bits with ACK (Received by SIPI from LFAST)	96	Rx
06	Write 32 bits with ACK (Received by SIPI from LFAST)	96	Rx
07	Reserved	—	—
08	ACK – OK (Issued to LFAST from SIPI)	32	Tx
09	ACK – Fault (Issued to LFAST from SIPI)(1)	32	Tx
0A	Read Answer – OK (Issued to LFAST from SIPI)	64	Tx
0B	Reserved	—	—
0C	Unimplemented – Trigger comm and with ACK	32	—
0D	Reserved	—	—
…	…	…	…
11	Reserved	—	—
12	ID Register Read Request	32	Rx
13	Reserved	—	—
…	…	…	…
16	Reserved	—	—
17	Unimplemented – Stream Data with ACK (32 bytes)	288	—
18	Reserved	—	—
…	…	…	…
1F	Reserved	—	—

1. ACK – Fault is also referred to as “NACK” and “ACK Error” in the HSSL/SIPI Interprocessor Bus Protocol Specification.

Figure 1313. Zipwire message format



Note: Identification Register Read is the same as the Register Read response format.

64.9 Debug Zipwire interconnections

Debug LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Connected to the LFAST Switch. This allows LFAST data to be dynamically routed to/from either Debug SIPI for Debug Zipwire operation or JTAGM for JTAG over LFAST operation.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

LFAST Switch has the following connections:

- Tx Data Port/Rx Data port directly connected to Debug SIPI.
- Tx Data Port/Rx Data port directly connected to JTAGM.
- Tx Data Port/Rx Data port directly connected to Debug LFAST.
- LFAST switch has no IPS interface; no registers; no interrupts.

Debug SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers. For the Debug SIPI, a restricted set of registers is implemented. In use, no configuration of these registers is needed from either s/w or a connected tool, as the default settings should be usable for typical operation.

- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.

64.10 Debug Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Inititator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

Bandwidth is the rate at which data can be read or written between the tool and the MCU. It assumes that read or write commands from the Inititator node (the Tool), can be sent continuously at the highest speed the Target node can consume those commands.

Latency is the time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

64.10.1 Read performance

A Zipwire read operation consists of three stages:

- Inititator sends SIPI Read command to Target.
- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns.

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 278 ns.

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of 6 × slow XBAR cycles to read different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, time for SIPI to read an address location is:

(13 × 50 MHz clocks) + (6 × 100 MHz clocks) = 320 ns

64.10.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

Read Bandwidth = 4 bytes in 320 ns = 12.5 MB/second

64.10.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

Read Latency = 278 ns + 320 ns + 278 ns = 876 ns

64.10.2 Write performance

A Zipwire write operation consists of three stages:

- Inititator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address
- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header
- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 378 ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 178 ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of 5 × slow XBAR cycles to write different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, the time for SIPI to write an address location is:

(13 × 50 MHz clocks) + (5 × 100 MHz clocks) = 310 ns

64.10.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = 4 bytes in 378 ns = 10.6 MB/second

64.10.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = 378 ns + 310 ns + 178 ns = 866 ns

65 Debug Serial Interprocessor Interface (SIPI)

65.1 Introduction

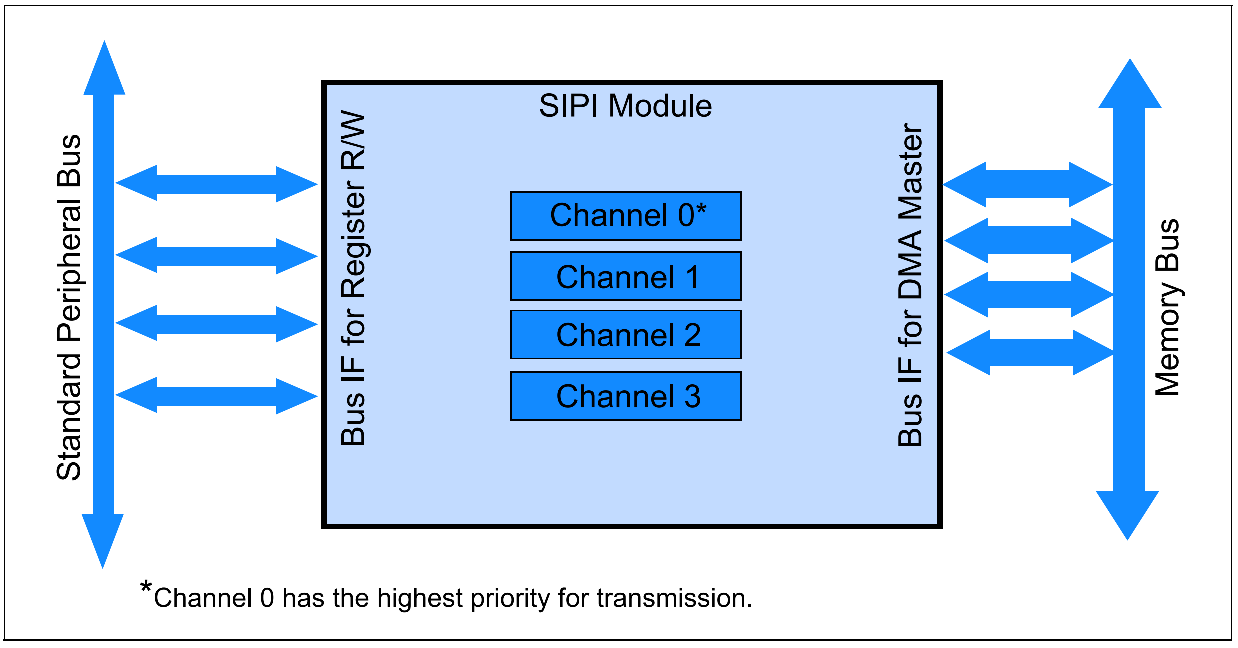
The Debug Serial Interprocessor Interface (SIPI) is an application layer protocol that runs on top of the LFAST module. It is used by the local device to access the shared memory of a remote device. Debug SIPI defines point-to-point full duplex communication between two nodes, where LFAST works as a physical medium of communication between both the devices.

Debug SIPI implements the Target mode of a communication protocol in hardware. Debug SIPI can interpret 'read' and 'write' commands received from an LFAST module and convert them into bus accesses to local memory; then send back to the LFAST module either read data or a write acknowledge response. This provides a mechanism for an external device, such as an external tool, to read and write the address map of the local MCU. The bandwidth of these read/write commands is approximately 10 MBytes/second when accessing random addresses using 32-bit transfers.

65.2 Overview

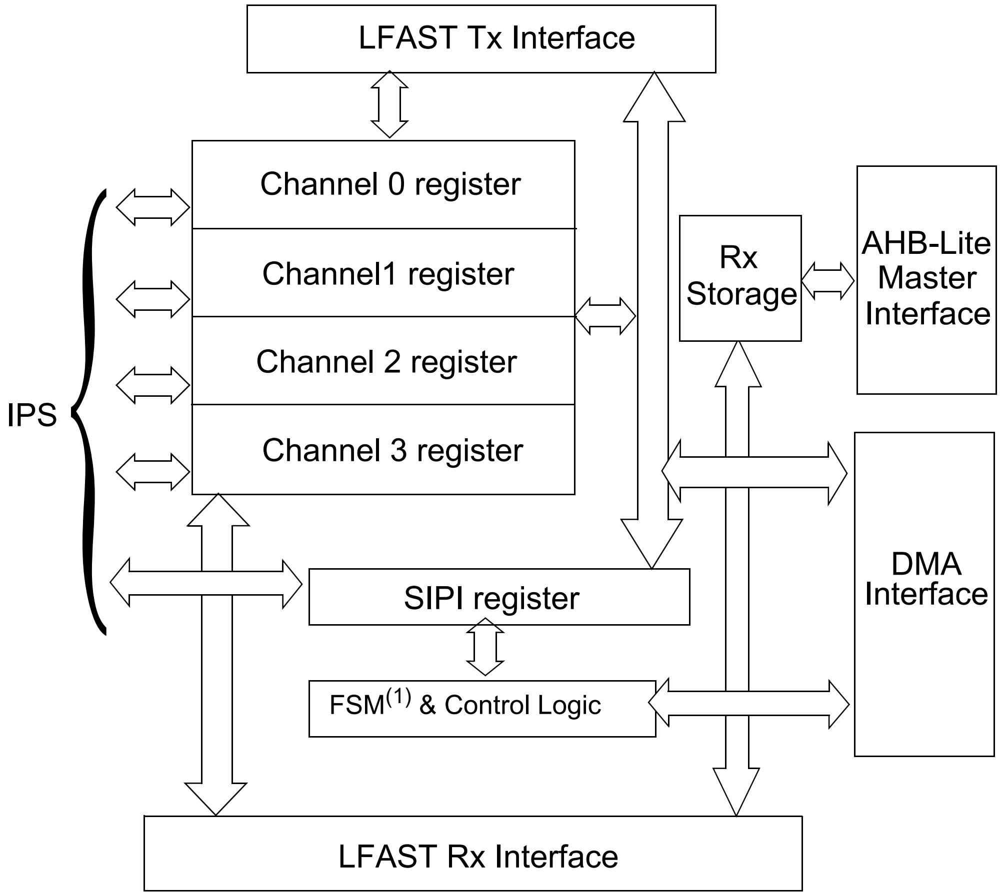
Debug SIPI can access memory mapped resources directly through its AHB master interface. Debug SIPI has four channels, 0, 1, 2, 3. Payload width for all channels is 32 bits.

Figure 1314. SIPI module



65.3 Debug SIPI block diagram

Figure 1315. SIPI block diagram



1. Finite State Machine

65.4 Feature description

This section describes the features of the Debug SIPI module.

65.4.1 Main features

- Supports 8, 16 and 32-bit read and write commands
- Command/response includes a 16-bit CRC to ensure data integrity
- Command/response includes a 2-bit tag to allow tracking of data to commands in a pipelined system
- Command/response includes a 3-bit channel identifier to allow multiple Initiators to send commands to a single target node
- Command/response includes a 16-bit header that defines, the function, channel and tag
- Every command generates a response to allow a 'sliding window' flow control protocol to be implemented
- AHB master interface that is used by target node to access memory mapped resources

65.4.2 Standard features

- IPS bus interface
- AHB master interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

65.5 Debug SIPI operation from reset

When the Debug SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

65.6 Functional description

65.6.1 External signals

The Debug SIPI has no chip external signals.

65.6.2 Frame format

All frames have the same general format:

- 16-bit header
- Address, address and data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID.

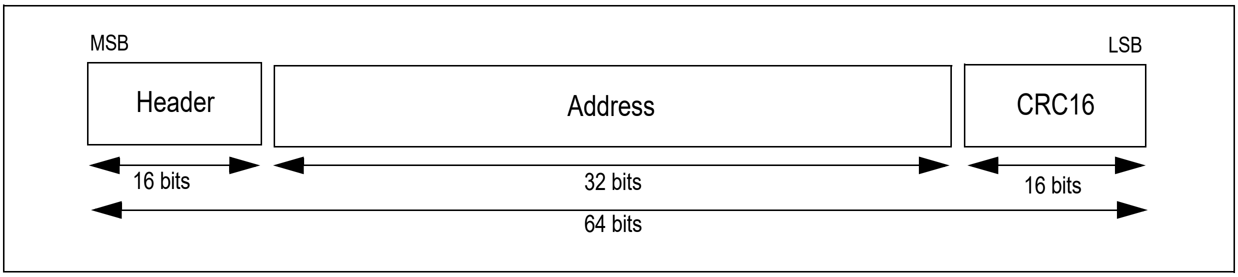
The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

Note: SIPI module architecture is always big endian but the storage in host memory depends on endianness architecture of host memory.

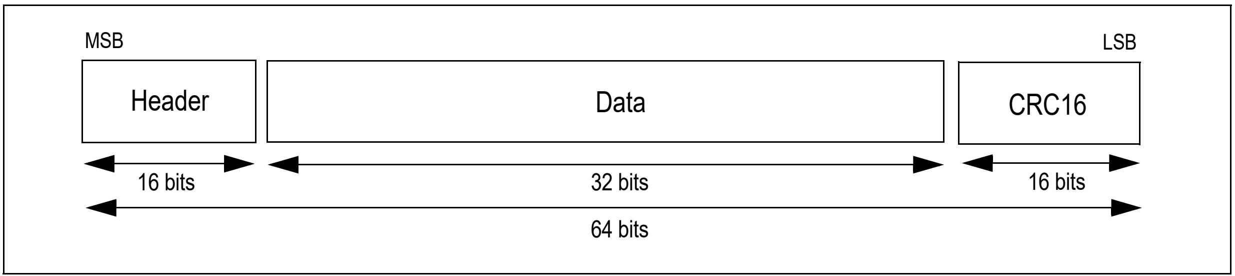
65.6.2.1 Register read request

Figure 1316. SIPI register read request



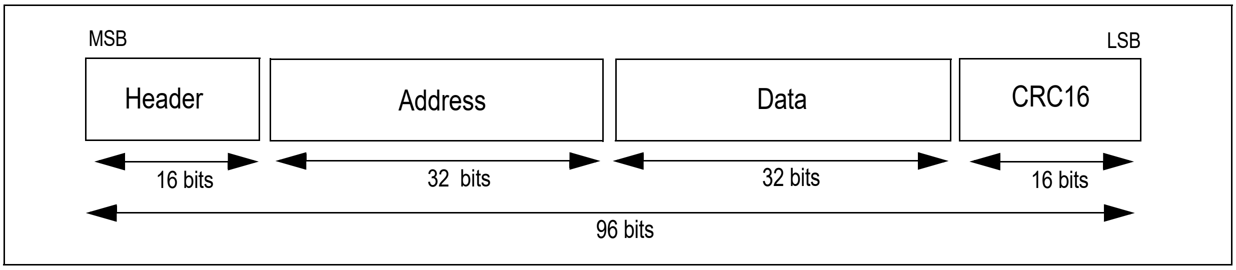
65.6.2.2 Register read response, ID request response

Figure 1317. SIPI read response



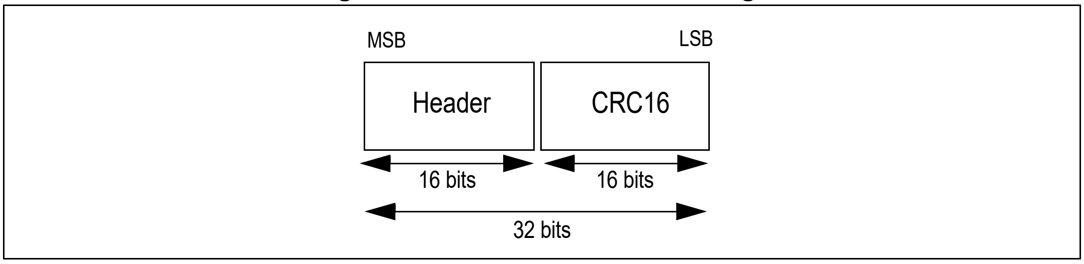
65.6.2.3 Register write request

Figure 1318. SIPI register write request



65.6.2.4 ID transfer, write acknowledge

Figure 1319. SIPI write acknowledge



65.6.2.5 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

65.6.2.5.1 Debug SIPI header coding

Figure 1320, Table 1309, and *Figure 1321* show how the Debug SIPI header bits are coded.

Figure 1320. SIPI header coding

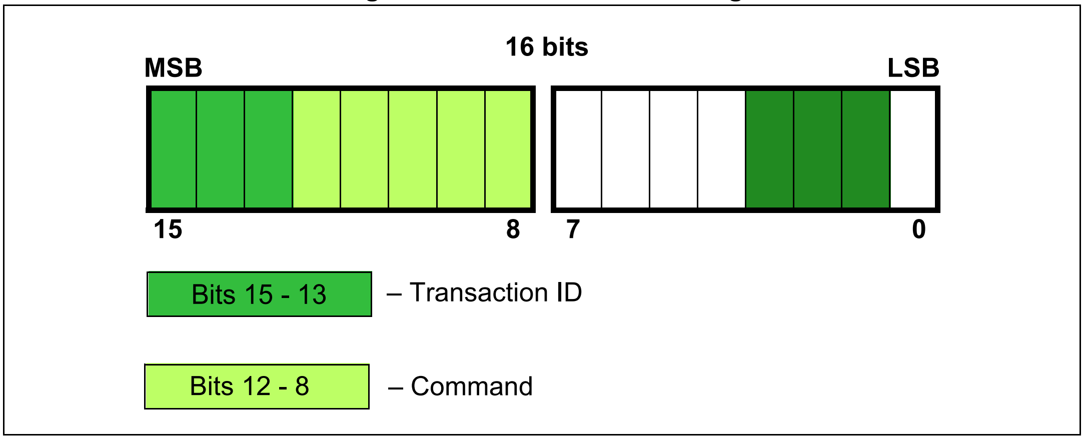


Table 1309 shows the command coding for the bits[12:8] of the header.

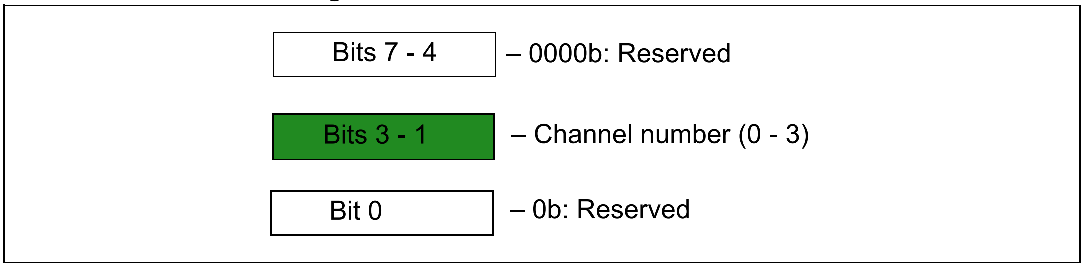
Table 1309. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
0x00	Read 8 bits	64
0x01	Read 16 bits	64
0x02	Read 32 Bits	64
0x03	Reserved	—
0x04	Write 8 bits with ACK	96
0x05	Write 16 bits with ACK	96
0x06	Write 32 bits with ACK	96
0x07	Reserved	—
0x08	ACK – OK	32
0x09	ACK – Fault	32
0x0A	Read Answer – OK	64
0x0B	Reserved	—
0x0C	Reserved	—
0x0D	Reserved	—
…	…	…
0x11	Reserved	—
0x12	ID Register Read Request	32
0x13	Reserved	—
…	…	…
0x16	Reserved	—
0x17	Reserved	—
0x18	Reserved	—
…	…	...
0x1F	Reserved	—

Figure 1321 shows the content of bits[7:0] in the SIPI header.

Figure 1321. SIPI header channel field



65.6.2.6 Address field

The address field is 32 bits wide with the MSB transmitted first.

65.6.2.7 Payload field

Table 1310 shows the payload sizes of LFAST frames.

Table 1310. Payload size of LFAST channel frame

LFAST code for payload size	Debug SIPI Code	LFAST payload size (bits)(1)	LFAST payload size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16
101b	101b	256	32
111b	111b	288	36

1. Only 32, 64, 96 and 288 bits sizes are used for SIPI.

Table 1311 shows the coding of LFAST channel for a given Debug SIPI channel code.

Table 1311. Converted coding of LFAST channel code for Debug SIPI headers

LFAST channel code	Debug SIPI channel code	Data channel(1)
0100b	100b	Data channel A
0101b	101b	Data channel B
0110b	110b	Data channel C
0111b	111b	Data channel D
1000b	000b	Data channel E (not used by Debug SIPI)
1001b	001b	Data channel F (not used by Debug SIPI)
1010b	010b	Data channel G (not used by Debug SIPI)
1011b	011b	Data channel H (not used by Debug SIPI)

1. Debug SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
Debug SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
Debug SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
Debug SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

65.6.2.8 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). The data stream is transmitted with the MSB sent first.

65.6.2.8.1 CRC examples

Example 1 – 32-bit write

- Header = 0x260A
- Address = 0x1122_3344
- Data = 0xCCDD_EEFF
- CRC = 0xBF7D

Example 2 – 32-bit read

- Header = 0x420C
- Address = 0x89AB_CDEF
- CRC = 0x6B80

Example 3 – Event command

- Header = 0x6C0E
- CRC = 0xB286

65.7 Transfer types

This section describes the available transfer types of the Debug SIPI module. The Debug SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

65.7.1 Read transfer

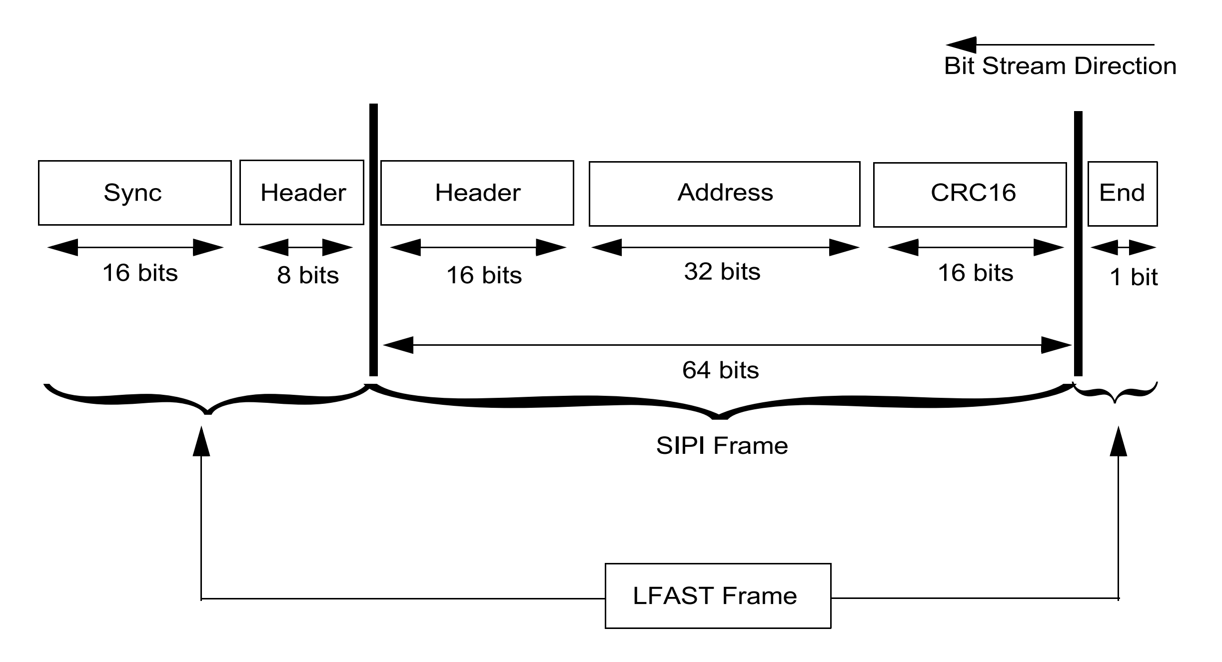
A Read transfer can be of two types:

- Read request transfer (at initiator node)
- Read response transfer (at target node)

65.7.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in *Figure 1322*.

Figure 1322. Read request transfer (showing LFAST frame encapsulation)



65.7.2 Register read answer transfer

In response to a read request, Debug SIPI sends header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (refer to *Figure 1323*). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (refer to *Figure 1324*).

Figure 1323. Read answer transfer (LFAST frame encapsulation is not shown)

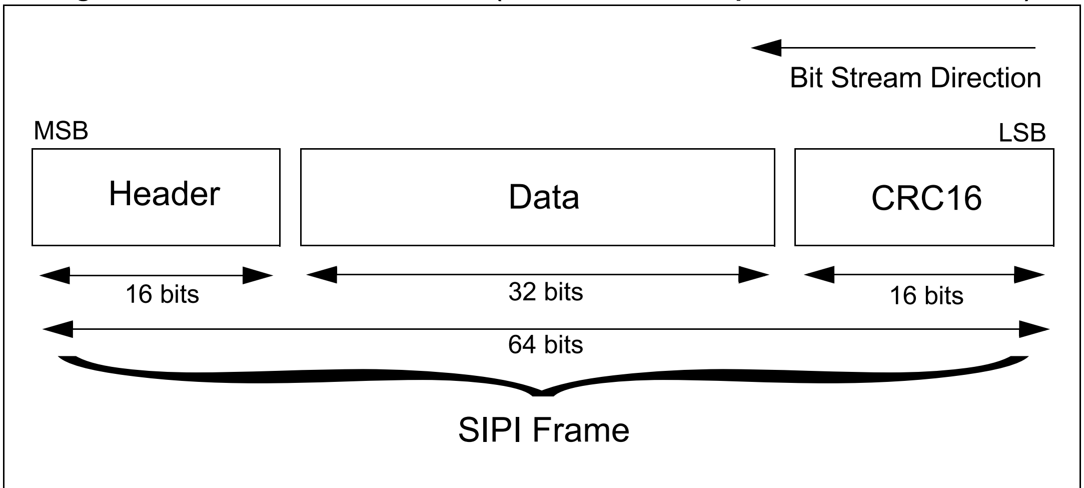


Figure 1324. Data allocation

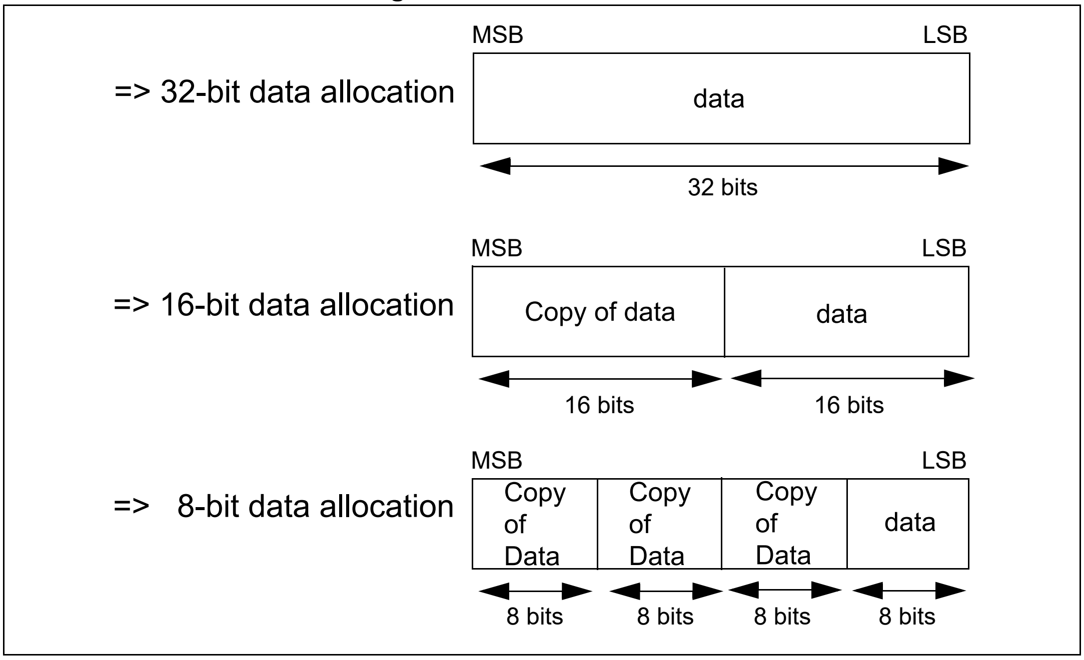


Note: For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables (big endian):

Bits[1:0]:

- *00: Byte 3 enabled (MSB)*
- *01: Byte 2 enabled*
- *10: Byte 1 enabled*
- *11: Byte 0 enabled (LSB)*

For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable (big endian).

Bit[0]:

- *0: Half-word 1 enabled (MSB)*
- *1: Half-word 0 enabled (LSB)*

Note: Byte Ordering depends on the address written in CAR and transfer width:
Example:

- *CDR content: 0x12345678*
- *CAR content: see table columns*

Table 1312. Target Memory content dependent on CAR content

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
32-bit transfer	0x02040	12	12	12	12
	0x02041	34	34	34	34
	0x02042	56	56	56	56
	0x02043	78	78	78	78

Table 1312. Target Memory content dependent on CAR content (continued)

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
16-bit transfer	0x02040	12	56	xx	xx
	0x02041	34	78	xx	xx
	0x02042	xx	xx	12	56
	0x02043	xx	xx	34	78
8-bit transfer	0x02040	12	xx	xx	xx
	0x02041	xx	34	xx	xx
	0x02042	xx	xx	56	xx
	0x02043	xx	xx	xx	78

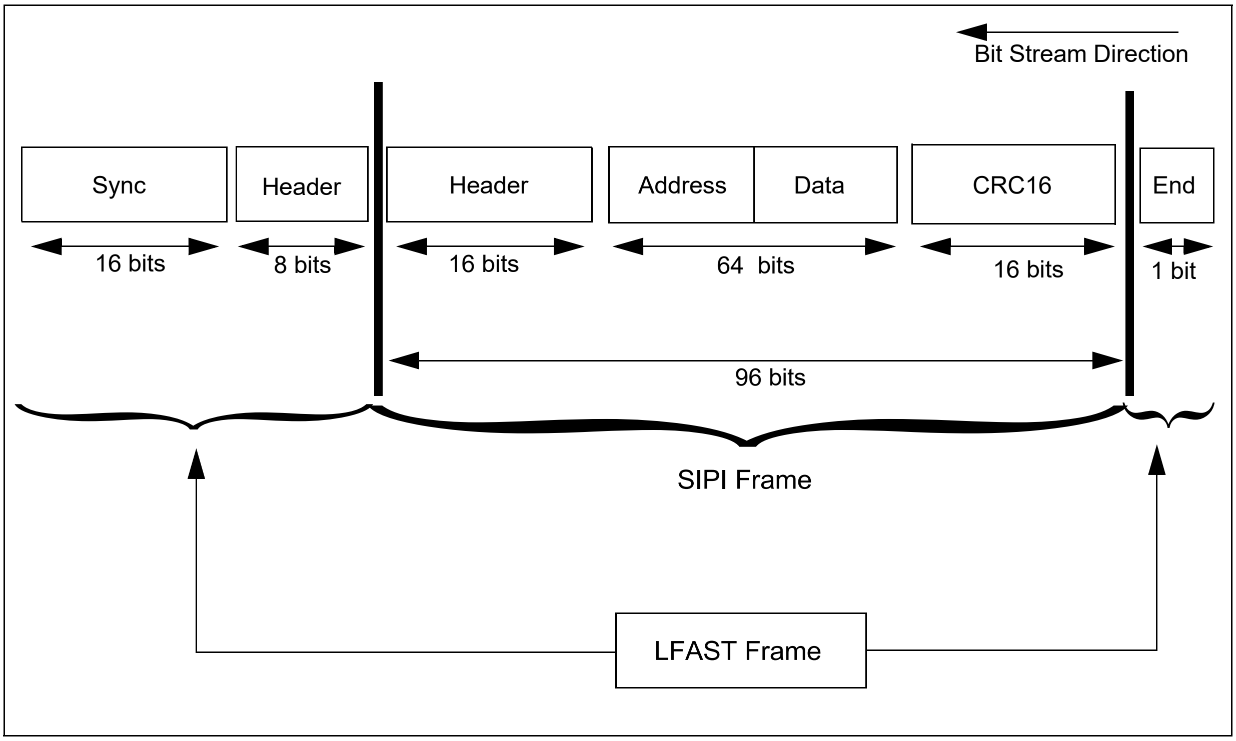
65.7.3 Register write transfer

Register write transfer can be of type:

- Normal write transfer – channels 0, 1, 2 and 3

A Register write transfer can be done through Normal write transfer - channels 0, 1, 2 and 3 (refer to *Section 65.7.3.1: Normal write transfer*) as shown in *Figure 1325*.

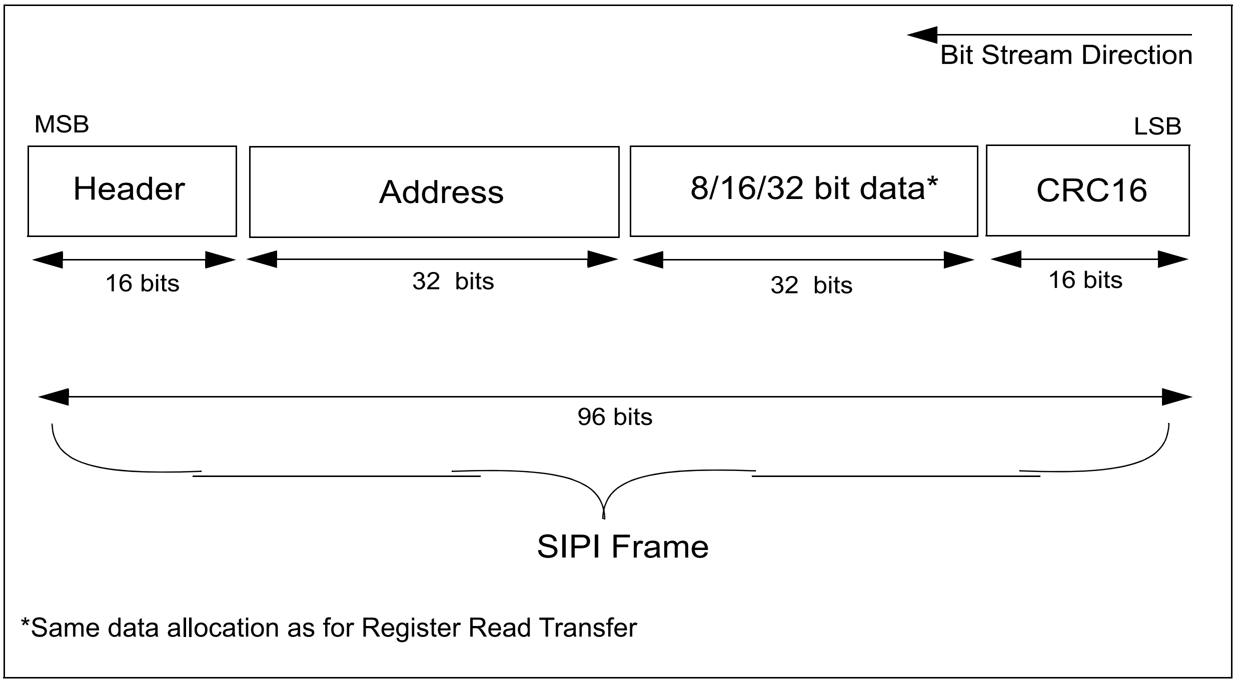
Figure 1325. Register write transfer (showing LFAST frame encapsulation)



65.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and 16-bit CRC as shown in *Figure 1326*.

Figure 1326. Write transfer (LFAST frame encapsulation is not shown)



Note: In the case of an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as a byte enable:

Bits[1:0]:

- *00 – byte 3 enabled (MSB)*
- *01 – byte 2 enabled*
- *10 – byte 1 enabled*
- *11 – byte 0 enabled (LSB)*

In the case of a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as a half-word enable:

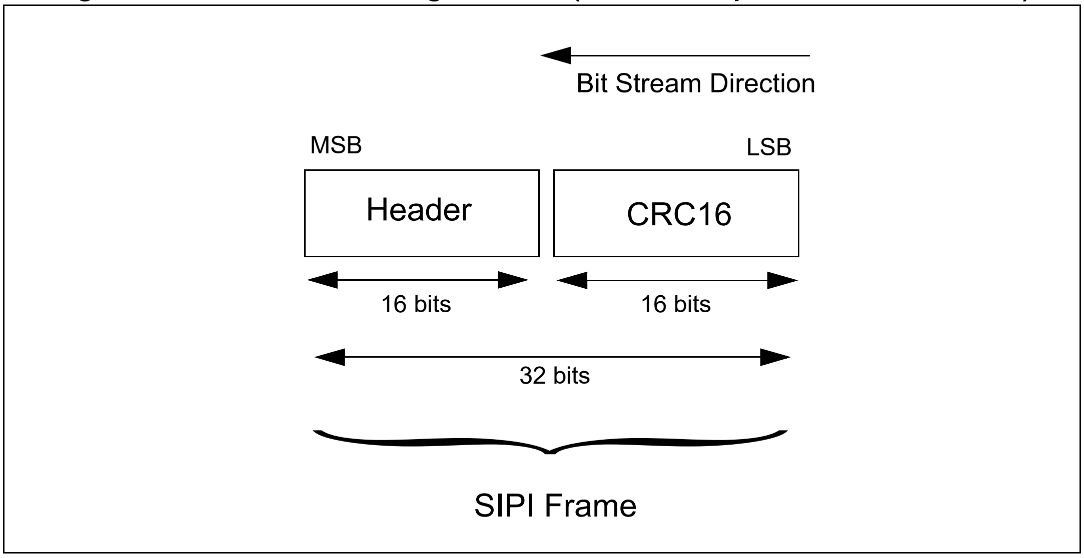
Bit[0]:

- *0 – half-word 1 enabled (MSB)*
- *1 – half-word 0 enabled (LSB)*

65.7.4 Write acknowledge transfer

A write acknowledge transfer contains only header and CRC bits (refer to *Figure 1327*). The CRC bits are calculated on the header field.

Figure 1327. Write acknowledge transfer (LFAST encapsulation is not shown)

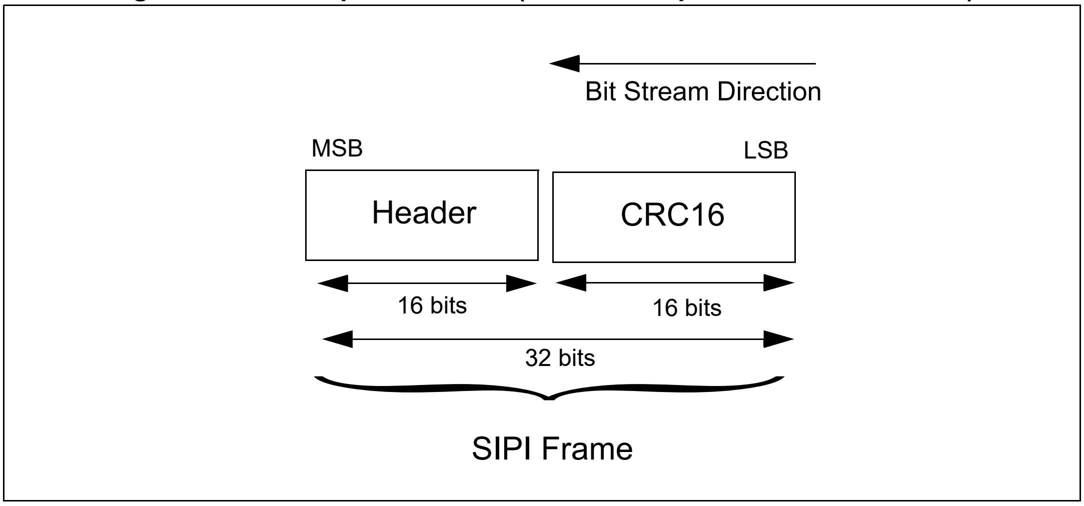


65.7.5 ID request response

65.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in *Figure 1328*.

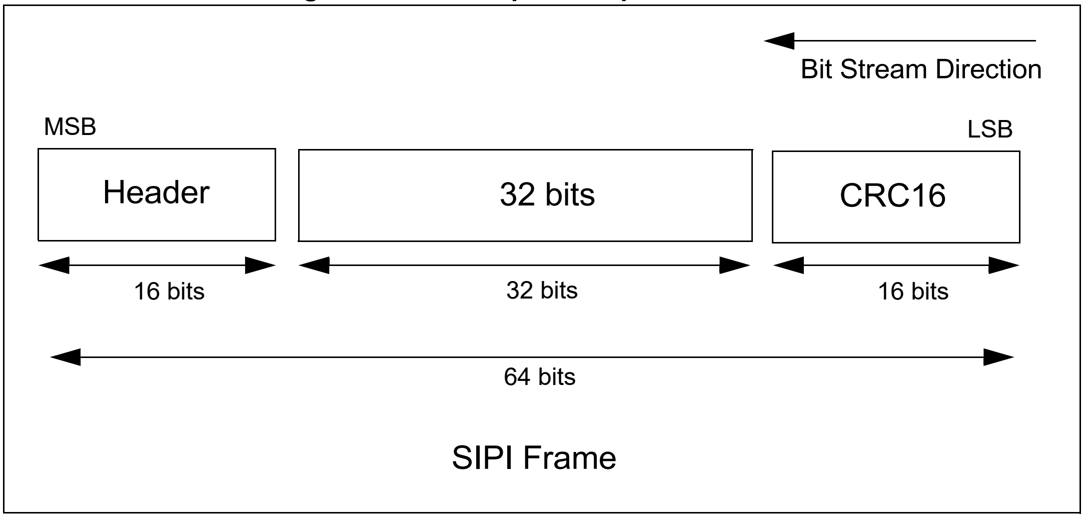
Figure 1328. ID request transfer (LFAST encapsulation is not shown)



65.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in *Figure 1329*.

Figure 1329. ID request response transfer



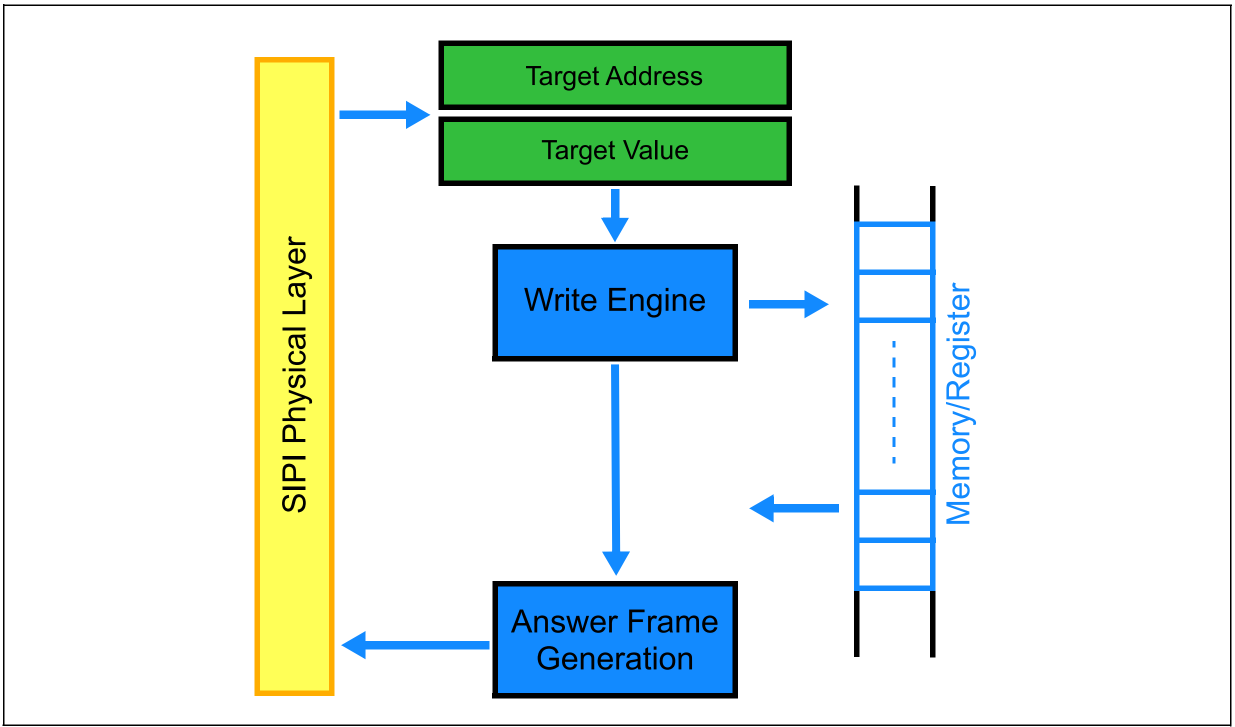
Note: The ID request response contains the value of the CHIP ID in place of data.

65.8 Transfer API and flow charts

On a single write transfer request reception (refer to *Figure 1330*):

1. Debug SIPI will place the address, data and control information on its AHB master interface.
2. When the process in completed, the Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

Figure 1330. SIPI single register write API – Flow chart



On multiple write transfer request reception:

1. Debug SIPI will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

On single read transfer request reception:

1. Debug SIPI will place the address and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will send read response back to LFAST.

On multiple read transfer request reception:

1. Debug SIPI then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

65.9 CRC calculation

Example 1

If header is 0xAABB, address is 0x1122_3344 and data is 0xCCDD_EEFF. Then CRC calculation will take place as follows:

1. The CRC seed is initialized by 0xFFFF_FFFF.
2. All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
3. So the header will be sent as 0xDD55_0000, byte_enable = 0xC.
4. Address will be sent as 0x22CC_4488, byte_enable = 0xF.
5. Data will be sent as 0xFF77_BB33, byte enable = 0xF.

65.10 Memory map and register description

Table 1313. SIPI memory map

Offset from SIPI base (hex)	Register	Section/Page

Figure 1331. SIPI Module Configuration Register (SIPI_MCR)

Table 1314. SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. 0 No Freeze mode request. 1 Enters Freeze mode if FRZ bit is asserted.
29 INIT	Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits cannot be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete. Statical configuration, data and address registers remain unchanged.

65.10.1.2 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Offset: 0x00A0 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FRZACK	LPMACK	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1332. SIPI Status Register (SIPI_SR)

Table 1315. SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI not in any low power modes 1 SIPI is in Disable mode

66 LVDS Fast Asynchronous Serial Transmission – High Speed Debug

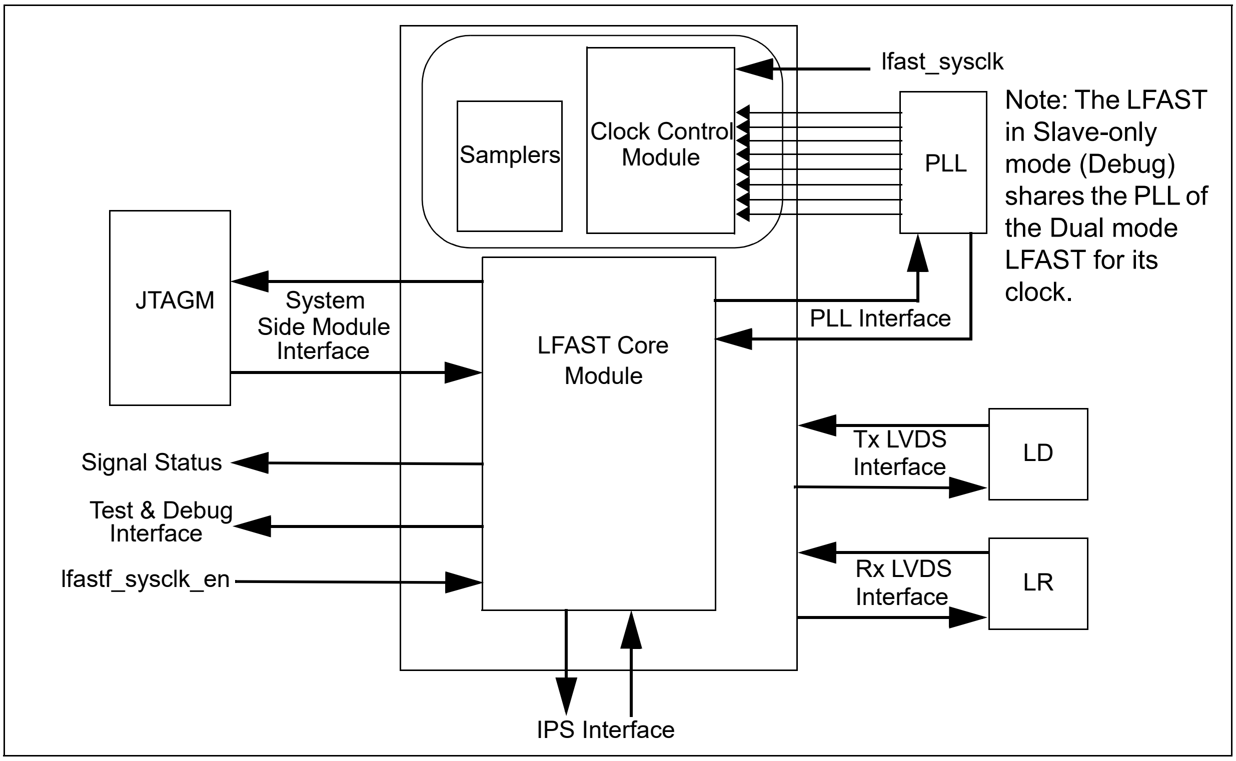
66.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

66.2 Block diagram

Figure 1333 depicts LFAST interaction with other modules on the device.

Figure 1333. LFAST block diagram



66.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
  - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

66.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

66.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.

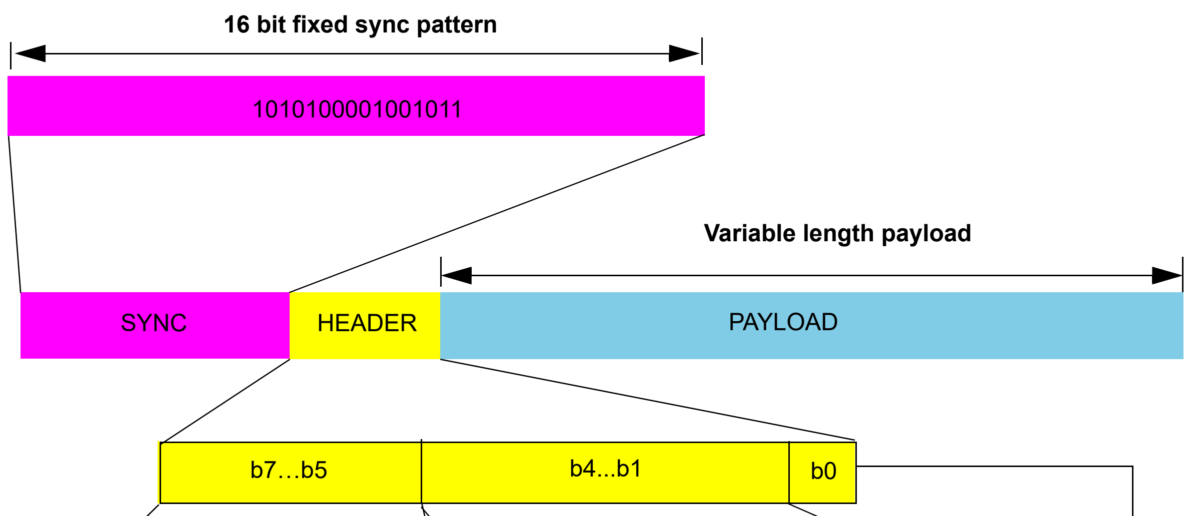
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See *Figure 1334* for details of the LFAST frame.

Figure 1334. LFAST frame structure



b7…b5	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported

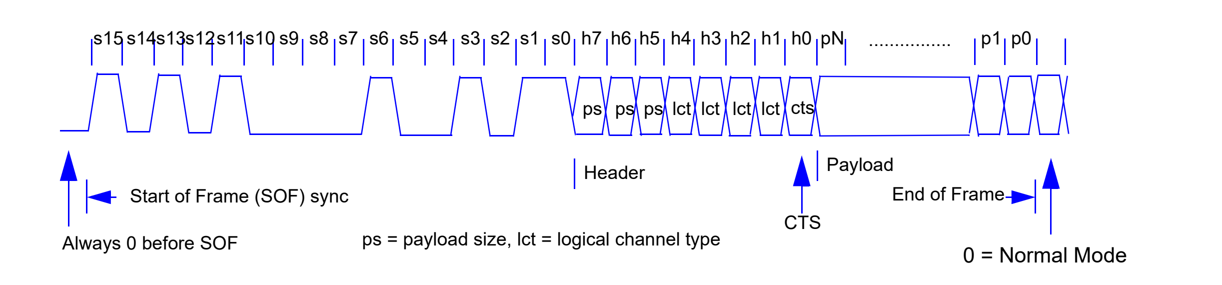
b7…b5 bits of the header

b4…b1	Channel type	Use case
0000	Interface Control	LFAST Master sends ICLC. LFAST Slave sends Ping response
0001	Unsolicited status	Both LFAST master and slave link.
0100	DATA Channel A	For Data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	—

b4…b1 bits of the header

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 1335. Serial frame structure



The frame structure is shown in *Figure 1335* and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto-correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to *Table 1316*.

Table 1316. Header payload sizes

b7-b5 (bin)	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

66.5 Features

- Supports slave only mode
- Supports asynchronous data transfer rates up to the maximum data rated shown in the product Datasheet
- Transmits and receives data and unsolicited frames
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes
- Supports flow control using sliding window protocol
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits
- Supports PLL configuration (such as feedback loop divider) through registers
- Supports LVDS configuration through registers
- Supports multiple loopback modes for checking the physical interface
- Supports automatic ping response generation
- Supports for detection of unsupported channel number and unsupported payload size

66.6 Memory map and register definition

All registers are 32-bit wide.

66.6.1 Memory map

Table 1317. LFAST memory map

Figure 1336. Mode Configuration Register (MCR)

1. Set by user software and cleared by system hardware.

Table 1318. MCR field descriptions

Field	Description
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode Refer to *Section 66.10.2: Slow speed clock* for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.

Table 1318. MCR field descriptions (continued)

Field	Description
17 RXEN	LFAST Receiver Enable This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave hardware on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
27 TXARBD	Tx Arbiter Disable This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
30 DRFRST	LFAST Soft Reset This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

66.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Offset: 0x0004 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Only writable when MCR[DRFEN] = 0.

Figure 1337. Speed Control Register (SCR)

Table 1319. SCR field descriptions

Field	Description
15 DRMD	Data Rate Controller mode Defines the mode set for LFAST slave device by the software or the LFAST master. This bit should not be modified by the software and left as SCR[DRMD] =1.
23 RDR	Receiver Data Rate This bit defines the receiver data rate. This bit should not be modified by the software.
31 TDR	Transmit Data Rate This bit defines the transmitter data rate. This bit should not be modified by the software.

66.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SMPSEL(1)								0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

1. Only writable only when MCR[RXEN] = 0.

Figure 1338. Correlator Control Register (COCR)

Table 1320. COCR field descriptions

Field	Description
0:7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection) Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 0x00 Sampler Data Path selected by correlator 0x01 Sampler Data Path 0 selected 0x02 Sampler Data Path 1 selected 0x04 Sampler Data Path 2 selected 0x08 Sampler Data Path 3 selected 0x10 Sampler Data Path 4 selected 0x20 Sampler Data Path 5 selected 0x40 Sampler Data Path 6 selected others Sampler Data Path 7 selected
28:30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation …. 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 0 8 phases 1 4 phases

66.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Offset: 0x000C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R/W	LPFRMTH[(1)]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Writable only when TMCR[LPON] = 0.

Figure 1339. Test Mode Control Register (TMCR)

Table 1321. TMCR field descriptions

Field	Description
6 CLKTST	Clock Test mode The software can define when the clock test mode is enabled. This bit can also be set and cleared by hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable The software can define when the loopback logic is enabled. This bit can also be written by LFAST slave hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled. 0 Loopback mode is disabled.
13:15 LPMOD	Loopback mode Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by the software)
16:31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Check 1 frame have correct sync, header and payload. … 0xFFFE: Check 65534 frames have correct sync, header and payload. 0xFFFF: Check 65535 frames have correct sync, header and payload.

66.6.2.5 Auto Loopback Control Register (ALCR)

Offset: 0x0010 Access: User read/write

R/W	LPFMCNT(1)															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Writable only when TMCR[LPON] = 0.

Figure 1340. Auto Loopback Control Register (ALCR)

Table 1322. ALCR field descriptions

Field	Description
15 LPCNTEN	Auto Loopback Frame Transmission Count Enable Enables fixed number of auto predefined loopback frame transmission. 0 Infinite predefined loopback frame transmission enabled 1 Fixed count of predefined loopback frame transmission enabled
16:31 LPFMCNT	Auto Loopback Frame Transmission Count Defines the number of predefined auto loopback frames to be sent. The predefined loopback frame has payload CBh, header 13h and valid sync. This mode is valid if TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Send 1 frame with correct sync, header and payload. ... 0xFFFE: Send 65534 frames with correct sync, header and payload. 0xFFFF: Send 65535 frames with correct sync, header and payload.

66.6.2.6 Rate Change Delay Control Register (RCDCR)

Offset: 0x0014 Access: User read/write

1. Only writable when MCR[DRFEN] = 0.

Figure 1342. Wakeup Delay Control Register (SLCR)

Table 1324. SLCR field descriptions

Field	Description
0:7 HSCNT	High Speed Sleep mode Exit Time Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. 0x00: cycle 0x01: 1 cycle … 0x12: 18 cycles (200 ns + 8 cycles of High speed clock) … 0xFE: 254 cycles 0xFF: 255 cycles
12:15 LSCNT	Low Speed Sleep mode Exit Time Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. 0x0: 0 cycle 0x1: 1 cycle (200ns + 1 cycle of Low speed clock) … 0xE: 14 cycles 0xF: 15 cycles
16:23 HWKCNT	Wake Up time for the LD Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. 0x00: 0 cycles 0x01: 1 cycle … 0x5F: 95 cycles (1.18 us) … 0xFF: 255 cycles Maximum
28:31 LWKCNT	Wake Up time for the LD Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. 0x0: 0 cycle 0x1: 1 cycle 0x2: 2 cycles (1.18 us) … 0xE: 14 cycles 0xF: 15 cycles

66.6.2.8 Ping Control Register (PICR)

Offset: 0x0020 Access: User read/write

W																
Reset	1	0	0	0	0	0	0	0	1	1	0	0	1	0	1	0

1. Set by user software and cleared by system hardware.
2. Only writable when MCR[DRFEN] = 0.

Figure 1343. Ping Control Register (PICR)

Table 1325. PICR field descriptions

Field	Description
15 PNGREQ	Ping Response Frame Request This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. This field can only be written when MCR[DRFEN] = 1. 1 Ping response frame transmission request is queued. 0 No pending Ping response frame transmission request.
16 PNGAUTO	Ping Response Enable Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master This bit should not be modified by the software.
24:31 PNGPYLD	Defines the LFAST slaves ping reply frame payload content.

66.6.2.9 PLL Control Register (PLLCR)

This register exists only when LFAST controls an external PLL.

Offset: 0x003C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1345. LVDS Control Register (LCR)

Table 1327. LCR field description

Field	Description
8 SWWKLD	Software signal to take LVDS LD out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep).
9 SWSLPLD	Software signal to put LVDS LD into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep.
10 SWWKLR	Software signal to take LVDS LR out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep).
11 SWSLPLR	Software signal to put LVDS LR into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up).
12 SWOFFLD	Software signal to turn OFF the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.

Table 1327. LCR field description (continued)

Field	Description
13 SWONLD	Software signal to turn ON the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
14 SWOFFLR	Software signal to turn OFF the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
15 SWONLR	Software signal to turn ON the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode.
17 LVTXOE	LVDS LD output buffer enable 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad.
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only). 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only). 0 Use for LFAST receiver baud rates less than maximum baud rate 1 Required for LFAST receiver maximum baud rate
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection 0 Micro-Second Bus selection 1 LFAST Bus selection

Table 1327. LCR field description (continued)

Field	Description
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 Normal clock used to sample the LVDS data 1 Adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

Figure 1355. Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Table 1337. UNSRDR8–UNSRDR0 field descriptions

Field	Description
0:31 UNRXD	Unsolicited Receive Data This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288-bit payload.

66.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements (Refer to the “Functional safety” chapter for register classification details). All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

66.7 Functional description

66.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

66.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCR are programmed according to the LVDS parameter in the device datasheet.
2. The PLLCR[t] is programmed with the configuration parameters of the PLL.
3. The LCR is programmed with the configuration parameters of the LVDS.
4. MCR[DATAEN] field is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 0x31 is received the hardware writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 0x00 frame is received and the hardware writes RIISR[ICPRF] = 1.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 0x02 is received and the hardware writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 0x80 is received and the hardware writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 0x10 is received and the hardware writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 0x00 is received and the hardware writes RIISR[ICPRF] = 1.

66.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

LFAST interface enable (lfast_sysclk_en) negation:

t. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then the software writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

1. The LD LVDS pad is power up, if all conditions are met:
   – LCR[SWOFFLD] = 0.
   – LCR[SWONLD] = 1.
   – MCR[TXEN] = 1.
   – When frame ICR[ICLCPLD] = 0x31 is received.
2. LR LVDS pad is powered up if all conditions are met:
   – LCR[SWOFFLR] = 0.
   – LCR[SWONLR] = 1.
   – MCR[RXEN] = 1.

66.7.3 Line Receiver (LR)

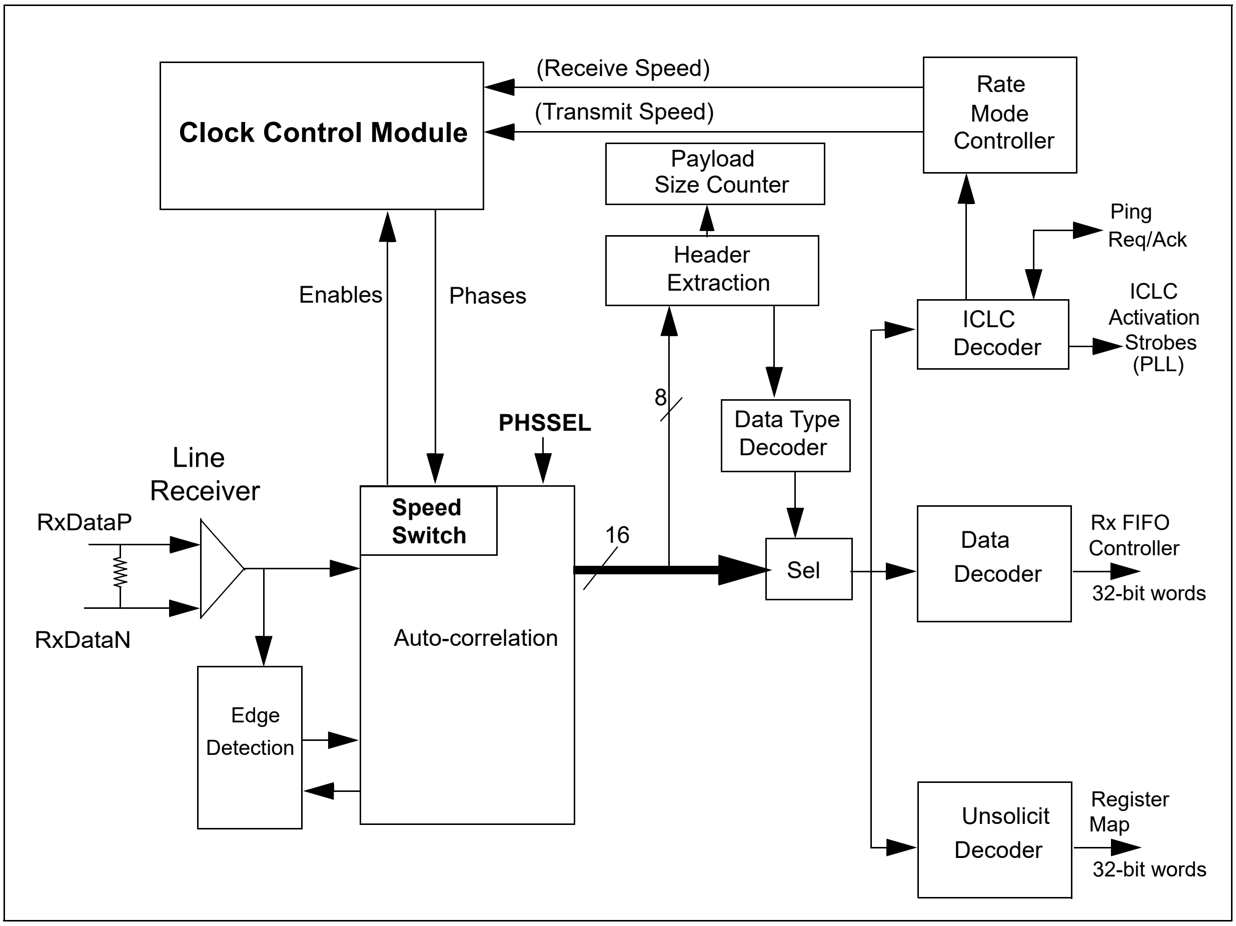
66.7.3.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto-correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 1356 shows the block diagram of Uplink controller.

Figure 1356. Top level receive controller



66.7.3.2 Edge-detection and auto-correlation

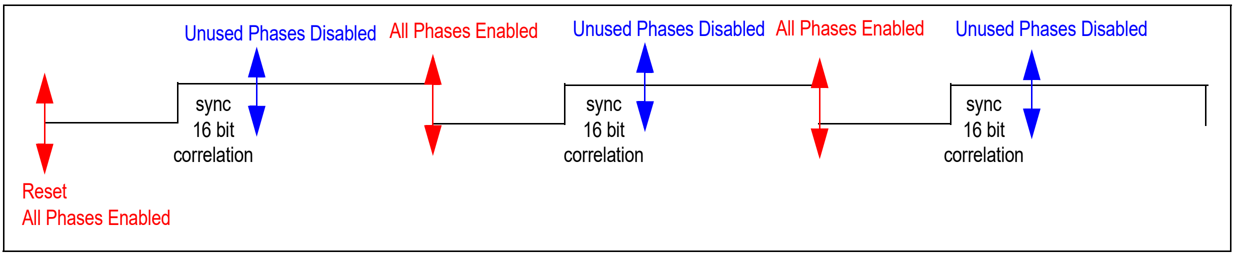
The edge-detection and auto-correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

66.7.3.2.1 Auto-correlation modes

66.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 1357. Hunt correlation mode



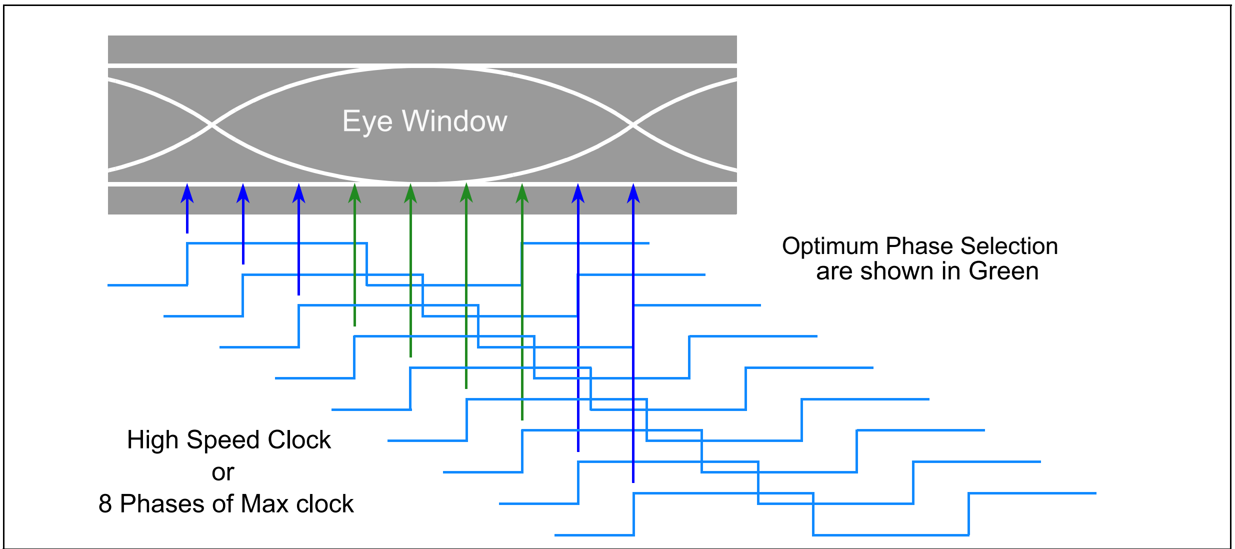
66.7.3.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

66.7.3.2.3 Auto-correlation

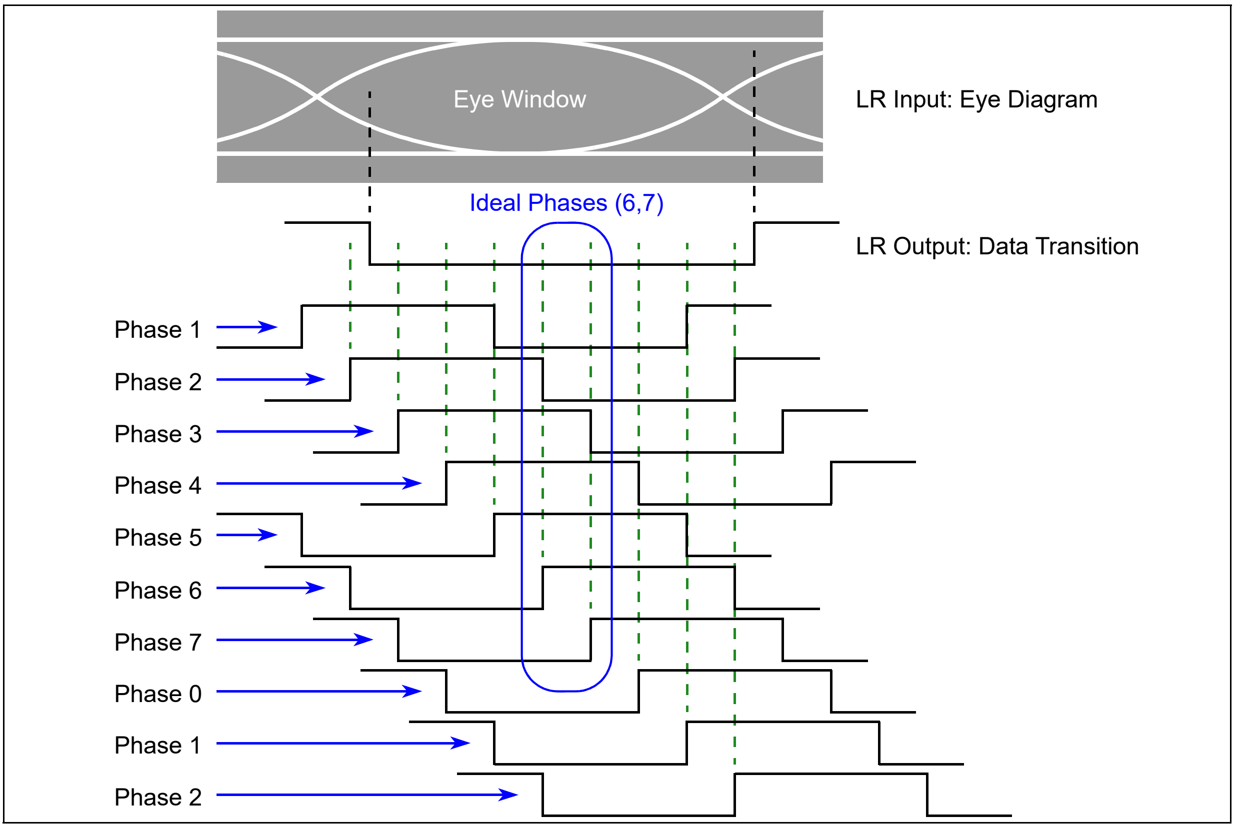
The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto-correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in *Figure 1358*.

Figure 1358. High speed 8 phase selection



The objective of the auto-correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in *Figure 1359*.

Figure 1359. High speed 8 phase clock alignment example



Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in *Figure 1360* and *Figure 1361*.

Figure 1360. High speed 4 phase clock alignment example

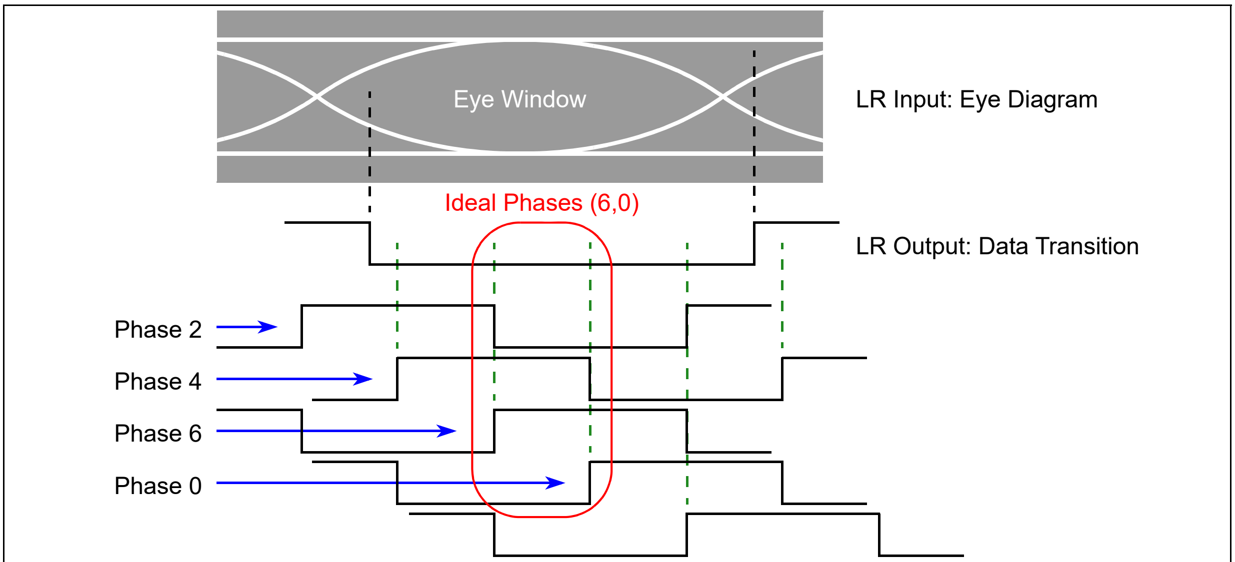


Figure 1361. Low speed 4 phase clock alignment example

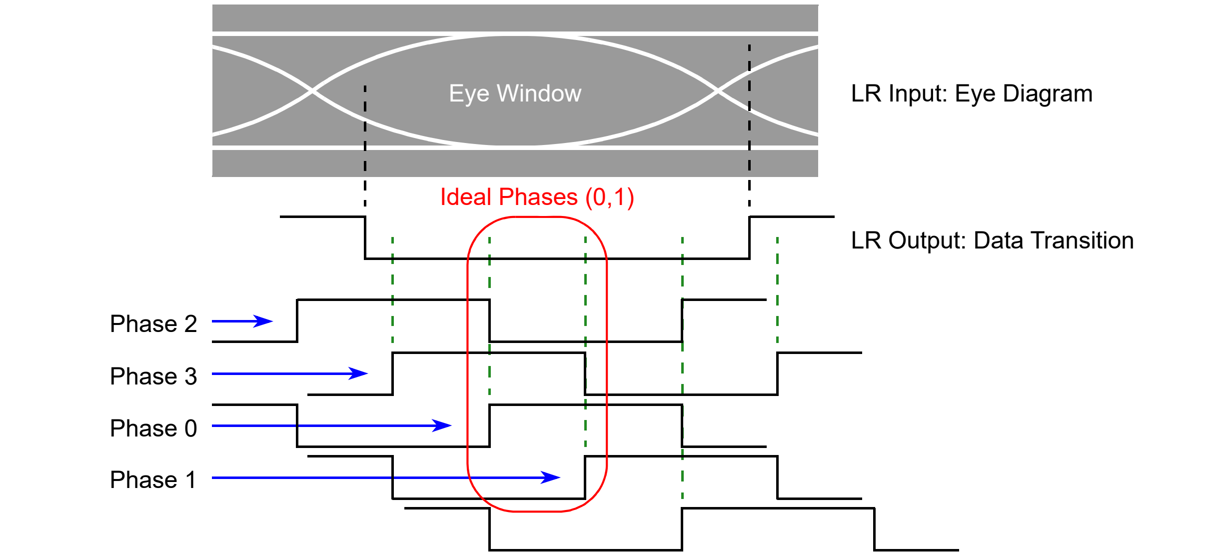


The auto-correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to an intermediate phase as shown in *Table 1338*, *Table 1339*, and *Table 1340* before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 1338. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0

Table 1338. High speed 8 phase selection - sampling procedure (continued)

Samplers	Initial Sample	Intermediate Sample	Final Sample
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 1339. High speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See *Table 1339*, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 1340. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See *Table 1340*, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

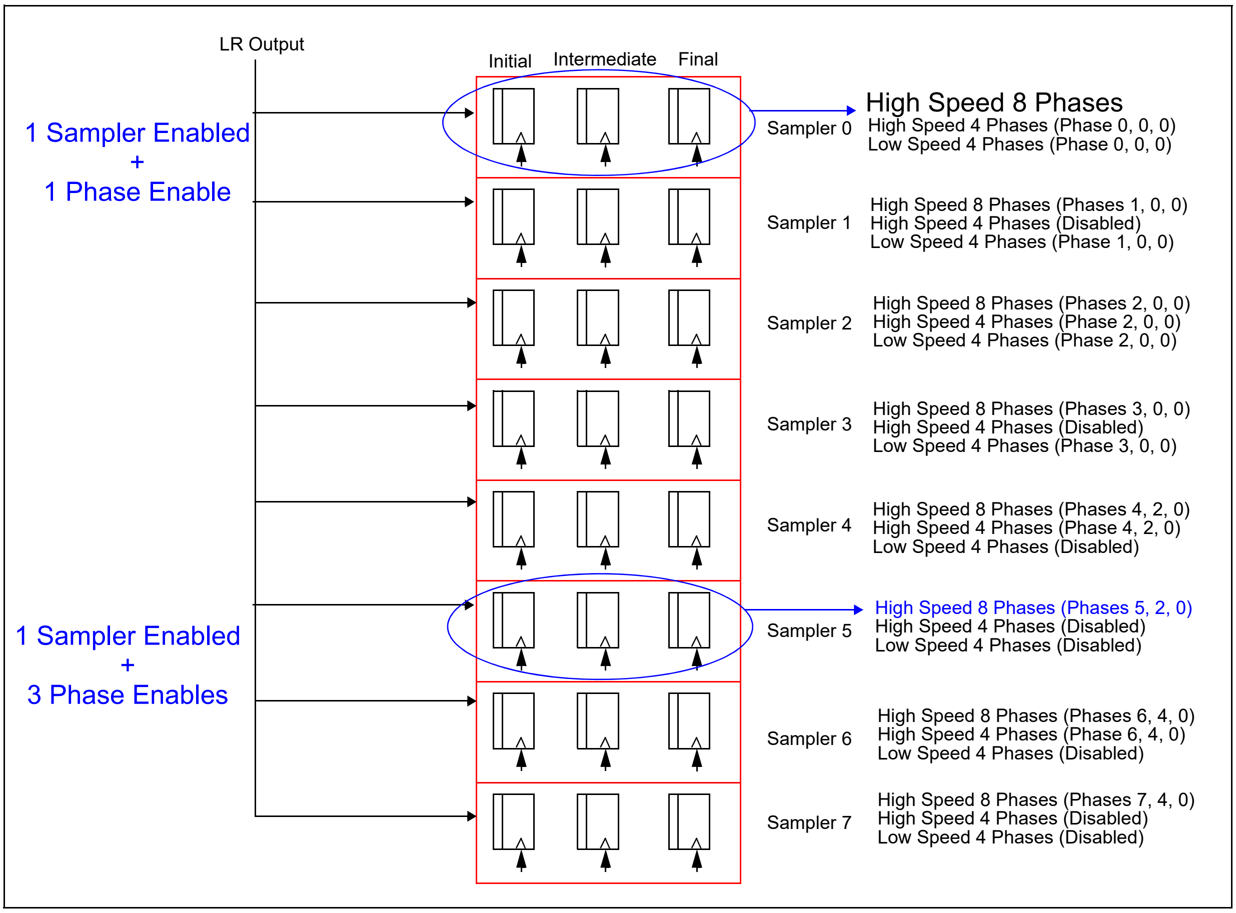
66.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto-correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in *Figure 1362*.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for instance Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

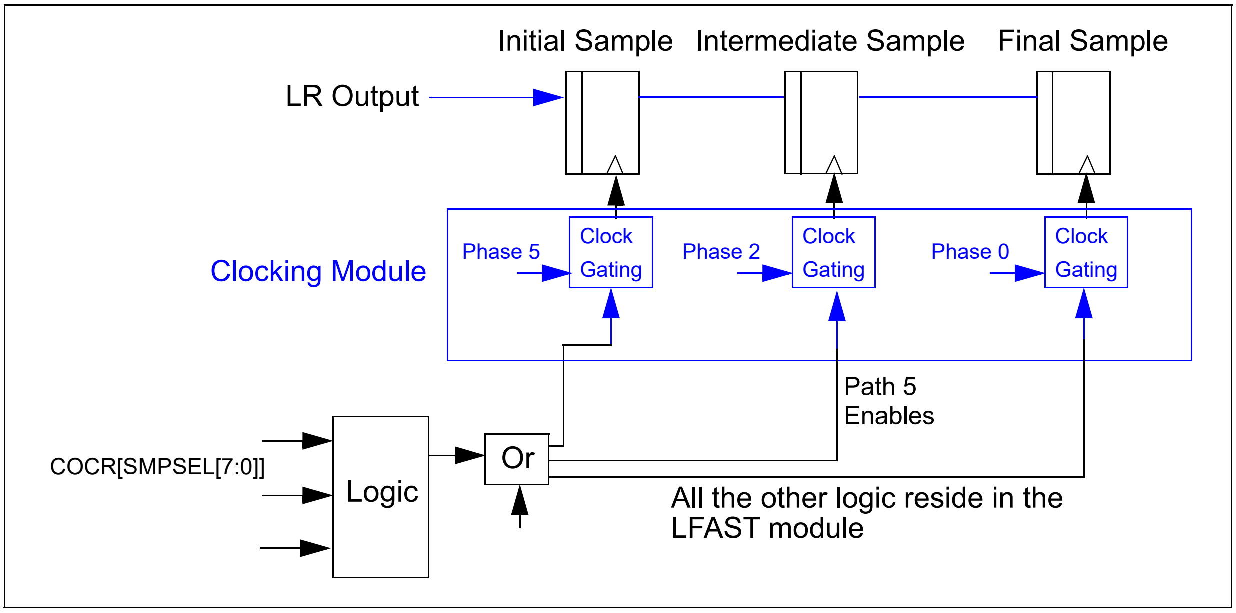
Figure 1362. Samplers, each sampler has 3 registers



In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in *Figure 1363*.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

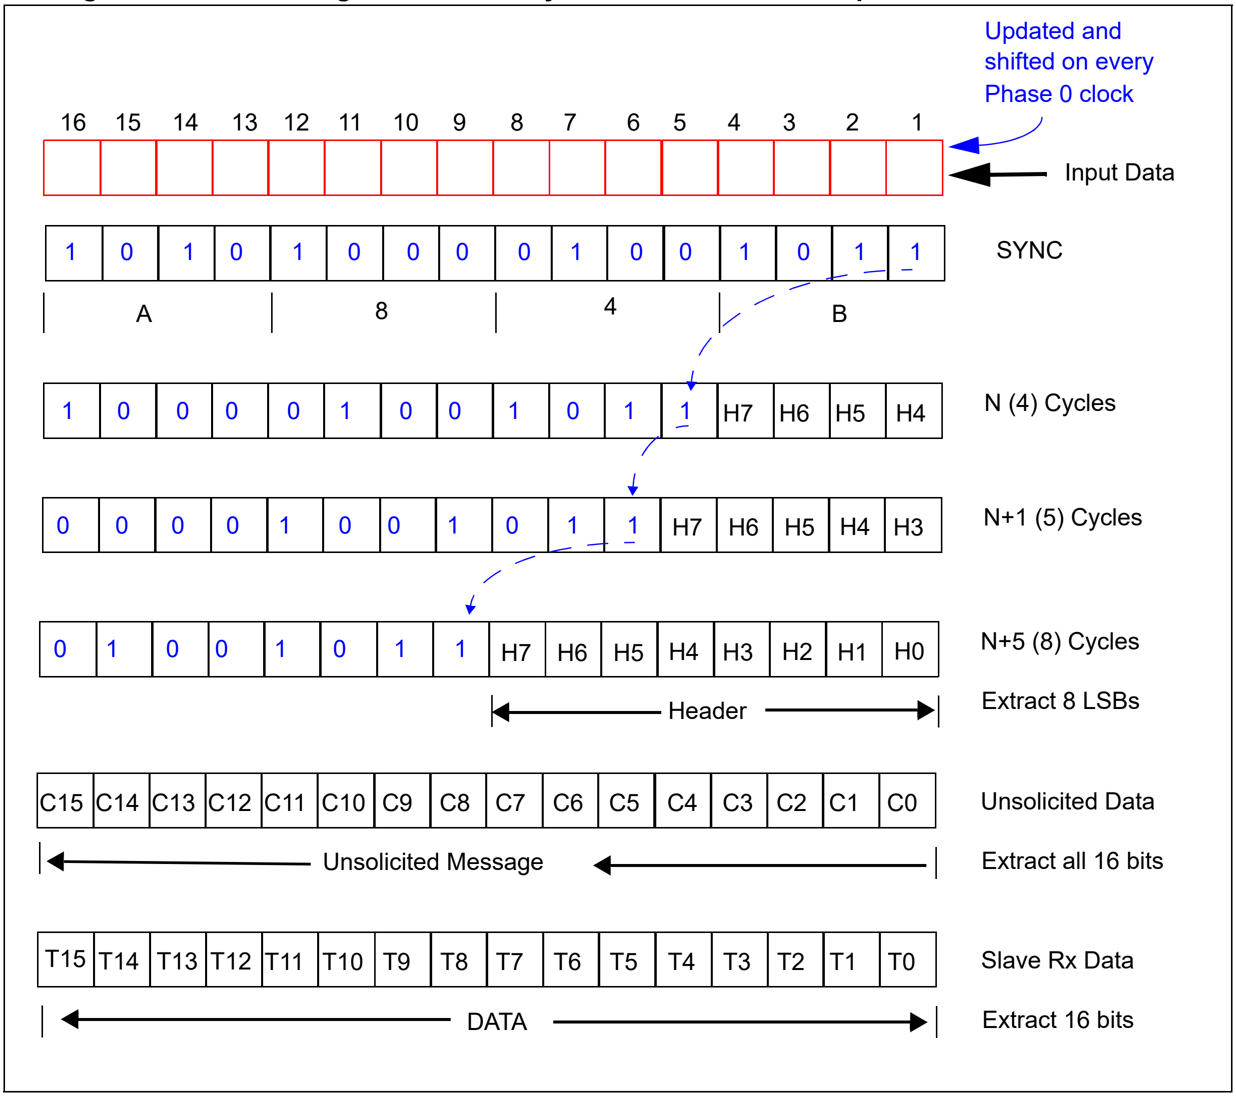
Figure 1363. Sampler 5 Logic



66.7.3.3 Header and Payload extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16-bit word, bit shifted every Phase 0 clock as shown in *Figure 1364*.

Figure 1364. Extracting Header and Payload from the 16-bit output from Auto-correlation



66.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown
  The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep
  The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- Normal
  In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 1341. Line Receiver state

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

66.7.4 Transmit controller

66.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, such as unsolicited, ICLC, ping. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

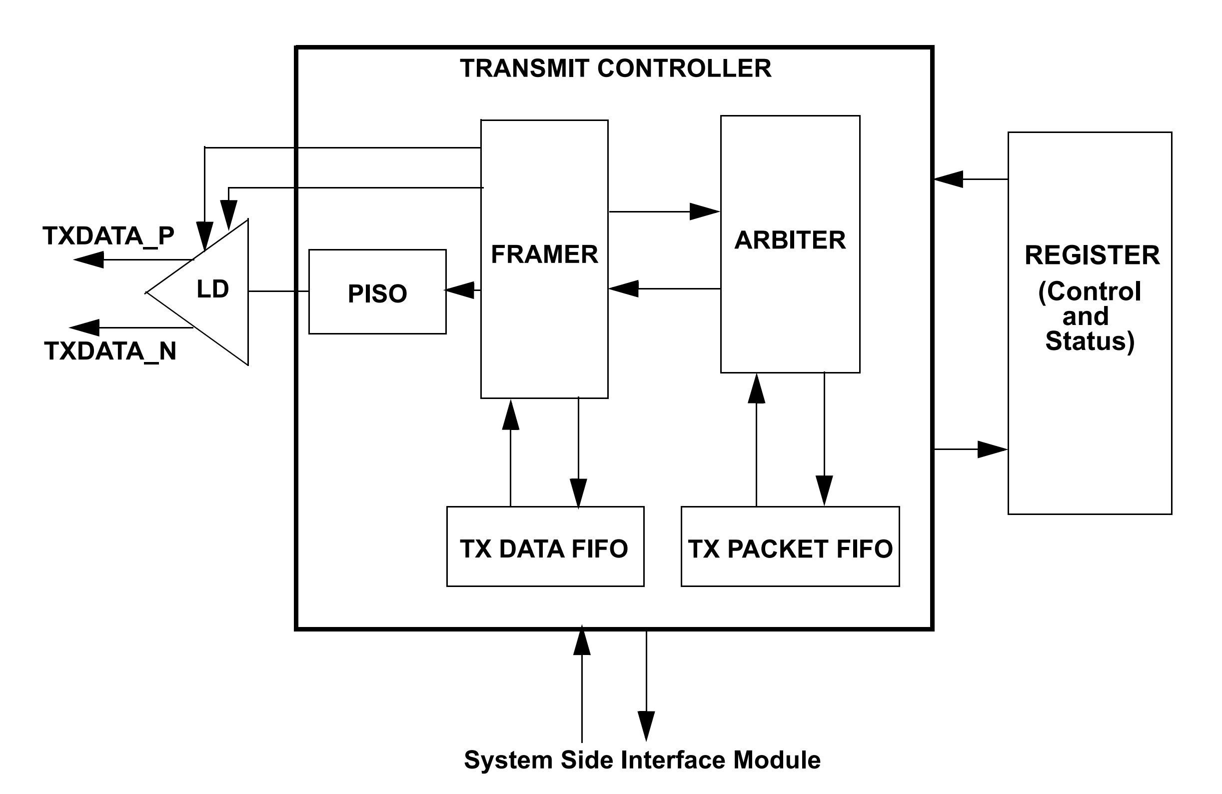
- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in *Figure 1365*.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 1365. Transmit controller connections



66.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- Software programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in *Table 1342*.

Table 1342. Priority levels for the Transmit controller

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 1342. Priority levels for the Transmit controller (continued)

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

Table 1343. Line driver states

LD state	LFAST slave triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

66.7.5 Frames supported

Table 1344 provides the frames supported and their permissible payload sizes

Table 1344. Frames supported by LFAST interfaces

Frame type	LCT code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload size (bits)
Data frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited frame	0001b	YES	YES	8, 32, 64, 96, 128, 256, 288
ICLC frame	0000b	YES	NO(1)	8
CTS frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

66.7.6 Frame flow

The following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

66.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

66.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

66.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.

66.7.6.1.2 Data receive

LFAST master and slave support reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

66.7.6.2 Unsolicited flow

66.7.6.2.1 Unsolicited frame transmit flow

The software is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

66.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the *Mode Configuration Register (MCR)* to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   – If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     – UNSTCR[USNDRQ] = 0
     – TISR[TXUNSF] = 1.
   – If UNSTCR[USNDRQ] = 0 then:
     – Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     – Program the unsolicited frame header in UNSTCR[UNSHDR].
     – Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

66.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

66.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

66.7.6.3.1 .ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

66.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The software can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame.The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

66.7.6.3.1.2 Start PLL ICLC

The Start PLL ICLC command will write bit RIISR[ICPONF] = 1.

66.7.6.3.1.3 Stop PLL ICLC

The Stop PLL ICLC command will write RIISR[ICPOFF] = 1.

66.7.6.3.1.4 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

66.7.6.3.1.5 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

66.7.6.3.1.6 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or software programs MCR[TXEN] = 1.

66.7.6.3.1.7 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

66.7.6.3.1.8 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

66.7.6.3.1.9 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

66.7.7 Test and debug support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

66.7.7.1 Loopback test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for software should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 1345. Loopback modes

LPMOD[2:0]	Mode selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by the software, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

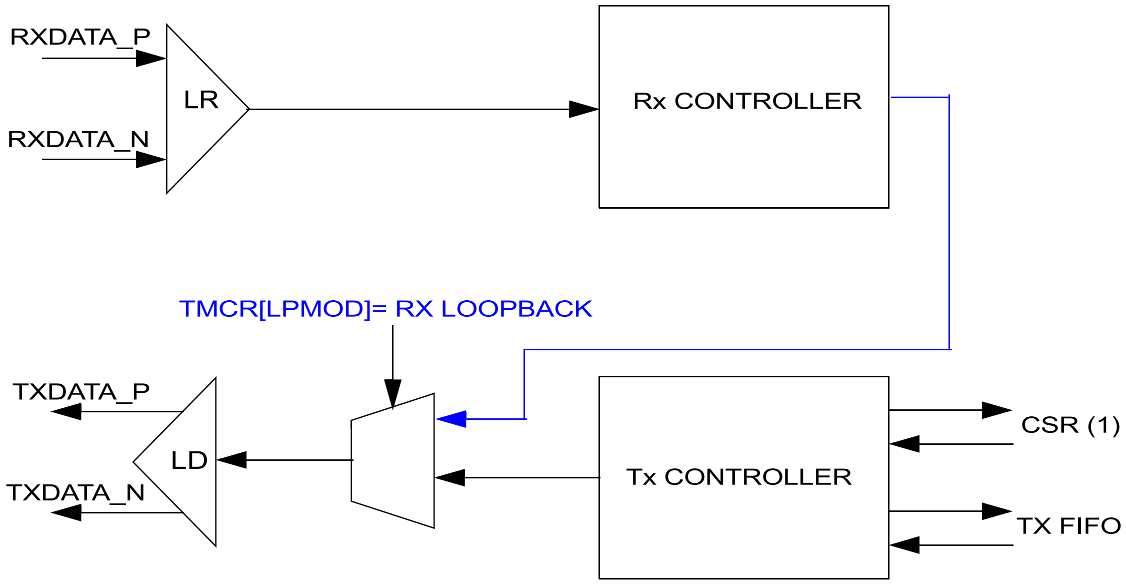
In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

66.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 1366. Rx Loopback mode



1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx Loopback mode:

1. Software programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload 0xFF (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

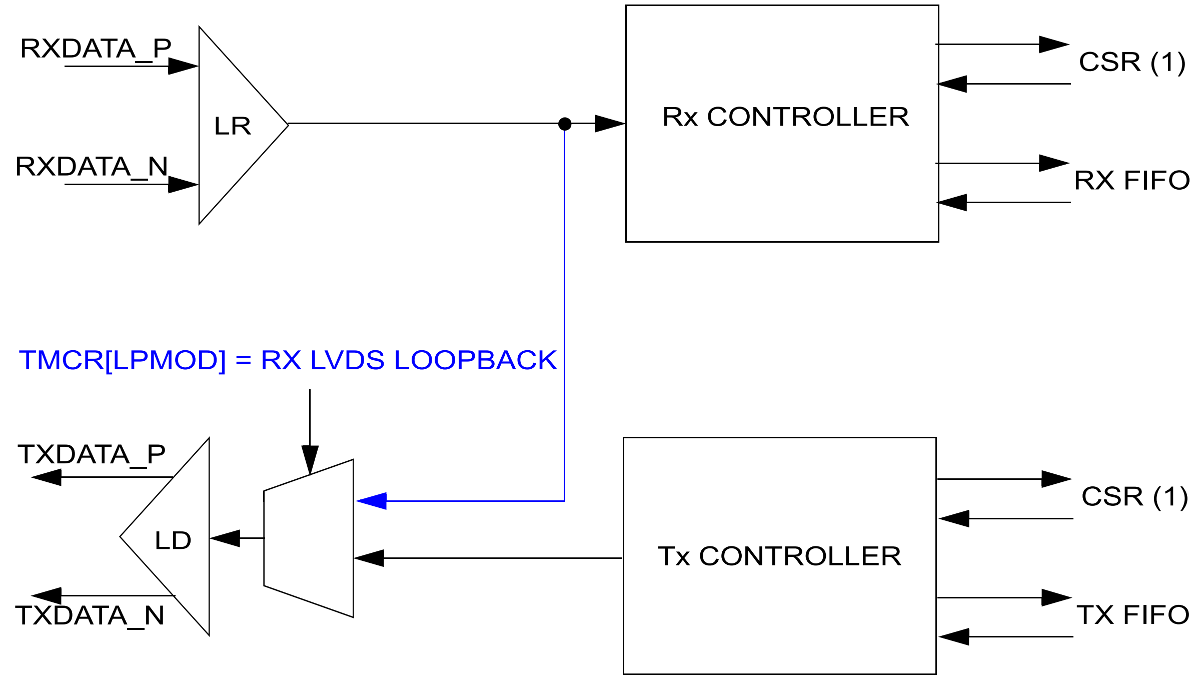
- Software programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 0x38 (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

66.7.7.1.2 Rx LVDS Loopback mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 1367. Rx LVDS LoopBack mode



1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx LVDS Loopback mode:

1. Software programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   – The software writes TMCR[LPON] = 1.
   – For Slave Only: - Reception of ICLC Frame with Payload = 0xFF (Loopback mode ON), from LFAST Master.

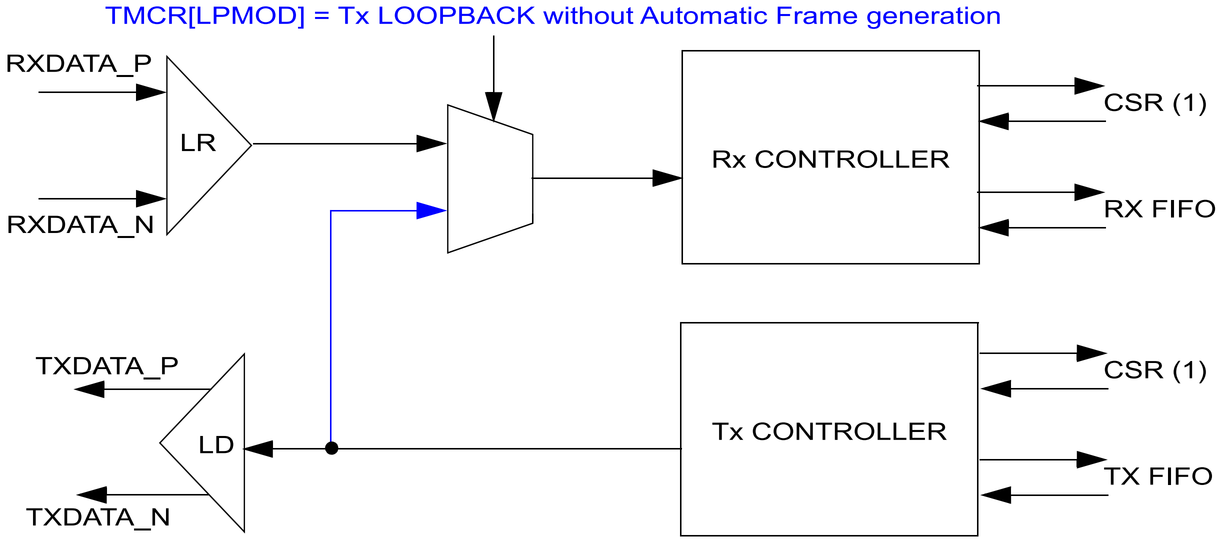
Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave:
  – Transmission of ICLC frame with payload 0x38 (Test mode off), from LFAST Master.
  – Deassertion of the LFAST interface enable (lfast_sysclk_en).

66.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 1368. Tx LoopBack mode without automatic frame generation



1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback without Automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

66.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal software intervention.

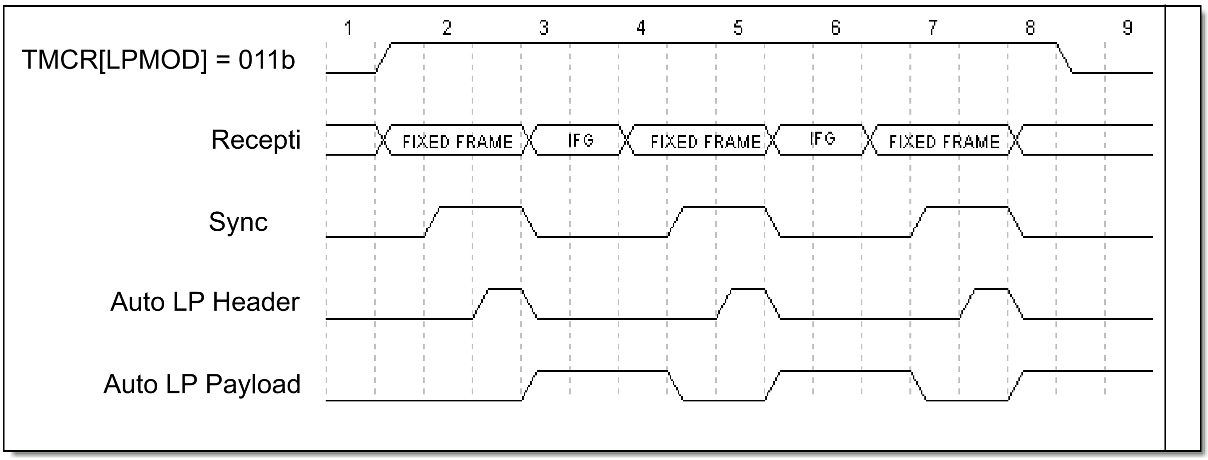
The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 0x13 received.
- GSR[LPCPDV]: Frame with Payload of 0xCB received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 1369. Automatic Loopback test status signal timings



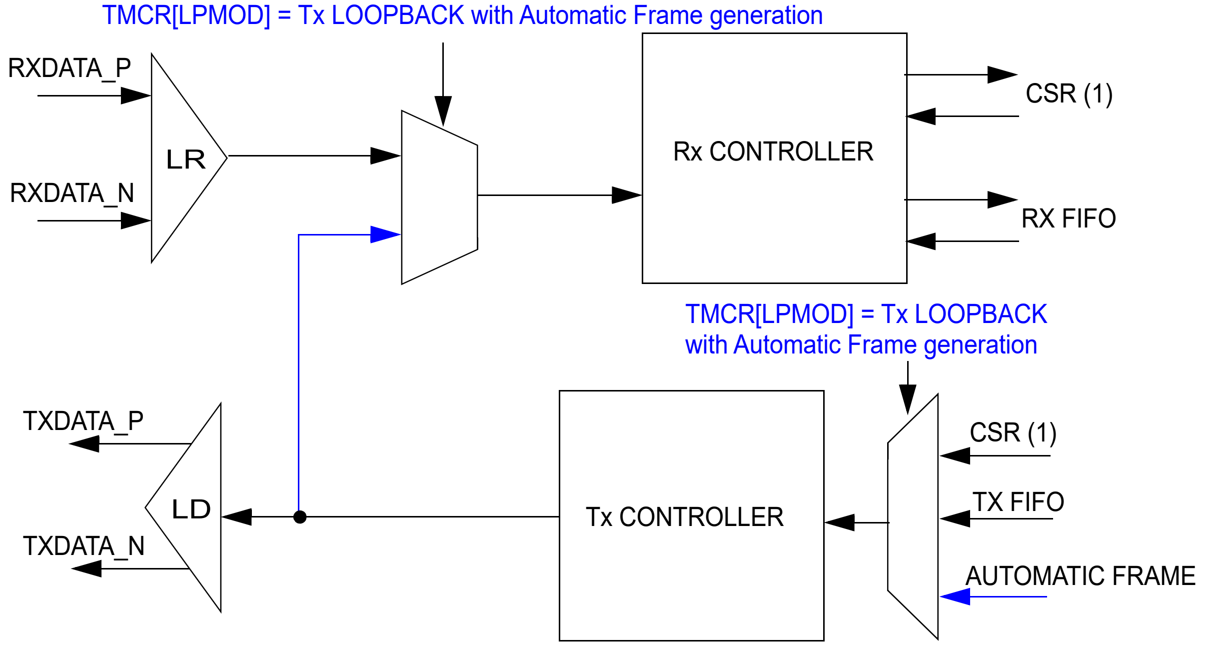
The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

66.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the software. The frames generated have fixed header of 0x13 and payload of 0xCB. The successful reception of this frame is indicated by the status signals and registers.

Figure 1370. Tx LoopBack mode with automatic frame generation



1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from the LFAST Master.

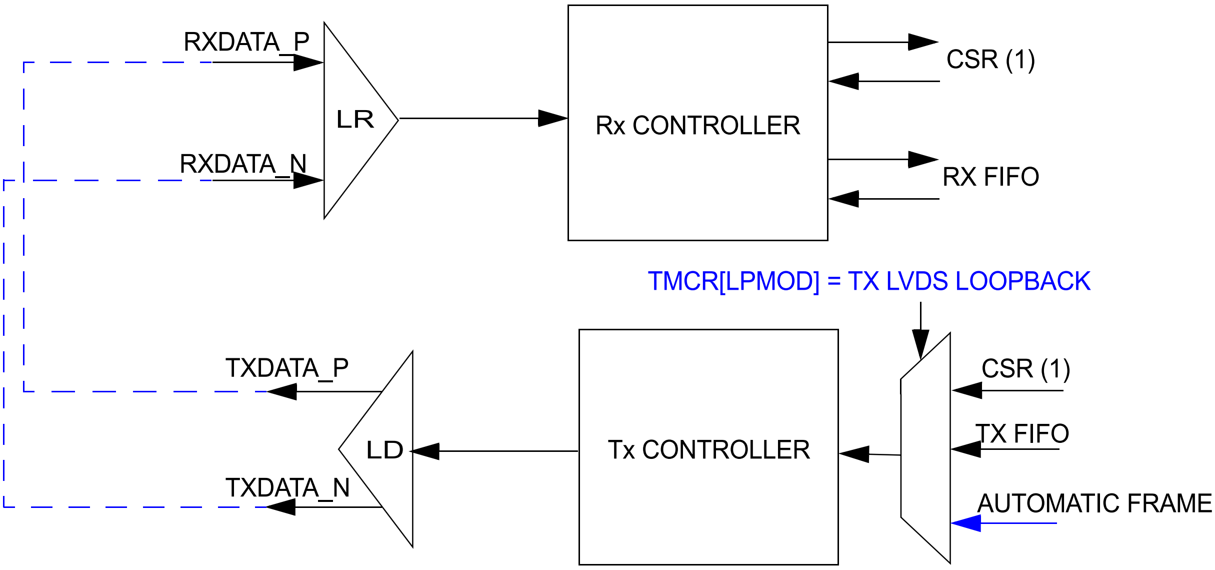
Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

66.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 1371. Tx LVDS Loopback (external) mode with automatic frame generation



1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx LVDS loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

66.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- Software programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 0x34 (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be canceled by any of the following methods:

- Software programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

66.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 1346. Frames supported by LFAST interfaces

Frame type	Tx buffer (in bits)	Rx buffer (in bits)	Memory type
Data frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC frame	N/A	1 × 8 max 1 packet(1)	Registers PICR[PNGPYLD]
CTS frame	N/A	N/A	N/A

1. Ping response packet.

66.9 Resets

The various blocks in LFAST are reset as described in *Table 1347*.

Table 1347. Recommended receive exception handling mechanism

Reset	Blocks reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of *Mode Configuration Register (MCR)*	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space

Table 1347. Recommended receive exception handling mechanism (continued)

Reset	Blocks reset
DRFEN bit of *Mode Configuration Register (MCR)*	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

66.10 Clocks

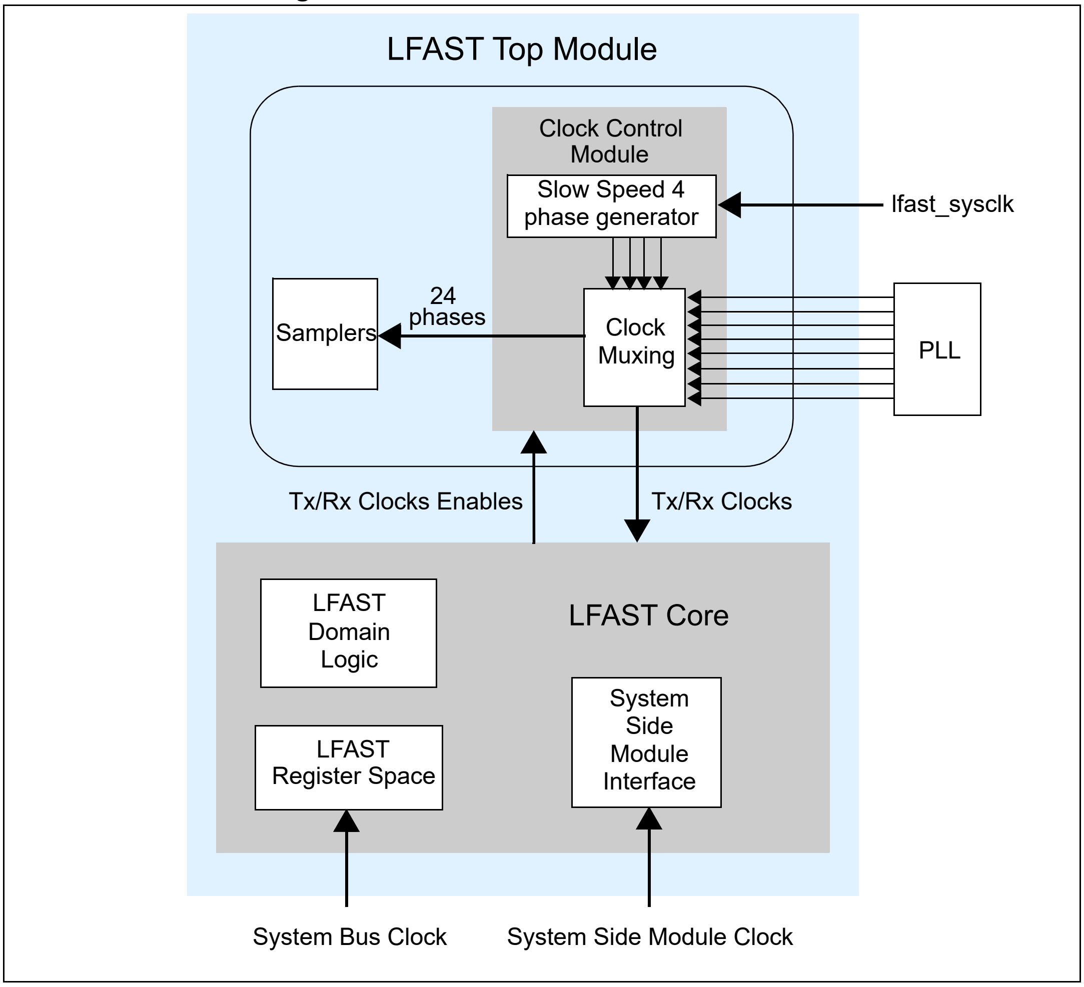
The LFAST mainly works on three clocks:

- System Bus Clock, used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

66.10.1 Clocking strategy

Figure 1372 shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 1372. LFAST module clock domains

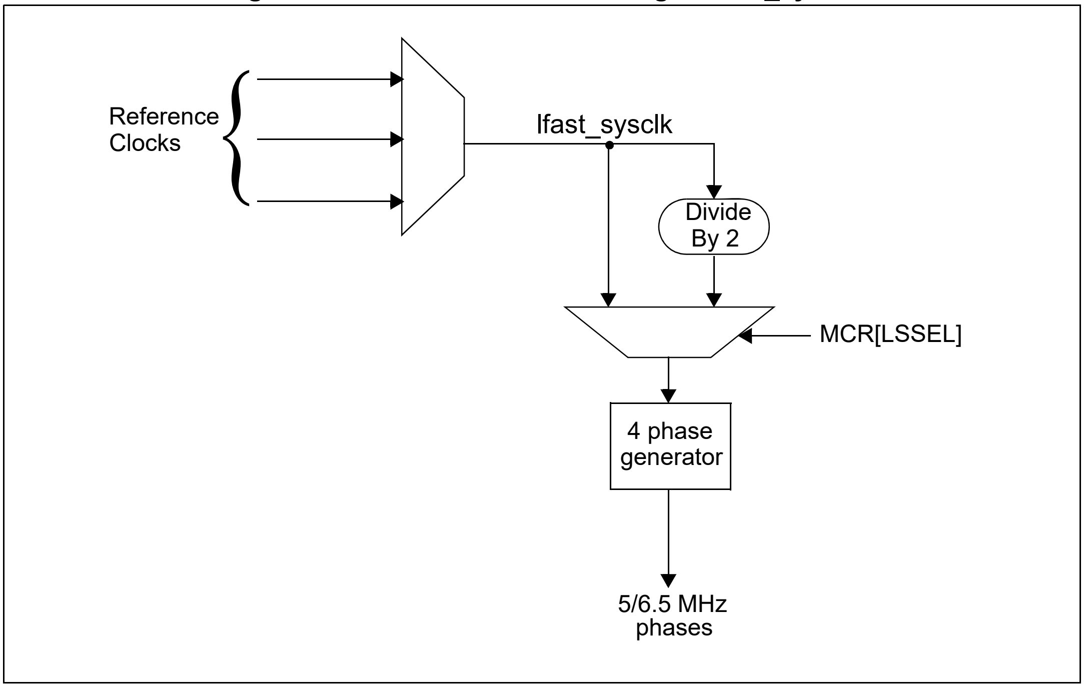


66.10.2 Slow speed clock

66.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in *Figure 1373*, *Figure 1374* and *Figure 1375*.

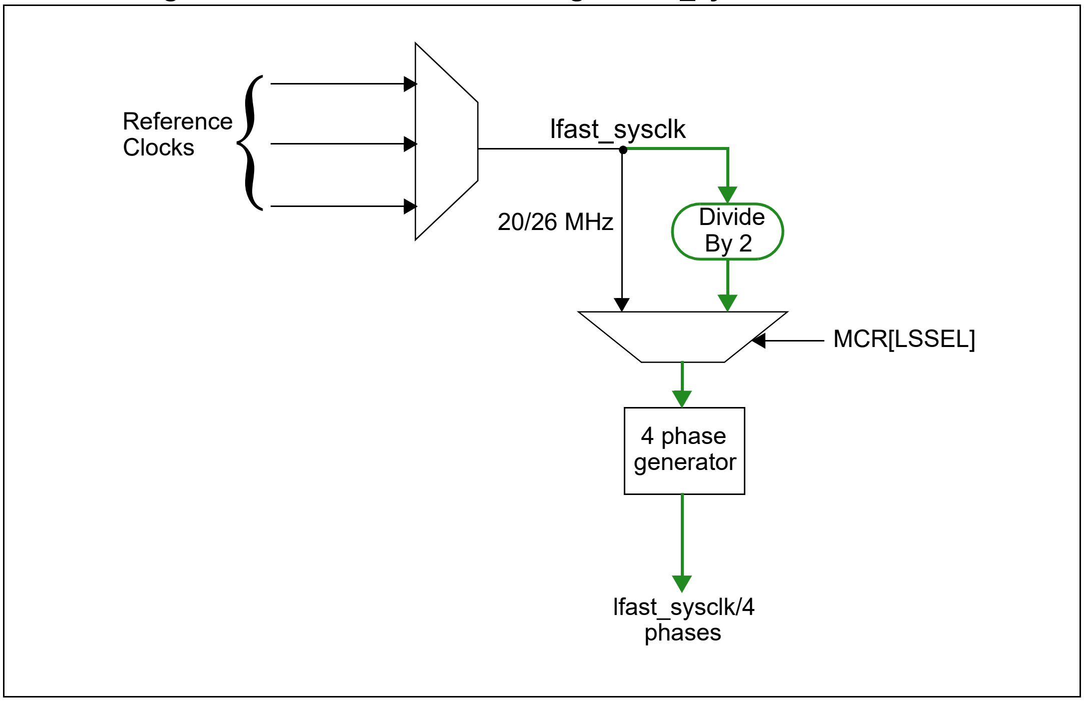
Figure 1373. External clock muxing of lfast_sysclk



All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in *Figure 1373*.

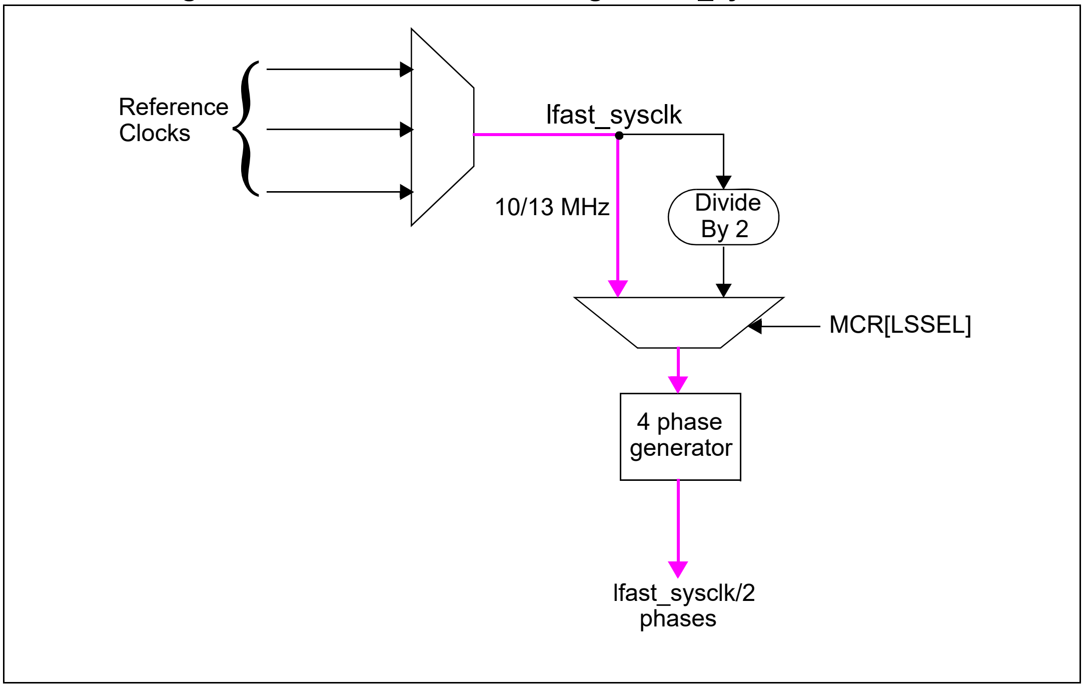
The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 1374* (selected clock path shown in green).

Figure 1374. External clock muxing of lfast_sysclk of 20/26 MHz



In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 1375* (selected clock path selected shown in magenta).

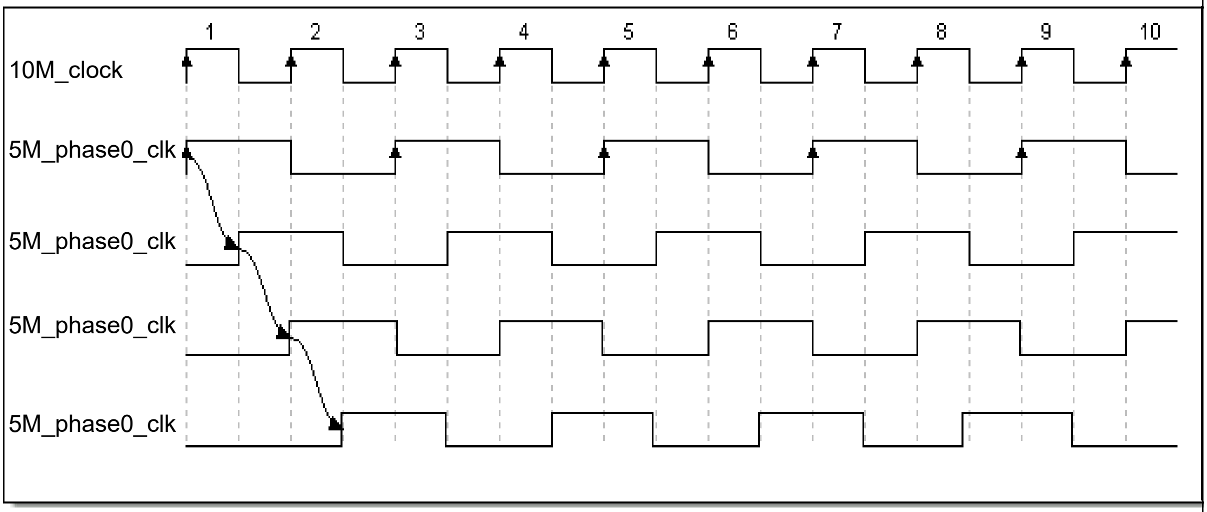
Figure 1375. External clock muxing of lfast_sysclk of 10 MHz



66.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. *Figure 1376* Shows 4 phases getting generated using lfast_sysclk.

Figure 1376. Slow speed 4 phases generation

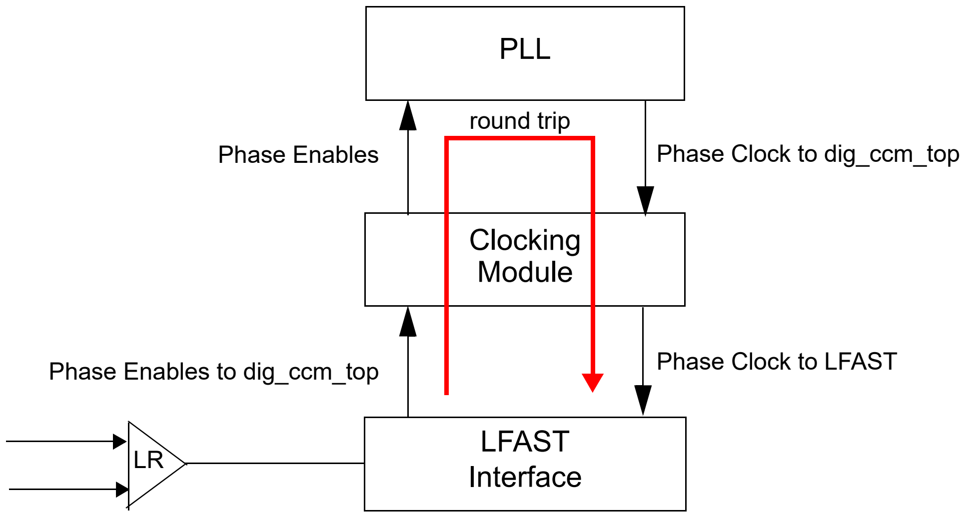


66.10.3 Rx controller clocks

66.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in *Figure 1377*.

Figure 1377. Clock enables and clock paths



The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

66.10.3.2 Clock module requirements for low speed phases

66.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 1348. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

66.10.4 Tx controller clocks

66.10.4.1 Clocking module requirements for speed phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See *Table 1349*.

The Tx phase 0 clock is enabled when all the resets are negated.

67 Development Trigger Semaphore (DTS)

67.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.

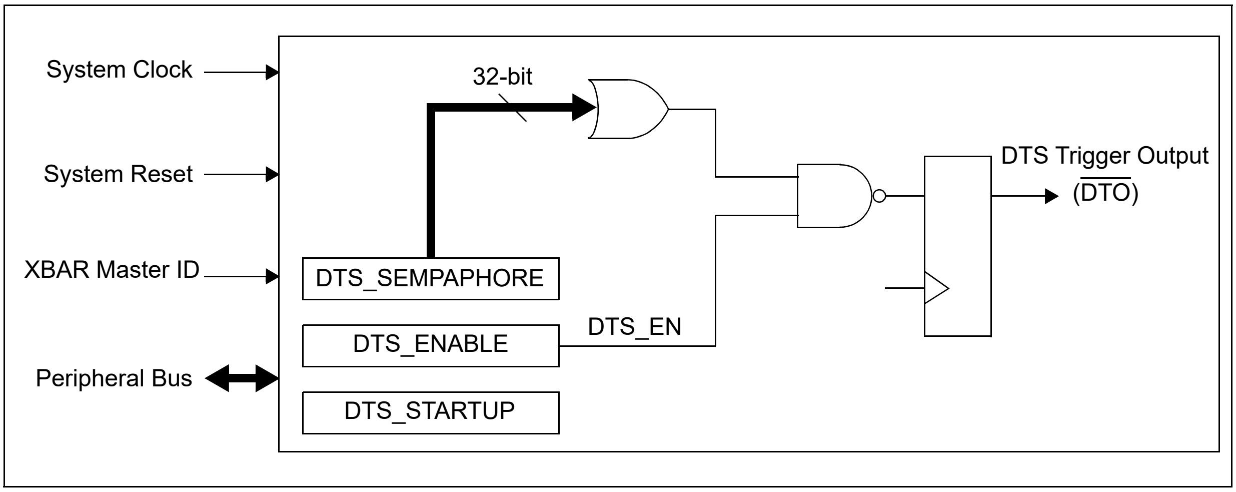
67.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal, DTS Trigger Output ($\overline{\text{DTO}}$). The registers are as follows:

- DTS_SEMAPHORE register: Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_STARTUP register: This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register: This register provides an enable/disable capability for the DTS feature.

The architecture is shown in *Figure 1379*.

Figure 1379. DTS block diagram

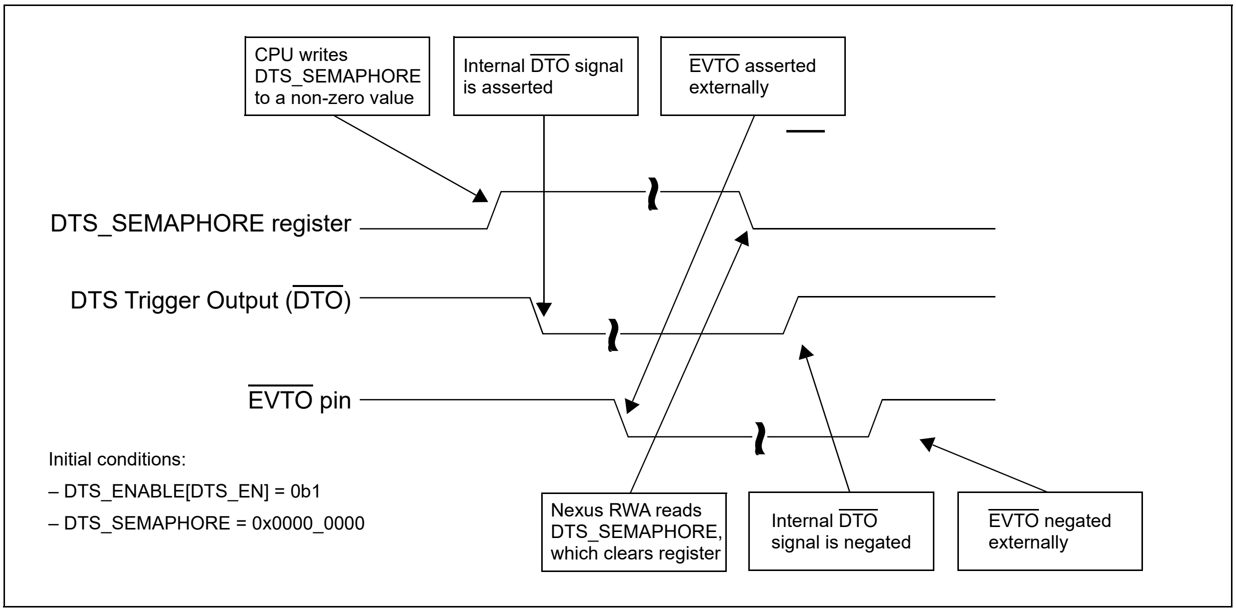


The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Debug and Calibration Interface (DCI). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 1380 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

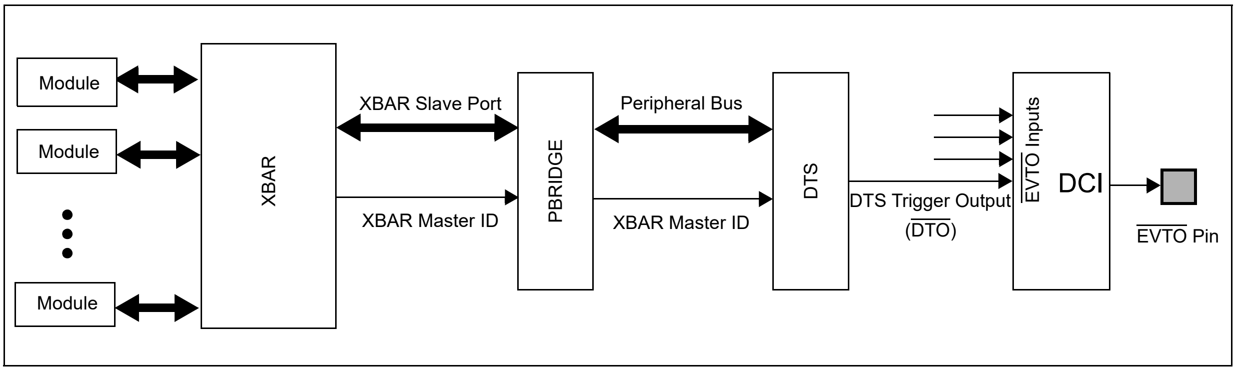
Figure 1380. DTO event sequence example



67.3 DTS device connections

Figure 1381 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 1381. DTS device connections



The registers have limited access as described in *Section 67.3.1: DTS register access*. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore register is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool or debug Zipwire can clear bits in the semaphore register (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access or debug Zipwire.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

67.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in *Table 1350*. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 1350. DTS register access effects

Register	32-bit read				32-bit write			
	RWA(1)	Core	eDMA	Other crossbar masters	RWA(1)	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear(2)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore register by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: The XBAR Master ID should not be confused with the Master Port number of the XBAR. See Chapter 17: Crossbar switch (XBAR), for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core or debug Zipwire. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

67.4 Memory map and register definition

Table 1351 shows the memory map of the DTS module registers.

Table 1351. DTS memory map

Offset address	Register name	Access	Reset Value	Location
0x0000	DTS Output Enable register (DTS_ENABLE)	Restricted R/W(1)	0x0000_0000	Section 67.4.1.1
0x0004	DTS Startup register (DTS_STARTUP)	Restricted R/W(1)	0x0000_0000	Section 67.4.1.2
0x0008	DTS Semaphore Register (DTS_SEMAPHORE)	Restricted R/W(1)	0xFFFF_FFFF	Section 67.4.1.3
0x000C	DTS Semaphore Extension (DTS_SEMAPHORE_B)	Restricted R/W(1)	0xFFFF_FFFF	Section 67.4.1.4

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

67.4.1 Register descriptions

67.4.1.1 DTS output enable register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. Figure 1382 shows the format of the DTS_ENABLE register. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA) or debug Zipwire.

Note: Access to the DTS_SEMAPHORE and DTS_STARTUP registers are unaffected by the state of this register.

Offset 0x0000 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

Figure 1382. DTS output enable register (DTS_ENABLE)

Table 1352. DTS_ENABLE field descriptions

Field	Description
30 DTS_EN_B	DTS Enable B Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
31 DTS_EN	DTS Enable Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

67.4.1.2 DTS startup register (DTS_STARTUP)

Figure 1383 shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA modules and other crossbar masters but can only be updated by a Nexus Read Write Access (RWA) or debug Zipwire.

Offset 0x0004 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. The DTS_STARTUP register can be read by the cores, the eDMA module and Nexusbut can only be updated by a Nexus Read Write Access (RWA).

Figure 1383. DTS startup register (DTS_STARTUP)

Table 1353. DTS_STARTUP field descriptions

Field	Description
0:31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access or debug Zipwire to update the contents of this register. **Note:** A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

67.4.1.3 DTS semaphore register (DTS_SEMAPHORE)

Figure 1384 shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Offset 0x08 Access: Restricted R/W

Figure 1385. DTS Semaphore extension register (DTS_SEMAPHORE_B)

Table 1355. DTS_SEMAPHORE_B field descriptions

Field	Description
0:31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

67.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

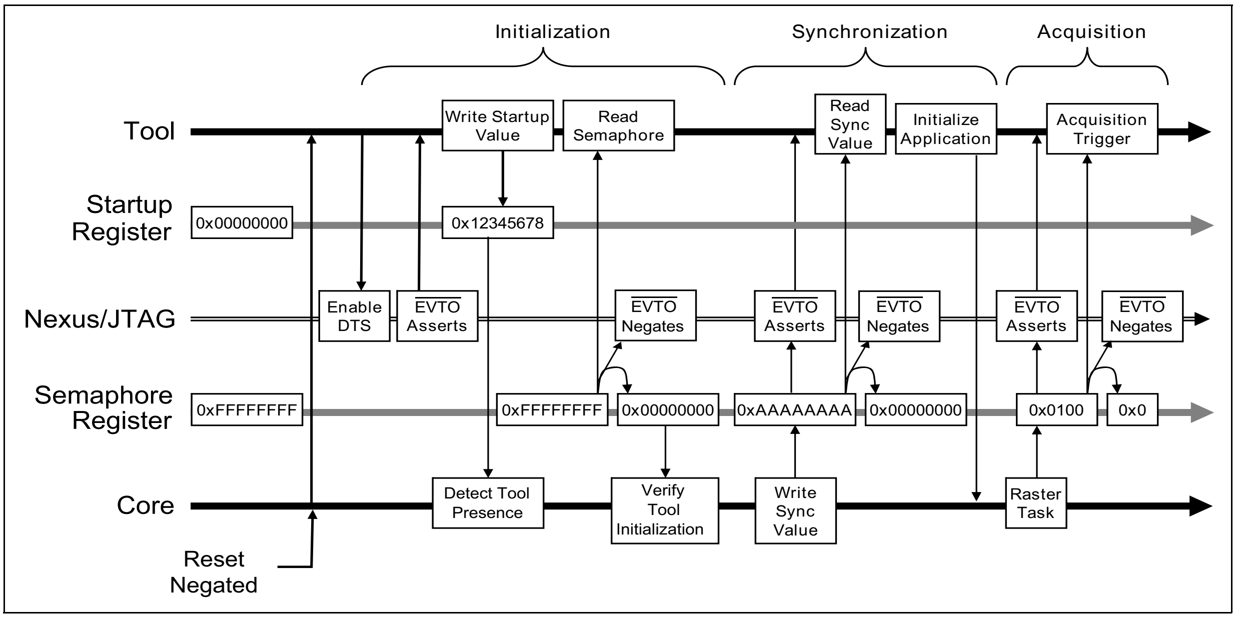
In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note: It is the user’s responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers *active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool not to receive every data set).*

Figure 1386 shows an example of DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA, all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 1386. DTS startup sequence example



68 Nexus Port Controller (NPC)

68.1 Information specific to this device

This section presents device-specific parameterization, customization, and feature availability information not specifically referenced in the remainder of this chapter.

68.1.1 Parameter values

The following table provides the parameter values for this device.

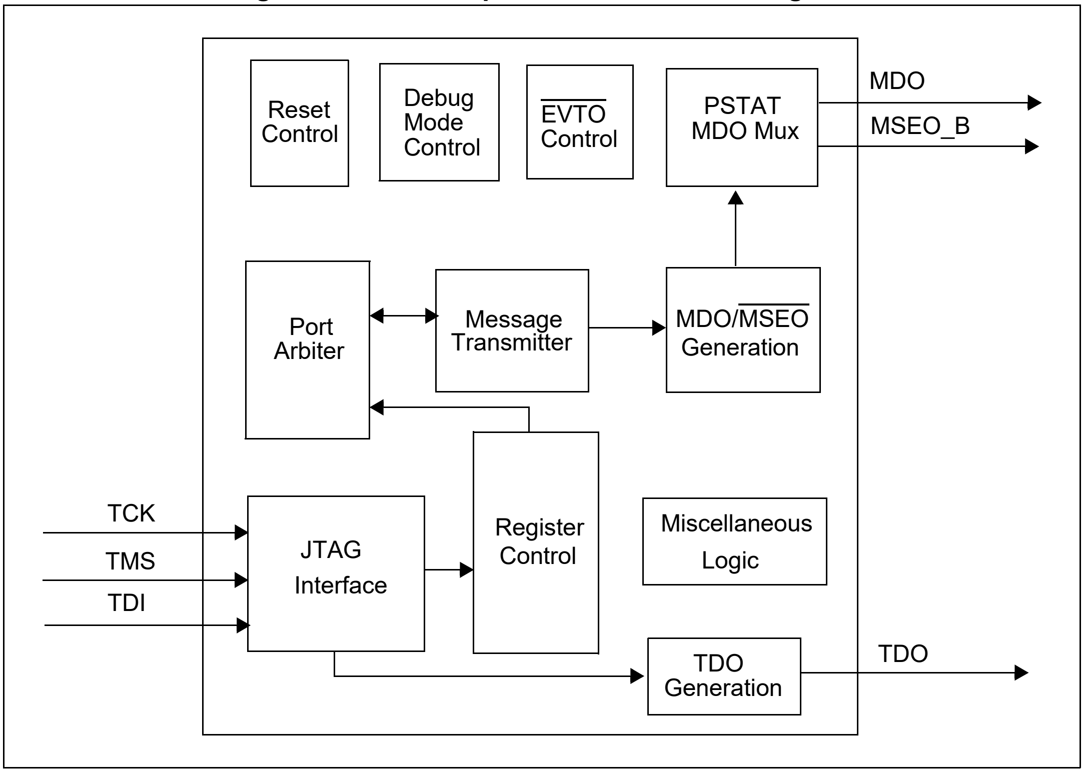
Table 1356. Device parameter values

Parameter	Value
Number of MDO pins available in reduced-port mode	4
Number of MDO pins available in full-port mode	12
Number of $\overline{\text{MSEO}}$ pins available	2

68.2 Introduction

The following figure shows the Nexus Port Controller (NPC) block diagram.

Figure 1387. Nexus port controller block diagram



68.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2003 standard. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

68.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Auxiliary Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Generates power-on reset status
- Provides Nexus support for censorship mode
- $\overline{\text{RDY}}$ pin support to increase the transfer rate of the IEEE 1149.1 port for large data read requests

68.2.3 Modes of operation

The NPC block uses the censorship status and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

68.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, the device enters censored mode, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The auxiliary output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset or censored mode only)
- Registers default back to their reset values

68.2.3.2 Disabled-Port mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages cannot be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

68.2.3.3 Full-Port mode

Full-port mode (FPM) is entered by asserting the MCKO_EN and FPM bits in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

68.2.3.4 Reduced-Port mode

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and deasserting the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

68.2.3.5 Censored mode

When the device is in censored mode, reading the contents of internal flash externally is not allowed. To prevent Nexus modules from violating censorship, the NPC is held in reset when in censored mode, asynchronously holding all other Nexus modules in reset as well. This prevents Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

68.2.3.6 Nexus Double Data Rate mode

Nexus double data rate (DDR) mode is enabled by asserting the DDR_EN bit in the PCR. DDR mode is only supported for MCKO_DIV settings of sys_clk/2, sys_clk/4 and sys_clk/8. In double data rate mode, message data is updated between the edges (both rising and falling) of MCKO, effectively doubling message throughput.

68.3 External signal description

68.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table.

Table 1357. NPC signal properties

Name	Port	Function	Reset state	Pull(1)
EVTO	Auxiliary	Event Out pin	0b1	—
MDO	Auxiliary	Message Data Out pins	0	—
MSEO	Auxiliary	Message Start/End Out pin	0b1	—
TCK	JTAG	Test Clock Input	—	Down
TDI	JTAG	Test Data Input	—	Up
TDO	JTAG	Test Data Output	High Z(2)	—
TMS	JTAG	Test Mode Select Input	—	Up
RDY	JTAG	Data ready for transfer to/from NRRs	—	—

1. The pull is not implemented in this block. Pullup/pulldown devices are implemented in the pads.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

68.3.2 Detailed signal descriptions

This section describes each of the signals listed in *Table 1357* in more detail. The JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

68.3.2.1 $\overline{\text{EVTO}}$ - Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

68.3.2.2 MDO - Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

68.3.2.3 MSEO_B - Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is one output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

68.3.2.4 TCK - Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

68.3.2.5 TDI - Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

68.3.2.6 TDO - Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

68.3.2.7 TMS - Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

68.3.2.8 $\overline{\text{RDY}}$ - Data ready for transfer

The $\overline{\text{RDY}}$ pin exists to increase the transfer rate of the IEEE 1149.1 port. It is used to signal when data are ready to be transferred to and from NRRs. This may eliminate the need to poll NRRs for status information for synchronization purposes. This capability becomes especially important when performing read/write access transfers to different speed target memories.

The $\overline{RDY}$ pin asserts (asynchronously) a logic low whenever the read/write access transfer has completed without error and then deasserts when the IEEE 1149.1 state machine has reached the CAPTURE_DR state.

68.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

Table 1358 shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers. Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 1358. NPC registers

Index	Register
0	Device ID Register (DID)
127	Port Configuration Register (PCR)

68.4.1 Register descriptions

This section contains the NPC register descriptions.

68.4.1.1 Bypass Register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

68.4.1.2 Instruction Register

The NPC block uses a 4-bit instruction register as shown in *Figure 1388*. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register’s read value when the TAP controller is sequenced into the Shift-IR state.

20:21 Technology_Node	01 40 nm
22:27 Design_Center	These bits indicate the device Design Center.
28:31 Minor_Mask	Minor mask revision

68.4.1.4 Port Configuration Register (PCR)

The PCR is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

Note: The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Figure 1390. Port Configuration Register (PCR)

Table 1360. PCR field descriptions

Name	Description
0 FPM	Full Port Mode The value of the FPM bit determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 1 All MDO pins are used to transmit messages 0 A subset of MDO pins are used to transmit messages
1 MCKO_GT	MCKO Clock Gating Control This bit is used to enable or disable MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 1 MCKO gating is enabled. 0 MCKO gating is disabled.
2 MCKO_EN	MCKO Enable This bit enables the MCKO clock to run. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 1 MCKO clock is enabled. 0 MCKO clock is driven to zero.
3:5 MCKO_DIV[2:0]	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. *Table 1361* shows the meaning of MCKO_DIV values. In this table, SYS_CLK represents the system clock frequency.
6 EVT_EN	$\overline{EVTO}$/$\overline{EVTI}$ Enable This bit enables the $\overline{EVTO}$/$\overline{EVTI}$ port functions. 0 $\overline{EVTO}$/$\overline{EVTI}$ port disabled 1 EVTO/EVTI port enabled

Table 1360. PCR field descriptions (continued)

Name	Description
7 DDR_EN	Double Data Rate Mode Enable This bit enables Nexus Double Data Rate (DDR) mode. In DDR mode, message data is updated on both rising and falling edges of MCKO, effectively doubling message throughput. 1 DDR mode enabled 0 DDR mode disabled
16 LP_DBG_EN	Low Power Debug Enable This bit enables debug functionality on exit from low power modes on supported devices. 1 Low power debug enabled 0 Low power debug disabled
22 LP2_SYN	Low Power Mode 2 Synchronization This bit is used to synchronize the entry into low power mode between the device and debug tool. Supported devices set this bit before a pending entry into low power mode. After reading the bit as set, the debug tool then clears the bit to acknowledge to the device that it may enter the low power mode. 1 Low power mode entry pending 0 Low power mode entry acknowledged
23 LP1_SYN	Low Power Mode 1 Synchronization This bit is used to synchronize the entry into low power mode between the device and debug tool. Supported devices set this bit before a pending entry into low power mode. After reading the bit as set, the debug tool then clears the bit to acknowledge to the device that it may enter the low power mode. 1 Low power mode entry pending 0 Low power mode entry acknowledged

Table 1361. PCR[MCKO_DIV] values

MCKO_DIV[2:0]	MCKO frequency
0d (000b)	SYS_CLK[1]
1d (001b)	SYS_CLK/2
2d (010b)	SYS_CLK/3[2]
3d (011b)	SYS_CLK/4
4d (100b)	Reserved
5d (101b)	Reserved
6d (110b)	Reserved
7d (111b)	SYS_CLK/8

1. The SYS_CLK setting for MCKO frequency should only be used if this setting does not violate the maximum operating frequency of the auxiliary port pins.
2. SYS_CLK/3 setting must not be used in DDR mode.

68.5 Functional description

68.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

The following table describes the NPC reset configuration options.

Table 1362. NPC reset configuration options

NPC_PCR[MCKO_EN]	NPC_PCR[FPM]	Configuration
X	X	Reset
0	X	Disabled
1	1	Full-Port mode
1	0	Reduced-Port mode

68.5.2 Auxiliary output port

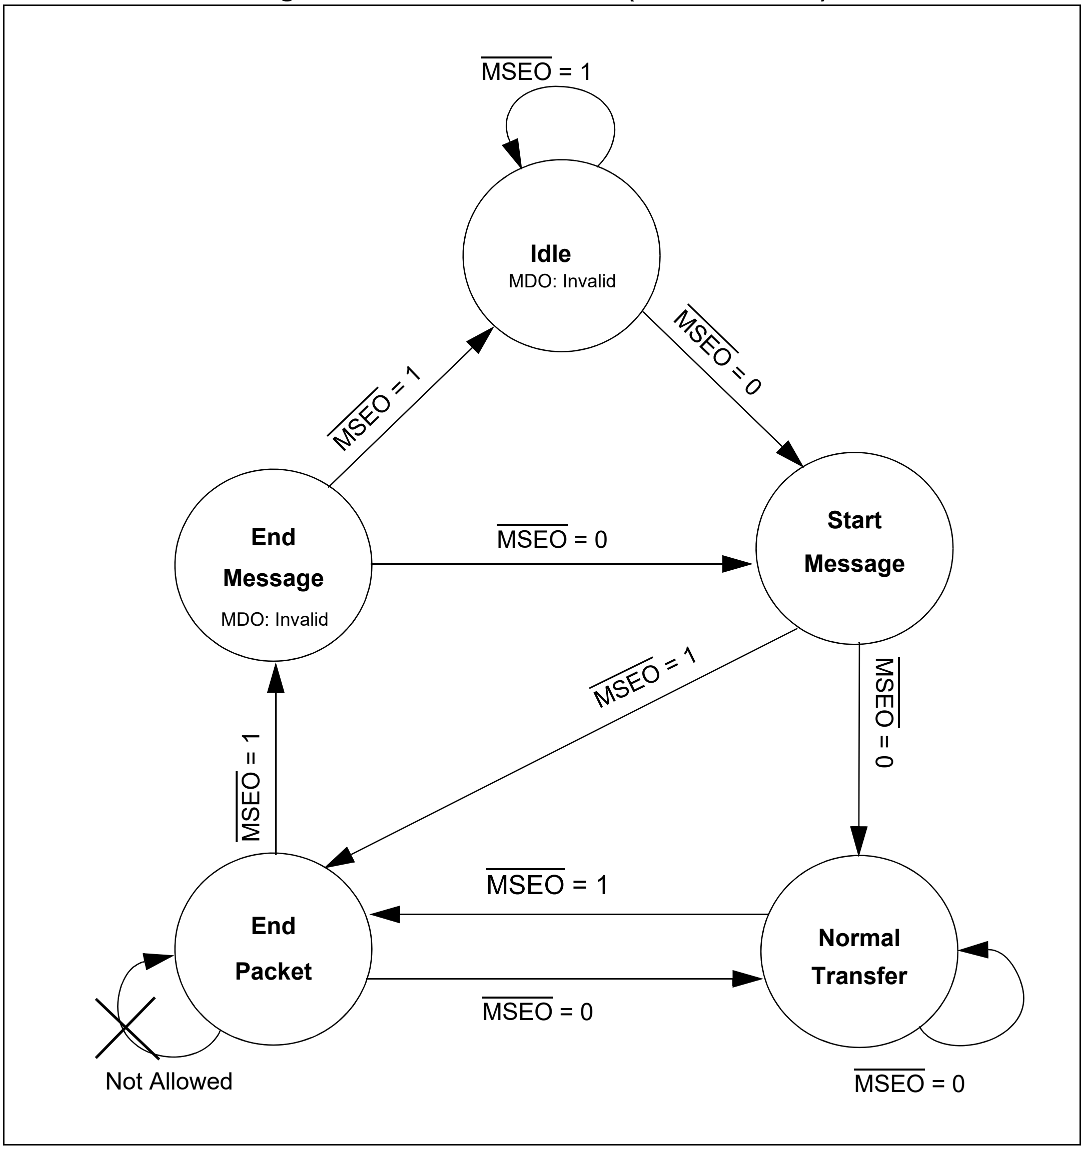
The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

68.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the MSEO functions. The MSEO pin is used to signal the end of variable-length packets and the end of messages. It is not required to indicate the end of fixed-length packets. MDO and MSEO are sampled on the rising edge of MCKO.

Figure 1391 illustrates the state diagram for MSEO transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 1391. $\overline{\text{MSEO}}$ transfers (for 1-bit $\overline{\text{MSEO}}$)



68.5.2.2 Output messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register and the port replacement output message on the MDO pins. The device ID message can also be sent out serially through TDO.

Table 1363 describes the device ID and port replacement output messages that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

Table 1363. NPC output messages

Message name	Packet				
	Size (bits)		Type	Name	Description
	Min	Max			
Device ID Message	6	6	fixed	TCODE	Value = 1
	32	32	fixed	ID	DID register contents

Figure 1392 shows the various message formats that the pin interface formatter has to encounter. Note that for variable-length fields, the transmitted size of the field is determined from the range of the least significant bit to the most significant non-zero-valued bit (that is most significant zero-valued bits are not transmitted).

Figure 1392. Message field sizes

Message	TCODE	Field #1	Field #2	Field #3	Field #4	Field #5	Size (bits) Min(1)	Size (bits) Max(2)
Device ID Message	1	Fixed = 32	—	—	—	—	38	38

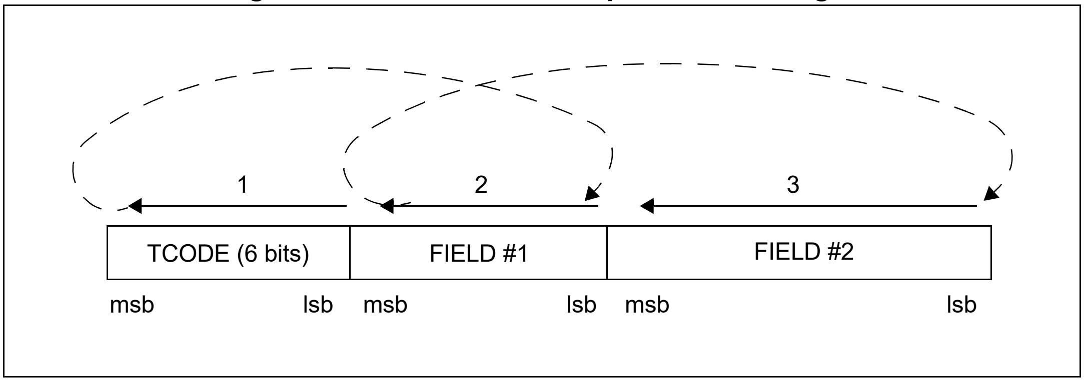
1. Minimum information size. The actual number of bits transmitted depends on the number of MDO pins.
2. Maximum information size. The actual number of bits transmitted depends on the number of MDO pins.

The double edges in *Figure 1392* indicate the starts and ends of messages. Fields without shaded areas between them are grouped into super-fields and can be transmitted together without end-of-packet indications between them.

68.5.2.3 Rules of message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. *Figure 1393* shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

Figure 1393. Transmission sequence of messages



68.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 TAP for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further details on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in *Figure 1395*. The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in *Figure 1396*.

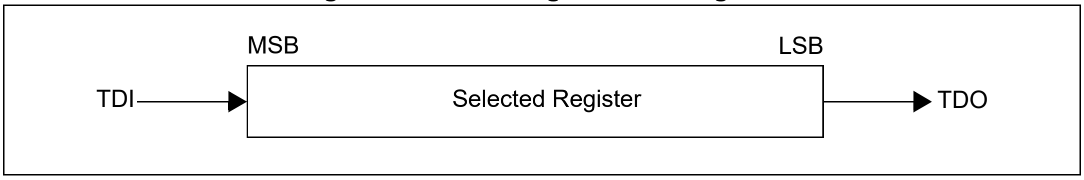
The instructions implemented by the NPC TAP controller are listed in *Table 1364*. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

Table 1364. Implemented instructions

Instruction name	Private/Public	Opcode	Description
NEXUS-ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in *Figure 1394*. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 1394. Shifting data into register

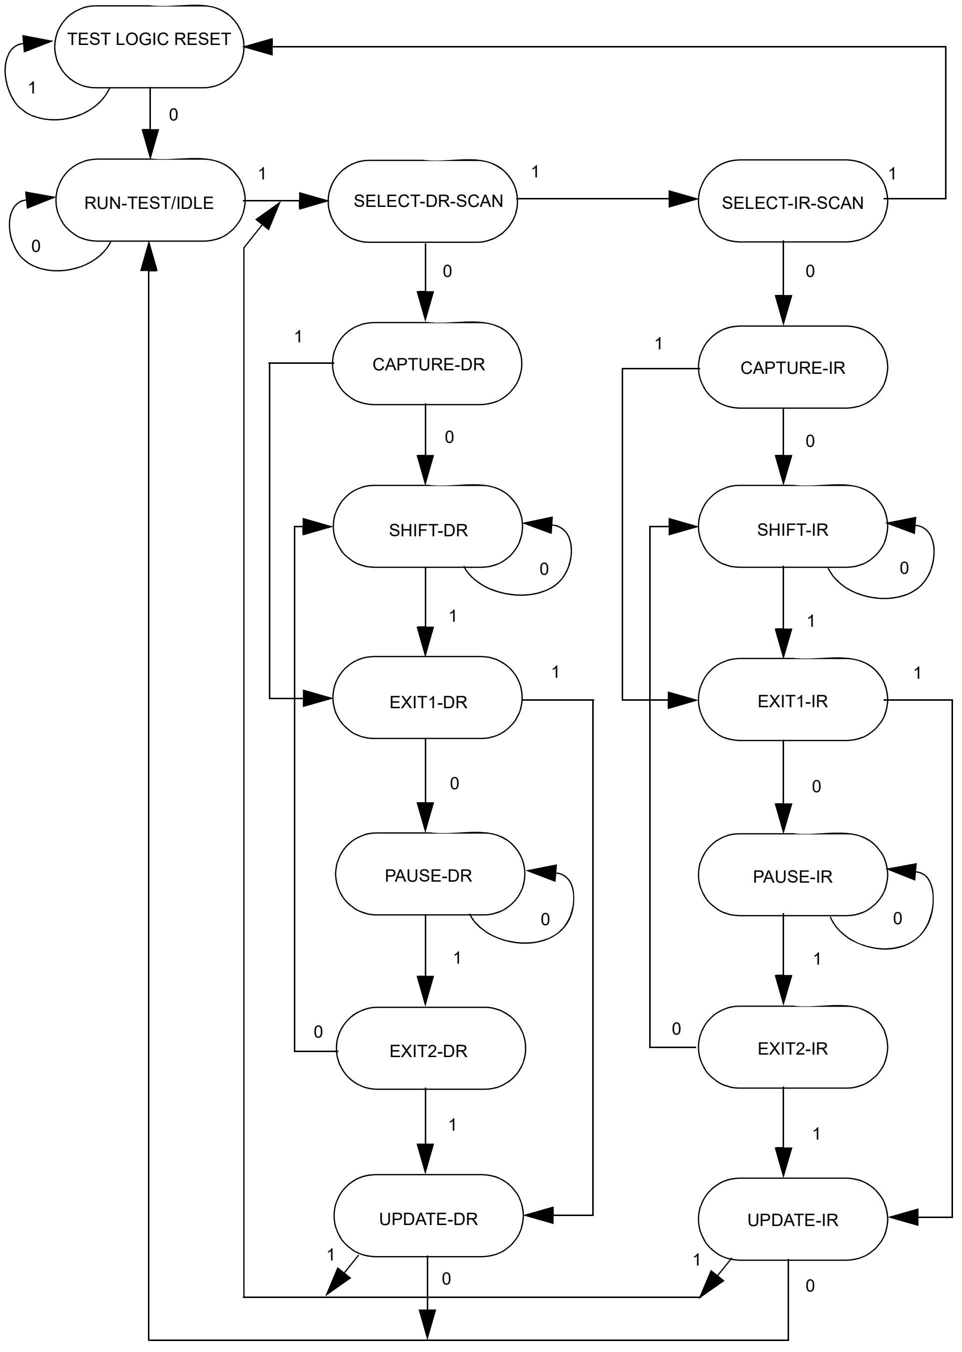


68.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or entry into censored mode resets the NPC TAP controller.

When not in power-on reset or censored mode, the NPC TAP controller is enabled exiting the Test-Logic-Reset state loading the NEXUS-ENABLE instruction in NPC TAP controller.

Figure 1395. IEEE 1149.1-2001 TAP controller state machine



Note: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

68.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the auxiliary output port or shifted out serially by accessing the Nexus Device ID register through the TAP. Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled. Transmission of the device identification message serially via TDO is achieved by performing a read of the register contents as described in *Section 68.5.3.4: Selecting a Nexus client register*.

68.5.3.3 Loading NEXUS-ENABLE instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 1396*, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. *Table 1365* illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 1396. NEXUS controller state machine

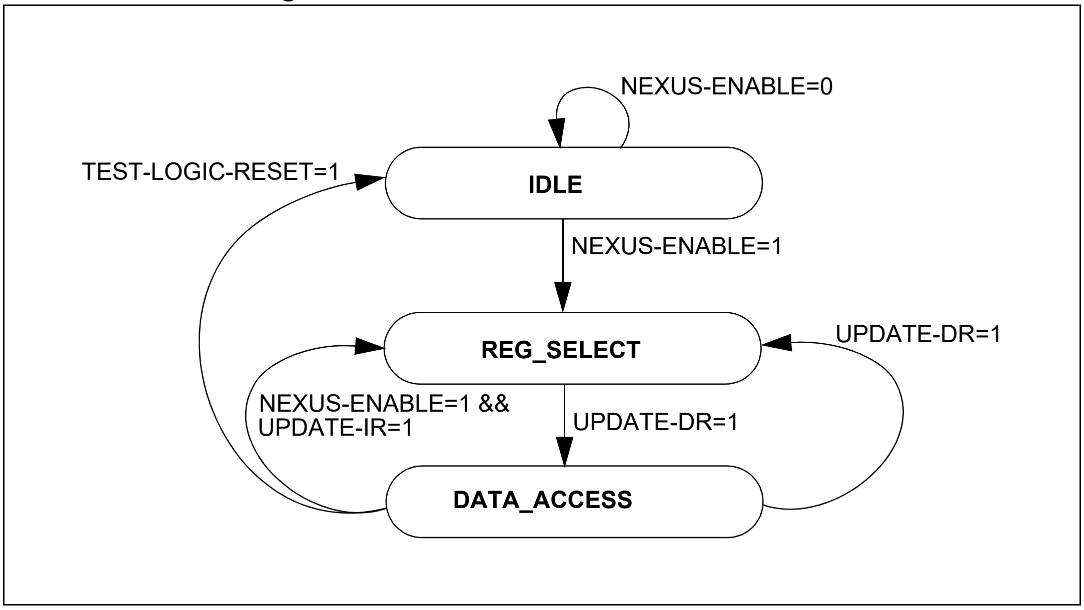


Table 1365. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in

Table 1365. Loading NEXUS-ENABLE instruction (continued)

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

68.5.3.4 Selecting a Nexus client register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 1397*. The read/write control bit is set to '1' for writes and '0' for reads.

Figure 1397. IEEE 1149.1 controller command input

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 1366. Write to a 32-bit Nexus Client Register

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register

Table 1366. Write to a 32-bit Nexus Client Register (continued)

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

68.5.4 Nexus JTAG port sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

68.5.5 MCKO and ipg_sync_mcko

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

68.5.6 $\overline{\text{EVTO}}$ sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

68.6 Initialization/Application information

68.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2003 standard for more details.

69 Nexus handshake module (NPC_HNDSHK)

This module enables debug entry/exit across low-power modes (Stop, Halt, Standby).

The NPC_HNDSHK supports:

- Setting and clearing of the NPC PCR sync bit on low-power mode entry and exit
- Putting the core into debug mode on low-power mode exit
- Generating a falling edge on the JTAG TDO pad on low-power mode exit

69.1 Entry into STOP/STANDBY from RUN modes

For the device to be in debug mode on low-power exit, the debugger should set the LP_DBG and LP1_SYNC bit in the NPC PCR register.

On STOP, STANDBY entry, the MC_ME asserts the lp_mode_entry_req input after the clock disable process has completed and before the processor enters its stopped state. The mode transition will then not proceed until the lp_mode_entry_ack output has been asserted.

The notification to the debugger of a low-power mode entry consists in setting the NPC PCR [LP1_SYNC] bit by the NPC Handshake module.

The debugger acknowledges that the transition into a low-power mode may proceed by clearing NPC PCR[LP1_SYNC] bit.

The device enters into the low-power modes. In anticipation of the low-power mode exit notification, the TDO pad is driven to '1'.

69.2 Exit from STOP/STANDBY into RUN modes

On STOP mode exit, the MC_ME asserts the lp_mode_exit_req input after ensuring that the regulator and memories are in normal mode and before the processor exits its stopped state. The mode transition will then not proceed until the lp_mode_exit_req has been acknowledged. The MC_RGM asserts the exit_from_standby input when executing a reset sequence due to a STANDBY exit. The reset sequence will then not complete until the lp_mode_exit_req has been acknowledged.

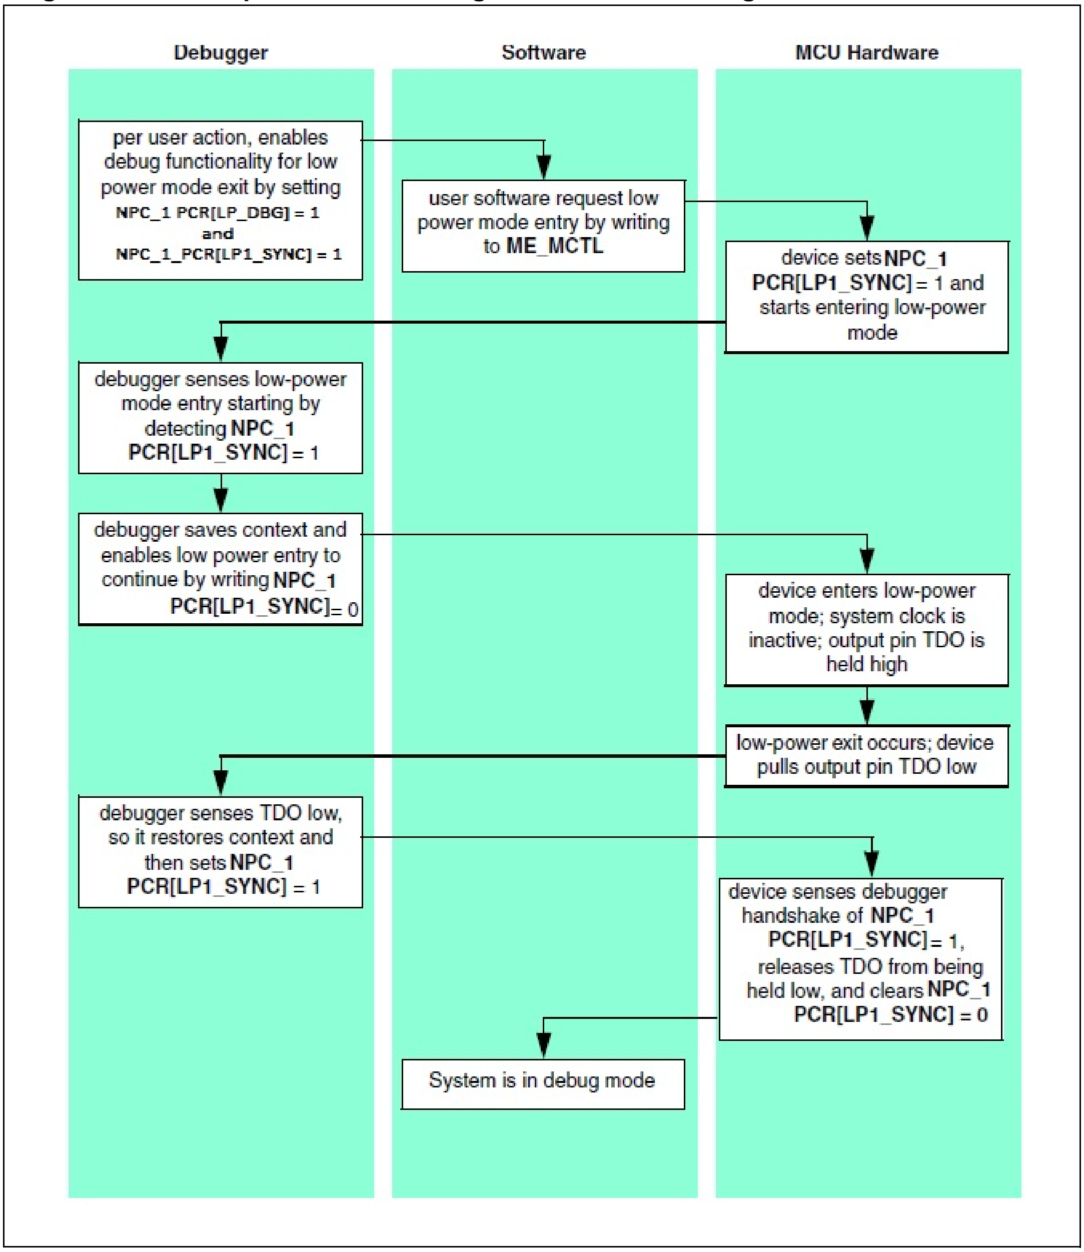
The notification to the debugger of a low-power mode exit consists in driving the TDO pad to '0'.

The debugger acknowledges that the transition from a low-power mode can continue by setting the NPC PCR[LP1_SYNC] bit.

Further, the NPC PCR[LP1_sync] bit is de-asserted by the hardware and the lp_mode_exit_ack output is sent to the MC_ME.

Note: The debugger clock multiplexer may not guarantee glitch free switching. Therefore, TCK should be disabled from when the debugger clears the sync bit in ENTRY_CLR until the debugger senses the falling edge of TDO in TDO_SET.

Figure 1398. Low-power mode debug handshake flow diagram for STOP, STANDBY



70 e200z420n3 Nexus 3 Module

The e200z420n3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

70.1 Introduction

70.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

70.1.2 Terms and Definitions

Table 1367 contains a set of terms and definitions associated with the Nexus 3 module.

Table 1367. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1367. Terms and Definitions (continued)

Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

70.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (such as direct and indirect branches, exceptions), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

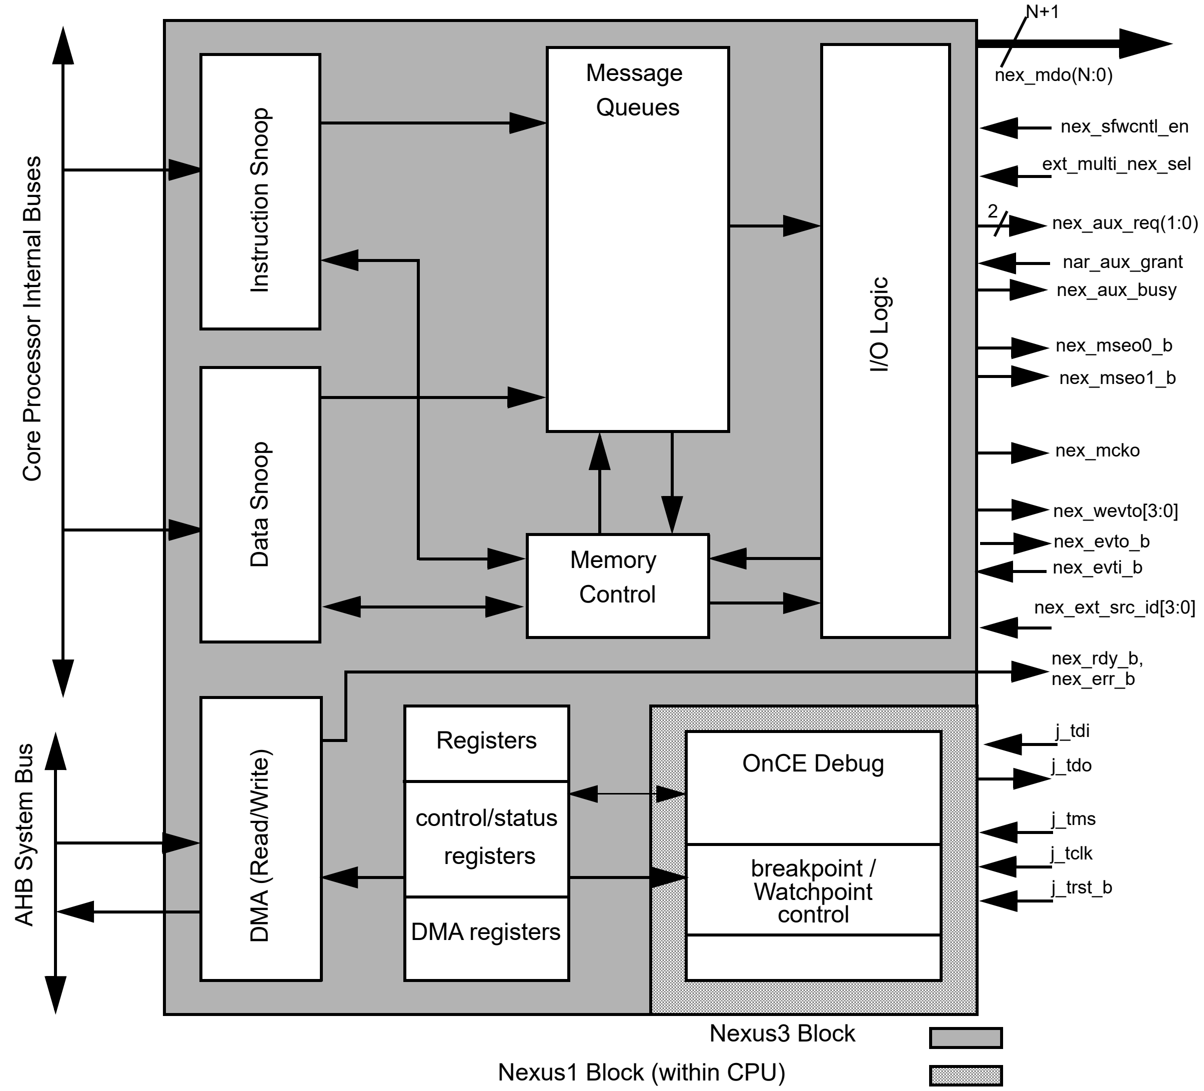
Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

70.1.4 Functional Block Diagram

Figure 1399. Nexus 3 functional block diagram



Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

70.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (NEXUS3-ACCESS) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module’s DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU’s **p_reset_b** signal, even when software has control of the module.

70.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

70.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 1368*.

Table 1368. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1373*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1373*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)

Table 1368. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	6	6	TCODE	fixed	TCODE number = 13
Data Trace — Data Write Message w/ Sync	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1373*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table 1368. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1373*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 1371*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See *Section 70.12.4: Resource Full Messages*.)
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 70.12.1: Branch Trace Messaging types*)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See *Section 70.12.1: Branch Trace Messaging types*.)

Table 1368. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to *Table 1372*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See *Section 70.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See *Section 70.12.5: Program Correlation Messages*.)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 70.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 1369 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1369. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (such as Debug Status messages)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 1370 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1370. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 1371 shows the encodings used for resource codes for certain messages.

Table 1371. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 1372 shows the event code encodings used for certain messages.

Table 1372. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 1373 shows the data trace size encodings used for certain messages.

Table 1373. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte

Table 1373. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

70.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 70.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 70.6: Nexus 3 Register Access via Software* for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 1374 details the register map for the Nexus 3 module.

Table 1374. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

70.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

7	6	5	4	3	2	1	0
Reserved				CS

Table 1375. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

70.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

70.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 1402* and its fields are described in *Table 1377*.

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enabled for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 70.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 70.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

70.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 1403* and its fields are described in *Table 1378*.

1. Refer to *Table 1372* for implemented EVCODEs.

70.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

DBG	LPS			LPC		0																									
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25:0	—	Reserved for future functionality (read as 0)

70.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allow the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

70.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Nexus Reg# 0x15; DCR: 408; Read/Write; Reset: 0x0

Figure 1422. Data Trace End Address 4 register

Table 1390 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1390. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (that is when the instruction prefetch is discarded).

70.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 1392*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RWCS[17:16]	—	Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR(2)	Read/Write Access Error (see *Table 1392*)
RWCS[0]	DV(2)	Read/Write Access Data Valid (see *Table 1392*)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 1392. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

70.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 1424. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 1393* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1393. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data) second RWD pass (high order data)	0 0 0	0 1 1	X X	X X	X X	X X

Table Notes:
"X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 1394 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1394. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]

Table Notes:
"—" indicates byte lanes that will contain unused data.

70.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 1425. Read/Write Access Address (RWA) register

70.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 1374*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 70.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 1374*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1426. JTAG DR format

(7 bits)	(1 bit)
Nexus Register Index	R/W

RESET Value: 0x00

Table 1395. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 1374*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

70.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these accesses only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 1374* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

70.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

70.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

70.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

70.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant ‘1’. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 1427. Relative address generation and recreation

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

70.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

70.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

70.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

70.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 70.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

70.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

Section 70.8.1: Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

70.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstance:

- More than three messages are generated in the same cycle

Table 1396 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 1396*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 1396. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)

Table 1396. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

70.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

70.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

70.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

70.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

70.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

70.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 1428. Debug Status message format

(8 bits)	(4 bits)	(6 bits)
DS[31:24]	Src. Proc.	TCODE (000000)

Fixed length = 18 bits

70.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see *Table 1369* and *Table 1370*):

Figure 1429. Error message format

(6 bits)	(4 bits)	(4 bits)	(6 bits)
Error Code	Error Type	Src. Proc.	TCODE (001000)

Fixed length = 20 bits

70.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

70.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

70.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z420n3) processors contain a *PowerISA 2.06* defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

Nexus 3 Process ID
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR — 517; Read/Write; Reset: 0

Figure 1430. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will

indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 1431. Ownership Trace Message format

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15–46 bits

70.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z420n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z420n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

70.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

70.12.1.1 Indirect Branch Message instructions

Table 1397 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1397. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfci, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

70.12.1.2 Direct Branch Message Instructions

Table 1398 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1398. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

70.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

70.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

70.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

70.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

Figure 1432. Indirect branch message (history) format

(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

70.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Figure 1433. Indirect branch message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

70.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 1434. Direct branch message format

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

70.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

70.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

70.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1399. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

70.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

70.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 1435. Resource Full Message format

(1–32 bits)	(4 bits)	(4 bits)	(6 bits)
RDATA	RCODE	Src. Proc.	TCODE (011011)

Max length = 46 bits; Min length = 15 bits

Table 1400 shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 1400. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

70.12.5 Program Correlation Messages

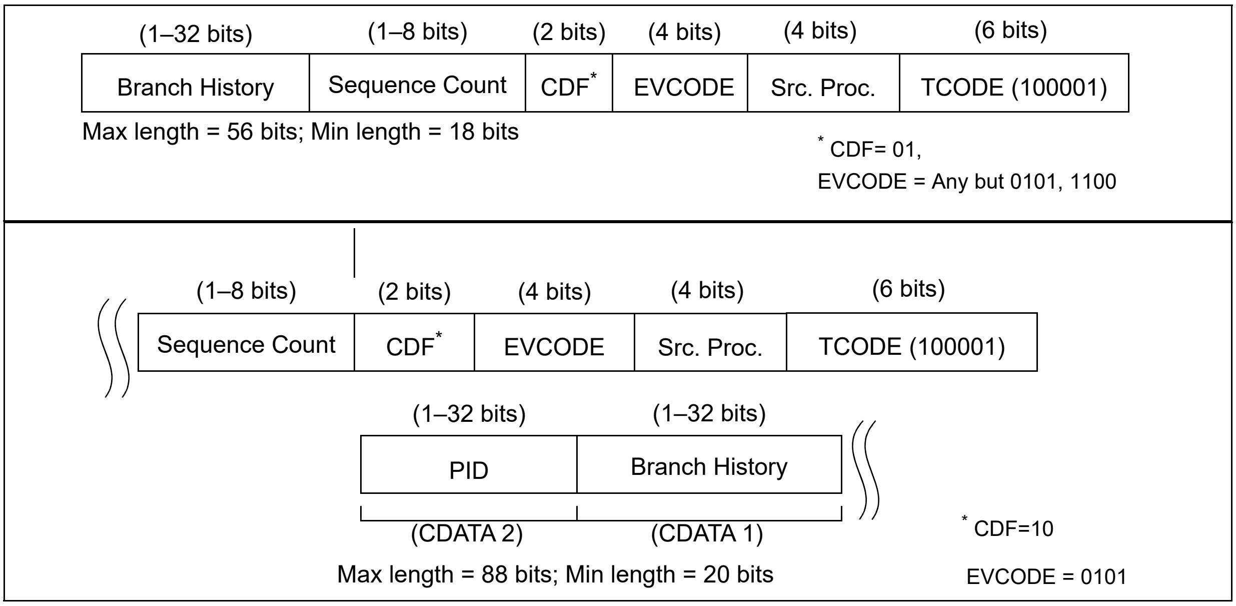
Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 1372* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 1436. Program Correlation message formats



70.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

70.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

70.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1401*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to MSR_{PMM} → ‘1’ with $DC4_{PTMARK}$=‘1’.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 1437. .Program Trace Synchronization message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in *Table 1401*.

Table 1401. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

70.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1401*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 1438. Direct/Indirect Branch with Sync message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 1439. Indirect Branch History w/ Sync message format

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 1402*.

Table 1402. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

70.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of four ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

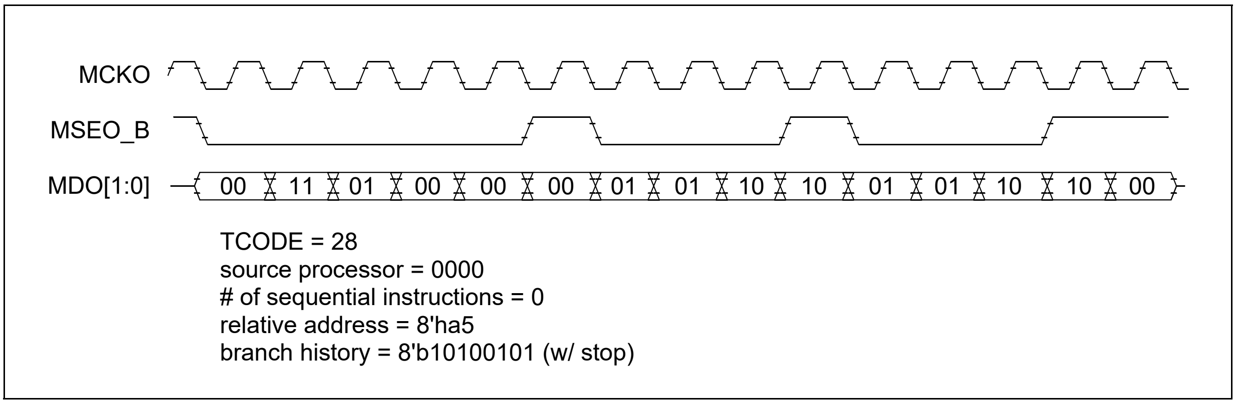

Figure 1442. Program Trace — Direct Branch (traditional) & Error messages

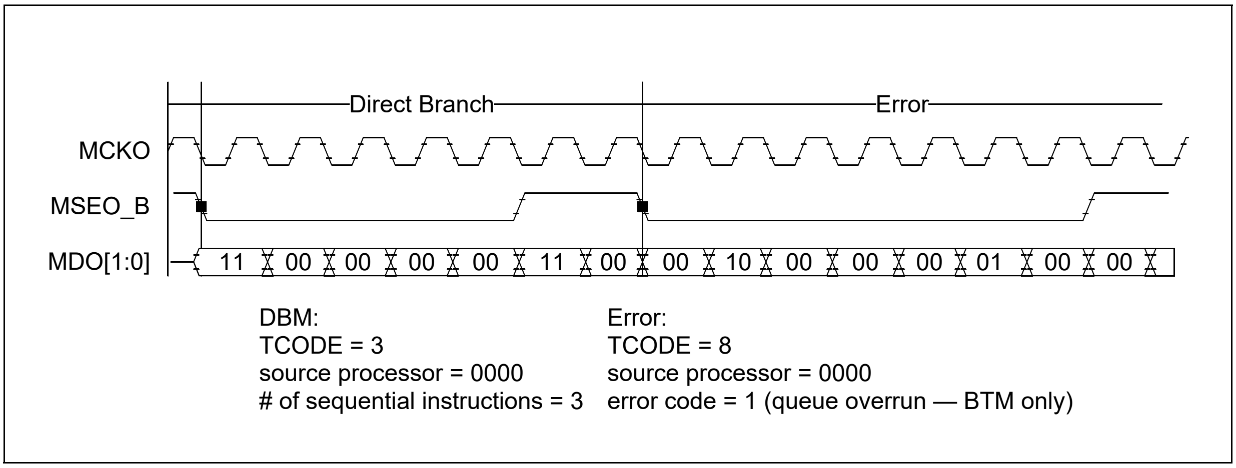

Figure 1443. Program Trace — Indirect Branch w/ Sync message

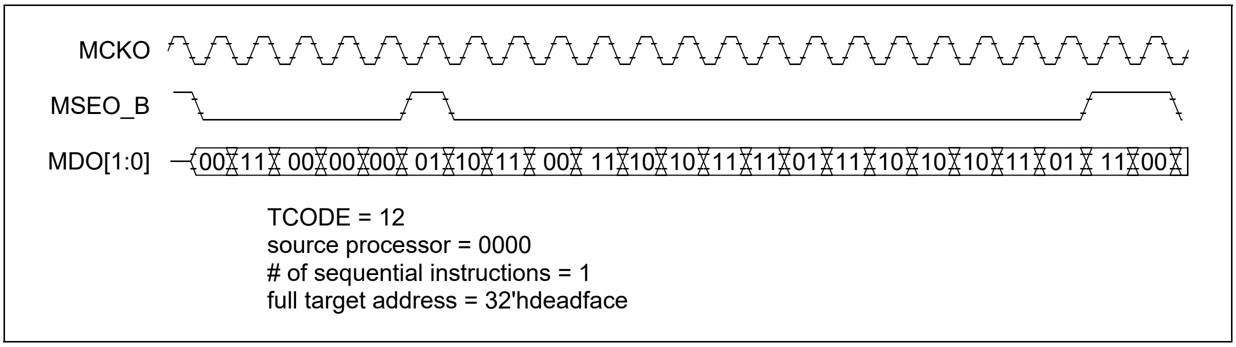

70.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

70.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z420n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

70.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

70.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 1444. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

70.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 1445. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

*Note: Core (e200z420n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.*

*For Core (e200z420n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.

70.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 1403*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 1446. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Exception conditions that result in Data Trace Synchronization are summarized in *Table 1403*.

Table 1403. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.

Table 1403. Data Trace Exception summary (continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

70.13.3 DTM operation

70.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

70.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

70.13.3.3 Data Trace filtering

Data Trace filtering is available based on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

70.13.3.4 Bus cycle special cases

Table 1404. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error(1)	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored

Table 1404. Bus cycle special cases (continued)

Special case	Action
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z420n3) Core Debug Support chapter.)

Note: A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

70.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 1447. Data Trace — Data Write message

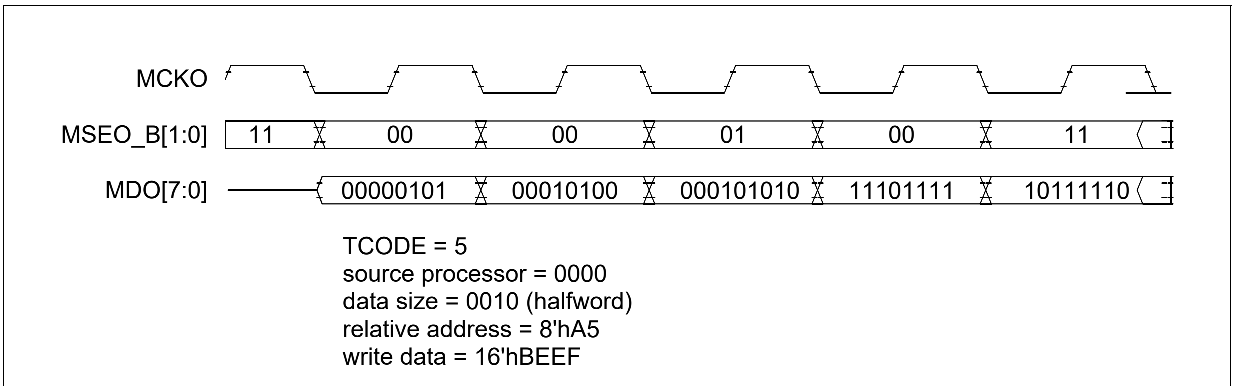

Figure 1448. Data Trace — Data Read w/ Sync message

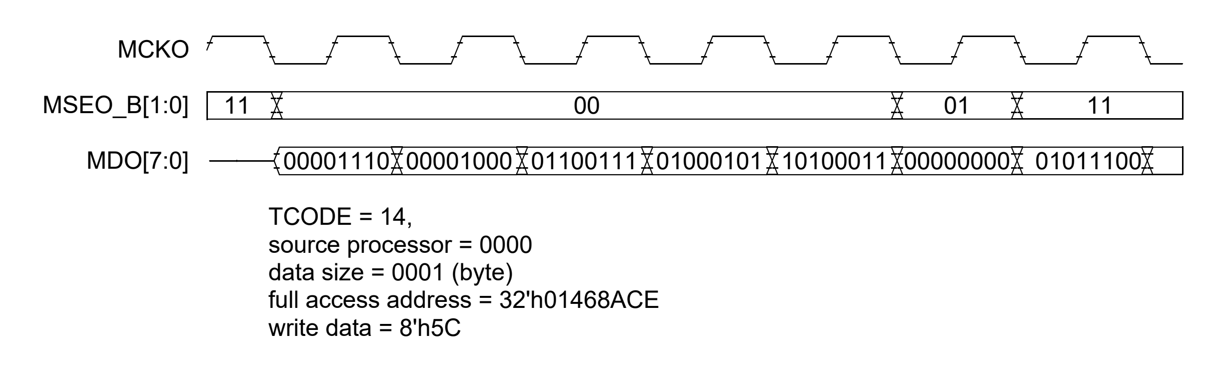

70.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

70.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

70.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

70.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z420n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Table 1405. .Data Acquisition message format

(1–32 bits)	(8 bits)	(4 bits)	(6 bits)
DQDATA	DQTAG	Src. Proc.	TCODE (011011)

Max length = 50 bits; Min length = 19 bits

70.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z420n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 1409* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 1449. Watchpoint message format

(1–30 bits)	(4 bits)	(6 bits)
Watchpoint Source	Src. Proc.	TCODE (001111)

Variable length = 11–40 bits

The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 1406. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
xxxxxxxxxxxxxxxxxxxxxxxxxxxxx1	Watchpoint #0 enabled for WTM

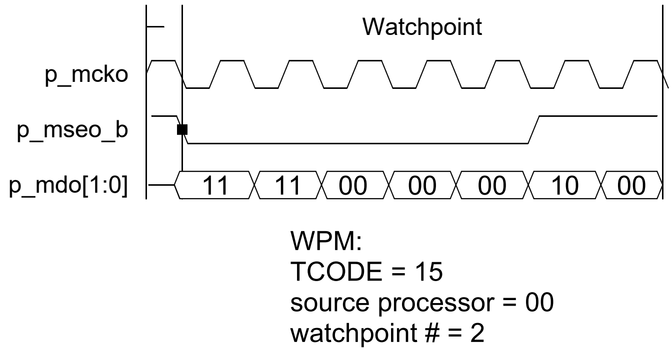
1xxxxxxxxxxxxxxxxxxxxxxxxxxxxx	Watchpoint #29 enabled for WTM

70.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1450. Watchpoint Message & Watchpoint Error message



70.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 1407* details the external hardware trigger signals.

Table 1407. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 1407. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

70.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are <u>NOT</u> supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

70.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 1409* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note: Only the **nex_ahb_start, nex_rdy_b, and nex_err_b** *pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

70.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 70.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 70.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

70.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 1409* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*.

*Note: Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

70.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 70.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see *Table 1409* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 1409* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 70.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 70.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (that is doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

70.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

70.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

70.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

70.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 1451. Error message format

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

70.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

70.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 1409*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 70.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z420n3) Core Debug Support chapter.

Table 1408. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 1409*.

Table 1409. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted

Table 1409. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 70.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

Table 1410. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 1412*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

70.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 1411*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

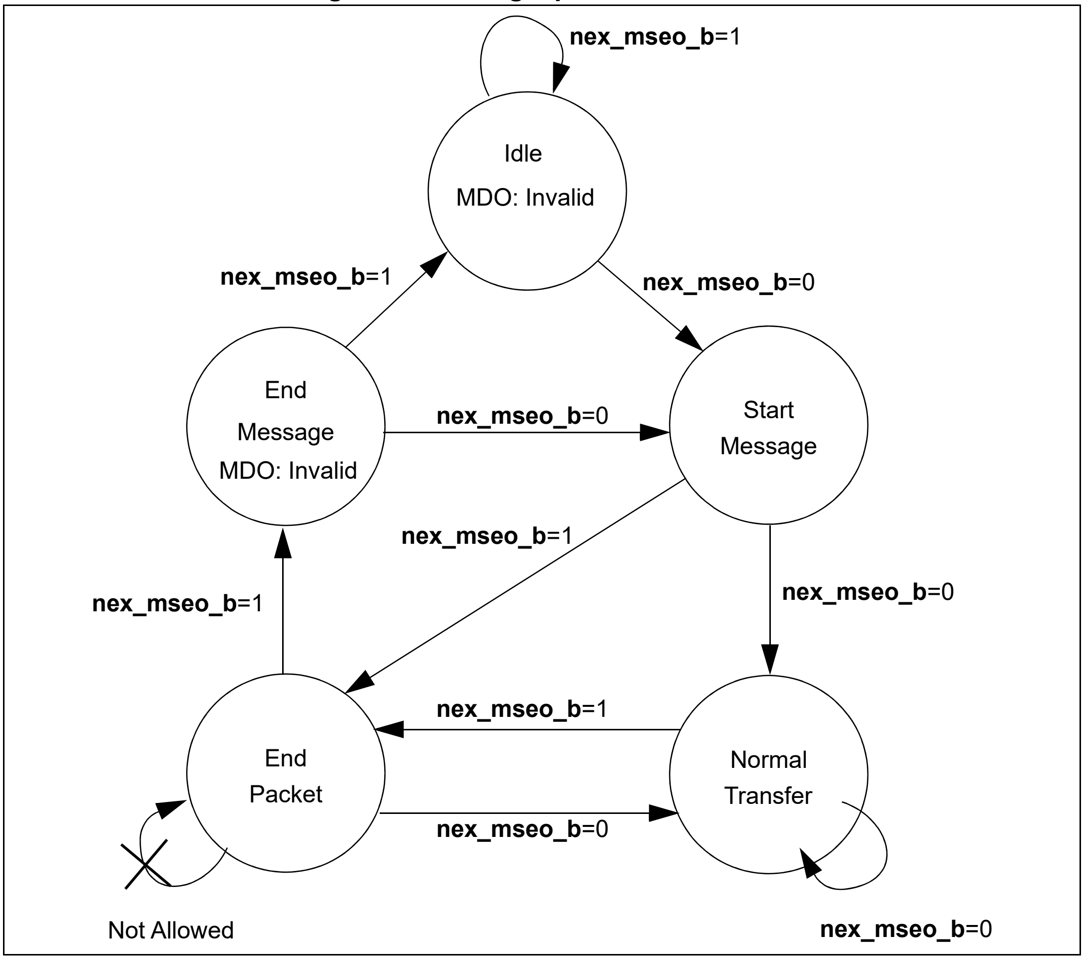
Single pin MSEO is not supported on the SPC584Bx.

Table 1411. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1’s)	00 (or 01)-11-(more 1’s)
End of variable length packet	0-1-0	00-01
Message transmission	0’s	00’s
Idle (no message)	1’s	11’s

Figure 1452 illustrates the state diagram for single pin MSEO transfers.

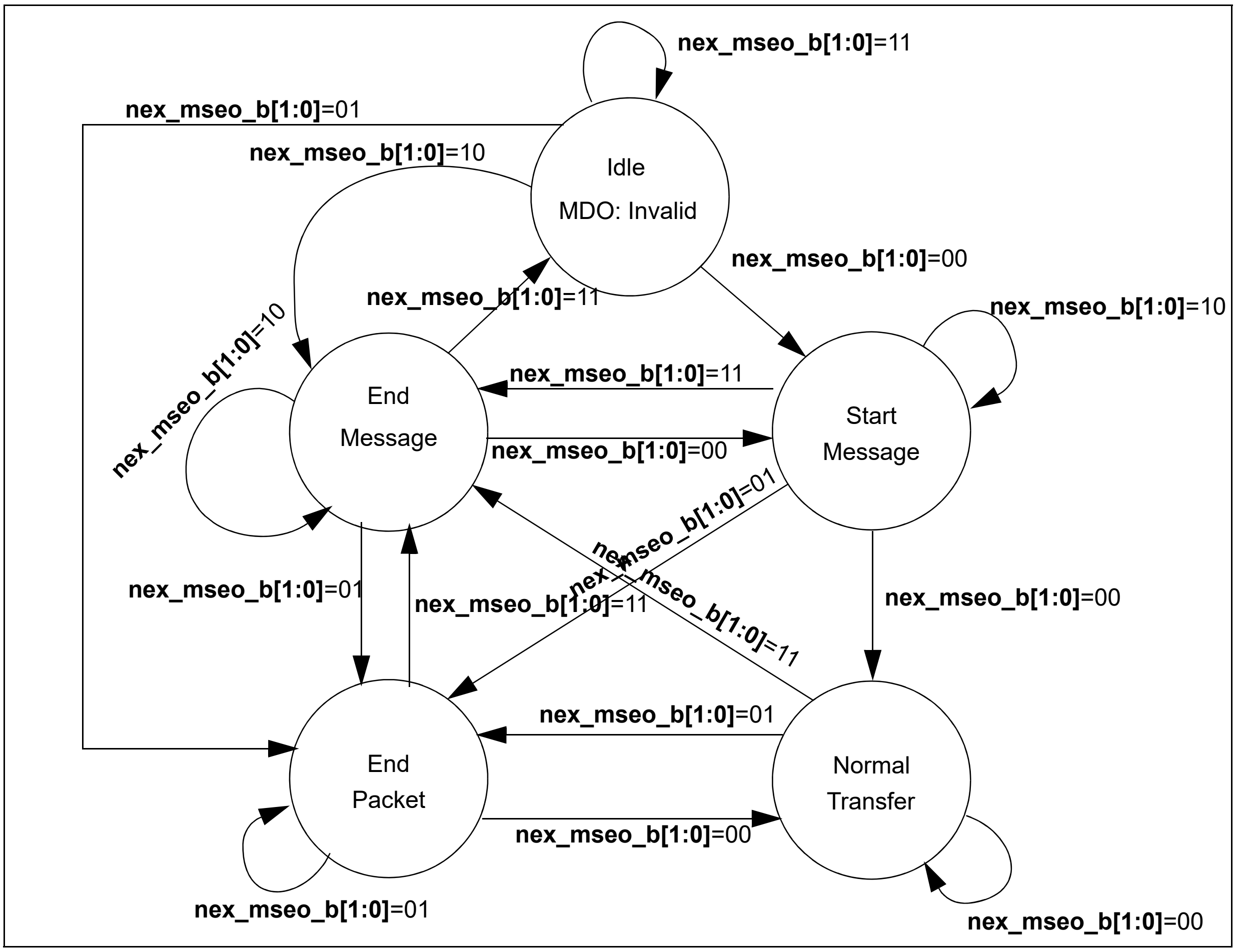
Figure 1452. Single pin MSE transfers



Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 1453 illustrates the state diagram for dual pin MSEO transfers.

Figure 1453. Dual pin MSEO transfers



The dual pin MSEO option is more robust than the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

70.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-

order bit so that it can end on a port boundary.

For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

70.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 1412* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 70.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 1412. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

70.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 1413 illustrates an example of Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 1414* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1413. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1414. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1415 and *Table 1416* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1415. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1416. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1417 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 1418* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 1417. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 1418. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

70.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC584Bx Data Sheet.

70.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

70.23.1 JTAG sequence for accessing internal Nexus registers

Table 1419. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

70.23.2 JTAG sequence for read access of memory-mapped resources

Table 1420. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

70.23.3 JTAG sequence for write access of memory-mapped resources

Table 1421. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

71 Nexus Crossbar Multi-Master Client (NXMC)

71.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA AHB, and CPU Data Bus AHB start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.This also provides the capability of sending user defined messages for the peripherals attached to it.

71.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to (selected) internal memory resources
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

71.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 1423*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (refer to *Section 71.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 1422* describes the JTAG pins.

Table 1422. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 1423. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (refer to *Section 71.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

71.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 1424*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 1424. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 1425*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 1425*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (refer to *Table 1426*)
	14	14	ECODE	fixed	Error code (refer to *Table 1427*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 1425*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1424. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 1425*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (refer to *Table 1439*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1425. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 1426. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved

Table 1426. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 1427. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description(1)
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved
Source (SRC) n = peripheral index		
CKSRCn	XXXXXXX1	Reserved
CKSRCn	XXXXXX1X	Reserved
CKSRCn	XXXXX1XX	Reserved
CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

71.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. Refer to *Section 71.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 1428*.

Table 1428. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	0x2	R/W	0x04	0x05
Development Control 2 (DC2)	0x3	R/W	0x06	0x07
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B
Data Trace Start Address1 (DTSA1)	0xE	R/W	0x1C	0x1D
Data Trace Start Address2 (DTSA2)	0xF	R/W	0x1E	0x1F
Data Trace End Address1 (DTEA1)	0x12	R/W	0x24	0x25
Data Trace End Address2 (DTEA2)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register1 (BWC1)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register2 (BWC2)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register1 (BWA1)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register2 (BWA2)	0x1F	R/W	0x3E	0x3F

71.4.1 Register definitions

Detailed register definitions for the current NXMC implementation are described in the following sections.

71.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. *Figure 1454* shows the format of the DC1.

Address: refer to *Table 1428* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0(1)	0(1)	0(1)	EOC		0	0	WEN	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	EIC		TM		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 1454. Development control register 1 (DC1)

The DC1 is described in *Table 1429*.

Table 1429. DC1 register field description

Field	Description
3:4 EOC	$\overline{\text{EVTO}}$ Control. 00 $\overline{\text{EVTO}}$ upon occurrence of watchpoint (internal or external) 01 $\overline{\text{EVTO}}$ upon entry into system-level Debug Mode 1x Reserved
7 WEN	Watchpoint Trace Enable. 0 Watchpoint Messaging disabled 1 Watchpoint Messaging enabled
27:28 EIC	$\overline{\text{EVTI}}$ Control 00 $\overline{\text{EVTI}}$ for synchronization (Data Trace) 01 Reserved 10 $\overline{\text{EVTI}}$ disabled 11 Reserved
29:31 TM	Trace Mode 000 No Trace 1xx Reserved x1x Data Trace enabled xx1 Reserved

71.4.1.2 Development control register 2 (DC2)

The Development Control Registers control the basic development features of the NXMC module. *Figure 1455* shows the format of the DC2.

Address: refer to *Table 1428* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EWC								0	0	0	0	0	0	0	0
W

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PME0(1)
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 1455. Development control register 2 (DC2)

The DC2 is described in *Table 1430*.

Table 1430. DC2 register field description

Field	Description
0:7 EWC	$\overline{\text{EVTO}}$ Watchpoint Configuration[1]. 00000000 No Watchpoints trigger $\overline{\text{EVTO}}$ 1XXXXXXX External Watchpoint #1 triggers $\overline{\text{EVTO}}$ X1XXXXXX External Watchpoint #2 triggers $\overline{\text{EVTO}}$ XX1XXXXX Reserved[2] XXX1XXXX Reserved[2] XXXX1XXX Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$ XXXXX1XX Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$ XXXXXX1X Reserved[2] XXXXXXX1 Reserved[2]
31 PME0	Peripheral Messaging Enable for the In-Circuit Trace (ICT) feature.[3] 0 Peripheral Interface disabled 1 Peripheral Interface enabled

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. Writing bits 2,3,6,7 has no impact and read value will be 0 for these bits.
3. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

71.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 1456* shows the format of the WT register.

Address: refer to *Table 1428* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	DTS			DTE			0	0	0	0
W

R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1456. Watchpoint trigger register (WT)

The WT register is described in *Table 1431*.

Table 1431. WT register field description

Field	Description[1]
6;8 DTS	Data Trace Start Control. 000 Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved
9;11 DTE	Data Trace End Control. 000Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

71.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. *Figure 1457* shows the format of the DTC register.

Address: refer to *Table 1428* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RWT1		RWT2		0	0	0	MME	0	0			MID

Figure 1457. Data trace control (DTC) register

The DTC register is described in *Table 1432*.

Table 1432. DTC field description

Field	Description
0:1 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x nable data write trace
2:3 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
7 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
12:15 MID	ID of the system bus Master to be traced(1)
24 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
25 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

71.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 1458* shows the format of the DTSA1 and DTSA2 registers.

Address: refer to *Table 1428* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1458. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

71.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. *Figure 1459* shows the format of the DTEA1 and DTEA2 registers.

Address: refer to Table 1428 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R/W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R/W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1459. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 1433 illustrates the ranges that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1433. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range – no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

71.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. Figure 1460 shows the format of the BWC1 register.

Address: refer to Table 1428 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	BWT1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1462. Breakpoint /watchpoint address registers 1 and 2 (BWA1 and BWA2)

71.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 1428*. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

71.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion, after the JTAG ID register has been read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

71.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 71.5.4: NXMC register access via JTAG*.

71.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

71.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set.

71.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 1428*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to *Table 1428*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 1463* and *Table 1436*.

	7	6	5	4	3	2	1	0
R W	Nexus Register Index							R/W
Reset	0	0	0	0	0	0	0	0

Figure 1463. JTAG DR for Nexus register access

Table 1436. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 1428*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

71.6 Functional description

71.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

71.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

71.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

71.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in *Figure 1464*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

Figure 1464. DTM message format for DATA width = 64 bits

TSTAMP is another optional field which is inserted based on the controls received from the NPC, refer to *Section 71.6.4: Timestamping feature*.

71.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

71.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 1465*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

Figure 1465. DTM error message format (fixed length = 48 bits)

71.6.1.2.3.1 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to *Table 1437*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message
- Upon returning from a low power state, the first data trace message is a synchronization message
- Upon returning from debug mode, the first data trace message is a synchronization message
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 1466*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Figure 1466. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 1437*.

Table 1437. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table 1437. Data trace exception summary (continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

71.6.1.3 DTM operation

71.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (that is DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure the correct DTM functionality.

71.6.1.3.2 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).

71.6.1.3.3 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 1467*.

Figure 1467. Relative addressing example

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

71.6.1.3.4 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

71.6.1.3.5 System bus cycle special cases

The system bus cycle special cases are shown in *Table 1438*.

Table 1438. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

71.6.1.3.6 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (refer to figure in *Section 71.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

71.6.1.3.7 HSM master filtering

For security reasons certain HSM masters need to be disabled or filtered from data tracing operations.

71.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

71.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (that are BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints: Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 71.6.1.3.6: System bus multi-master tracing*).
- External watchpoints: The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level.The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (that is on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 1468* and *Table 1439*.

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Figure 1468. Watchpoint message format (fixed length = 18 bits)

Table 1439. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1(1)	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

71.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 1469*.

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

Figure 1469. Error message format (fixed length = 28 bits)

71.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

MSB	6 bits		(54-6) bits				LSB
	CKSRCn		DATAn				
54-1		54-6	54-6-1		2	1	0

n = peripheral number

Figure 1470. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

71.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in *Figure 1471*. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

1–44 bits	6 bits	4 bits	6 bits
CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 1471. Peripheral message format (max length = 60 bits, min length = 17 bits)

71.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in *Figure 1472*.

14 bits	4 bits	4 bits	6 bits
ECODE(CKSRCn,ErrCODE)	ETYPE	SRC	TCODE (001000)

Figure 1472. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in *Table 1426* and *Table 1427*.

71.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NPC. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. *Figure 1473* shows an example of ICTM message with a TSTAMP field.

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 1473. Message with TSTAMP field example

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via such as TM, PME0 control bits)

72 Cyclic Redundancy Check (CRC) Unit

72.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

72.2 Main features

- 4 contexts for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 4 hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
  - Support for byte, halfword, or word width of the input data stream

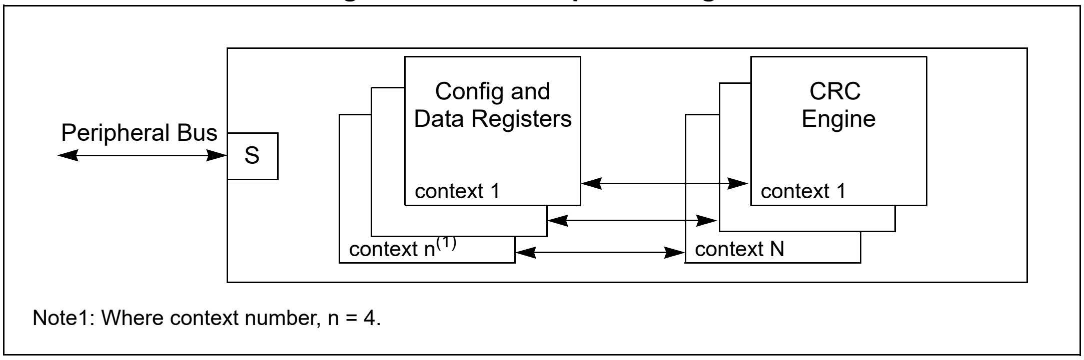
72.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

72.3 Block diagram

The top level diagram of the CRC module is given in *Figure 1474*.

Figure 1474. CRC top level diagram



72.4 Signal description

The CRC module does not generate any external signals.

72.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

72.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

72.5.1 Register description

Table 1440 shows the memory map for the CRC registers.

Table 1440. CRC unit memory map

Table 1444. CRC_OUTPn field descriptions

Field	Description
0:31 OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

72.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 50*, *Equation 51* and *Equation 52* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

Equation 50 CRC8 VDA CAN:

$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 51 CRC-CCITT (x.25 protocol):

$$x^{16} + x^{12} + x^5 + 1$$

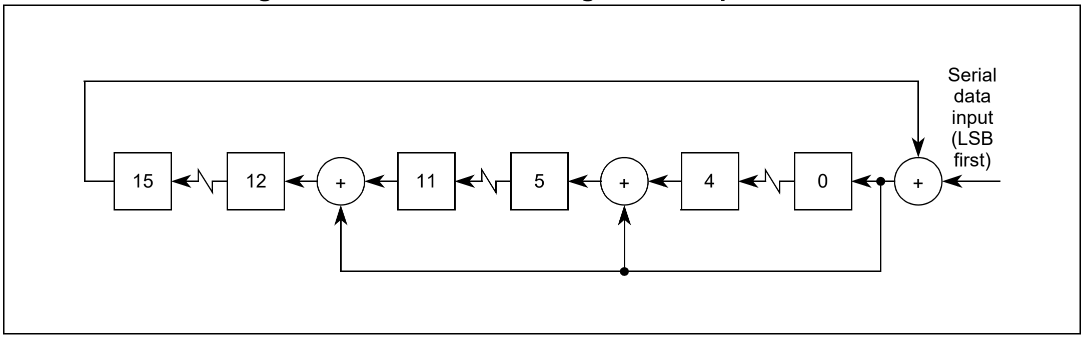
Equation 52 CRC-32 (Ethernet protocol):

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 53 CRC-8-H2F (Autosar 4.0 protocol):

$$x^8 + x^5 + x^3 + x^2 + x + 1$$

Figure 1479. CRC-CCITT engine concept scheme

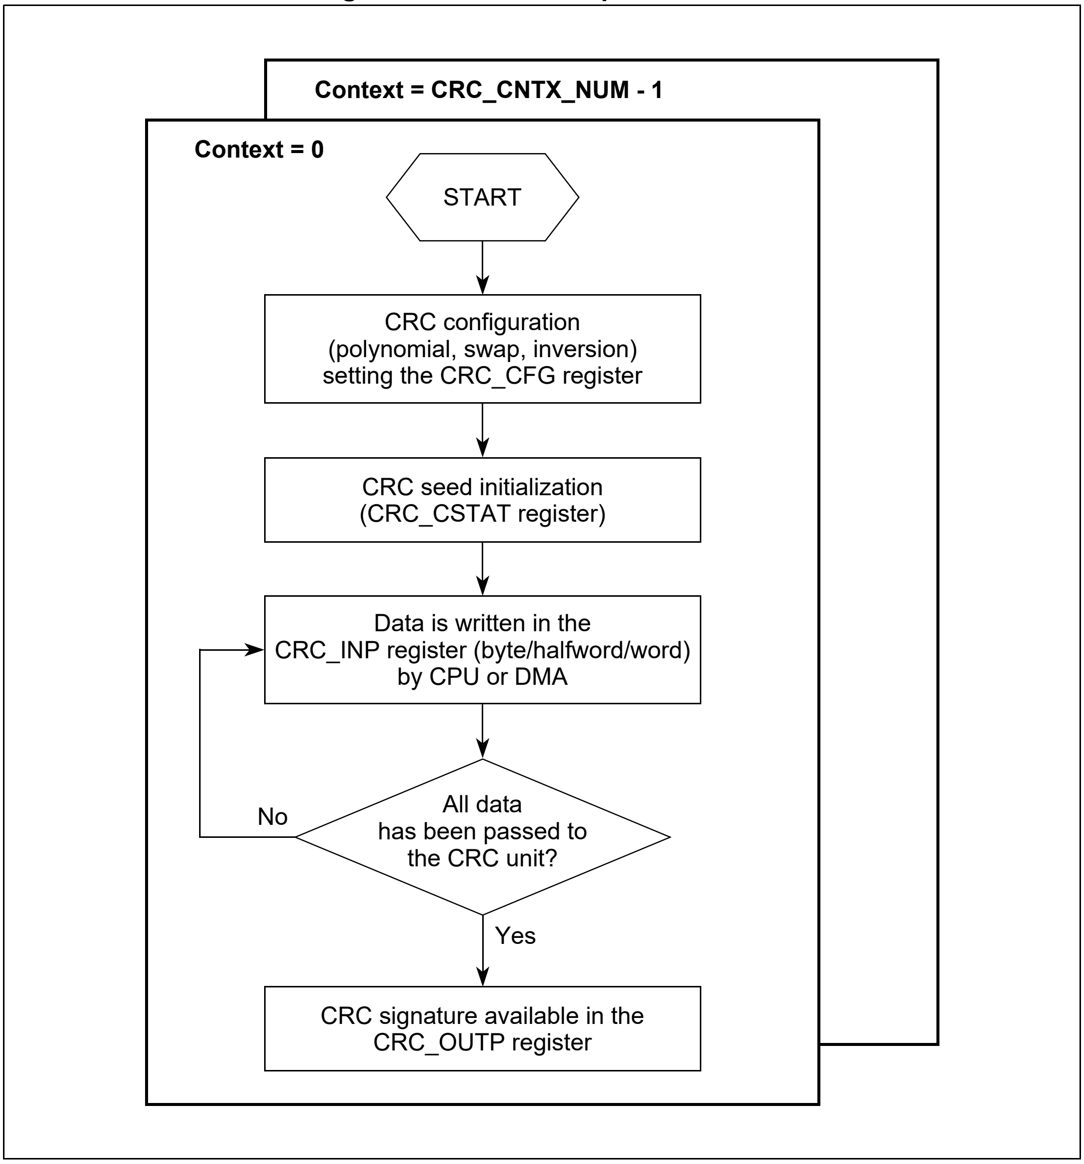


The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 1479* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (such as SPI), a bit swap (MSB → LSB, LSB → MSB) or bit inversion of the final CRC signature, or both can be applied (CRC_OUTP register) before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in *Figure 1480*.

Figure 1480. CRC computation flow



72.7 Use cases

72.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

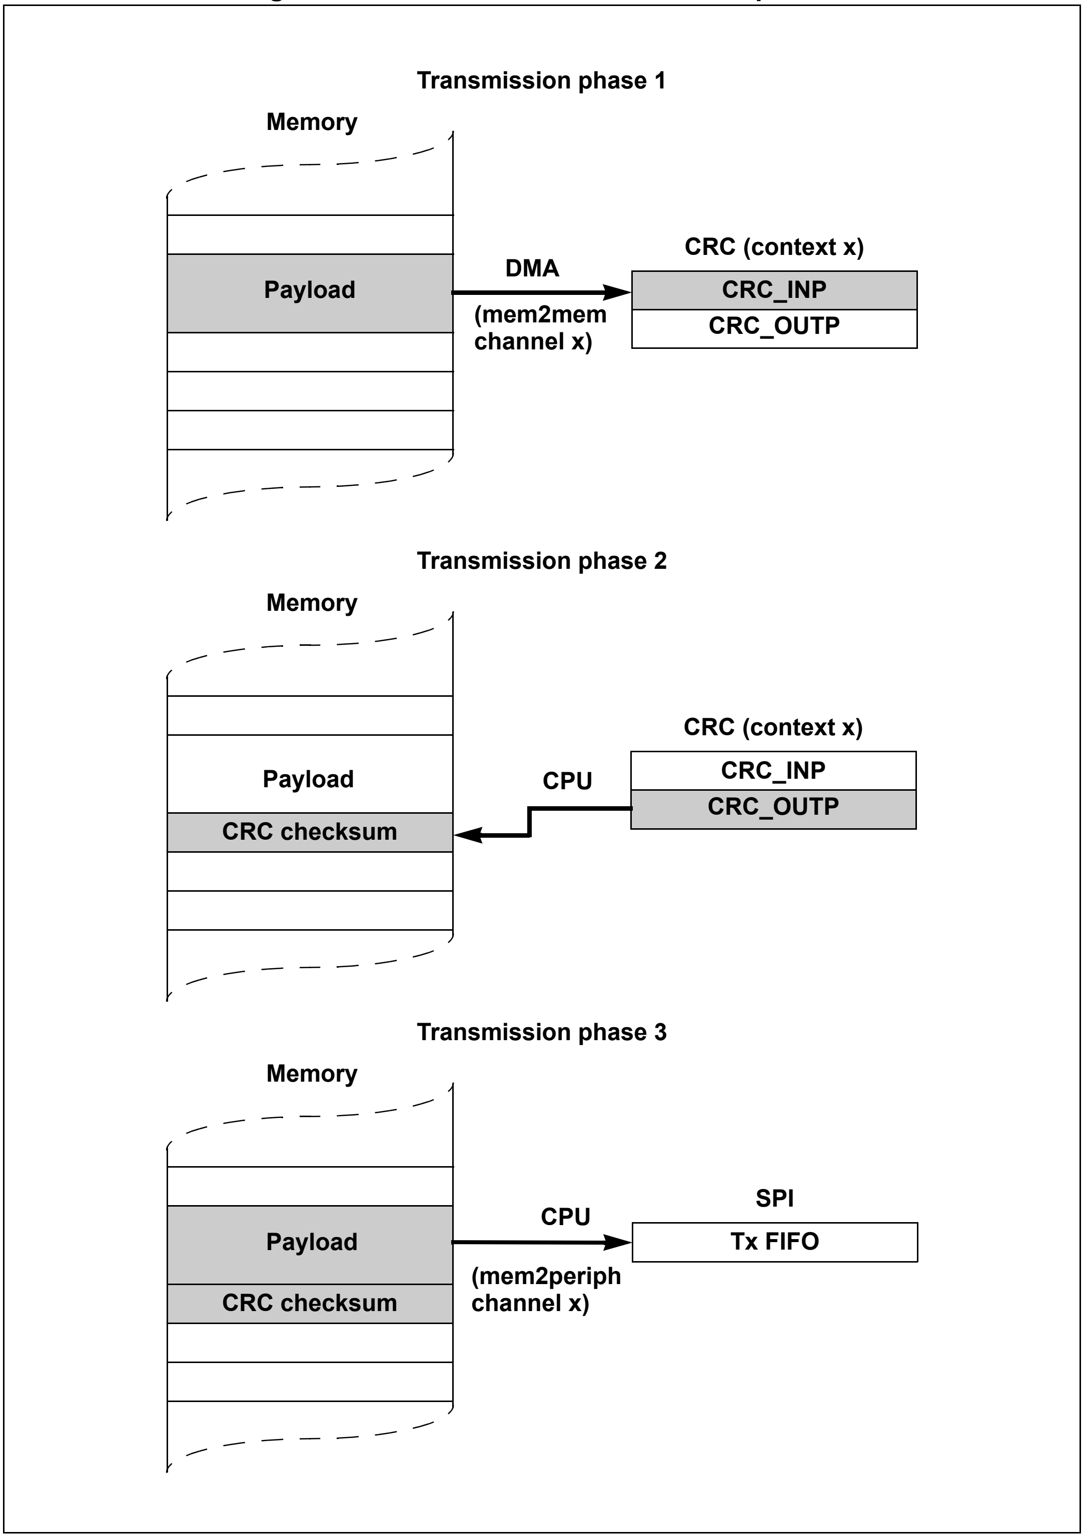
- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer: mem2mem, periph2mem, mem2periph; then this sequence, as shown in *Figure 1481*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 1481. DMA-CRC transmission sequence



72.7.2 Register programming

- INV or SWAP, or both (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

73 Memory Error Management Unit (MEMU)

73.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- SRAM
- Peripheral RAM
- Flash memory.

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single/Double bit error in the data part that is detected via ECC for flash memory. Reporting of single/double bit error as correctable error depends on CTRL.FLASH_ERR_SELECT configuration.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Double/Multiple (more than two) bit error that is detected via ECC for Flash Memory. Reporting of double bit error as uncorrectable error depends on CTRL.FLASH_ERR_SELECTION configuration.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

When multiple errors are indicated from various sources at the same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independently of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral SRAM ECC
- Flash memory ECC.

Each instance has two reporting tables–Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 73.4: Design overview* for the reporting block details.

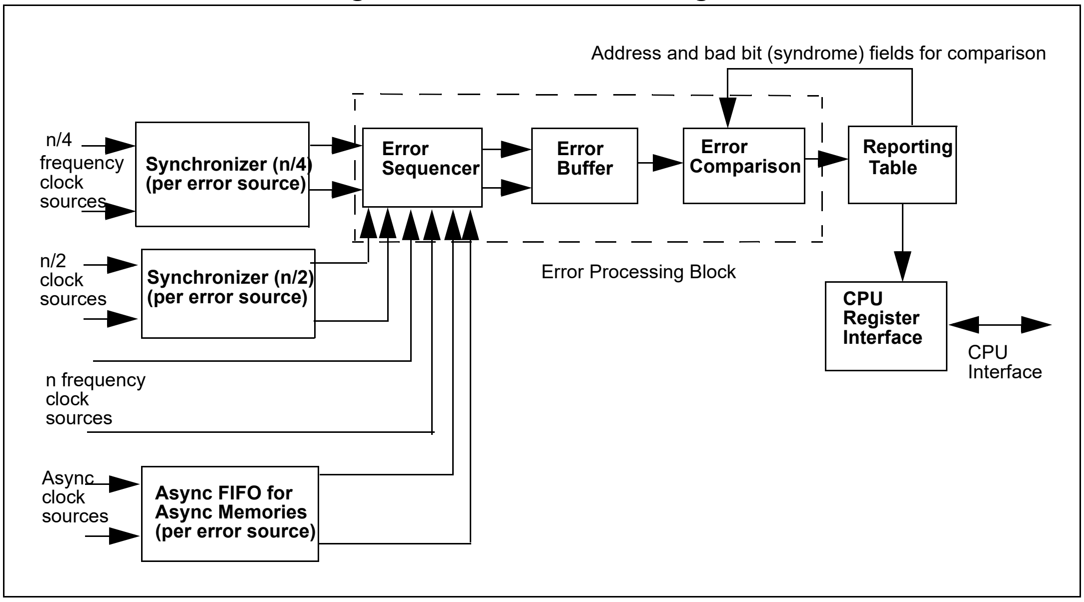
73.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral SRAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

73.3 Block diagram

Figure 1482. MEMU block diagram



73.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 73.7.3: Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set, else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error (Correctable Error: CE or Uncorrectable Error: UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique.

- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable).
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (*System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

   The software, in principle, is not supposed to write VLD to 1 if it is already 1.

   The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 1483. MEMU error buffer uniqueness check flow chart

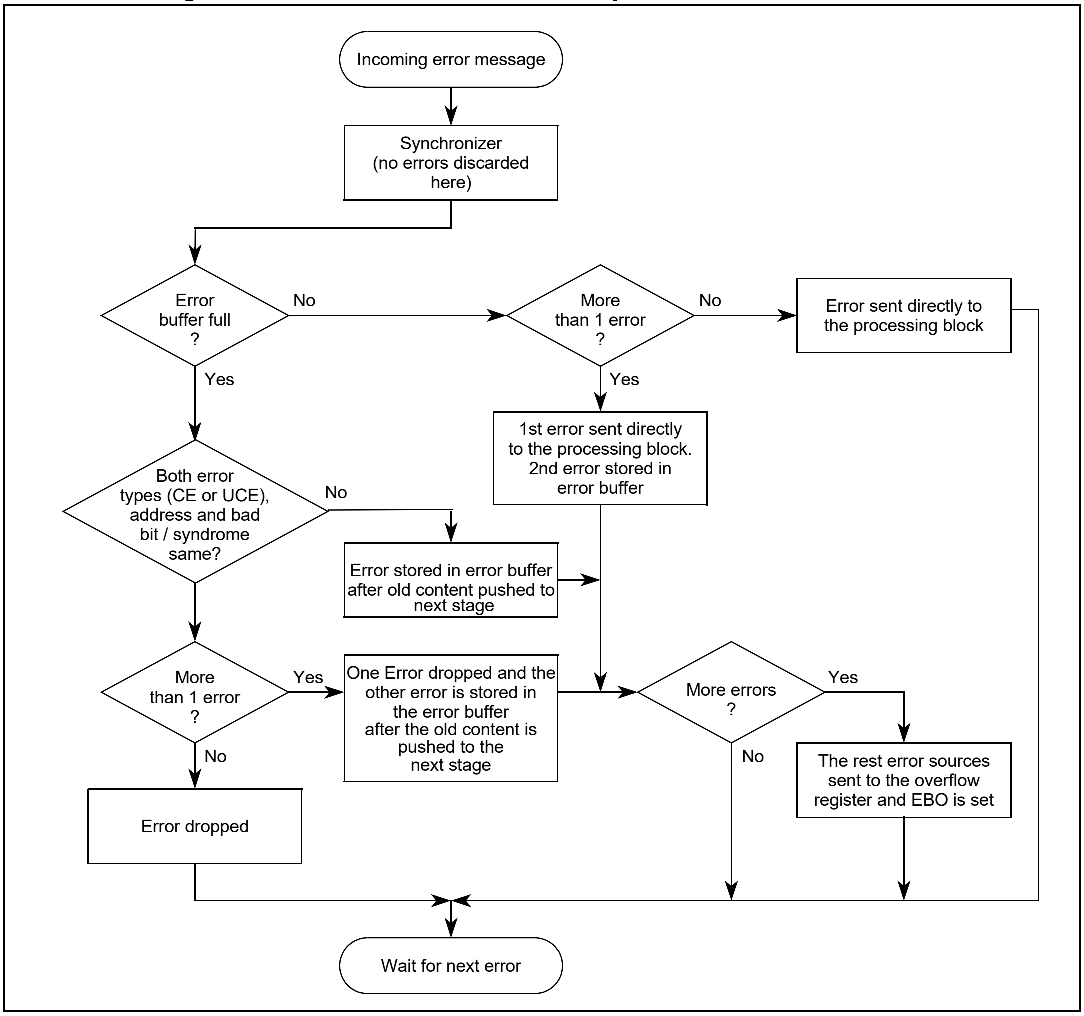


Figure 1484. MEMU reporting table uniqueness check flow chart

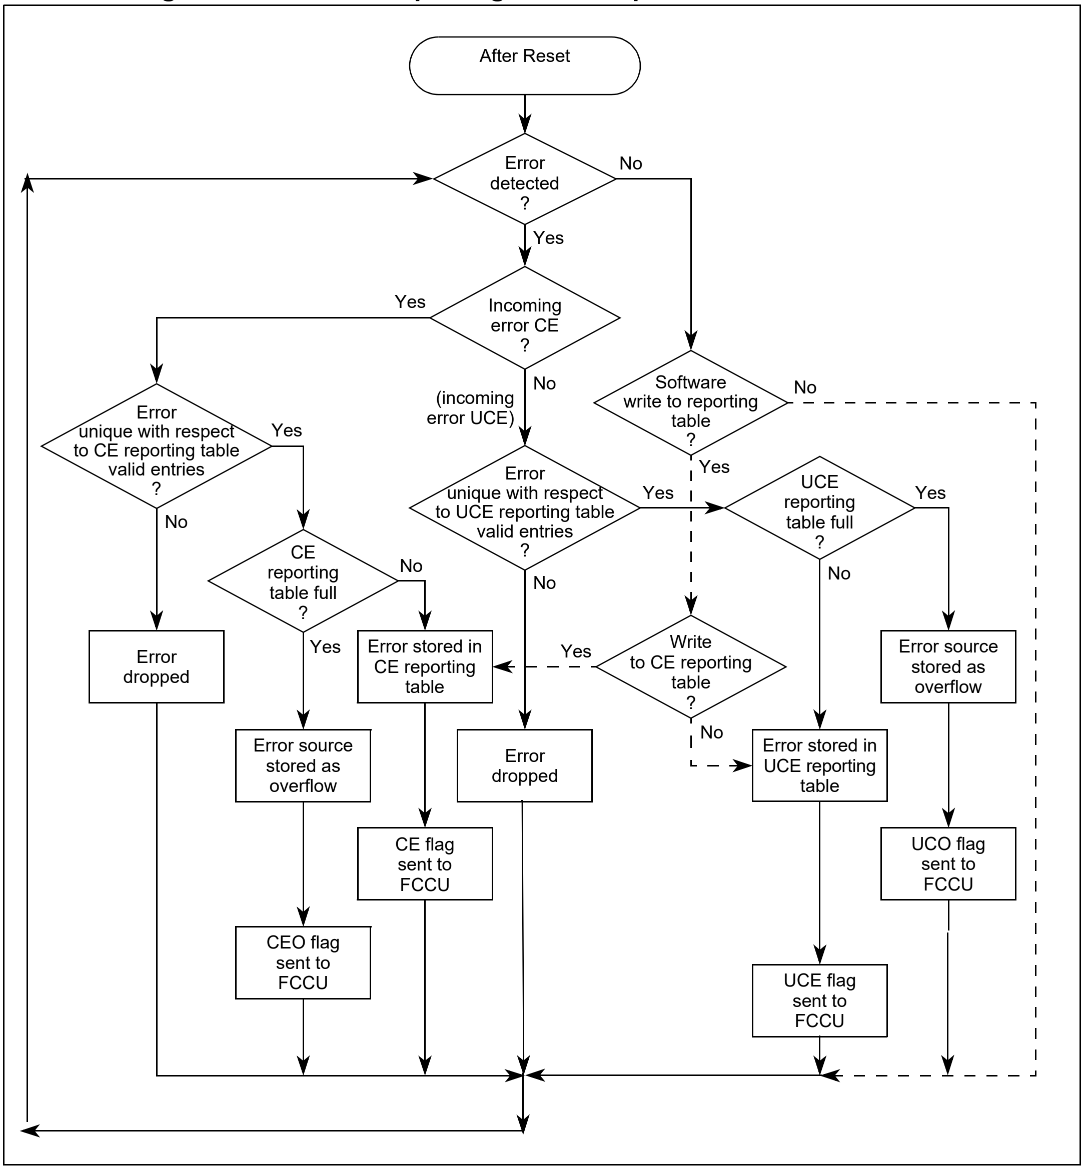

73.5 External signal description

MEMU has no external signals.

73.6 Memory map and register definition

73.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see Chapter 7: Device configuration that describes how modules are configured and connected.

Table 1446. CTRL field descriptions

Field	Description
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
30:31 FLASH_ER R_SELECT	FLASH_ERR_SELECT[1:0] 00 Store 20xDEC (Default). Flash Double-bit error corrections only are stored as correctable errors. 01 Store 20xDEC or SEC. Flash Single-bit or Double-bit error corrections, both are stored as correctable errors. 10 Store 20xSEC. Flash Single-bit error corrections only are stored as correctable errors 11 Reserved

73.6.2.2 Error Flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a ‘1’. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 1486. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 1447. ERR_FLAG field descriptions

Field	Description
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table 1447. ERR_FLAG field descriptions (continued)

Field	Description
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.

Table 1447. ERR_FLAG field descriptions (continued)

Field	Description
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

73.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Field	Description
0:31 OFLW	Overflow Bit Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 73.7.3: Handling overflows (Multiple error reporting)* occurs.

73.7 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

73.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address.The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

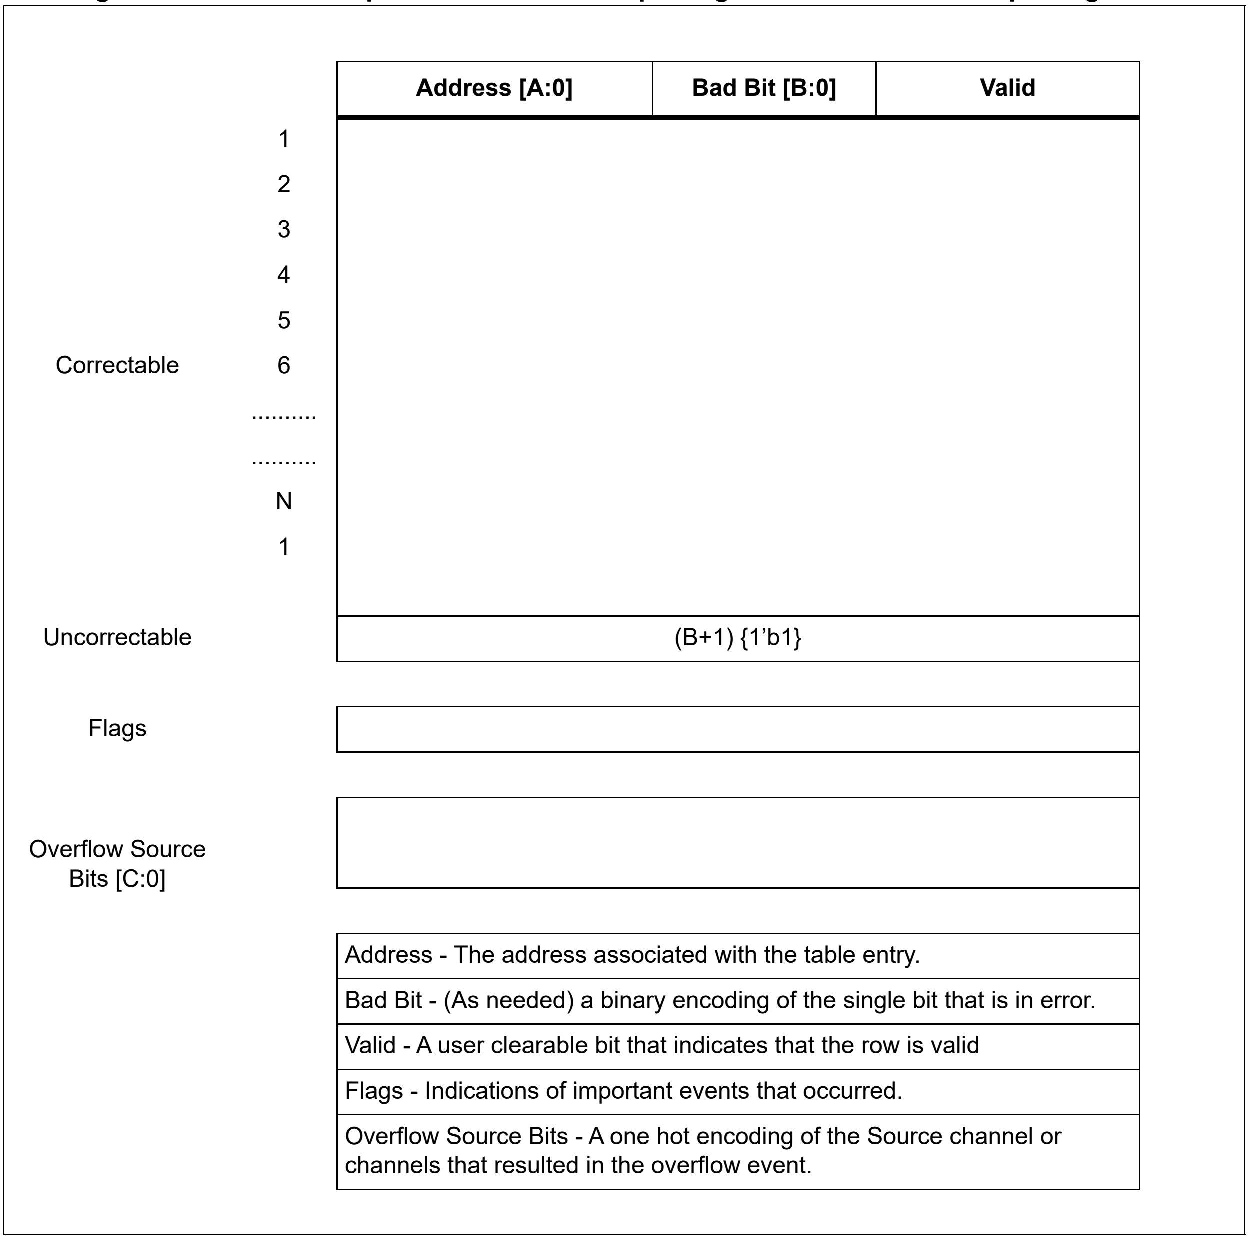
1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (duplicate entries).

73.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To in-validate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 1503. Generic representation of the reporting table of one MEMU reporting block



73.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
   – More than 2 errors detected at the same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
   – An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order which means that if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

74 Indirect Memory Access (IMA)

74.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading or modifying data, or both, including ECC check bits. This capability is useful for test activities, for example, verifying ECC functionality.

The SPC584Bx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays.
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. Refer to the Device Configuration chapter for details.

74.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no backdoors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed: I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

74.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control register (CDACNTL)
- Cache Debug Access Data register (CDADATA)

These registers are summarized in the following sections.

74.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

0	1:2	3	4:5	6:12	13:15	16:23	24:27	28	29	30:31
T/D	0	CWAY	0	CSET	WORD	PARITY CHECK BITS	0	CACHE	R/W	GO
DCR - 351; Read/Write; Reset - 0x0										

Figure 1504. Cache Debug Access Control register (CDACNTL)

The CDACNTL bits are described in *Table 1464*.

Table 1464. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1:2	—	Reserved - read as zeros.
3	CWAY	Cache Way: Specifies the cache way to be selected.
4:5	—	Reserved - read as zeros.
6:12	CSET	Cache Set: Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13:15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set.
16:23	PARITY CHECK BITS	Parity check bits (I or D-cache): D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24:27	—	Reserved - read as zeros.
28	CACHE	Cache Select: Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30:31	GO	GO command bits: 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

74.2.1.2 Cache Debug Access Data register (CDADATA)

The Cache Debug Access Data register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

Figure 1505. Cache Debug Access Data register (CDADATA)

The CDADATA bits are described in *Table 1465*.

Table 1465. CDADATA field descriptions

Bits	Name	Description
0:31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1- Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23 byte 2 24–31 byte 3

74.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

74.2.2.1 e2eECC Error Control/Status register 0 (E2EECSR0)

The e2eECC Error Control/Status register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

0–3	4–11	12–15	16–17	18–19	20–23	24–31
0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
DCR - 511; Read/Write; Reset - 0x0; Privileged						

Figure 1506. e2eECC Error Control/Status register 0 (E2EECSR0)

The E2EECSR0 bits are described in *Table 1466*.

Table 1466. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros.
4:11	RCHKBIT	Read Checkbits: This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12:15	—	Reserved - read as zeros.
16:17	WRC	Write Control: 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control: 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection

Table 1466. E2EECSR0 field descriptions (continued)

Bits	Name	Description
20:23	—	Reserved - read as zeros.
24:31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask: This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

74.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Note the following restrictions on memory access via IMA:

- When a bus master performs an IMA access, no other bus master shall perform an access to the same memory.
- Before any IMA access, the user shall disable the FCCU fault related to the IMA. If not, the FCCU triggers a fault.
- The IMA must be unlocked for reads.

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

74.3.1 Features

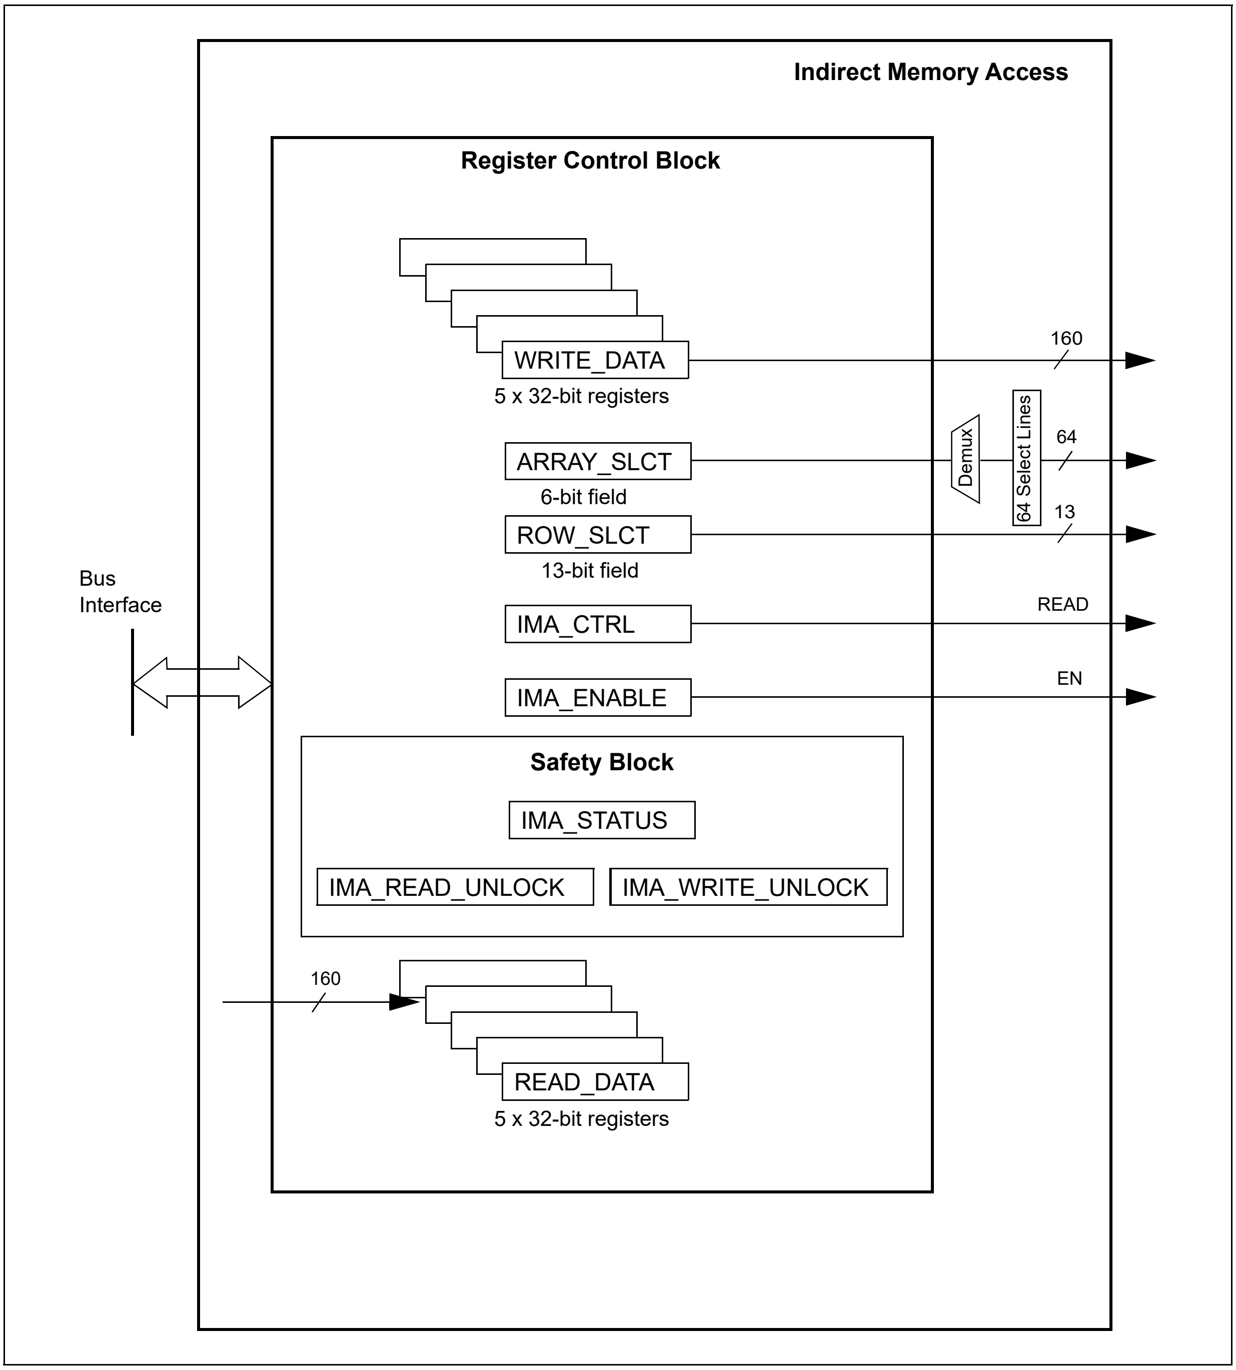
The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads.
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data
  - Writes have no effect
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

74.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it too.

Figure 1507. IMA block diagram



74.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 1467. IMA memory map

Offset Address	Register	Section

74.3.3.1 IMA Control register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Offset: 0x00 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1468. IMA_CTRL field descriptions

Field	Description
31 READ	IMA Read This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

74.3.3.2 IMA Enable Access register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: Back to back writes to the enable bit is not valid. It will still generate a two-clock enable pulse and will be considered as a single access initiation.

Offset: 0x04 Access: User read/write

Figure 1510. IMA Status register (IMA_STATUS)

Table 1470. IMA_STATUS field descriptions

Field	Description
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed. 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

74.3.3.4 IMA RAM Select register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, such as accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. Refer to the Device Configuration chapter for details.

Offset: 0x0C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1511. IMA RAM SELECT register (IMA_SLCT)

Table 1471. IMA_SLCT field descriptions

Field	Description
3:15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is 32 KB RAM.
26:31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

74.3.3.5 IMA Write Unlock register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

Offset: 0x10 Access: User read/write

Field	Description
0:31 WRITE_KEY	Key to unlock the IMA. – 0x04A43F95 is the first key that has to be written to start the unlock process. – 0xE4A9EBF7 is the second key that has to be written to unlock the IMA.

74.3.3.6 IMA Read Unlock register (IMA_READ_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The READ_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for reads.

Offset: 0x14 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 READ_KEY	Key to unlock the IMA Read Access to RAMs. – 0xF06AB5BC is the first key that has to be written to start the unlock process. – 0x14081B56 is the second key that has to be written to unlock the IMA.

74.3.3.7 IMA RAM Write Data register n (IMA_WRITE_DATA_*n*)

The IMA_WRITE_DATA_*n* registers hold the data values to be written to the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

Offset: 0x2C (WRITE_DATA_4)
0x30 (WRITE_DATA_3)
0x34 (WRITE_DATA_2)
0x38 (WRITE_DATA_1)
0x3C (WRITE_DATA_0)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 WRITE	Contains data to be written to RAM. – WRITE_DATA_4[WRITE] contains write data bits[159:128] – WRITE_DATA_3[WRITE] contains write data bits[127:96] – WRITE_DATA_2[WRITE] contains write data bits[95:64] – WRITE_DATA_1[WRITE] contains write data bits[63:32] – WRITE_DATA_0[WRITE] contains write data bits[31:0]

74.3.3.8 IMA RAM Read Data register n (IMA_READ_DATA_*n*)

The IMA_READ_DATA_*n* registers hold the data values read from the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_*n* registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Offset: 0x4C (READ_DATA_4)
0x50 (READ_DATA_3)

74.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

74.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

74.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

74.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Refer to the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

74.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

74.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY.
2. Write 0x14081B56 to READ_KEY.

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY.

74.3.4.3.3 Unlocking writes

The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY.
2. Write 0xE4A9EBF7 to WRITE_KEY.

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY.
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

74.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

74.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections show the different accesses that are available depending on the options.

74.3.4.5.1 Read access

Read Accesses are expected to follow the sequence below:

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register.
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

74.3.4.5.2 Write access

Write Accesses are expected to follow the sequence below:

1. Unlock Write Access by performing appropriate consecutive writes to WRITE_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

74.3.5 Application information

Caution: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

75 Fault Collection and Control Unit (FCCU)

75.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a systematic approach to fault detection and control. The FCCU provides a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

75.2 Features

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; refer to the implementation-specific details)
- Bi-stable, Dual Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Redundant collection of hardware checker (for example RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal (SoC) reactions
  - ALARM state: interrupt request
  - FAULT state: long functional reset request pulse, short functional reset request pulse, NMI
- Internal reactions (independently configurable for each RF)
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU
- Configuration lock: The FCCU's configuration is lockable in two ways
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into

FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register

- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol that is dual rail and time switching
- After power-on the error out pins have high impedance[u]. FCCU goes to operational state only on software request
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms
- The overall error detection, processing and indication time is less than 10 ms
- The actual maximum time is five safe (IRCOSC) clock cycles

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster than the IRC clock.

75.2.1 Standard features

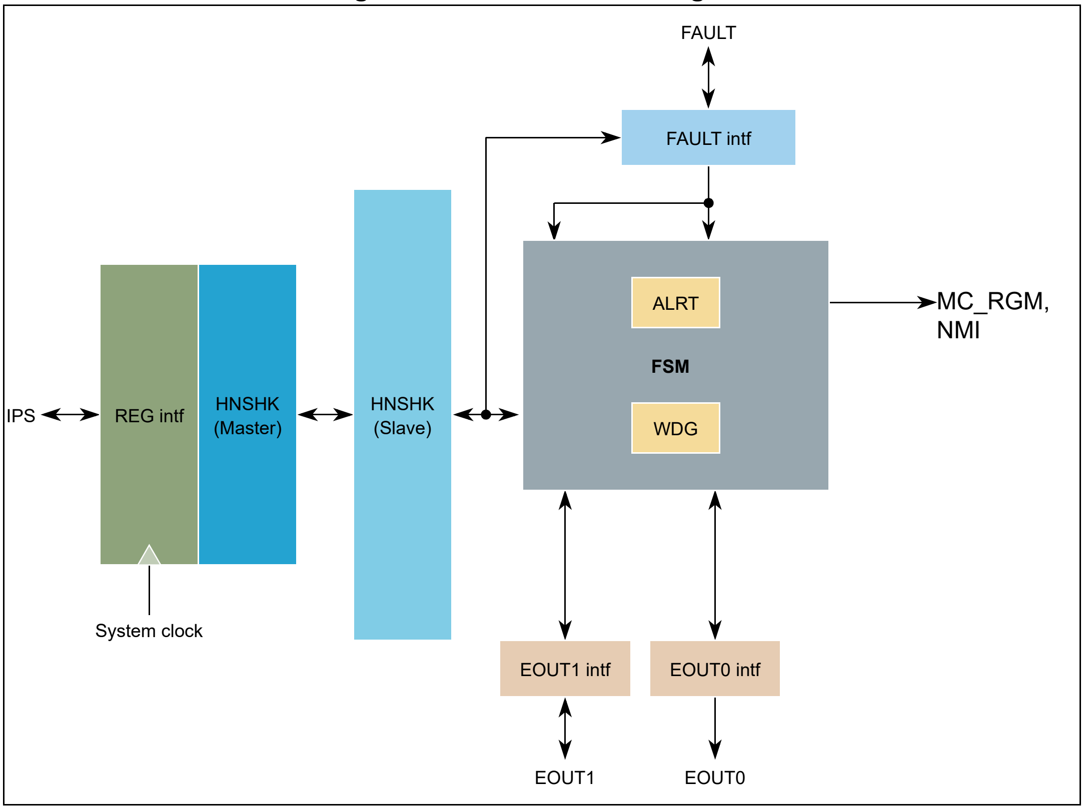
- IPS (slave bus signals) bus interface

75.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 1516*.

u. Actual value depends on the SoC settings at pad level.

Figure 1516. FCCU block diagram



The FCCU module includes the submodules listed in *Table 1476*.

Table 1476. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of two asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: Watchdog timer (WDG) Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

75.4 Signal description

75.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 75.5.9: EOUT interface*.

For the availability of these signals on a chip, refer to the device configuration chapter.

75.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers.
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0] data write/read operations to any registers.
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (for example FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 1485: FCCU memory map*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode.

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

75.5 Functional description

75.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization.
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization.
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

75.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 1517*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Succeeding one of the following events:
  - unmasked recoverable faults with the timeout disabled → the FCCU moves to the FAULT state.
  - unmasked recoverable faults with the timeout enabled → the FCCU moves to the ALARM state.
  - masked recoverable faults → the FCCU stays in NORMAL state.
- ALARM: the FCCU moves into the ALARM state when an unmasked recoverable fault occurs and the timeout is enabled. The transition to the ALARM state goes along with an interrupt request (ALARM state), if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the

FAULT state. The timeout is re-initialized if the FCCU state moves to the NORMAL state. The timeout restarts following the recovery from the FAULT state.

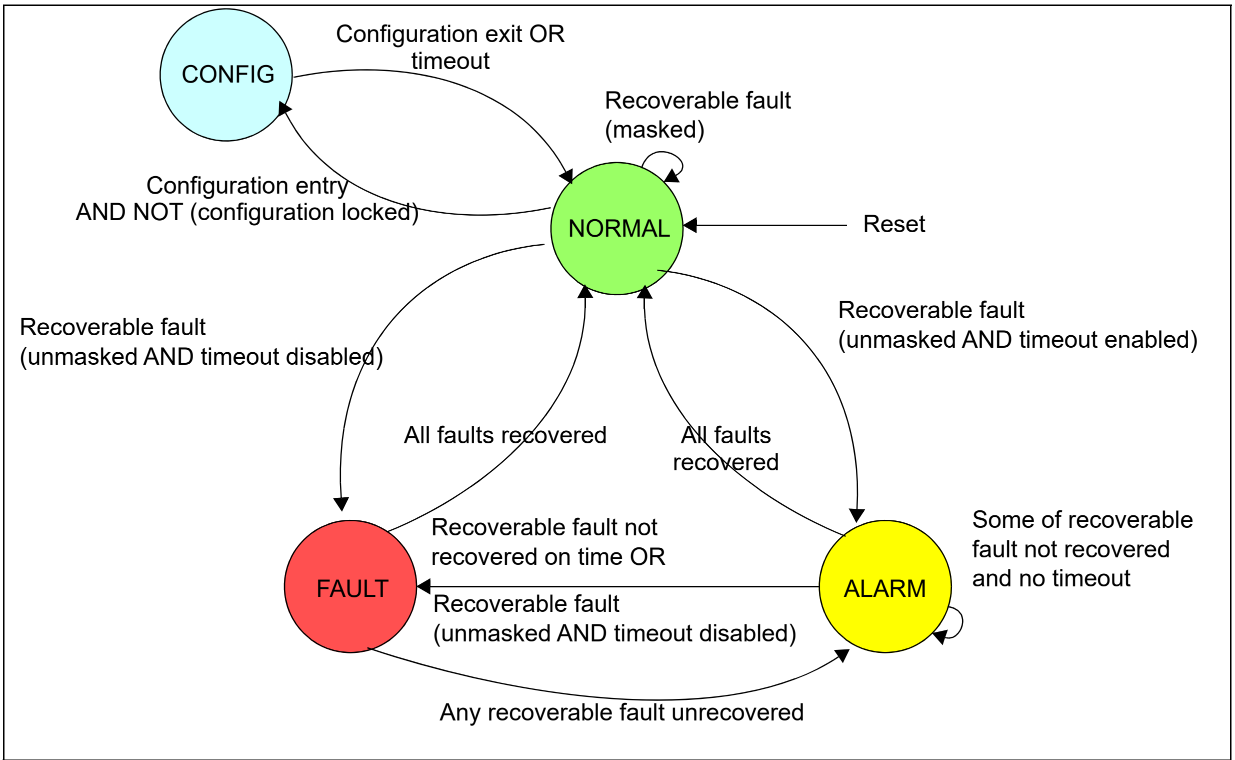
- FAULT: the FCCU moves into the FAULT state when one of the following conditions occurs:
  - timeout related to a recoverable fault when the FCCU is in the ALARM state.
  - unmasked recoverable faults with the timeout disabled.

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional).
- EOUT signaling (optional).
- SW option: Soft reaction (Short functional reset request pulse if configured).
- SW option: Hard reaction (Long functional reset request pulse if configured).

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 1517. FCCU state diagram



75.5.3 Reset interface

The FCCU has two input resets, as described in *Table 1477* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 1478* for each type of fault reaction (hard, soft or self-checking), the respective output reset (Long functional reset, Short functional reset) is activated. In *Table 1479* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit generates the corresponding input reset as described in *Table 1477*.

Table 1477. Input reset

Input reset	Description
System reset	Global reset of the FCCU synchronous to the system clock.
System reset (RC oscillator)	Global reset of the FCCU synchronous to the IRCOSC.

Table 1478 and *Table 1479* describe a typical reset strategy at system level.

Table 1478. Reset reactions

FAULT reaction	Active reset	System reset signal
Hard	Long functional reset	disabled
Soft	Short functional reset	disabled

Table 1479 shows the Reset sources.

Table 1479. Reset sources

Reset source	System reset signal
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 1480 summarizes the MC actions corresponding to each reset generated by FCCU.

Table 1480. MC actions

Active reset	MC action
Long functional reset	Reset Flash and digital modules excluded FCCU, STCU
Short functional reset	Reset digital modules excluded FCCU, STCU

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for two IRCOSC clock periods.

75.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (possible for RFs only) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a RF (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any RF is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the RF that causes an ALARM to FAULT state transition. In this case the alarm timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

75.5.5 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a RF management (ALARM state), refer to *Figure 1518* and *Figure 1519*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if configured)
  - Timeout running
- System state: RUN
- Alarm interrupt management: FAULT recovery (by SW): FCCU state transition ALARM → NORMAL

Figure 1518. RF (ALARM state) recovery (a)

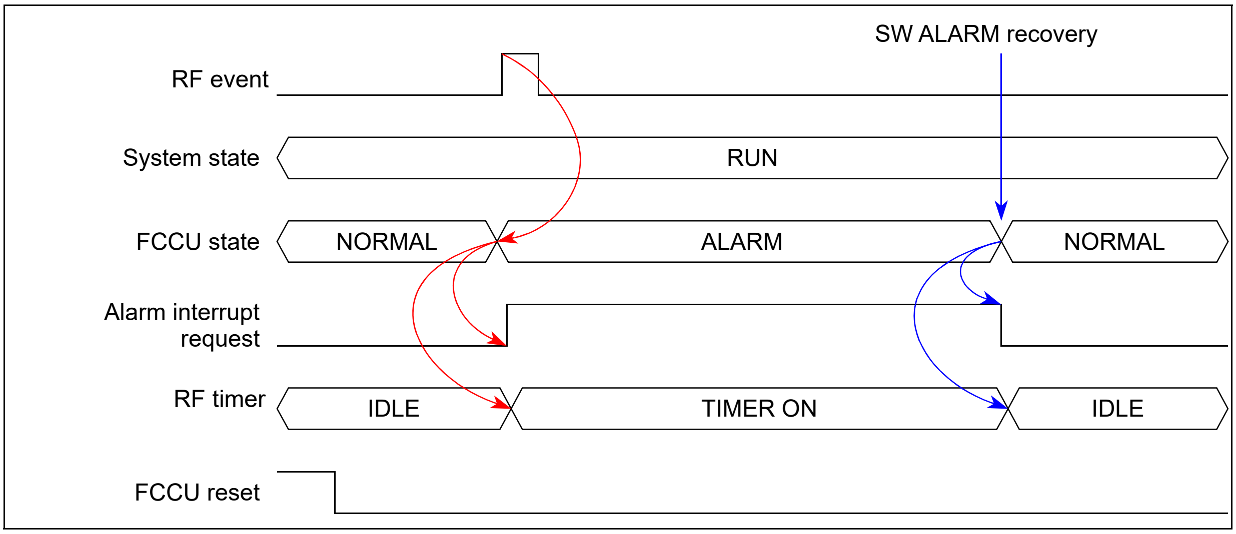


Figure 1519. RF (ALARM state) recovery (b)

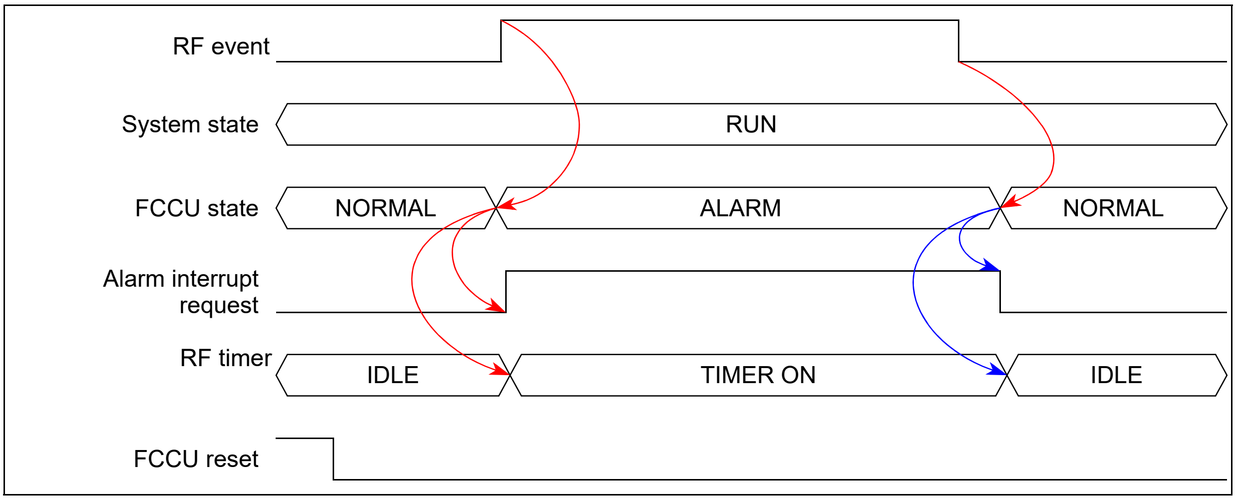
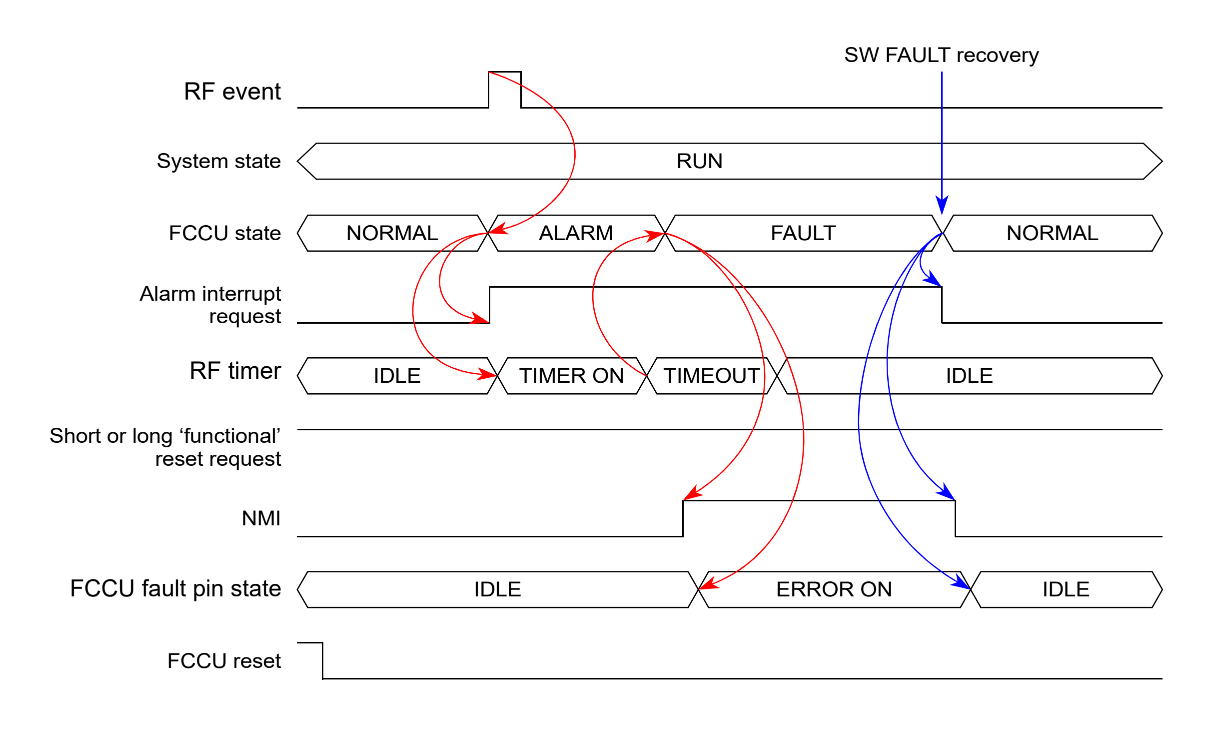


A typical sequence related to a RF management (ALARM → FAULT state), refer to *Figure 1520*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if enabled)
  - Timeout running
- FCCU state transition (following the timeout trigger): ALARM → FAULT: NMI assertion (if enabled)
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL

Figure 1520. RF(ALARM -> FAULT state) recovery



75.5.6 NMI/WKPU interface

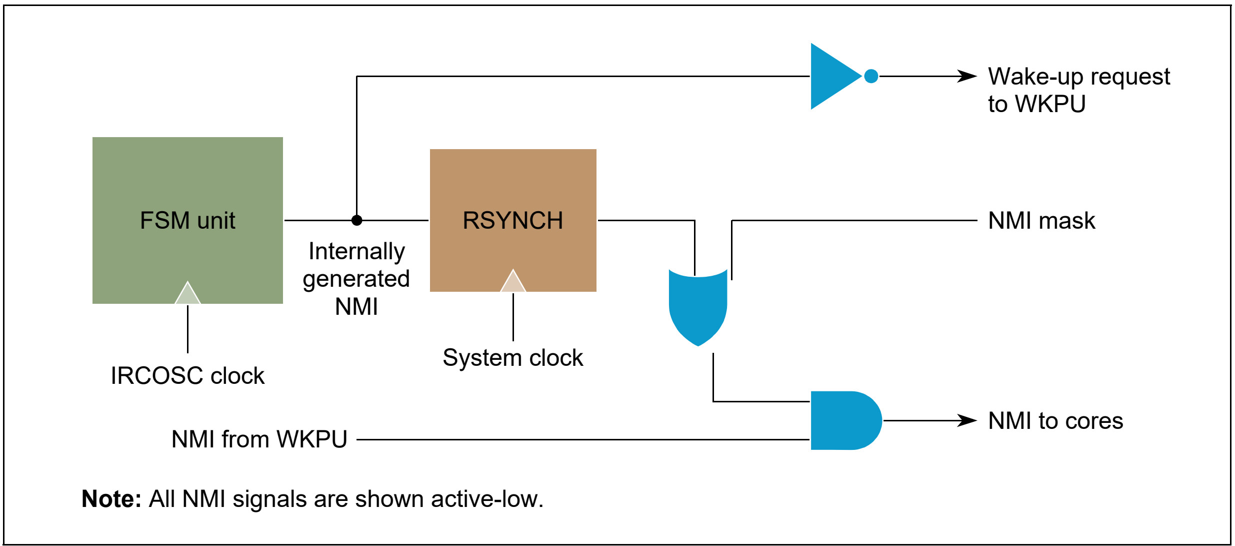
The wake-up interface includes Non-maskable interrupt: NMI interrupt source generated by the WKPU. It is synchronous with the system clock and active low. A logical AND interconnects the NMI sources (internally generated by FCCU and by WKPU) in order to provide a single NMI output.

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (MC state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (MC mode SW change request = 1).

Figure 1521. NMI/WKUP scheme



75.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple, programmable edge-sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1522*. The fault injection is executed by a write operation in the FCCU_RFF register.The reaction following a fake RF cannot be masked. The fault injection mechanism is optional; refer to the implementation-specific details. Refer to “FCCU failure inputs” table in Functional Safety chapter, for more details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (FCCU recoverable faults clear) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1523*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_S*n*. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 1522. FAULT injection

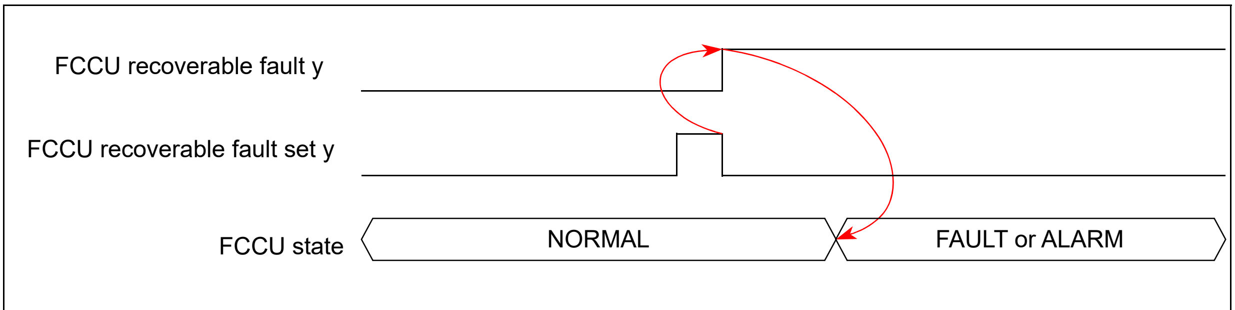


Figure 1523. FAULT clearing

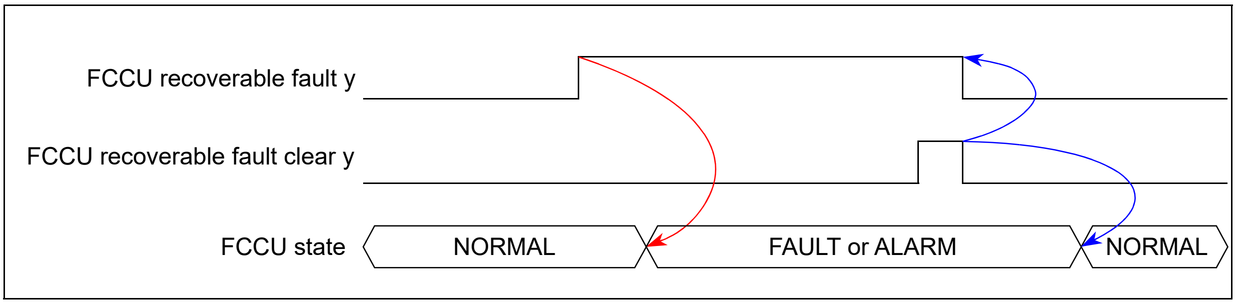

75.5.8 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the following FCCU fault:
  – Recoverable
- The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- A mask (EOUT mask[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible for providing a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible for providing the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 1524. STCU-FCCU (case a)

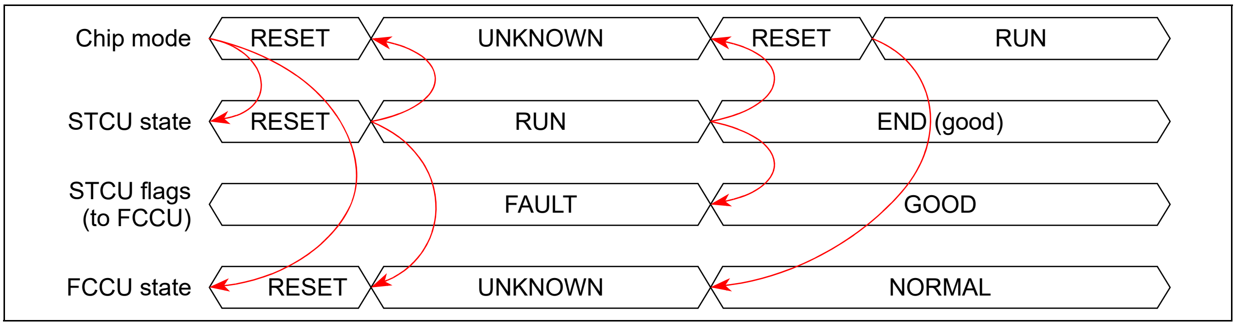

Figure 1525. STCU-FCCU (case b)

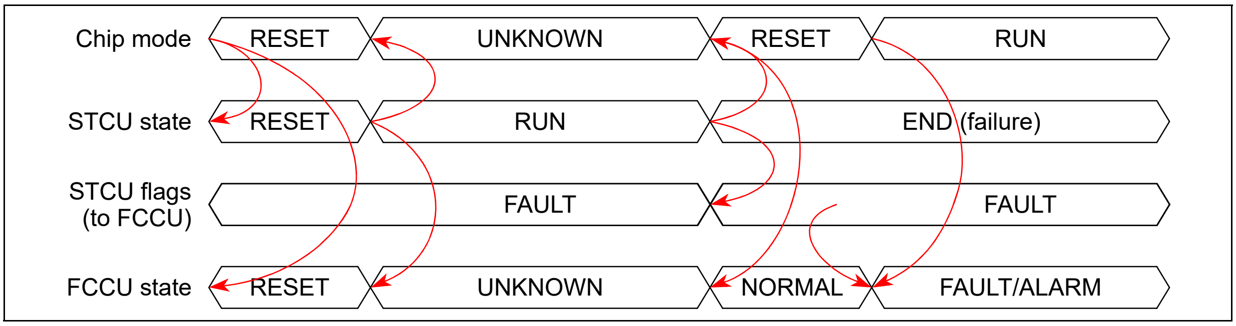

Figure 1526. STCU-FCCU (case c)

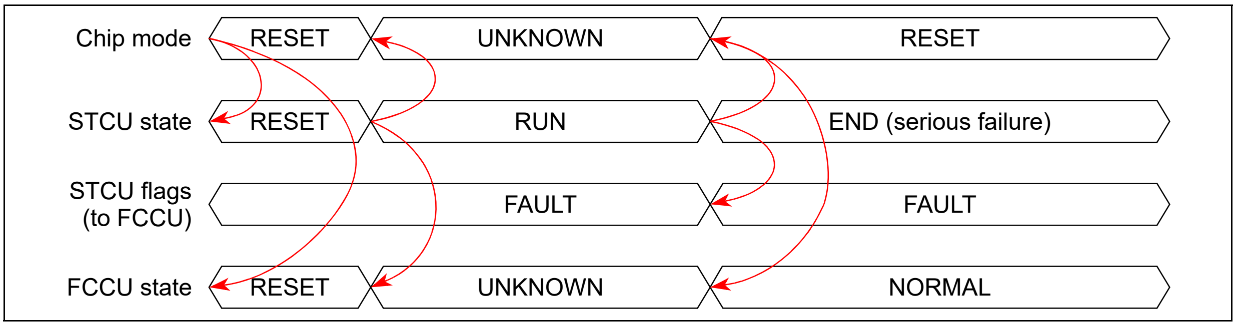


75.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (refer to table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS field in the FCCU_CFG register. For example, for PS = 0, FCCU Error output[0] = 0 and FCCU Error output[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual rail or time switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL). The EOUT protocol transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.

- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occur in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18}. With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual rail or time switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, that is an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset, and software bit FCCU_RST in RGM_PRST5) should not influence the state of the failure indication, pins.

Note: The transition from FAULT to CONFIG state is not possible but is shown to display the behavior in all four states: RESET, NORMAL, FAULT and CONFIG.

Table 1481. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written FCCU_SET_AFTER_RESET bit to 1.

Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

75.5.9.1 Dual rail protocol

Dual rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 1482 and the related timing diagram is given in Figure 1527 and Figure 1528.

Table 1482. Dual rail encoding

Logical state	Dual rail encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	00	toggling
faulty	11	
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

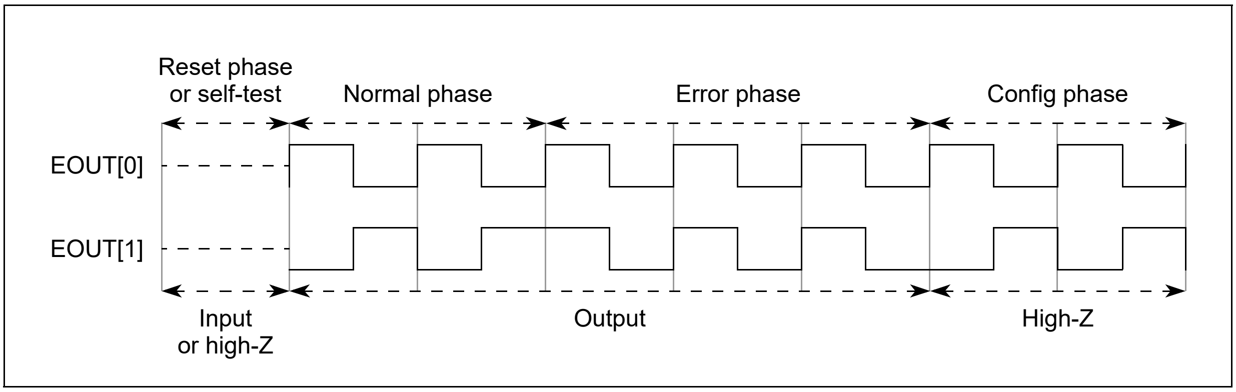
1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the RESET phase the output pins are set as “high impedance”[v].

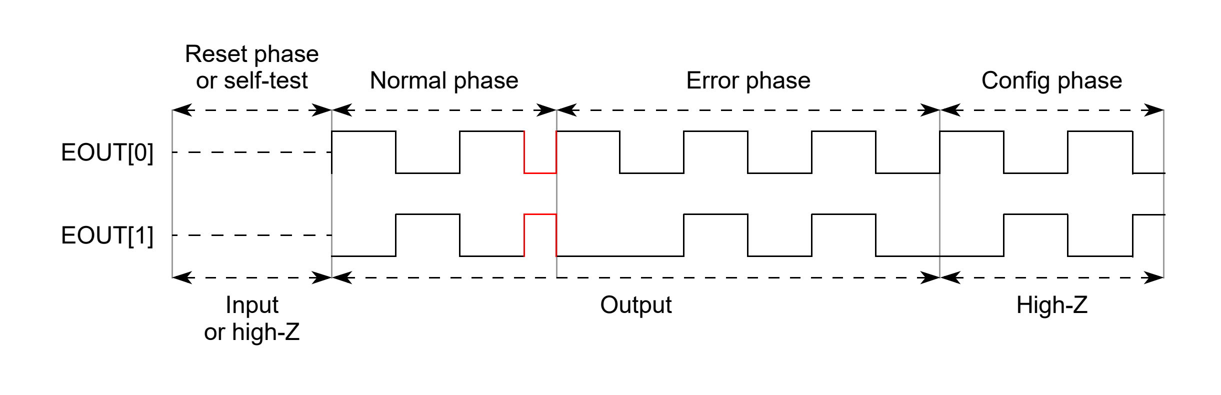
Note: Figure 1527 and Figure 1528 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 1527. Dual rail protocol (slow switching mode)



v. Actual value depends on the SOC settings at pad level.

Figure 1528. Dual rail protocol (fast switching mode)



75.5.9.2 Time switching protocol

The encoding scheme is given in *Table 1483* and the related timing diagram is given in *Figure 1529*.

Table 1483. Time switching encoding

Logical state	Time switching encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the FAULT state, the output pin FCCU Error output pin[0] is set as low.

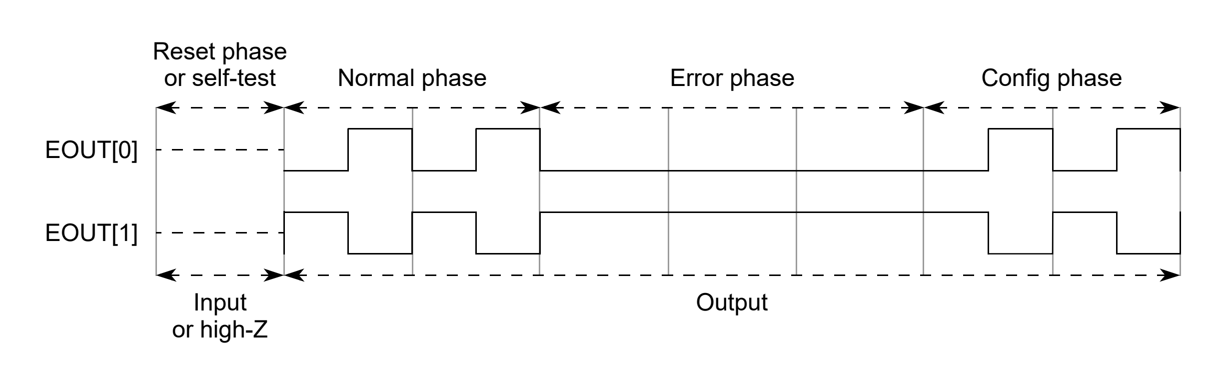
In Time Switching mode the second output (FCCU Error output pin[1]) is the inverted signal of first output (FCCU Error output pin[0]).

In the RESET phase the output pins are set as “high impedance”[w].

Note: Figure 1529 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

w. Actual value depends on the SOC settings at pad level.

Figure 1529. Time switching protocol



75.5.9.3 Bi-stable protocol

The encoding scheme is given in Table 1484 and the related timing diagram is given in Figure 1530.

Table 1484. Bi-stable encoding

Logical state	Bi-stable encoding (FCCU Error output pins [1:0])	Note
nonfaulty	01	no toggling
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	no toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

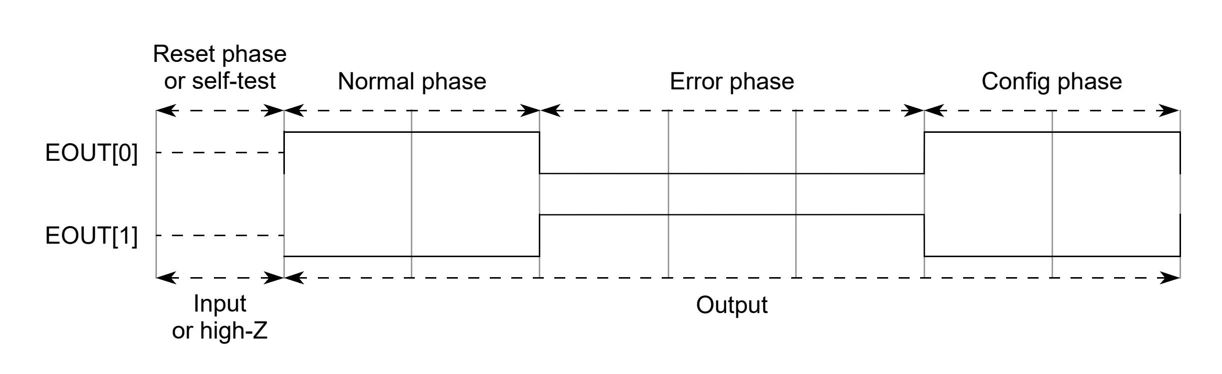
In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (FCCU Error output[1]) is the inverted signal of first output (FCCU Error output[0]).

In the RESET phase the output pins are set as "high impedance"(x).

Note: Figure 1530 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

x. Actual value depends on the SOC settings at pad level.

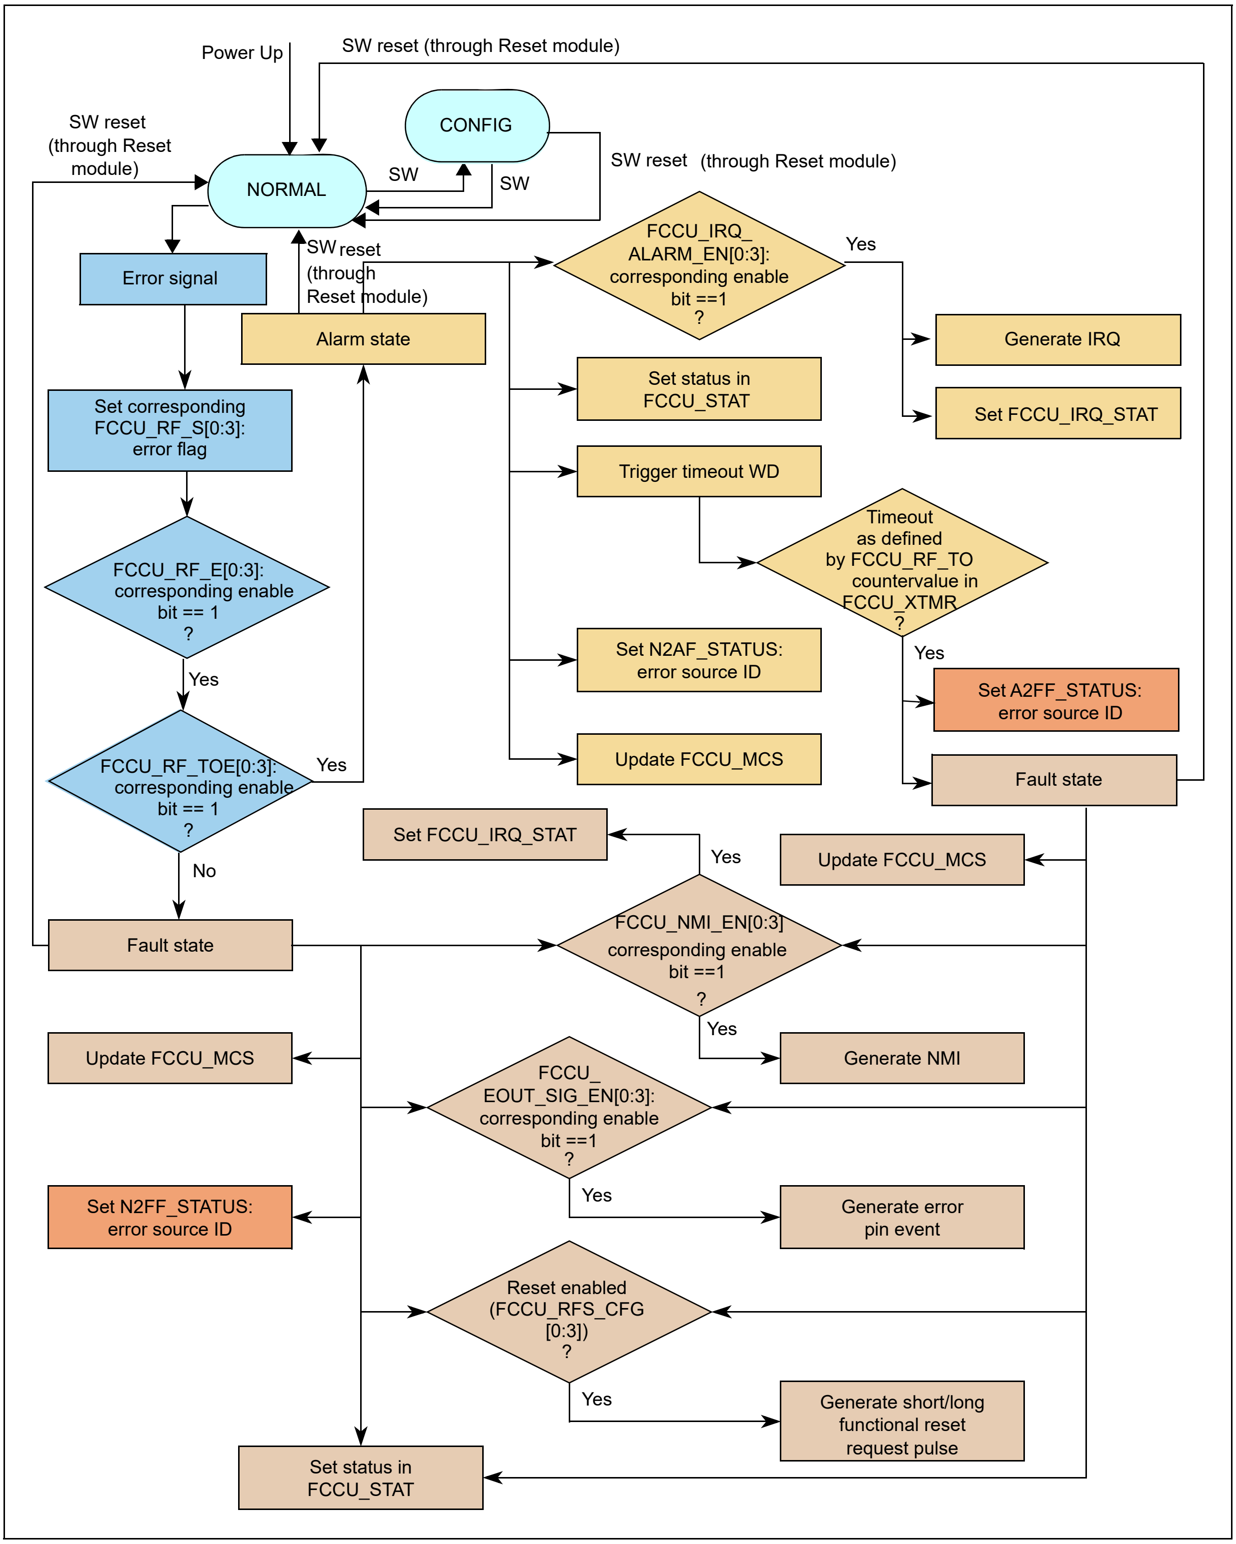
Figure 1530. Bi-stable protocol



75.5.10 Error signal flow for RF case

On Power up, FCCU moves to NORMAL state. SW can configure it by moving it to CONFIG and back again. SW reset leads to movement back to NORMAL. On reaching ALARM state, depending on ALARM being enabled, FCCU generates IRQ (alarm) and the FCCU_IRQ_STAT's alarm status is also set. FSM status is set in FCCU_STAT along with N2AF_STATUS. If Error is enabled (FCCU_RF_E) and timeout disabled (FCCU_RF_TOE), FCCU moves straight to FAULT state and depending on FCCU_NMI_EN or FCCU_SIG_EN, or both, being set, it generates a NMI or signals error, or both, out to the external world. FCCU FSM status is also captured in FCCU_STAT.

Figure 1531. Error signal flow



75.6 Register description

The FCCU registers are listed in *Table 1485*. Any address offset not explicitly mentioned in *Table 1485* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 1485*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

Table 1485. FCCU memory map

75.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state.
- moving the FCCU state from the CONFIG state into the NORMAL state.
- reading or to clear the RF status register.
- reading the FCCU FSM status register.
- reading or to clear the FCCU freeze registers.
- reading the ALARM timer.
- reading the Watchdog timer.
- configure the glitch filter present on EIN0 input (FCCU failure input #96).

Some critical operations require a key as defined in the FCCU_CTRLK register.

The Glitch filter, filters out pulses of widths up to 50/75/100 µs, as governed by FCCU_CTRL[FILTER_WIDTH]. It becomes active as soon as FCCU_CTRL[FILTER_BYPASS] is de-asserted (default value).

The implementation is as follows:

1. Fault line assertion - If a Fault is asserted, then the output of the filter is asserted after the delay, equal to the programmed glitch width time. If the fault is de-asserted before

the programmed glitch width time, then the output of the filter is not asserted and stays at the deactivated level (after having rejected the spurious glitch).

2. Fault line de-assertion - If a Fault, which was kept asserted for a time greater than the programmed pulse width is de-asserted (and glitch filter output is at asserted level now), then the output of the filter is de-asserted only after the delay equal to the programmed glitch width time. If the fault is again asserted before the programmed glitch width time, then the output of the filter is not de-asserted and stays at the active level (after having rejected the spurious glitch).

The output of the filter becomes the effective fault input fed to the FCCU error management engine. Since there is an inherent latency involved, SW must either wait for the programmed delay value before trying to clear the fault status flag, FCCU failure input #96 or first set FCCU_CTRL[FILTER_BYPASS] to one and then try to clear the fault status flag. This bit should not be made '1' again, till the filter width time elapses, else fault status will be latched again.

Offset: 0x000 Access: User read/write

1:2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs for 20 MHz IRC clock 11 filters glitches up to 100 µs for 20 MHz IRC clock Make sure that the filter width does not cross the FOSU timeout value else unintended reset may occur.

Table 1486. FCCU_CTRL field descriptions (continued)

Field	Description
22 DEBUG	Debug mode entry 0 Normal operation 1 Put FCCU into debug mode When Debug pin signal is asserted and this bit is set, FCCU moves into debug state and suspend the transition of the FSM by suspending timer elapse time effect.
24:25 OPS	Operation status 00 Idle 01 In progress 10 Aborted 11 Successful These bits can be read and cleared (via OP15 operation) by the software.

Table 1486. FCCU_CTRL field descriptions (continued)

Field	Description
27:31 OPR	Operation run 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (refer to the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (refer to the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (refer to the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (refer to the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (refer to the F2A_STATUS register) [OP7] 01000 Reserved 01001 Reserved 01010 Read the RF status register (refer to the FCCU_RF_S register) [OP10] 01011 Reserved 01100 RF status clear operation in progress (refer to the FCCU_RF_S register) [OP12] 01101 Clear the freeze status registers (refer to the freeze registers) [OP13] 01110 CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111 Clear the operation status (OPS=Idle) [OP15] 10000 Reserved 10001 Read the ALARM timer (refer to the FCCU_XTMR register) [OP17] 10010 RESERVED 10011 Read the CFG timer (refer to the FCCU_XTMR register) [OP19] 10100 Read the Error Pin low counter value (refer to *Section 75.6.21: FCCU XTMR Register (FCCU_XTMR)*) [OP20] 10101 Reserved ... 11111 Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution The max timing needed for ABORT/SUCCESS response is 15 IRC cycles

75.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There shall not be any other operation in between the above steps and the 32 bits need to be written in one cycle. So, store FCCU_CTRLK, merge with OP1 or OP2 then send it.

The FCCU_CTRLK register is not readable, a 0x0000_0000 value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

R	Reserved	Reserved		OD	0	SM	PS	FOM			Reserved					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0[(2)]	0	0	0

1. Writable only in the CONFIG state.
2. After powerup, reset value will be 0. If configuration timeout occurs then default value will be changed to 1.

Figure 1534. FCCU Configuration Register (FCCU_CFG)

Table 1488. FCCU_CFG field descriptions

Field	Description
7 FCCU_SET_ AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0 FCCU's Error indication stops functioning and error pins are in HI-Z state[(1)]. 1 write to start FCCU functioning. After power-on the error out pins shall be in high impedance[(1)]. They will go to normal state only on software request, this bit is set to 1. It is Software responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
8:9 FCCU_SET_ CLEAR	Error pin state can be controlled by these bits 01 Error Pin driven to logic 0. 11 Error Pin driven to logic 1 (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault). 00 FCCU acts independent of above SW control. 10 FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z(1). Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state. This bit feature may not work with toggling protocols for example say EOUT pins are set high by SW using this bit followed by switching to a toggling protocol after returning control to FCCU FSM via setting this bit to 00 or 10, the user may find that EOUT pins do not toggle as was being expected.

Table 1488. FCCU_CFG field descriptions (continued)

Field	Description
19 OD	Open Drain Mechanism to select between Push-pull and Open drain (OD) mode for the error indicating pin(s). 0 push-pull 1 OD
21 SM	Switching mode 0 EOUT protocol (dual rail, time switching) slow switching mode. 1 EOUT protocol (dual rail, time switching) fast switching mode. SM has no effect on the bi-stable protocol.
22 PS	Polarity selection 0 FCCU Error output[1] active high, FCCU Error output[0] active low. 1 FCCU Error output[1] active low, FCCU Error output[0] active high. This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non toggling in Error phase.
23:25 FOM	Fault Output Mode selection 000 Dual Rail (default state) [FCCU Error output[1:0]= outputs] 001 Time Switching [FCCU Error output[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [FCCU Error output[0]= input, FCCU Error output[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= input] **Note:** In Test mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.

1. Actual value depends on the SOC settings at pad level.

75.6.4 FCCU RF Configuration Register *n* (FCCU_RF_CFG*n*)

The FCCU_RF_CFG*n* registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

Offset: 0x01C + *n**0x4 (*n* = 0 to 3) Access: User read/write(1)

75.6.6 FCCU RF Status register *n* (FCCU_RF_S*n*)

The FCCU_RF_S*n* register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_S*n* register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field
3. Wait for the completion of the operation (FCCU_CTRL.OPS field)
4. Read the FCCU_RF_S*n* register in order to verify the effective deletion and in case of failure to repeat the sequence

As a result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (refer to *Section 75.5.7: FAULT interface*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_S*n* read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_RF_S*n* register

In case of reconfiguration of the FCCU (CONFIG state), before returning in NORMAL state the pending status bits into the FCCU_RF_S*n* must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

75.6.7 FCCU RF Key register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_S*n* register.

The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx

The key must be written for each FCCU_RF_S*n* clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0x0000_0000 value is always returned in case of read operation.

75.6.8 FCCU RF Enable Register *n* (FCCU_RF_E*n*)

The FCCU_RF_E*n* registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_S*n* register is anyway set, only the reaction is masked.

These registers are writable only in the CONFIG state.

75.6.9 FCCU RF Timeout Enable Register *n* (FCCU_RF_TOE*n*)

The FCCU_RF_TOE*n* registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective timeout is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

75.6.10 FCCU RF Timeout Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state. The alarm timeouts value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU timeout.

This register is writable only in the CONFIG state.

Field	Description
0:31 TO	Recoverable fault timeout Timeout = (TO) x $T_{RC16MHz}$

75.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 1485: FCCU memory map*. The watchdog timeout is clocked with the RC oscillator clock (16 MHz). The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

75.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the FCCU Error output pin[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the FCCU Error output pin[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the FCCU Error inputs level

Table 1502: Bi-stable encoding shows Bi-stable encoding.

Table 1502. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

1. FCCU Error input x depends on the PAD configuration, that is, internal pull-up enabled as default or pull-down and therefore EINx bit is 1 or 0 upon reset.
2. Refer to the Device Configuration chapter for chip-specific reset value.

Figure 1543. FCCU IO Control Register (FCCU_EINOUT)

Table 1503. FCCU_EINOUT field descriptions

Field	Description
26 EIN1	Error input 1 0 when FCCU Error input[1] = 0 1 when FCCU Error input[1] = 1 The EIN1 captures the respective FCCU Error input[1] signal.
27 EIN0	Error input 0 0 when FCCU Error input[0] = 0 1 when FCCU Error input[0] = 1 The EIN0 captures the FCCU Error input[0] signal.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => FCCU Error output[1] configured in output mode). 0 force FCCU Error output[1] = 0 1 force FCCU Error output[1] = 1 The EOUT1 set/clear the respective FCCU Error output[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a “do not care” value.
31 EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => FCCU Error output[0] configured in output mode) 0 force FCCU Error output[0] = 0 1 force FCCU Error output[0] = 1 The EOUT0 set/clear the respective FCCU Error output[0] signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a “do not care” value.

75.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status. The FCCU finite state machine (FSM) operates by the RC oscillator clock asynchronous with the System clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Figure 1544. FCCU Status Register (FCCU_STAT)

Table 1504. FCCU_STAT field descriptions

Field	Description
26:27 PhysicErrorPin	Physical Error Pin state PhysicErrorPin[26] corresponds to error pin 0, PhysicErrorPin[27] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0 Error Pin is at logical 0 1 Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. **Note:** This field indicates the real time status of the Error pin as driven by FCCU (at FCCU boundary) to the pad and not what is seen at/from the pad, which is based on different IPs (such as SIUL2) configurations of the SoC.
28 ESTAT	Current Error Pin Status SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in nonfaulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state.This state is taken from the FCCU Eout logic (That is, as late as possible).
29:31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state Other: UNKNOWN state

75.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the recoverable source (FCCU recoverable fault x) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

75.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recoverable fault in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 75.5.7: FAULT interface*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

75.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The external interrupt line (Interrupt request) is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

75.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The external interrupt line “Interrupt request (miscellaneous conditions)” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

75.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

EOUTMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it loads (a value corresponding to T_min = 250 µs + value programmed in FCCU_DELTA_T register) and then starts down-counting and becomes 0 on the expiry of T_min window. It reloads on occurrence of another fault event which has EOUT signaling enabled. T_min feature is available only in Bi-Stable

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   a) OP17
   b) OP19
   c) OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

75.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

75.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (that is FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a "static" input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state.The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC.The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset.
- IRQ: NMI or Alarm.
- Error out triggered (by FCCU or by SW).

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is de-asserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.
The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as it is used by the FCCU (System reset), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is de-asserted.

The following conditions show a use case of the FOSU:

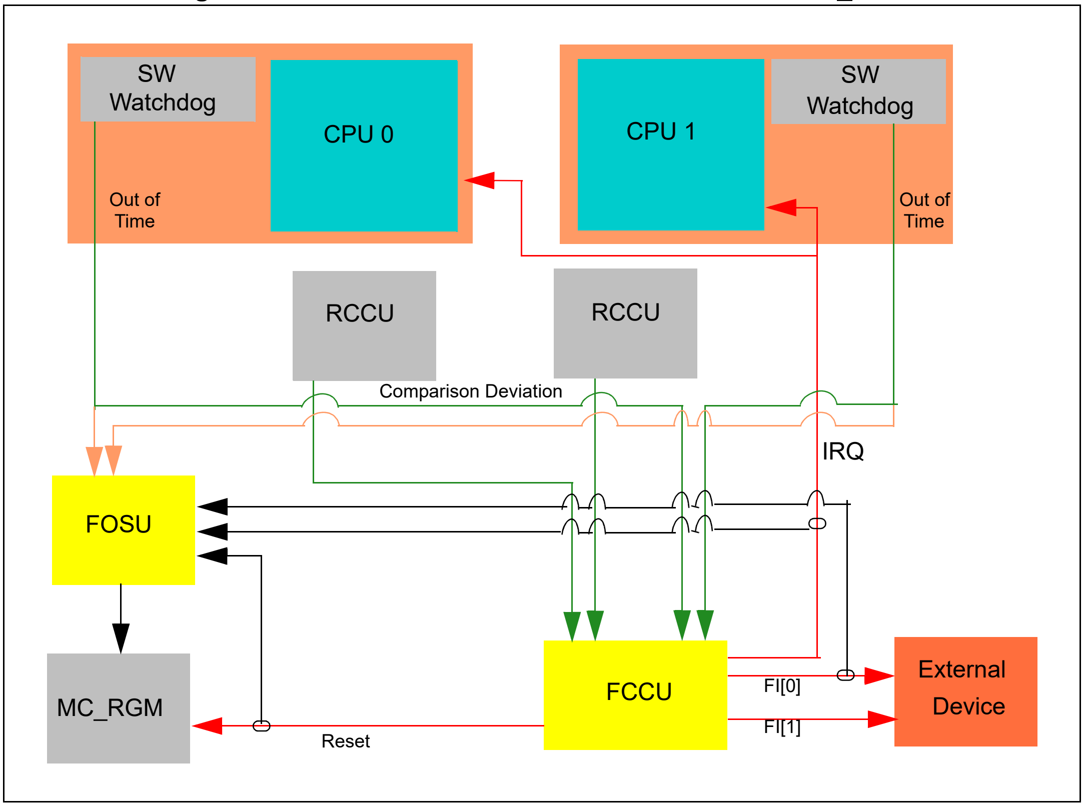
1. The user configures the channel x of the FCCU to react with a functional reset, either long or short.
2. The user sets the EOUTEN[x] flag of EOUT_SIG_EN register to 0.
3. The software does not clear the FCCU status flag related to the fault x after its first occurrence.
4. The fault x triggers again after the functional reset. Under these circumstances, the FOSU triggers a destructive reset after the FOSU timeout.

The rationale behind is that the functional reset is not able to clear the source of the fault. If the software can't react to the second occurrence of the fault before the FOSU timeout expires, the FOSU triggers a destructive reset.

If the users want to increase the availability of the system by avoiding the destructive reset, they can set the EOUTEN[x] flag of EOUT_SIG_EN register to 1. In such a case, the FOSU does not trigger the destructive reset.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 1560. FOSU connections to the FCCU and MC_RGM



It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

75.8 Use cases and limitations

75.8.1 Mis-configurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.

Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.

4. Software reset is optional.
5. The user must program the FCCU for a higher timeout value than the value hard-coded for FOSU. In this way FCCU reacts later than FOSU expects and as a result, FOSU generates a destructive reset request on its timeout, if a fault occurred when the FCCU was in CONFIG state.

75.8.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, the following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status.
   b) Verify FCCU is in NORMAL state, else repeat step (a) above.
   c) Configure FCCU.
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire.
   b) Check and clear fault status.
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires.
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state.
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU.
   f) Check and clear any new pending fault status until FCCU is in NORMAL state.
   g) Reconfigure FCCU.

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

76 Self-Test Control Unit (STCU2)

76.1 Introduction

The self-test control unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the offline or online, or both, conditions. The hardware can manage the Memory (SRAM or ROM) built-in self-test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the self-test parameters (MBIST scheduling activity, unrecoverable faults (UF) or recoverable faults (RF) management, CRC and MISR expected values, PLL management, and so on) from Flash memory during the offline self-test phase. This interface is only able to write the configuration parameters and start the self-test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the offline self-test and to load or check the execution of the online self-test.

The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the self-test run to increase the STCU2’s self-checking capability.
- A programmable watchdog timer (WDG) to check the MBIST self-test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before watchdog timeout.
- Direct PLL control during the offline self-test sequence.
- Two interrupt lines enabled only during the online self-test to simplify the software handling of self-test execution end.
- A set of registers to collect the MBIST results during offline and online self-test.

To increase the security of this module, a different security key sequence is also required during offline and online self-test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after self-test sequence is completed.
- The register ITF clock when the WDG timeout is detected after a double security key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

76.2 Main features

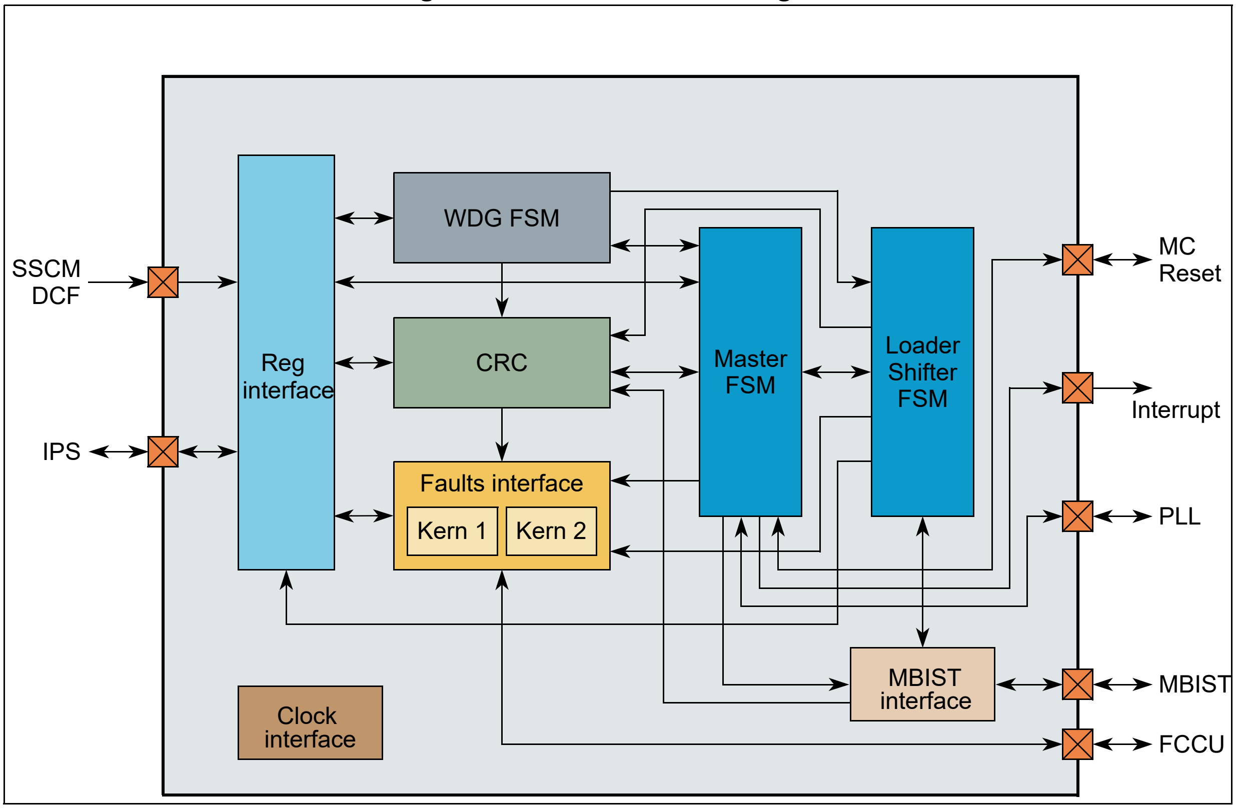
- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG[WRP] bit) register interface.
- Programmable scheduler for MBIST execution.
- MBIST concurrent/sequential execution.
- 32-bit CRC for STCU2 self-checking capability (enabled by STCU_CFG[CRCEN] bit).
- Online hardware self-test sequence abort capability.
- Programmable internal clock prescaler to reduce internal and MBIST TCK clocks.
- Programmable PLL direct control during offline self-test sequence.

- PLL lock signal monitoring during offline and online self-test.
- MBIST dedicated online interrupt source generation.
- Programmable WDG timer for self-check MBIST time execution.
- Hard-coded WDG timeout to flag offline initialization errors.
- Hard-coded WDG timeout to auto-lock STCU2 write access after double key sequence.
- SRAM or ROM MBIST offline status flags.
- STCU2 internal errors offline status flag.
- SRAM or ROM MBIST online status flags.
- STCU2 internal errors online status flag.
- Online hardware abort status flag.
- SRAM or ROM MBIST offline or online programmable failure severity (UF/RF).
- STCU2 internal errors offline or online programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software.
- Self-test bypass capability.
- Protection mechanism of the global write register based on double security key.
- STCU2 global auto power-saving when:
  - Self-test is completed.
  - bypass mode is selected.
  - WDG timeout is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).
- STCU2 ITF/WDG auto power-saving when hard-coded WDG timeout is detected after software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).

76.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 1561*.

Figure 1561. STCU2 block diagram



The STCU2 module includes the following submodules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface.
- **CRC**: This module is the core of the self-checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface:** This module collects the error conditions respective to MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the set or clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- **Clock Block:** This module manages the internal and the MBIST TCK clock prescaler, the internal clock gating power saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different watchdogs:
  – A hard-coded Watchdog used to auto-lock the STCU2 access, forcing a reset condition on the double security key registers.
  – A dual function watchdog:

    - After a reset event initializes the STCU2, it is used as a hard-coded watchdog timeout.

    - During MBIST runs, it is used as a programmable watchdog timer to check the MBIST has completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the self-test sequence.

- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the MBIST registers and read back the data to be checked at the end of each self-test operation.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

76.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The self-test sequence parameters are loaded before offline self-test is executed.
- The IPS access on some specific registers (see *Section 76.5: Register description*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following R/W bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register.
- Any write operation on double security key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the double security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed offline on registers where writes are only allowed during the online self-test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on read only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 76.5: Register description*.

76.4 Functional description

76.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the self-test operations and the other state machines.
- Loader/Shifter State Machine: used to program the MBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the master state machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and the timeouts in case of incorrect STCU2 programming.

76.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the offline self-test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the self-test execution phase depends on the self-test conditions reported in the following subsections.

In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the associated MC_RGM module.

76.4.2.1 Offline reset generation

At the end of the offline self-test execution, the STCU2 raises the global functional reset. In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module.

76.4.2.2 Online reset generation (only MBIST)

The online execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences respective to the write operations performed by the MBIST execution other than prevent any read/write operation during the self-test execution. If necessary, the software must also restore the memory content (only for RAM) at the end of the self-test execution.

76.4.3 MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 76.6.4: Design implementation information*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first MBIST is mapped at the address 0x10, the second on 0x11 and so on. The additional pointers are in the bitfield STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 76.5.22: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*.

76.4.4 ABORT management

The STCU2 module provides online self-test execution abort. When the abort is detected, the online self-test operation stops running and the status of the currently running MBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run.

76.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a functional reset that requires the self-test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the online self-test execution run.

76.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the offline self-test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 76.5.2: STCU2 Run Software Register (STCU_RUNSW)*.

When STCU_RUN[RUN] is set to start the offline self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configuration parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end of the MBIST run, the clock source reverts to the original one.

76.4.6 Interrupt interface

There is one interrupt source:

- triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1.

As described in *Section 76.5.2: STCU2 Run Software Register (STCU_RUNSW)*, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential runs in the same session, the number of interrupts generated is equivalent to the number of sequential sessions, thus providing fine granularity with respect to the completed run.

The MBIFLG bit in the *STCU2 Interrupt Flag Register (STCU_INT_FLG)* registers flag interrupt condition and allows the clearing of interrupt requests. Interrupt bit to be cleared by writing the respective bit to 1 to enable the next interrupt request.

76.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an unrecoverable failure (UF) or a recoverable failure (RF) during the self-test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of

FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

76.4.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished on time.

76.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the self-test sequence (safety mode).
- Bypass the self-test sequence by setting the STCU_RUN[BYP] bit. If Bypass bit is configured/set by DCF it cannot be anymore changed on the device even though STCU_RUN register itself is not Write once.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded watchdog timeout flags the incorrect behavior. See *Section 76.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* for more details.

76.4.8.2 MBIST scheduling

The MBIST execution time is configured as described in *Chapter 76.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* to account for the overall execution time of the self-test sequence. If the selected MBISTs are not yet completed:

- During an offline self-test assigned time, the current MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBE1/2 registers.
- During an online self-test, the current MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBE1SW/2SW.

In case of multiple sequential runs in the same online or offline session and the timeout occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 76.4.2: Reset management*.

76.4.8.3 Write access timeout

The access on the STCU2 registers during the self-test configuration phase (both online or offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software self-test configuration as the software application may enable write access to the STCU2 registers.

76.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomy to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the self-test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

76.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

76.5 Register description

The STCU2 registers are listed in Table 1524.

Note: k represents the repeated register blocks of the multiple MBISTs: k ranges from 0 up to 34.

76.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the offline self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

31 RUN	RUN The RUN bit is automatically cleared by the STCU2 when the offline self-test procedure has been completed. 0 Idle 1 Offline self-test procedure is running

76.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the online self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- Online self-test phase is active. The online condition starts when the offline condition finishes. In this condition, the system is alive and the SW can program the STCU.

Figure 1563. STCU2 Run Software Register (STCU_RUNSW)

Table 1526. STCU_RUNSW field descriptions

Field	Description
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories, the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are concluded. If there is a sequence of concurrent runs in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[MBIFG] bit in between.
22 MBSWPLLEN	Online MBIST with PLL1 Enabled 0 Online MBIST is executed without waiting for PLL1 lock. 1 Online MBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the online self-test procedure has been completed. 0 Idle 1 Online self-test procedure is running

76.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2 asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the offline or online test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: Note that after the self-test sequence has been completed or the bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.

In case of invalid access or sequence (Keys1 and 2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG timeout, STCU2 write access is locked and the WDG and register ITF clocks are switched off. Also in this case the correct sequence must be applied in order to re-enable write access to the STCU2 and the WDG and register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG timeout expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 0x00000000.

76.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the offline and online test steps.

Access to this register is described in *Figure 1565*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the online self-test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Offset: 0x000C Access: User read/write

1. You can always read this field. In the offline self-test phase, you can always write to this field. In the online self-test phase, you can write to this field only when WRP = 0.

Figure 1565. STCU2 Configuration Register (STCU_CFG)

Table 1528. STCU_CFG field descriptions

Field	Description
0:7 PTR	MBIST pointer. PTR defines the logical pointer to the first MBIST to be scheduled when the self-test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution.
23 WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after offline self-test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after offline self-test sequence has completed, thus preventing any user application write operation.
26 CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values. 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS test is not enabled 1 MBIST PMOS test is enabled

Table 1528. STCU_CFG field descriptions (continued)

Field	Description
28 MBU	MBIST MBU Test Enabled. 0 MBIST full algorithm or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified multi-bit upset algorithm is used to check the RAM. If a ROM is selected, the applied algorithm will be standard one without PMOS test. ***This bit overwrites the PMOSEN feature***.
29:31 CLK_CFG	Logic, memory BIST and STCU2 core clock configuration. CLK_CFG defines the ratio between the STCU2 core clock and the TCK used to program both the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 PBRIDGE_CLK 001 PBRIDGE_CLK/2 010 PBRIDGE_CLK/3 011 PBRIDGE_CLK/4 100 PBRIDGE_CLK/5 101 PBRIDGE_CLK/6 110 PBRIDGE_CLK/7 111 PBRIDGE_CLK/8 **Note:** refer to Clocking chapter for PBRIDGE_CLK clock frequency value.

76.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the offline MBISTs are performed and STCU_RUN[MBPLLEN] = 1.

In the online state, these bits are not effective. It is also possible to set the PLL during active online mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is active.

Figure 1566. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Note: *f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.*

Table 1529. STCU_PLL_CFG field descriptions

Field	Description
2:7 PLLODF	PLL Output Division Factor. The value of this field drives the output division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the respective PLL's output division factor.
13:15 PLLIDF	PLL Input Division Factor. The value of this field drives the input division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the respective PLL's input division factor.
25:31 PLLLDF	PLL Loop Division Factor. The value of this field drives the loop division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the respective PLL's loop division factor.

76.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for MBIST execution, providing protection against dead-locks or infinite loop conditions during the self-test procedure. When the offline self-test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15 to 0 define the timeout before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the offline or online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active
- Online self-test phase is active and STCU_CFG[WRP] = 0

Offset: 0x0014 Access: User read/write

Figure 1567. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 1530. STCU_WDG field descriptions

Field	Description
0:31 WDGEOC	Watchdog End of Count Timer. This value must be set in order to define the time budget respective to the offline and online self-test execution and check that everything is working correctly in this timeslot. The allowed time delays are: 0x00000000 1*k*STCU2 core clock cycles 0x00000001 2*k*STCU2 core clock cycles 0x00000002 3*k*STCU2 core clock cycles … 0xFFFFFFFD 4294967294*k*STCU2 core clock cycles 0xFFFFFFFE 4294967295*k*STCU2 core clock cycles 0xFFFFFFFF 4294967296*k*16 STCU2 core clock cycles where k is: – ‘1’ for offline self-test – ‘16’ for online self-test **Note:** STCU2 core clock is specified through STCU_CFG[CLK_CFG] field.

76.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST interrupt pending bit. This bit is effective only during the online self-test phase and managed only when the respective control bit in the STCU_RUNSW register (MBIE) is enabled.

Offset: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
30 MBIFLG	MBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled MBIST is completed is pending. Write 1 to clear the bit.

76.5.8 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the self check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

CRC-32 (ethernet protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

Table 1532. STCU_CRCE field descriptions

Field	Description
0:31 CRCE	CRC expected signature

76.5.9 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the offline and online self-test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Offset: 0x0020 Access: User read

Table 1533. STCU_CRCR field descriptions

Field	Description
0:31 CRCR	Read CRC signature

76.5.10 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the online and offline self-test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 76.6.4: Design implementation information*.

Access to this register is described in *Figure 1571* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

Offset: 0x0024 Access: User read/write

1. You can always read this field. The content of this field is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Figure 1571. STCU2 Error Register (STCU_ERR_STAT)

Table 1534. STCU_ERR_STAT field descriptions

Field	Description
6 ABORTHW	Online hardware abort flag. 0 No hardware abort was requested during the online self-test sequence 1 A hardware abort was detected during the online self-test sequence
11 LOCKESW	Online LOCK Error. 0 If PLL is enabled, it is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the online self-test sequence execution. The online self-test run is stopped and the status of the current running MBISTs is saved in the respective registers. The LOCK signal is monitored during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1.
12 WDTOSW	Online Watchdog timeout. 0 MBIST time slots have completed within the assigned watchdog time. 1 MBIST time slots have not completed in the assigned watchdog time or there are internal mismatches in the end of execution signals. The condition that flags the failures is the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished
13 CRCSSW	Online CRC Status. This flag is activated *only* when online self-test is performed and STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to 0) 1 Failed CRC comparison

Table 1534. STCU_ERR_STAT field descriptions (continued)

Field	Description
14 ENGESW	Online Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	Online Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial MBIST pointer is out of range – Error in MBIST linking (execution generates an infinite loop)
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the unrecoverable faults condition 1 There are errors that trigger the unrecoverable faults condition
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the recoverable faults condition 1 There are errors that trigger the recoverable faults condition
27 LOCKE	Offline LOCK Error 0 The PLL is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the offline self-test sequence execution. The online self-test run is stopped and the status of the current running MBISTs is saved in the respective registers. The LOCK signal is monitored during the MBIST run when STCU_RUN[MBPLLEN] = 1.
28 WDTO	Offline Watchdog timeout. 0 MBIST time slots have been completed within the assigned watchdog time. 1 MBIST time slots have not been completed within the assigned watchdog time or there are internal mismatches among end of execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the watchdog reach the end of count – MBIST BEND status flags that at least one of the selected MBIST run is not finished
29 CRCS	Offline CRC status. This flag is activated *only* when offline self-test is performed STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison

Table 1534. STCU_ERR_STAT field descriptions (continued)

Field	Description
30 ENGE	Offline Engine Error. 0 Valid engine execution 1 Invalid engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Offline Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial MBIST pointer is out of range – Error in MBIST linking (execution generates an infinite loop)

76.5.11 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of Unrecoverable or recoverable faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Figure 1583. STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

Table 1546. STCU_MB_CTRL*k* field descriptions

Field	Description
0:7 PTR	Next MBIST pointer PTR defines the logical pointer to the next MBIST to be scheduled. The next MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current MBIST has been completed. PTR = 0x10 + $MBIST_i$ (Pointer to MBIST) for i = 0 to XX: please refer to the MBIST partitions table for the $MBIST_i$ code. PTR = 0xFF: Pointer to NIL. No additional MBIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode

76.6 Use cases and limitations

The STCU2 module is designed to give high flexibility during the online and offline self-test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Offline self-test sequence after a reset trigger event
- Bypass mode of the self-test sequence after a reset trigger event
- Online self-test sequence

The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.

76.6.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and MBIST execution parameters stored in the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the system RAM or ROM according to the system specifications. The sequence is the following:

- Unlock the offline STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFM1/2 registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for MBIST execution.
- Program the STCU_CFG register to define:
  - the core and MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the offline self-test sequence in the STCU_CRCE register.
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.
- Program the RUN bit in the STCU_RUN register to enable the offline self-test execution and the LMPLLEN bits to enable the PLL during MBIST execution according to STCU_PLL_CFG register content.
- Start the offline self-test depending on PLL management and MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the self-test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_MBS1/2 flag registers, depending on the number of memories, to check the failed RAM or ROM memory BIST when UF or RF are detected.
- The software application reads the STCU_MBE1/2 flag registers, depending on the number of memories, to check the RAM or ROM memory BIST still running when UF or RF are detected.
- The software application reads the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.

Note: The software application read operations on the STCU2 CRC register after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

76.6.2 Online self-test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the MBIST execution. Since the online operations clean up the content of the RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the online STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 online self-test registers.
- The MBIST and STCU2 internal fault reaction should already be programmed during the offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_MBUFM1/2 and STCU_ERR_FM.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for MBIST execution.
- Overwrite/Program the STCU_CFG register to define:
  - the core and MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the online self-test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the online self-test execution, the MBIE to enable the Interrupt requests, and the MBSWPLLEN bits to enable the PLL lock signal monitor during MBIST execution.
- Start the online self-test depending on PLL management and MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- If the MBIE is enabled, an interrupt is generated at the end of all the MBIST runs. The software application has to manage these interrupt signals and clean up the respective flag (MBIFLG) in the STCU_INT_FLG register.
- The STCU2 switches off the core clock at the end of the self-test run.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_MBS1SW/2SW flag registers, depending on the number of memories, to check the failed RAM/ROM memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBE1SW/2SW flag registers, depending on the number of memories, to check the RAM/ROM memory BIST is still running when UFs or RFs are detected.

- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.

Note: The software application read operations on the STCU2 CRC register after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

76.6.3 Bypass USER Mode

In this mode, the user application parameters stored in Flash and read by SSCM are written to skip the self-test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the offline Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the self-test sequence is not applied and the system can wake up and start the user application.

76.6.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST can be run one time during the on/offline self-test procedure.
- As the software has full control of the system while applications are running during the online self-test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

77 Register Protection (REG_PROT)

77.1 Introduction

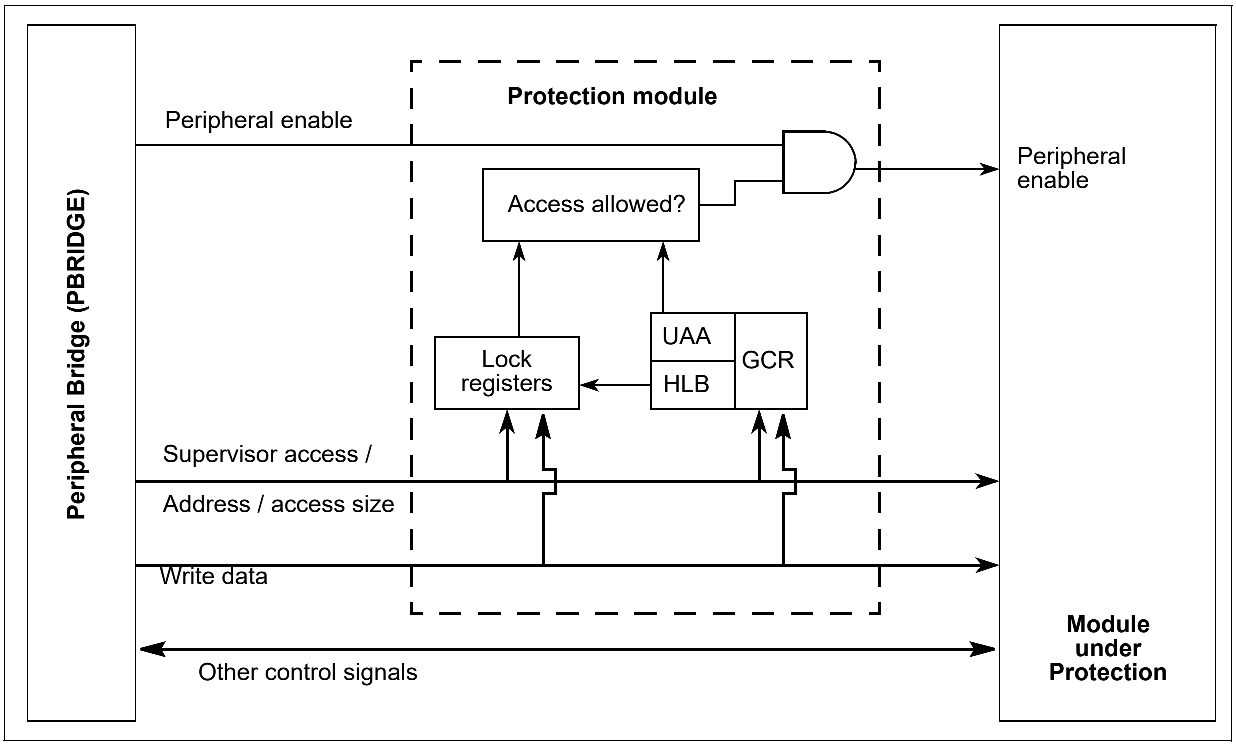
77.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Refer to the Device configuration chapter for protected registers.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 1584*.

Figure 1584. REG_PROT block diagram



77.1.2 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set.

77.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.

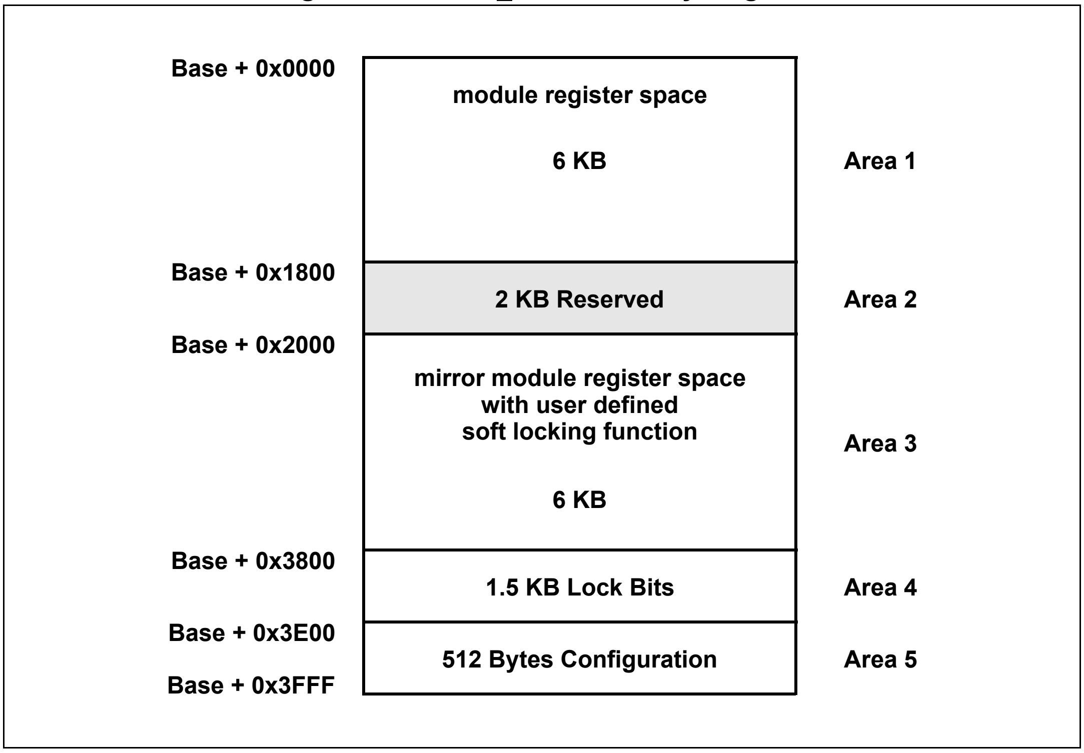
77.2 External signal description

There are no external signals.

77.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 1585*.

Figure 1585. REG_PROT memory diagram



- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

77.3.1 Memory map

Table 1547 shows the memory map for a module which is protected via a REG_PROT module.

Table 1547. REG_PROT memory map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*Section 77.3.2.1*
0x0001	Module Register 1 (MR1)	*Section 77.3.2.1*
0x0002	Module Register 2 (MR2)	*Section 77.3.2.1*
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	*Section 77.3.2.1*
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	*Section 77.3.2.2*
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	*Section 77.3.2.2*
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	*Section 77.3.2.2*
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3	*Section 77.3.2.3*
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	*Section 77.3.2.3*
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	*Section 77.3.2.3*
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	*Section 77.3.2.4*

Note: Reserved registers in area #1 will be handled as specified in the protected module's documentation.

77.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

77.3.2.1 Module registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

77.3.2.2 Module register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 1549*.

77.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 1548. Soft lock bits vs. protected address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

Note: As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3800-0x3DFF

Access: Read always
Supervisor write

	0	1	2	3	4	5	6	7
R	0	0	0	0	SLB0	SLB1	SLB2	SLB3
W	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

Figure 1586. Soft Lock Bit Register (SLBR*n*)

Table 1549. SLBR*n* field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR*n* register: SLB0 can block accesses to MR[*n* *4 + 0] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[*n* *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[*n* *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[*n* *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable

77.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3FFC

Access: Read Always
Supervisor write

Figure 1587. Global Configuration Register (GCR)

Table 1550. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register cannot be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and cannot be modified 0 All SLB bits are accessible and can be modified.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

77.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

77.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size is device and module specific, please refer to *Chapter 7: Device configuration for details.*

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

77.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

77.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 1588 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 1588. Change lock settings directly via Area #4

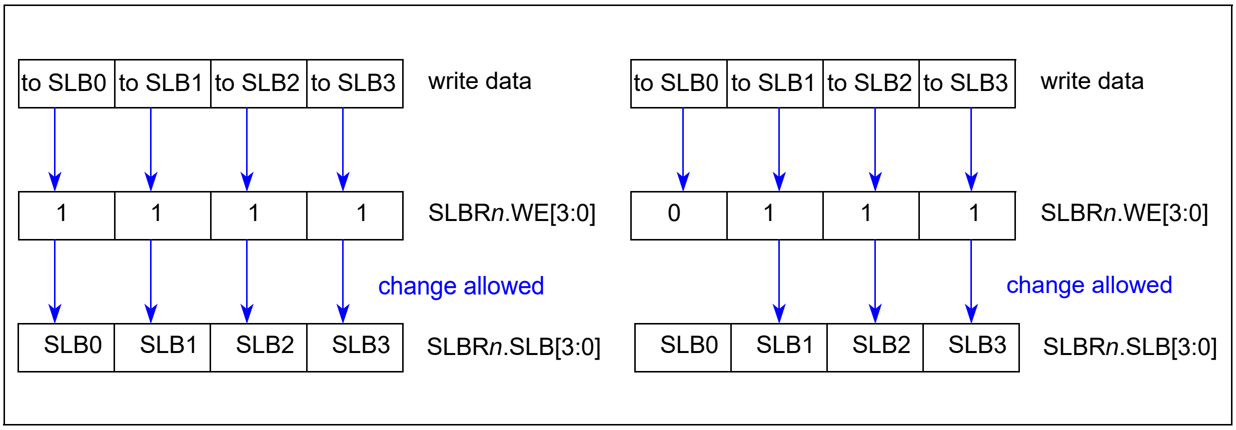

Figure 1588 shows four registers that can be protected 8-bit wise. In *Figure 1589* registers with 16-bit protection and in *Figure 1590* registers with 32-bit protection are shown:

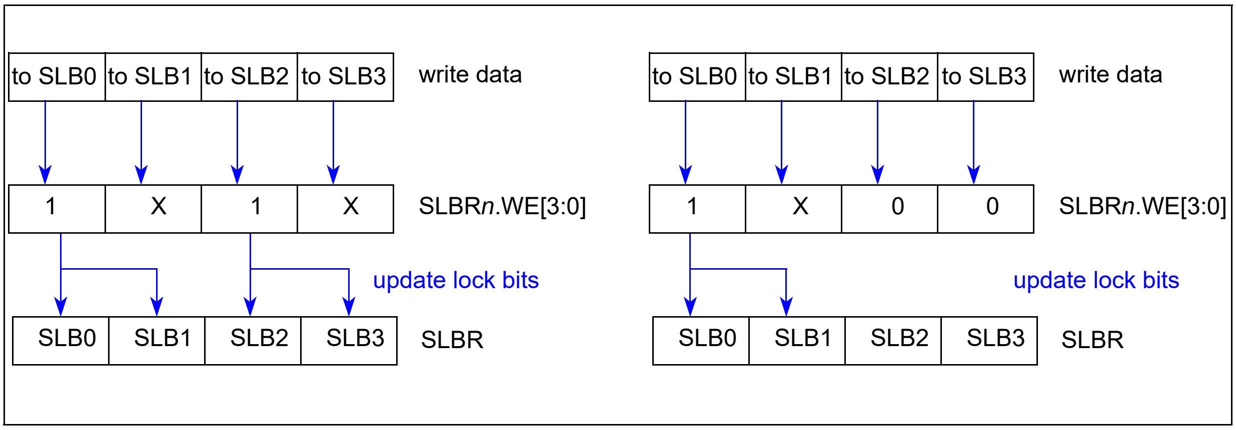
Figure 1589. Change lock settings for 16-bit protected addresses

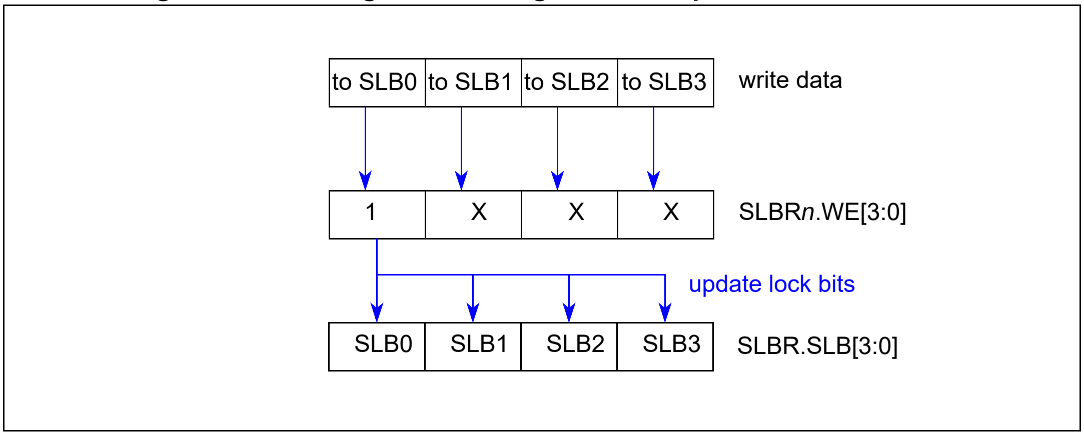


On the right side of *Figure 1589* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 1589* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

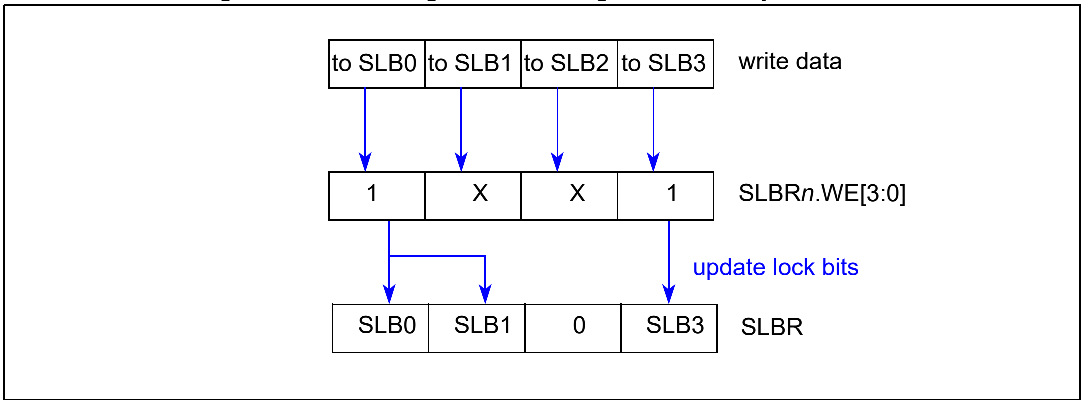
In *Figure 1590* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 1590. Change lock settings for 32-bit protected addresses



In *Figure 1591* an example is shown which has a mixed protection size configuration:

Figure 1591. Change lock settings for mixed protection

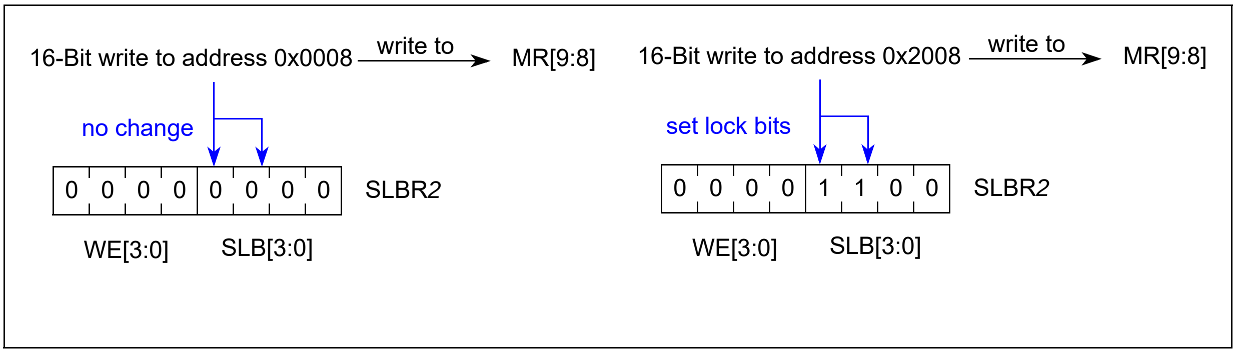


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

77.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 1592* shows one example:

Figure 1592. Enable Locking Via Mirror Module Space (Area #3)

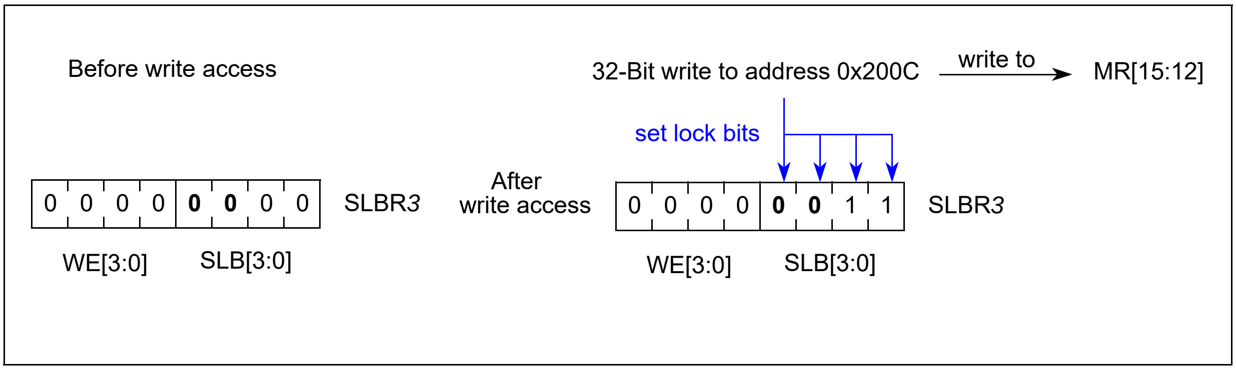


When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 1589*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 1589*).

Figure 1593 shows an example where some addresses are protected and some are not:

Figure 1593. Enable locking for protected and unprotected addresses



In the example in *Figure 1593* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

77.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 77.4.2.1: Change lock settings directly via Area #4* and *Section 77.4.2.2: Enable locking via mirror module space (Area #3)* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

77.4.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 1585*.

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set.

77.5 Initialization/application information

77.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 77.3.2*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.

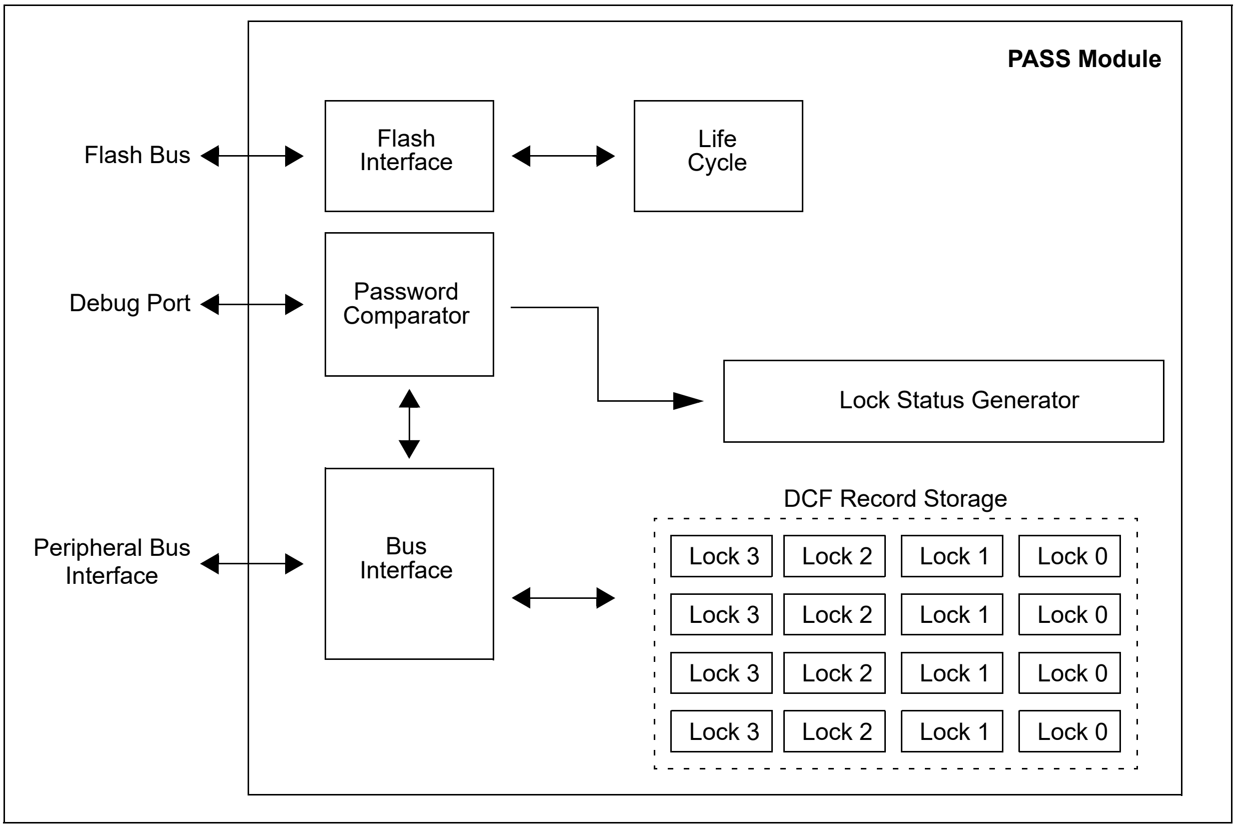
78 Password and Device Security Module (PASS)

78.1 Introduction

78.1.1 Overview

The Password and Device Security (PASS) module shown in *Figure 1594* receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 1594. PASS module block diagram



78.1.2 Features

The PASS includes these distinctive features:

- Lifecycle status
- Password comparison
- JTAG password comparison
- Fuse Bypass Configuration and Password Comparison

78.1.3 Modes of operation

The PASS operates identically in all system modes.

78.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 78.3: DCF clients*.)

Table 1551 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

Table 1551. PASS memory map

Offset	Register	Access	Reset Value	DCF Client Address(1) (ADDR[14:0])	Section

Password Group 2					
0x0120	Lock 0 Status Register (LOCK0_PG2)	R/W	0xXXXXXXXX(2)	0x0120	Section 78.2.1.5
0x0124	Lock 1 Status Register (LOCK1_PG2)	R/W	0x0000XXXX(2)	0x0124	Section 78.2.1.6
0x0128	Lock 2 Status Register (LOCK2_PG2)	R/W	0xXXXXXXXX(2)	0x0128	Section 78.2.1.7
0x012C	Lock 3 Status Register (LOCK3_PG2)	R/W	0xXFXXXXXX(2)	0x012C	Section 78.2.1.8
Password Group 3					
0x0130	Lock 0 Status Register (LOCK0_PG3)	R/W	0xXXXXXXXX(2)	0x0130	Section 78.2.1.5
0x0134	Lock 1 Status Register (LOCK1_PG3)	R/W	0x0000XXXX(2)	0x0134	Section 78.2.1.6
0x0138	Lock 2 Status Register (LOCK2_PG3)	R/W	0xXXXXXXXX(2)	0x0138	Section 78.2.1.7
0x013C	Lock 3 Status Register (LOCK3_PG3)	R/W	0xXFXXXXXX(2)	0x013C	Section 78.2.1.8

1. DCF Client Address column shows what is the DCF used to preload the register value during reset. If the column value is “None”, it means that the register value at reset is fixed in hardware.
2. Reset value depends on password group lock state.

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

78.2.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

78.2.1.1 Lifecycle Status register (LCSTAT)

The Lifecycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device lifecycle forward), but never to revert the lifecycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external lifecycle management module (like SSCM). It is a 3-bit lifecycle. This register simply displays the lifecycle input from external blocks.

Offset: 0x0000 Access: Software Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

1. Reset value depends on the Censorship DCF client.

Figure 1595. Lifecycle Status register (LCSTAT)

PASS_LCSTAT register functions are as shown in *Table 1552*.

Table 1552. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the state of the Censorship DCF Client. The bit can be set (or cleared) via DCF Record in UTEST Flash. Refer to *Section 78.5.3: Censoring and uncensoring the device*. 0 Device is uncensored 1 Device is censored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit. **Note:** Refer to the SPC584Bx Microcontroller Security Reference Manual for details.
2 FBE	Fuse Bypass enable This field indicates whether the Fuse Bypass DCF Client is set to Fuse Bypass Enable. 0 No Fuse Bypass 1 Fuse Bypass Enable **Note:** Refer to *Section 78.3.2* for details.
29:31 LIFE	The lifecycle setting is manipulated externally (SSCM). Pass displays a 3-bit input lifecycle. 000 Failure Analysis mode 001 Reserved 010 OEM Production 011 Customer Delivery 110 ST Production 111 In Field

78.2.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.

The ID of the accessing master sets the CMST field of the Challenge Status register.

Offset: 0x0008 Access: Software Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1598. Challenge Input register (CIN*n*)

CIN register functions are as shown in *Table 1555*.

Table 1555. CIN*n* register field descriptions

Field	Description
0:31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

78.2.1.5 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the lifecycle has matured to *OEM Production* or older.

Offset: 0x0100 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R / W	TSLOCK	ATSL	LOWLOCK													
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R / W	MIDLOCK															
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 1599. Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

LOCK0_PG*n* register functions are as shown in *Table 1556*.

Table 1556. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTEST NVM Lock. This bit is used to lock the UTEST NVM block from programs on the alternate interface (erase protection not needed since UTEST NVM is OTP and not erasable).
2:15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16:31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, indicating that a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password

groups before lifecycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

78.2.1.6 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x0104 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 1600. Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

LOCK1_PG*n* register functions are as shown in *Table 1557*.

Table 1557. LOCK1_PG*n* register field descriptions

Field	Description
16:31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

78.2.1.7 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle is matured to *OEM Production* or older.

Offset: 0x0108 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit resets to ‘1’.

Figure 1601. Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 1558*.

Table 1558. LOCK2_PG*n* register field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: **When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.**
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

78.2.1.8 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x010C + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Not all devices include this field. Refer to the device reference manual’s chip configuration chapter for details.
2. Reset value depends on lifecycle. If lifecycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 1602. Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

LOCK3_PG*n* register functions are as shown in *Table 1559*.

Table 1559. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally (if lifecycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked).
1 DBL	Debug Interface Lock The default value of this bit would be ‘1’ if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM). 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked.
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared. 1 Only the Master which unlocked the passgroup can change the passgroup settings.
4:7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.

Table 1559. LOCK3_PG*n* register field descriptions (continued)

Field	Description
11 RL4	Read Lock Region 4 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
12 RL3	Read Lock Region 3 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
13 RL2	Read Lock Region 2 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
14 RL1	Read Lock Region 1 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
15 RL0	Read Lock Region 0 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
16:31 A256KLOCK	256K address space block lock A256KLOCK[47:32] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password

groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to *Section 78.4.3: Flash Memory Read Protection*.

Once a censored device enters the *Failure Analysis* lifecycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash UTest region controlled by LOCK3[0]is read unlocked in Failure Analysis lifecycle.

78.3 DCF clients

Where a DCF client is listed, the reset value of that register may automatically be preloaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

78.3.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Censorship DCF client defines whether the MCU is censored or not (Refer to *Table 1551*).

DCF Client Address: 0x00B0 Censorship

Access: DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 1603. Censorship register (not accessible)

Table 1560. Censorship register field descriptions

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored. If this value is anything other that 0x55AA, the MCU is censored.

78.3.2 Fuse Bypass DCF Client

This DCF client is used to configure the password protected Fuse bypass feature. Refer to *Section 78.4.5: Fuse Bypass* for details.

The Fuse Bypass DCF Client is not directly readable in software, but the state of the Fuse Bypass bit can be read in the LCSTAT register (refer to *Lifecycle Status register (LCSTAT)*).

The DCF client is written during Destructive Reset Phase 3 and compared during Functional Reset Phase 3; if this compare does not match the data already written, the logic will decode No fuse bypass.

DCF Client Address: 0x00E0 Fuse Bypass

Access: DCF Record Write Once Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 1604. Fuse Bypass DCF Client

Table 1561. Fuse Bypass register field descriptions

Field	Description
31 FB	Fuse Bypass enable 0 The Fuse can NOT be Bypassed 1 Bypass of the fuse is possible with a password

78.3.3 Password Slot Access

Password Slot Access is a write-once DCF client. The DCF controls access for both read and write starting from Lifecycle = OEM Production. If the bit is 1, the slot is still accessible when Life Cycle = OEM Production (and blocked starting from Life Cycle = In Field). Otherwise if the bit is set to 0, the slot is blocked starting from Life Cycle = OEM Production.

DCF Client Address: 0x00B4 Password Slot Access

Access: DCF Record Write Once

Figure 1605. Password Slot Access DCF Client

Table 1562. Password Slot Access DCF Client field descriptions

Field	Description
28:31	Password Slot Access per password group

78.4 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

78.4.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (refer to *Section 78.3.1: Censorship*).

78.4.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (refer to *78.2.1.8: Password Group n - Lock 3 status register (LOCK3_PGn)*). Both of these debug enabling options are further conditioned by lifecycle.

The following table describes all options for enabling/blocking Debug Interface access.

Table 1563. Debug Interface Enable Truth table

<table>
<tr><th colspan="4">Input Conditions</th><th>Outcome</th></tr>
<tr><th>Lifecycle</th><th>Censorship</th><th>Debug Enable (LOCK3[DBL] bit)</th><th>JTAG Password</th><th>Debug Interface Enable</th></tr>
<tr><td>Customer Delivery</td><td>Don't Care</td><td>Don't Care</td><td>Don't Care</td><td>Enabled</td></tr>
<tr><td rowspan="4">OEM Production</td><td>Not censored</td><td>Don't Care</td><td>Don't Care</td><td>Enabled</td></tr>
<tr><td rowspan="3">Censored</td><td>Unlocked (DBL=0)</td><td>Don't Care</td><td>Enabled</td></tr>
<tr><td rowspan="2">Locked (DBL=1)</td><td>Matched</td><td>Enabled</td></tr>
<tr><td>Not Matched</td><td>Blocked</td></tr>
<tr><td rowspan="4">In Field</td><td>Not censored</td><td>Don't Care</td><td>Don't Care</td><td>Enabled</td></tr>
<tr><td rowspan="3">Censored</td><td>Unlocked (DBL=0)</td><td>Don't Care</td><td>Enabled</td></tr>
<tr><td rowspan="2">Locked (DBL=1)</td><td>Matched</td><td>Enabled</td></tr>
<tr><td>Not Matched</td><td>Blocked</td></tr>
<tr><td>Failure Analysis</td><td>Don't Care</td><td>Don't Care</td><td>Don't Care</td><td>Enabled</td></tr>
</table>

The HSM can also block Debug Interface Access, even if it enabled by PASS. This allows HSM to granted Debug Interface Access after an encrypted secure challenge/response protocol with an external tool (refer to the SPC584Bx Microcontroller Security Reference Manual).

78.4.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

78.4.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 1564: Flash Memory Read Protection truth table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The Flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (refer to *Chapter 7: Device configuration*, *Section 7.11.1: Password and Device Security Module (PASS) configuration*).

Table 1564. Flash Memory Read Protection truth table

INPUTS				OUTPUTS	
Lifecycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
STMicroelectronics Production / Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable

78.4.4 UTEST protection

During the *Customer Delivery* lifecycle, the user must program a valid password or a DCF record that writes LOCKm_PGn registers to unprotect the UTest for each password group in order to prevent permanent and irreversible locking of Flash blocks.

78.4.5 Fuse Bypass

78.4.5.1 Fuse

Some devices include an additional security feature, whereby a silicon fuse is used to gate access to Flash Test Mode when the device is in Failure_Analysis lifecycle. The fuse must be blown, creating physical damage to the silicon, before access is granted to Flash Test Mode. The PASS implements a configurable feature to bypass the requirement to blow the fuse to enter flash test mode, by entering a password instead. This feature is called Fuse Bypass.

78.4.5.1.1 Use Case: No Fuse Bypass

Customers who want no alternative to the Fuse to enter Flash Test Mode in FA lifecycle:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 0.
- And as a back-up, during customer assembly, the customer could program the Fuse Bypass Password to a random value.

78.4.5.1.2 Use Case: Fuse Bypass Password

Customers who require a password to enter Flash Test Mode in FA lifecycle, but do not require the added sophistication of blowing a fuse:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 1.
- During customer assembly, the customer programs the Fuse Bypass Password into Flash.
- The customer maintains a system for retrieving these passwords for the life of the module.
- If the part is returned to STMicroelectronics for FA, the customer must provide the Fuse Bypass password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA can only be performed if the die is removed from the package and the fuse blown.

78.4.5.1.3 Use Case: No Fuse. No Password

Customers who are less concerned with security and will accept neither fuse nor password to enter Flash Test Mode in FA lifecycle:

- Customer need do nothing special for this mode in customer assembly.
- When the part is returned to STMicroelectronics for FA, The DCF Client is still in the default state of 1. This is Fuse Bypass.
- The Fuse Bypass password should still be in the erased state (all 1). The tester can enter all 1 as the password to gain access to Flash Test Mode.

78.4.5.2 Fuse Bypass Password

The Fuse Bypass Password is a password entered by the STMicroelectronics via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA lifecycle. Flash blocks that are assigned as sealed during production are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

78.4.5.2.1 Fuse Bypass Password Generation

The Fuse Bypass password is created by the customer during their module assembly process. It must be programmed into UTest Flash while in CUSTOMER_DELIVERY lifecycle.

When an MCU is returned to STMicroelectronics for FA, the MCU must be in FA lifecycle and this password must also be provided to STMicroelectronics to allow access to Flash Test Mode without blowing the fuse. Therefore the customer should develop a process for managing Fuse Bypass passwords for the life of the module.

If the password is not available when a device is returned for FA, STMicroelectronics must remove the die from the package and blow the fuse before entry is possible to Flash Test Mode and Flash FA can be undertaken.

78.4.5.2.2 Fuse Bypass Password storage

The Fuse Bypass Password is 224 bits (28 bytes) wide and is to be stored in UTest Flash at a fixed location. Refer to the device reference manual for the address of the Fuse Bypass password.

The password region of UTest Flash is readable only when in CUSTOMER_DELIVERY lifecycle. In any lifecycle after this (including FA lifecycle), this region is read protected.

78.4.5.2.3 Fuse Bypass Password Challenge entry

The Fuse Bypass password challenge is entered by an external tool to the password register in JTAGC.

As the Fuse Bypass Password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

78.4.5.2.4 Fuse Bypass Password compare

The Fuse Bypass Password challenged, is compared against the password stored in UTest Flash. Only the least significant 224 bits are compared.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

78.5 Initialization/application information

78.5.1 Reset

The reset state of each individual bit is shown within *Section 78.2.1: Register descriptions*. However, many bits receive their values based on DCF records stored in the UTest Flash memory block.

78.5.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 1565. CS/ADDR values for Lock registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xXXXX0100(1)
Lock1	0xXXXX0104(1)
Lock2	0xXXXX0108(1)
Lock3	0xXXXX010C(1)
PW Group 1	
Lock0	0xXXXX0110(1)

Table 1565. CS/ADDR values for Lock registers (continued)

Register	DCF CS/ADDR
Lock1	0xXXXX0114(1)
Lock2	0xXXXX0118(1)
Lock3	0xXXXX011C(1)
PW Group 2	
Lock0	0xXXXX0120(1)
Lock1	0xXXXX0124(1)
Lock2	0xXXXX0128(1)
Lock3	0xXXXX012C(1)
PW Group3	
Lock0	0xXXXX0130(1)
Lock1	0xXXXX0134(1)
Lock2	0xXXXX0138(1)
Lock3	0xXXXX013C(1)

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 1566*.

Table 1566. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA55AF	Start Record
0x04	0x00000000	
0x08	0x000000FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xXXXX0110(1)	
0x10	0xFFFFFFFF	Stop Record
0x14	0xFFFFFFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

78.5.3 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTest Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS) and the address 0x00B0. Therefore 0xXXXX00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is censored.

79 Tamper Detection Module (TDM)

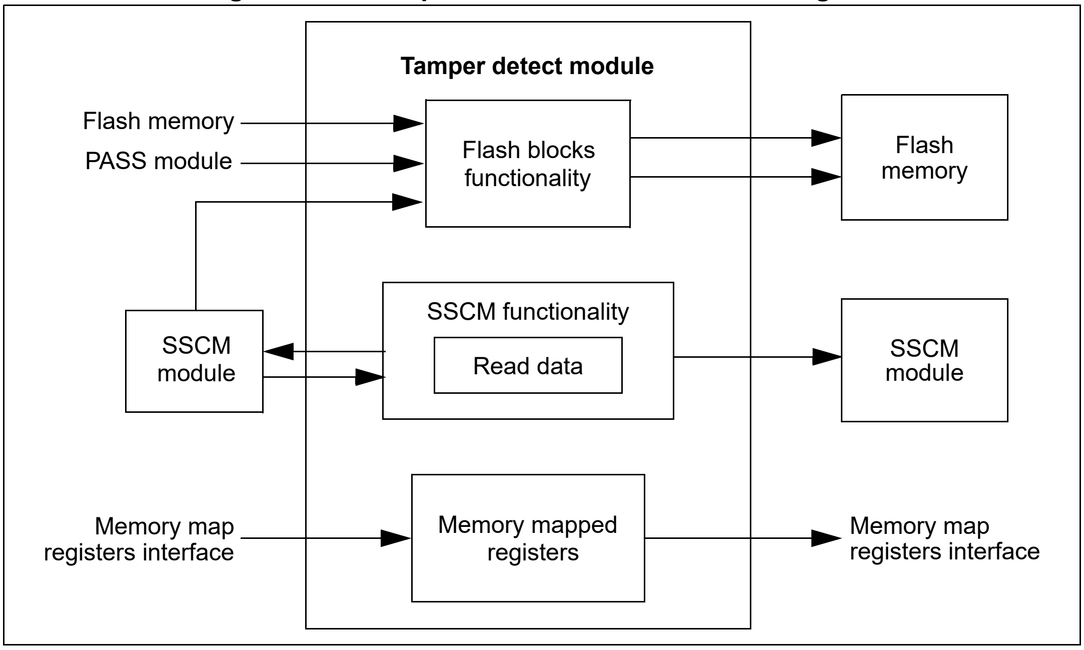
79.1 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR: it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

Figure 1606 shows the block diagram of the TDM and its interface to other system components.

Figure 1606. Tamper Detection Module block diagram



Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One-Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information (via the DCF bus)
- Software tamper region override

The TDM module controls the flash blocks for erase operations and sets them as OTP

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

Note: The PASS module provides the control for erase operation for each flash block as well as for each region of the flash memory, and the PASS settings have priority over the settings of the TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

79.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 128-bit records
  - The diary block should be assigned as OTP region in flash
  - The diary area can store any type of relevant information
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled
- 32-bit Erase Lock DCF clients for each flash memory TDR defined
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[y]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation
- Memory Map Registers Interface for reading via software of specific registers

79.3 External signal description

There are no external signals driving or being driven by the TDM.

79.4 DCF client

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

---

y. The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 1567. DCF client address map

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write-once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR – "*n*" specifies a TDR – "*m*" specifies the flash blocks as per the LOCK registers of the flash memory	write 0 to 1 only

79.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. *Figure 1607* shows the diagram for this register.

Caution: This DCF client is implemented as Write Once and is writable from 1 to 0 only. After one DCF record has written to this client, all subsequent writes are ignored.

79.4.3 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. *Figure 1609* depicts this client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash block to OTP irreversible.

The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

79.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0)

This DCF client holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF client however holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. Therefore, the diagram of this register mirrors the LOCK0 register in the flash memory. *Figure 1613* depicts the TDR*n*_LOCK0 DCF client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned to the TDR*n* 1 Corresponding flash blocks are assigned to the TDR*n*

79.4.10 Tamper Region Assignment DCF client (TDR*n*_LOCK3)

This DCF Clients holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF Clients however holds the assignment information for only those blocks specified in the LOCK3 register in the flash memory. Therefore, the diagram of this DCF Clients mirrors the LOCK3 register in the flash memory. *Figure 1616* depicts the TDRn_LOCK3 DCF client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

DCF client Address: 0x14 + ((n * 4) + 3) Access: DCF write

79.5 Memory Map and Registers

Note: The Tamper Detection Module's memory-mapped registers are read-only. Any attempted write generates a transfer error.

Table 1578. TDM memory map

Address offset (hex)	Register name	Location
0x00	TDR Status Register (TDM_TDRSR)	*Section 79.5.1*
0x04	Last Flash Programmed Address Register (TDM_LFPAR)	*Section 79.5.2*
0x08	Diary Base Address (TDM_DBA)	*Section 79.5.3*
0x10–0x24	Software Tamper Override Key Region (TDM_STO_KEY0–TDM_STO_KEY5)	*Section 79.5.4*

79.5.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, such as locked or unlocked, of each tamper region, such as TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

Note: TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.

If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Table 1582. TDM_STO_KEY*n* field descriptions

Field	Description
0:31 STO_KEY	Software Tamper Override Key Diary *n* This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Note:** The STO_KEYn registers can only be written once. **Note:** Refer to the section *Section 52.3.6: TDM Diary Operation* for programming details.

79.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

79.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Dairy is defined by a DCF Record .

The diary is divided into 6 parts where each part consists of 256 × 128-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region . These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM , which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR.As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR Diary Location and then unlocks the blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the next program operation on any block, other than Diary, is performed with program completion interrupt enabled or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programmed in the diary. If diary is detected to be full, TDM provides a means to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

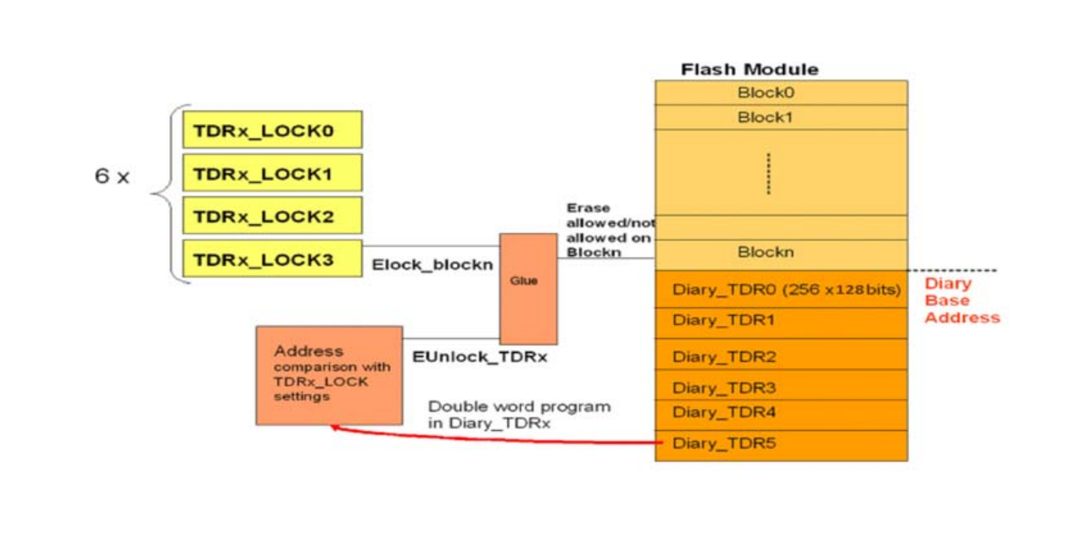
Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from “override tamper region lock” DCF record (refer to *Section 79.6.3: Diary*) has priority over the settings in the TDRn_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDRn_LOCK*m* settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in *Figure 1621*.

Figure 1621. Diary implementation



Note: The settings in the Tamper Region Override Register have priority over the TDRn_LOCKm Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programmed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

79.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 × 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDRn_LOCKm where n is the number of a tamper region, that is, 0-5 and m varies from 0-3 as flash contains four Lock registers .

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They cannot be read nor written. They can only be initialized by DCF record within the UTEST flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

Note: No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

79.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 4 KB, and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector to honor OTP restrictions. Therefore, each diary can hold a maximum of two-hundred and fifty-six 128-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients cannot be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

79.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records are defined by the customer. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is ‘0’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 4 KB section of the diary. With 6 TDRs, 24 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b000_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b001_0000_0000_0000
- TDR2 = Diary_Base_Address + 0b010_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b011_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b100_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b101_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b110_0000_0000_0000

79.6.5 Diary Base Address Verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as “TDR Erase Blocked”. Refer to *Section 79.5.1: TDR Status Register (TDM_TDRSR)* for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning “TDR Erase Enabled”.

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. Refer to *Section 79.5.1: TDR Status Register (TDM_TDRSR)*. The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. Refer to *Section 79.5.2: Last Flash Programmed Address Register (TDM_LFPAR)*.

79.6.5.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each record within the 4 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. Refer to the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

79.6.6 One Time Programmable (OTP)

79.6.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

80 Wakeup unit (WKPU)

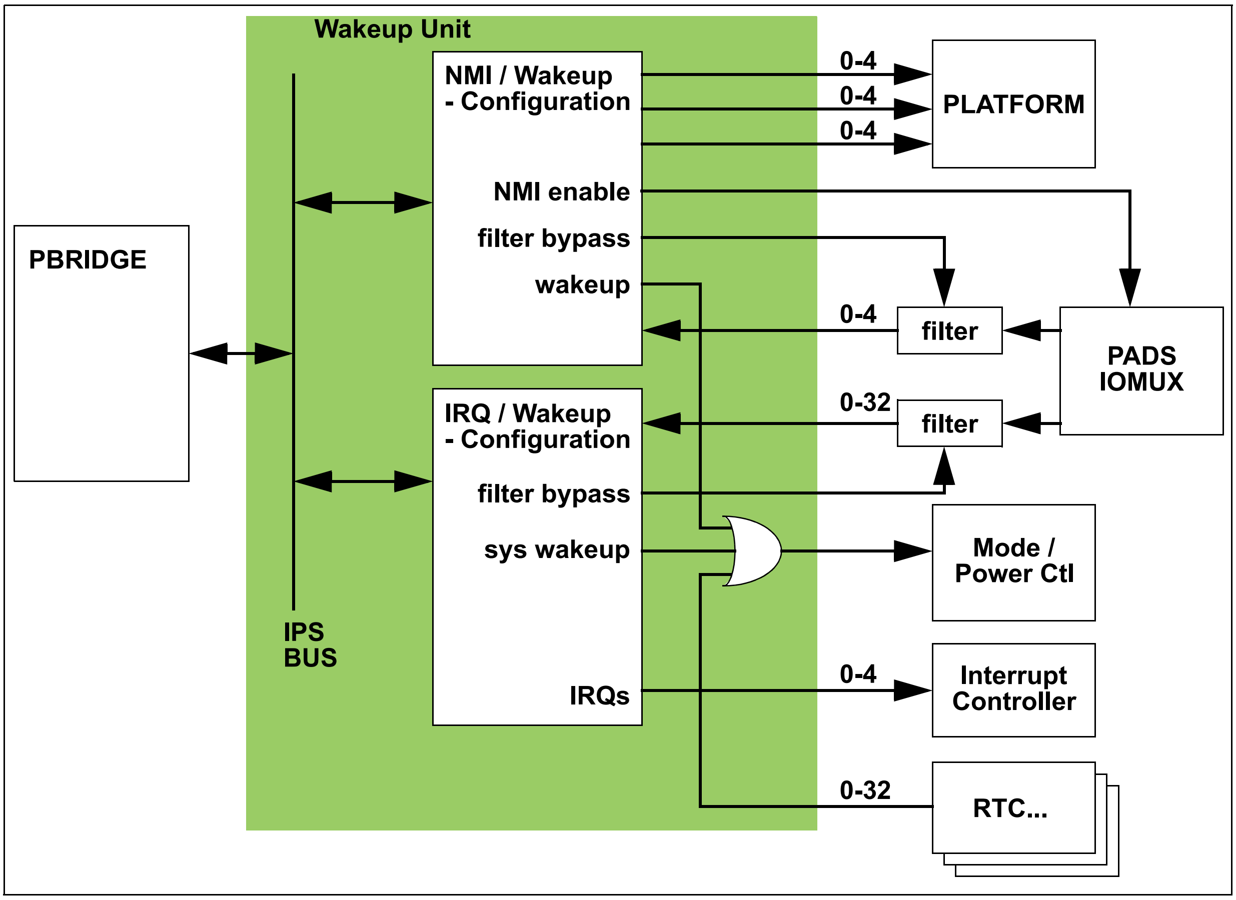
80.1 Introduction

80.1.1 Overview

The Wakeup unit supports up to 32 external sources that can generate CPU exceptions or wakeup events and up to 3 external sources that can cause non-maskable interrupt requests or wakeup events. In addition, it combines its wakeup events with those generated from up to 32 other wakeup sources to supply a single wakeup to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 1622* is a block diagram of the Wakeup unit and its interfaces to other system components.

Note: For the chip-specific implementation details of this module refer to the Device Configuration chapter.

Figure 1622. Wakeup unit block diagram



80.1.2 Features

The Wakeup unit supports these distinctive features:

- Non-maskable interrupt support with:
  – Up to 4 NMI sources
  – Up to 4 analog glitch filters
  – Independent CPU exceptions destination: non-maskable interrupt, critical interrupt, or machine check request
  – Edge detection
  – Configurable system wakeup triggering from all NMI sources
- External wakeup/interrupt support with:
  – Up to 4 system interrupt vectors for up to 32 interrupt sources
  – Up to 32 analog glitch filters
  – Independent interrupt mask
  – Edge detection
  – Configurable system wakeup triggering from all interrupt sources
  – Configurable pull functionality
- On-chip wakeup support with:
  – Up to 32 wakeup sources
  – Wakeup status mapped to same register as external wakeup/interrupt status

Note: For the chip-specific feature details of this module refer to the Device Configuration chapter.

80.2 External signal description

The Wakeup unit has 0 to 32 signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

The module has 0 to 4 signal inputs that can be used as non-maskable interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

80.3 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

80.3.1 Memory map

Table 1583 gives an overview on the WKPU registers implemented.

Table 1583. WKPU memory map

Address offset	Registers	Supported access sizes	Location
0x0000	NMI Status Flag Register (NSR)	32/16/8	*Section 80.3.2.1*
0x0004–0x0007	Reserved		
0x0008	NMI Configuration Register (NCR)	32/16/8	*Section 80.3.2.2*

Table 1583. WKPU memory map (continued)

Address offset	Registers	Supported access sizes	Location
0x000C–0x0013	Reserved		
0x0014	Wakeup/Interrupt Status Flag Register (WISR)	32	*Section 80.3.2.3*
0x0018	Interrupt Request Enable Register (IRER)	32	*Section 80.3.2.4*
0x001C	Wakeup Request Enable Register (WRER)	32	*Section 80.3.2.5*
0x0020–0x0027	Reserved		
0x0028	Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)	32	*Section 80.3.2.6*
0x002C	Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)	32	*Section 80.3.2.7*
0x0030	Wakeup/Interrupt Filter Enable Register (WIFER)	32	*Section 80.3.2.8*
0x0034	Wakeup/Interrupt Pullup Enable Register (WIPUER)	32	*Section 80.3.2.9*
0x0038–0x3FFF	Reserved		

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

80.3.2 Register descriptions

This section describes in address order all the Wakeup unit registers.

80.3.2.1 NMI Status Flag Register (NSR)

This register holds the non-maskable interrupt status flags.

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 1623. NMI Status Flag Register (NSR)

Table 1584. NSR field descriptions

Field	Description
16 NIF2	NMI Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE2 and NFEE2 has occurred. 0 No event has occurred on the pad.
17 NOVF2	NMI Overrun Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 1 An overrun has occurred on NMI input 2. 0 No overrun has occurred on NMI input 2.
24 RIF	ESR1 External Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (that is if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An event as defined by RREE and RFEE has occurred. 0 No event has occurred on the pad.
25 ROVF	ESR1 External Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An overrun has occurred on NMI input. 0 No overrun has occurred on NMI input.

Note: Refer to the Device Configuration chapter to see how the NMI Status Flag Register (NSR) is used in the device.

80.3.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 1624. NMI Configuration Register (NCR)

1. Writing this bit has no functional impact.

Table 1585. NCR field descriptions

Field	Description
16 NLOCK2	NMI Configuration Lock Register 2 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
17:18 NDSS2	NMI Destination Source Select 2 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request
19 NWRE2	NMI Wakeup Request Enable 2 1 NMI2 wakeup is enabled. A set NIF2 bit or set NOVF2 bit causes a system wakeup request. 0 NMI2 wakeup is disabled. System wakeup requests from the corresponding NIF2 bit are disabled.
21 NREE2	NMI Rising-edge Events Enable 2 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
22 NFEE2	NMI Falling-edge Events Enable 2 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
23 NFE2	NMI Filter Enable 2 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
24 RLOCK	ESR1 External Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
25:26 RDSS	ESR1 External Reset Destination Source Select This value is reset on system reset. 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	ESR1 External Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request. 0 System wakeup requests from the corresponding RIF bit are disabled. **Note:** To wake up the system from standby by this way, ESR1 option has to be disable in MC_RGM. To disable the MC_RGM ESR1 function, the bit 30 of RGM_FERD and RGM_FEAR registers have to be set.
29 RREE	ESR1 External Reset Rising-edge Events Enable 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.

Table 1585. NCR field descriptions (continued)

Field	Description
30 RFEE	ESR1 External Reset Falling-edge Events Enable 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
31 RFE	ESR1 External Reset Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Note: Refer to the Device configuration chapter to see how the NMI Configuration Register (NCR) is used in the device.

Note: Writing a '0' to both NREEx and NFEEx disables the NMI functionality completely (no system wakeup or interrupt will be generated on any pad activity).

80.3.2.3 Wakeup/Interrupt Status Flag Register (WISR)

This register holds the wakeup/interrupt flags.

Offset: 0x0014 Access: User read/write

Figure 1625. Wakeup/Interrupt Status Flag Register (WISR)

Table 1586. WISR field descriptions

Field	Description
0 EIF31	External Wakeup/Interrupt Status Flag 31 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER31), EIF31 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
1 EIF30	External Wakeup/Interrupt Status Flag 30 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER30), EIF30 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
2 EIF29	External Wakeup/Interrupt Status Flag 29 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER29), EIF29 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 1586. WISR field descriptions (continued)

Field	Description
3 EIF28	External Wakeup/Interrupt Status Flag 28 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER28), EIF28 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
4 EIF27	External Wakeup/Interrupt Status Flag 27 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER27), EIF27 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
5 EIF26	External Wakeup/Interrupt Status Flag 26 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER26), EIF26 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
6 EIF25	External Wakeup/Interrupt Status Flag 25 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER25), EIF25 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
7 EIF24	External Wakeup/Interrupt Status Flag 24 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER24), EIF24 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
8 EIF23	External Wakeup/Interrupt Status Flag 23 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER23), EIF23 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
9 EIF22	External Wakeup/Interrupt Status Flag 22 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER22), EIF22 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
10 EIF21	External Wakeup/Interrupt Status Flag 21 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER21), EIF21 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
11 EIF20	External Wakeup/Interrupt Status Flag 20 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER20), EIF20 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 1586. WISR field descriptions (continued)

Field	Description
12 EIF19	External Wakeup/Interrupt Status Flag 19 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER19), EIF19 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
13 EIF18	External Wakeup/Interrupt Status Flag 18 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER18), EIF18 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
14 EIF17	External Wakeup/Interrupt Status Flag 17 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER17), EIF17 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
15 EIF16	External Wakeup/Interrupt Status Flag 16 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER16), EIF16 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
16 EIF15	External Wakeup/Interrupt Status Flag 15 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER15), EIF15 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
17 EIF14	External Wakeup/Interrupt Status Flag 14 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER14), EIF14 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
18 EIF13	External Wakeup/Interrupt Status Flag 13 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER13), EIF13 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
19 EIF12	External Wakeup/Interrupt Status Flag 12 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER12), EIF12 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
20 EIF11	External Wakeup/Interrupt Status Flag 11 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER11), EIF11 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 1586. WISR field descriptions (continued)

Field	Description
21 EIF10	External Wakeup/Interrupt Status Flag 10 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER10), EIF10 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
22 EIF9	External Wakeup/Interrupt Status Flag 9 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER9), EIF9 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
23 EIF8	External Wakeup/Interrupt Status Flag 8 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER8), EIF8 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
24 EIF7	External Wakeup/Interrupt Status Flag 7 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER7), EIF7 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
25 EIF6	External Wakeup/Interrupt Status Flag 6 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER6), EIF6 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
26 EIF5	External Wakeup/Interrupt Status Flag 5 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER5), EIF5 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
27 EIF4	External Wakeup/Interrupt Status Flag 4 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER4), EIF4 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
28 EIF3	External Wakeup/Interrupt Status Flag 3 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER3), EIF3 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
29 EIF2	External Wakeup/Interrupt Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER2), EIF2 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 1586. WISR field descriptions (continued)

Field	Description
30 EIF1	External Wakeup/Interrupt Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER1), EIF1 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
31 EIF0	External Wakeup/Interrupt Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER0), EIF0 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Note: Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

80.3.2.4 Interrupt Request Enable Register (IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

Offset: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

20 EIRE11	External Interrupt Request Enable 11 1 A set EIF11 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF11 bit are disabled.
21 EIRE10	External Interrupt Request Enable 10 1 A set EIF10 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF10 bit are disabled.
22 EIRE9	External Interrupt Request Enable 9 1 A set EIF9 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF9 bit are disabled.
23 EIRE8	External Interrupt Request Enable 8 1 A set EIF8 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF8 bit are disabled.
24 EIRE7	External Interrupt Request Enable 7 1 A set EIF7 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF7 bit are disabled.
25 EIRE6	External Interrupt Request Enable 6 1 A set EIF6 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF6 bit are disabled.
26 EIRE5	External Interrupt Request Enable 5 1 A set EIF5 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF5 bit are disabled.
27 EIRE4	External Interrupt Request Enable 4 1 A set EIF4 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF4 bit are disabled.
28 EIRE3	External Interrupt Request Enable 3 1 A set EIF3 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF3 bit are disabled.
29 EIRE2	External Interrupt Request Enable 2 1 A set EIF2 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF2 bit are disabled.
30 EIRE1	External Interrupt Request Enable 1 1 A set EIF1 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF1 bit are disabled.
31 EIRE0	External Interrupt Request Enable 0 1 A set EIF0 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF0 bit are disabled.

80.3.2.5 Wakeup Request Enable Register (WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

Note: Any wakeup pad must be properly driven either externally or internally (enabling weak pull-up/pull-down) before enabling its corresponding WREx bit.

Offset: 0x001C Access: User read/write

80.3.2.8 Wakeup/Interrupt Filter Enable Register (WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

Note: Glitch filter must be enabled in case the wake-up sources are used to exit from Standby.

80.3.2.9 Wakeup/Interrupt Pull Enable Register (WIPUER)

This register is used to enable a pull on the corresponding interrupt pads. The pull direction (up or down) is selected by SIUL2_MSCR_IO_n.WPDE-WPUE bits.

Note: WIPUER bits related to those bonded LP pads that are used to wake-up the device from STANDBY Mode, should be left at 0 default value.

- *Bits setting has undesired effect in STANDBY mode (extra consumption or anticipated exiting from STANDBY mode)*
- *In running mode, pull-up/down IO configuration shall be done only through SIUL*

80.4 Functional description

80.4.1 General

This section provides a complete functional description of the Wakeup unit.

80.4.2 Non-maskable interrupts

The Wakeup unit supports up to 4 non-maskable interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports the generation of 3 types of interrupts per NMI input to the SoC. The Wakeup unit supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a by-passable analog glitch filter.

Note: Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

80.4.2.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 1624*). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note: After reset, NREE and NFEE are set to ‘0’, therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad’s NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 1585* for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see *Figure 1623*). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (it has not yet been cleared).

Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

80.4.3 External wakeups/interrupts

The Wakeup unit supports up to 32 external wakeup/interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports up to 4 interrupt vectors to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N - 1, the next is for N through N + M - 1, and so forth.

The parameter IRQ_VEC defines the number of interrupt vectors (the ipi_int_pins output size).

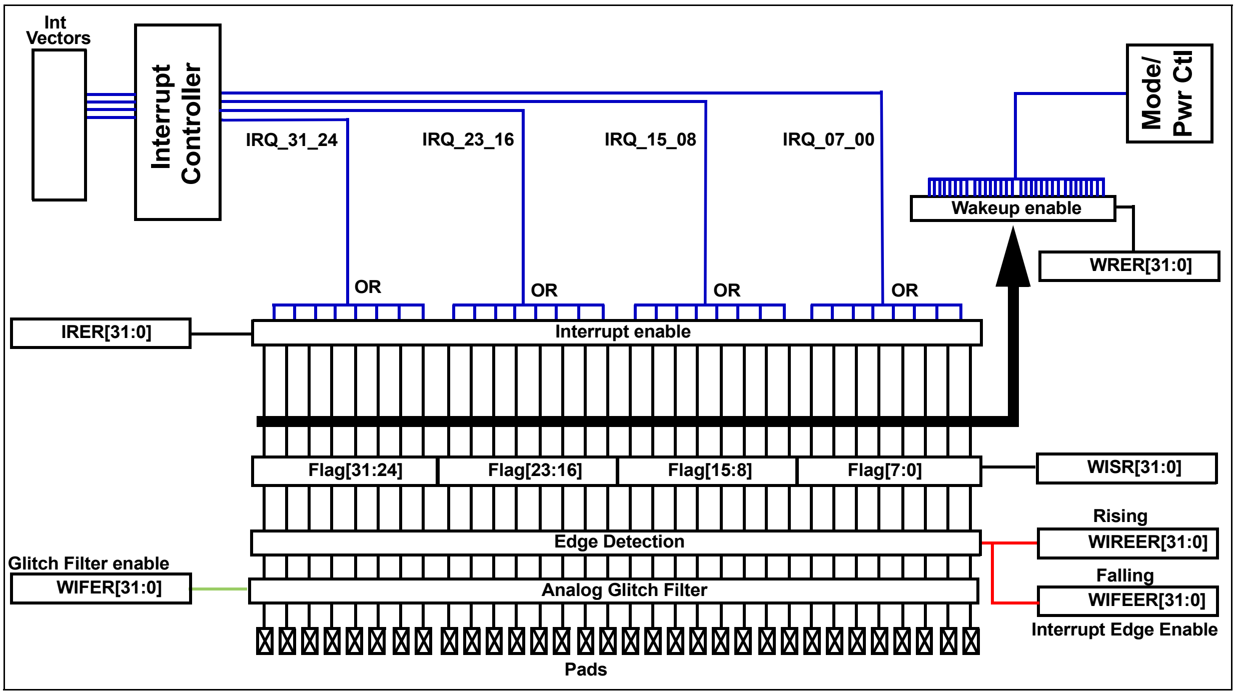
The parameter EIRQ_PER_VEC defines the number of external interrupt sources assigned to each interrupt vector. It is split up into four 6-bit fields, one for each possible interrupt vector, with the lowest field corresponding to ipi_int_pins[0], the second field to ipi_int_pins[1], and so forth.

For example, for EIRQS = 17, IRQ_VEC = 3 and EIRQ_PER_VEC = {6'd0, 6'd5, 6'd3, 6'd9}, ipp_ind_int[8:0] are assigned to ipi_int_pins[0], ipp_ind_int[11:9] are assigned to ipi_int_pins[1], and ipp_ind_int[16:12] are assigned to ipi_int_pins[2]. The signals ipp_ind_int[31:17] and ipi_int_pins[3] do not exist.

Note: If EIRQS = 0, the unused ipp_ind_int[0] input has no effect on the sys_wakeup output.

Refer to *Figure 1632* for an overview of the external interrupt implementation for the example of four interrupt vectors with eight external interrupt sources each.

Figure 1632. External interrupt pad diagram



All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

An SoC specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 0 to 32.

Note: Glitch filter control and pad configuration should be done while the external interrupt line is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

80.4.3.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (*Figure 1626*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.

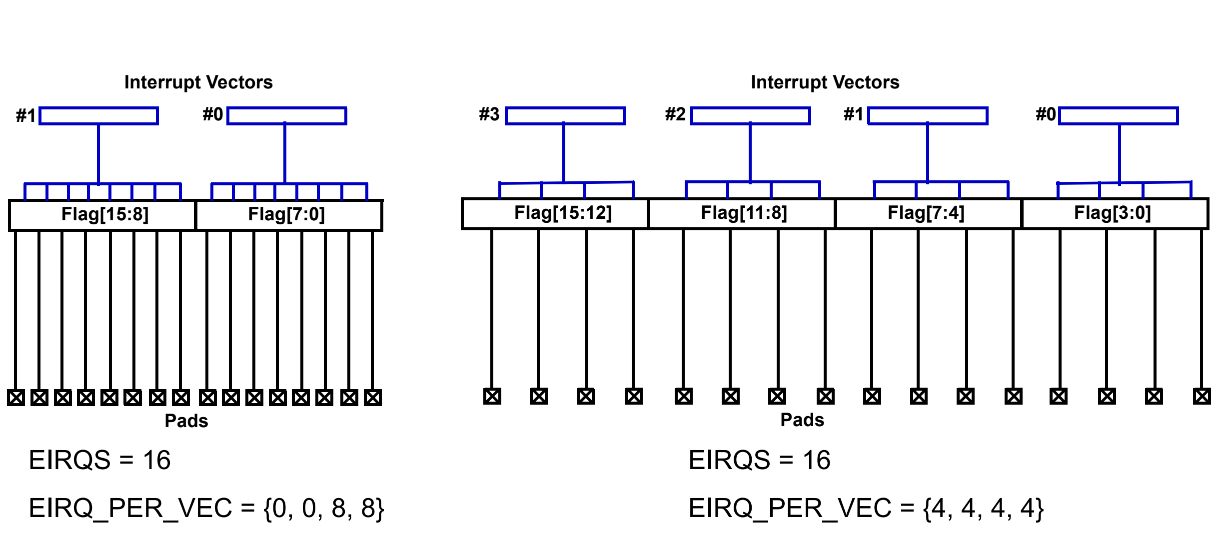
Note: Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (no system wakeup or interrupt will be generated on any activity on that pad)!

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

For devices with less than the maximum number of interrupt sources, it is possible for the SoC to implement either all four interrupt vectors with fewer sources or to reduce the number of vectors as the number of sources are reduced. *Figure 1633* shows two examples of how this could be supported.

Figure 1633. Example of different interrupt to vector mapping at SOC level



80.4.4 On-Chip wakeups

The Wakeup unit supports up to 32 on-chip wakeup sources. It combines the on-chip wakeups with the external ones to generate a single wakeup to the system.

Note: If WUPS = 0, the unused wakeup_in input has no effect on the sys_wakeup output.

80.4.4.1 On-Chip wakeup management

In order to allow software to determine the wakeup source at one location, on-chip wakeups are reported along with external wakeups in the WISR register (see *Figure 1625* for details). Enabling and clearing of these wakeups are done via the on-chip wakeup source's own registers.

81 Real Time Clock / Autonomous Periodic Interrupt (RTC/API)

81.1 Overview

The RTC is a free running counter used for time keeping applications. The RTC may be configured to generate an interrupt at a predefined interval independent of the mode of operation (run mode or low power mode). When the RTC interval is reached, the RTC will generate a wakeup request to the wakeup unit. The RTC can be configured to generate an interrupt on the RTC interval timeout.

The RTC also supports an autonomous periodic interrupt (API) function which can be used to generate a periodic event to the wakeup unit or an interrupt request.

81.2 Features

Features of the RTC/API include:

- 3 selectable counter clock sources:
  - LPRC prescaled by 8 (128 kHz)
  - SXOSC (32 kHz)
  - IRCOSC (16 MHz)
- Clock sources can optionally be prescaled by 512 or 32
- 32-bit counter
  - Supports times up to 1.5 months with 1 ms resolution
  - Runs in all modes of operation, including normal RESET
  - Reset when disabled by software and by POR
- 32-bit compare value to support an extended range of interrupt intervals
- RTC compare value changeable while counter is running
- RTC status and control register are reset only by POR
- Autonomous periodic interrupt (API) to support an extended range of interrupt intervals
- Configurable interrupt for RTC match, API match, and RTC rollover
- Configurable wakeup event for RTC match and API match

Figure 1634. RTC/API block diagram

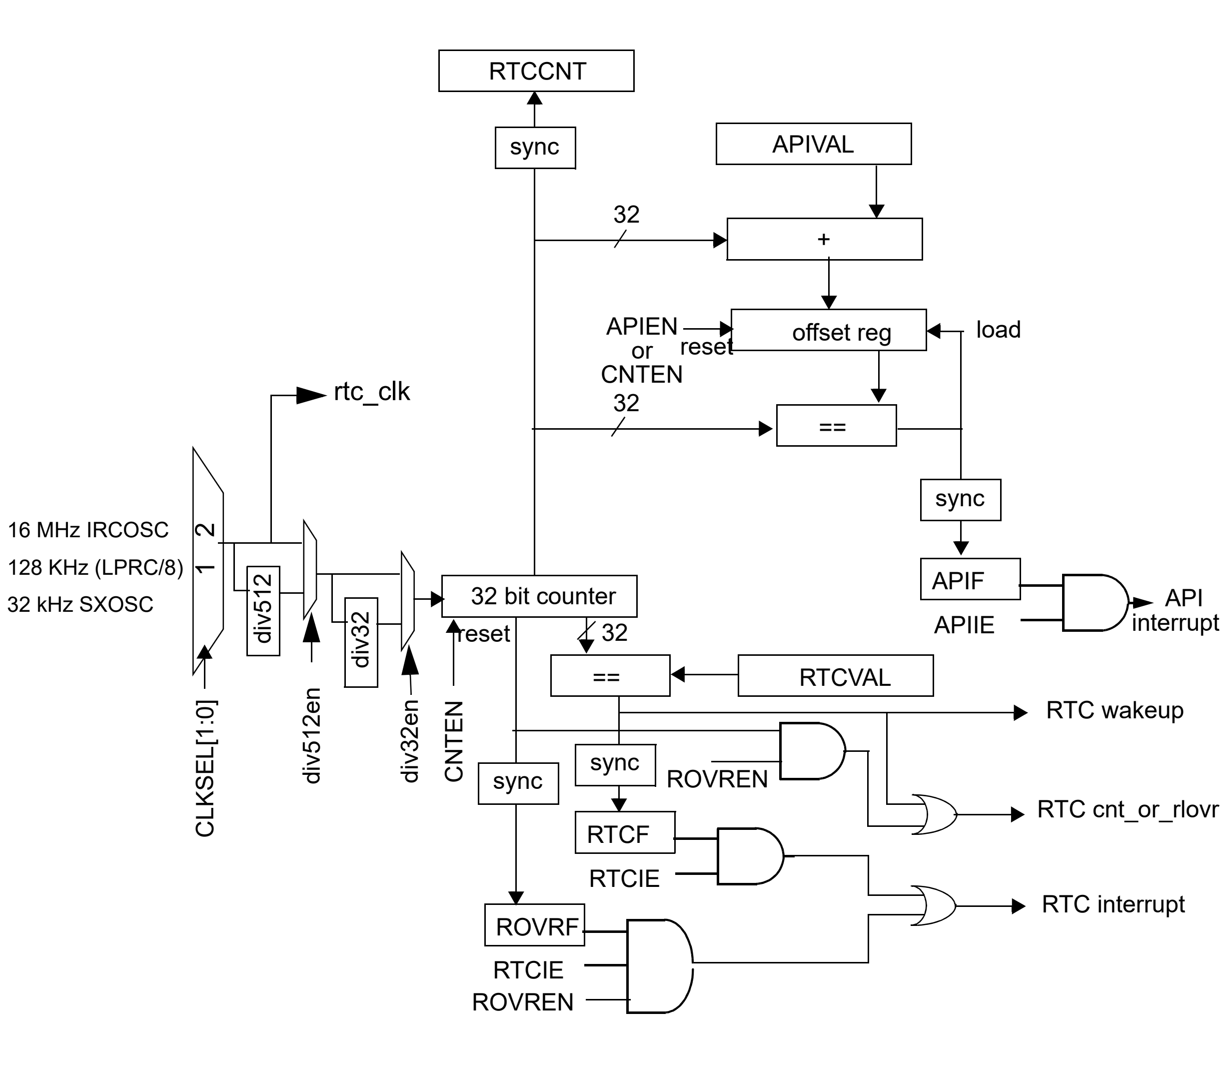


Figure 1635. Clock gating for RTC clocks

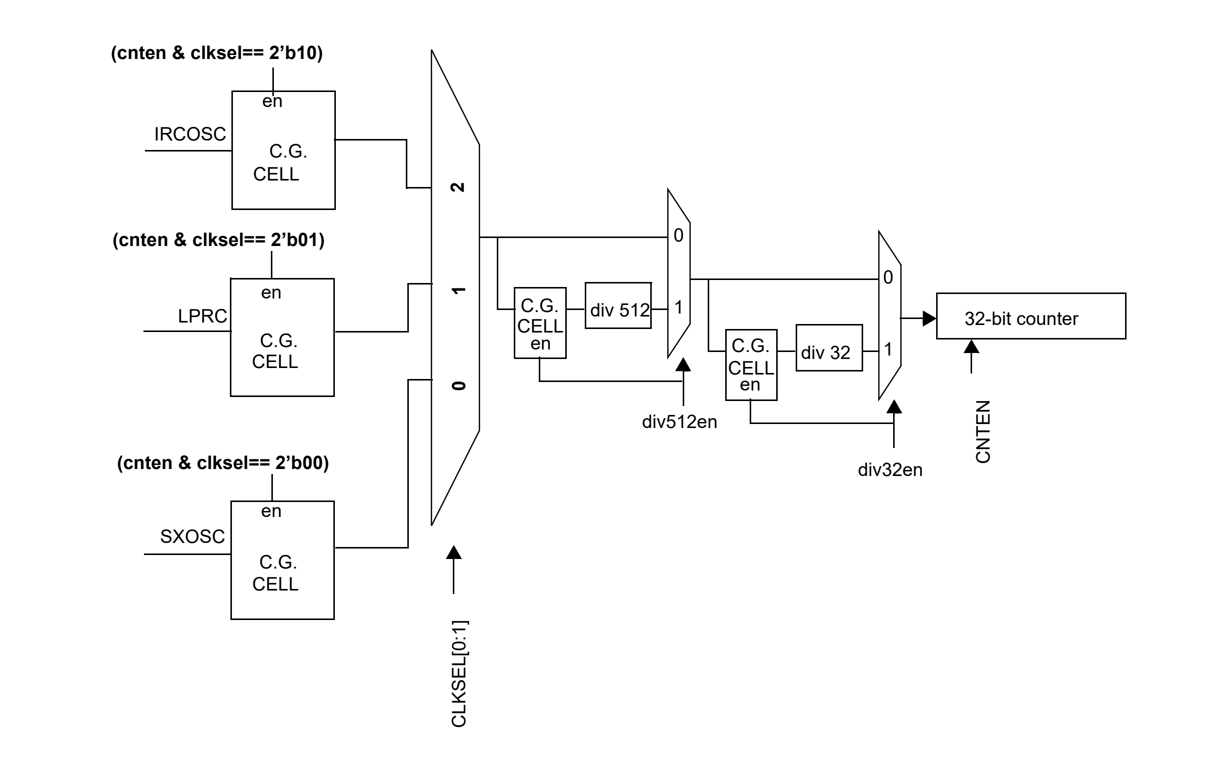

81.3 Modes of operation

81.3.1 Functional mode

There are two functional modes of operation for the RTC: normal operation and low power mode. In normal operation, all RTC registers can be read or written. The RTC/API and associated interrupts are optionally enabled. In low power mode, the bus interface is disabled and no configuration changes are permitted. The RTC/API is enabled if enabled prior to entry into low power mode.

81.3.2 Debug mode

If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. If RTCC[FRZEN] is clear, the counter will continue counting (and set flags accordingly) when the device is in debug mode.

81.4 Register descriptions

The registers listed in *Table 1593* are described in the following sections.

Table 1593. RTC/API register map

Address offset	Register	Location
0x0000	RTC Supervisor Control Register (RTCSUPV)	*Section 81.4.1*
0x0004	RTC Control Register (RTCC)	*Section 81.4.2*
0x0008	RTC Status Register (RTCS)	*Section 81.4.3*
0x000C	RTC Counter Register (RTCCNT)	*Section 81.4.4*
0x0010	API Compare Value Register (RTC_APIVAL)	*Section 81.4.5*
0x0014	RTC Compare Value Register (RTC_RTCVAL)	*Section 81.4.6*

81.4.1 RTC Supervisor Control Register (RTCSUPV)

The RTCSUPV register contains the SUPV bit which determines whether other registers are accessible in supervisor mode or user mode.

Note: RTCSUPV register is accessible only in supervisor mode.

Offset: 0x0000 Access: Supervisor R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SUPV	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1636. RTC Supervisor Control Register (RTCSUPV)

Table 1594. RTCSUPV register field descriptions

Field	Description
0 SUPV	RTC Supervisor Bit 0 All registers are accessible in both user as well as supervisor mode. 1 All other registers are accessible in supervisor mode only.

81.4.2 RTC Control Register (RTCC)

The RTCC register contains:

- RTC counter enable
- RTC interrupt enable
- RTC clock source select
- RTC compare value
- API enable
- API interrupt enable
- API compare value

Offset: 0x0004 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1637. RTC Control Register (RTCC)

Table 1595. RTCC register field descriptions

Field	Description
0 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Clearing CNTEN has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic as well as resetting the 32-bit counter. This allows for the RTC configuration and clock source selection to be updated without causing synchronization issues. 0 Counter disabled and reset 1 Counter enabled
1 RTCIE	RTC Interrupt Enable The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0 RTC interrupts disabled 1 RTC interrupts enabled
2 FRZEN	Freeze Enable Bit If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. 0 Counter running in debug mode 1 Counter stops (freezes) in debug mode
3 ROVREN	Counter Roll Over Interrupt Enable The ROVREN enables interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0 RTC rollover interrupt disabled 1 RTC rollover interrupt enabled
16 APIEN	Autonomous Periodic Interrupt Enable The APIEN bit enables the autonomous periodic interrupt function. 0 API disabled 1 API enabled

Table 1595. RTCC register field descriptions (continued)

Field	Description
17 APIIE	API Interrupt Enable The APIIE bit enables interrupts requests to the system if APIF is asserted. 0 API interrupts disabled 1 API interrupts enabled
18:19 CLKSEL	Clock Select The CLKSEL[0:1] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. 00 SXOSC 01 LPRC prescaled by 8 10 IRCOSC
20 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0 Divide by 512 is disabled. 1 Divide by 512 is enabled.
21 DIV32EN	Divide by 32 enable The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0 Divide by 32 is disabled. 1 Divide by 32 is enabled.
31 TRIG_EN	Trigger enable Used for self clearing of WKPU API event. This bit is required in case API event is being used to trigger SSWU eCTU commands. 0 Trigger enable is disabled. 1 Trigger enable is enabled.

81.4.3 RTC Status Register (RTCS)

The RTCS register contains:

- RTC interrupt flag
- API interrupt flag
- ROLLOVR Flag

Offset: 0x0008 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	RTCF	0	0	0	0	0	0	0	0	0	0	INV_RTC	INV_API	INV_ANL
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	APIF	0	0	ROVRF	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1638. RTC Status Register (RTCS)

Table 1596. RTCS register field descriptions

Field	Description
2 RTCF	RTC Interrupt Flag The RTCF bit indicates that the RTC counter has reached the counter value matching RTCVAL. RTCF is cleared by writing a 1 to RTCF. Writing a 0 to RTCF has no effect. 0 RTC counter is not equal to RTCVAL. 1 RTC counter matches RTCVAL.
13 INV_RTC	Invalid RTC write This bit becomes value 1 after a value has been written to the RTCVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the RTCVAL register again will be ignored.
14 INV_API	Invalid APIVAL write This bit becomes value 1 after a value has been written to the APIVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the APIVAL register again will be ignored.
15 INV_ANL	Invalid ANLCMP write This bit becomes value 1 after a value has been written to the ANLCMP_CNT register and the synchronization process is continuing. During this synchronization period, any attempt to write to the ANLCMP_CNT register again will be ignored.
18 APIF	API Interrupt Flag The APIF bit indicates that the RTC counter has reached the counter value matching API offset value. APIF is cleared by writing a 1 to APIF. Writing a 0 to APIF has no effect. 0 No API interrupt 1 API interrupt
21 ROVRF	Counter Roll Over Interrupt Flag The ROVRF bit indicates that the RTC has rolled over from 0xffff_ffff to 0x0000_0000. ROVRF is cleared by writing a 1 to ROVRF. 0 RTC has not rolled over. 1 RTC has rolled over.

81.4.4 RTC Counter Register (RTCCNT)

The RTCCNT register contains the current value of the RTC counter.

Offset: 0x000C Access: User read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RTCCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RTCCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1639. RTC Counter Register (RTCCNT)

Table 1597. RTCCNT register field descriptions

Field	Description
0:31 RTCCNT	RTC Counter Value Due to the clock synchronization, the RTCCNT value may actually represent a previous counter value.

81.4.5 API Compare Value Register (RTC_APIVAL)

The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted.

Offset: 0x0010 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	APIVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	APIVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1640. API Compare Value Register (RTC_APIVAL)

Table 1598. RTC_APIVAL register field descriptions

Field	Description
0:31 APIVAL	API Compare Value The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted. **Note:** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to rtc clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. Minimum supported value of APIVAL is 4. This is due to synchronization issues.

81.4.6 RTC Compare Value Register (RTC_RTCVAL)

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set.

Note: If RTC interrupt is enabled (RTCIE), it is required after each RTC counter match to reload the RTCVAL via software, to enable the interrupt again.

With RTCC[CTNEN] = 1 (RTC running) the user needs to wait the RTCS[RTC_INV] goes to zero (completed the synchronization process) before updating the RTCVAL counter. Otherwise the latter update will have no effect.

Offset: 0x0014 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1641. RTC Compare Value Register (RTC_RTCVAL)

Field	Description
0:31 RTCVAL	RTC Compare Value The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. **Note:** Minimum supported value of RTCVAL is 4. This is due to synchronization issues.

81.4.7 RTC Analogue Comparator Count Register (RTC_ANLCMP_CNT)

This register contains the number of API clocks corresponding to the trigger_en_out_pulse to be generated.

Offset: 0x0018 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R/W	ANLCMP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R/W	ANLCMP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1642. RTC Analogue Comparator Count Register (RTC_ANLCMP_CNT)

Table 1600. RTC_ANLCMP_CNT register field descriptions

Field	Description
0:31 ANLCMP	The trigger_en_out pulse will be generated (after the generation of wakeup_api signal) as per the number of API clocks programmed into this register.

81.5 RTC functional description

The RTC consists in a 32-bit free running counter enabled with the RTCC[CNTEN] bit. (When CNTEN is cleared, the counter is asynchronously reset.) The value of the counter may be read via the RTCCNT register. Note that due to the clock synchronization, the RTCCNT value may actually represent a previous counter value. The difference between the counter and the read value depends on ratio of counter clock and main clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the RTCC[CLKSEL] field, which gives four options for clocking the RTC/API. The three clock sources are:

- LPRC prescaled by 8 (128 kHz)
- SXOSC (32 kHz)
- IRCOSC (16 MHz)

The output of the clock mux can be optionally divided by combination of 512 and 32 to give a 1 ms RTC/API count period for different clock sources. Note that the RTCC[CNTEN] bit must be disabled when the RTC/API clock source is switched.

When the counter value matches the 32-bit value in the RTCC[RTCVAL] field, then the RTCS[RTCF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[RTCIE] interrupt enable bit is set, then the RTC interrupt request is generated. If there is a match while in low power mode then the RTC will first generate a wakeup request to force a wakeup to run mode, then the RTCF flag will be set.

A rollover interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. Rollover events are enabled by setting the RTCC[ROVEN] bit. If this bit is set, an RTC rollover will cause a request. To enable interrupts on a rollover request, the RTCC[RTCIE] bit also needs to be set.

All the flags and counter values are synchronized with ipg_clk the main clock. It is assumed that ipg_clk the main clock frequency is always more than or equal to the rtc_clk RTC clock used to run the counter.

81.6 API functional description

Setting the RTCC[APIEN] bit enables the autonomous interrupt function. The 32-bit RTCC[APIVAL] field selects the time interval for triggering an interrupt and/or wakeup event. Since the RTC is a free running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, a interrupt and/or wakeup request is generated. Then the offset value is recalculated and re-triggers a new request when the new value is reached. APIVAL may only be updated when APIEN is disabled. When a compare is reached, the RTCS[APIF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[APIIE] interrupt enable bit is set, then the API interrupt request is generated. If there is a match while in low power mode, then the API will first generate a wakeup request to force a wakeup into normal operation, then the APIF flag will be set.

Appendix A Acronyms and abbreviations

Table 1601 lists acronyms and abbreviations used in this document.

Table 1601. Acronyms and abbreviations

Term	Meaning
AHB	Advanced high-performance bus
AIC	PBRIDGE (AIPS) integrity checker
AMBA	Advanced microcontroller bus architecture
APFC	Auxiliary pin function control
APU	– Advanced protocol unit – Auxiliary processing unit
ASILB	Automotive SIL B
AUTOSAR	Automotive Open System Architecture
AVB	Audio Video Bridging
BAF	Boot assist flash
BCU	Buffer control unit
BIST	Built-in self test
BIU	Bus interface unit
BMIF	Bus master interface
CAN	Controller area network
CC	Communication controller
CDC	Clock domain crosser
CF	Critical fault
CGM	– Clock generation module – Conditional group member
CGMC	Conditional group membership count
CHI	Controller host interface
CID	Controller ID
CJTAG	Compact JTAG
CLTAPC	Chip-level TAPC
CP	Check packet
CPA	Check process active
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check

Table 1601. Acronyms and abbreviations (continued)

Term	Meaning
CSI	Combined serial interface. DSPI configuration that alternates DSI and SPI frames.
CTU	Cross triggering unit
DCF	Device configuration format
DCU	Data channel unit
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DSI	Deserial serial interface. DSPI configuration that serializes and deserializes registers or signals to allow for pin reduction.
EBI	External bus interface
ECC	Error correction code
ECSM	Error correction status module
EIM	Error injection module
EMI	Electromagnetic interference
EOT	End of transfer
EOUT	Error out
EPU	Extended protocol unit
ESD	Electromagnetic static discharge
FCCU	Fault collection and control unit
FMPLL	Frequency-modulated phase-locked loop
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
FSS	Frame start sequence
FTTI	Fault tolerant time interval
GPIO	General-purpose I/O
HIF	Host interface
HVD	High voltage detector
HW	Hardware
ID	LIN identifier field
IEEE	Institute of Electrical and Electronics Engineers
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety

Table 1601. Acronyms and abbreviations (continued)

Term	Meaning
IPS	– Internal peripheral system – IPI slave bus
IRQ	Interrupt request
ISR	Interrupt service routine
JDC	JTAG data communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
Jscan	JTAG scan
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LRAM	Look up table RAM
LUT	Look up table
LVD	Low voltage detector
LWB	Late-write buffer
MB	Message buffer
MBIDX	Message buffer index
MBIST	Memory built-in self test
MBM	Message buffer management
MBNum	Message buffer number
MC	MC_CGM, MC_ME, MC_PCU, and MC_RGM modules
MCU	Microcontroller unit
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit
MFD	Multiplication factor divider
Mscan	Maximum-flexibility scan
MT	Macrotick
MTS	Media access test symbol
Mux	Multiplex
NCF	Non-critical fault
NIT	Network idle time
NMI	Non-maskable interrupts
nTRST	Active low test reset
NVM	Non-volatile memory
OPP	Over-program protection
OSC	Oscillator

Table 1601. Acronyms and abbreviations (continued)

Term	Meaning
Oscan	Optimized scan
OTP	One time programmable
PASS	Password and device security module
PBRIDGE	Peripheral bridge
PCM	Platform configuration module
PCU	Power control unit
PE	Protocol engine
PFLASH	Platform flash controller
PIT	Periodic interrupt timer
PLL	Phase-locked loop
PMC	Power management controller
POC	Protocol operation control
PRAM	Platform RAM controller
PSS	Pause selection state
PWD	Password
RC	– Resistance-capacitance – Resistor-capacitor
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RSU	Reset and selection unit
RTL	Register transfer language
RWW	Read-while-write
RX	Receive
SAG	Safety application guide
SAR ADC	Successive approximation register analog-to-digital converter
SECDED	Single-bit error correction, double-bit error detection
SEQ	Sequencer engine
SIL	Safety integrity level
SIUL	System integration unit lite
SMPU	System memory protection unit

Table 1601. Acronyms and abbreviations (continued)

Term	Meaning
SoC	System-on-chip
SOR	Sphere of redundancy
SP	Scan packet
SPA	Scan packet active
SPI	Serial peripheral interface
Sscan	Segmented scan
SSCM	System status and configuration module
SSD	Scan selection directive
SSM	Scan state machine
STCU	Self-test control unit
STL	System test logic
STM	System timer module
SW	Software
SWT	Software watchdog timer
TAP	Test access point
TAP.1	An IEEE 1149.1 test access port
TAP.7	An IEEE 1149.7 test access port
TBD	To be defined
TCA	Tap controller access
TCD	Transfer control descriptor
TCK	Test clock
TCKC	Test clock compact
TCU	Time control unit
TDI	Test data input
TDIC	Test data input compact
TDO	Test data output
TDOC	Test data output compact
TMS	Test mode select
TMSC	Test mode select compact
TS	Target System
TSENS	Temperature sensor
TX	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault
VCO	Voltage controlled oscillator

Table 1601. Acronyms and abbreviations (continued)

Term	Meaning
VREG	Voltage regulator
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar
XBIC	XBAR integrity checker
ZBS	Zero bit scan
µT	Microtick

Revision history

Table 1602. Document revision history

Date	Revision	Changes
26-Jul-2017	1	Initial release
25-Apr-2018	2	Following are the changes in this version of the Reference manual: *Section : Overview* on cover page – Removed text “or symmetrical dual”. – Updated operating speed from 180 MHz to 120 MHz. *Chapter 2: Introduction* *Section 2.1: SPC584Bx microcontroller*: Updated the section. *Chapter 5: Memory Map* *Table 5: Flash memory map* Data Flash Blocks: removed “FMC” from the description for all addresses *Table 6: System and stand-by RAM memory map*: Replaced HSM memory spaces by a cross-reference to HSM memory map table. Updated HSM end offset. Updated *Table 8: HSM memory map* *Chapter 6: Functional safety* *Table 12: PMHF module categories*: Updated definition of Non-safety modules *Section 6.4.3.2: All-x words and ECC*: – Added sentence starting with “Memories that include addresses in the ECC...” – Reworked the paragraph starting with “In case of not valid codeword...” *Section 6.4.3.3: ECC failure handling*, *Section 6.4.3.4: Memory Error Management Unit (MEMU)* and *Section 6.4.3.4.1: Interface to ECC units*: Added “with same (optional) syndrome” *Table 13: Module classification*: Moved Concentrator DMA from NoSaMos to ViMos *Table 14: FCCU failure inputs* – Added fault 48. – Added event in failure descriptions 49 and 50. – Removed faults 115-123 not available for users. *Table 15: ECC RAM implementations*: Removed I-MEM Memory for Core_2 *Chapter 7: Device configuration* Made extensive changes in this chapter. *Chapter 8: Reset and Boot* *Section 8.3.3*, *Section 8.3.4*, *Section 8.3.5*, *Section 8.3.8* and *Section 8.3.9*: Deleted all indications of duration of each phase (“This phase is completed in...”) *Chapter 9: Device Configuration Format (DCF) Records* *Table 107: DCF client list*: Added “User serial boot”.

Date	Revision	Changes
25-Apr-2018	2 (cont'd)	*Chapter 10: Power management* *Figure 45: Device power management framework*. Replaced Core 0 with Core 2 and SRAM size for PD3 to 96 KB. *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* *Section 11.3: Architecture*: Added the paragraph starting with "In STANDBY mode, only RTC is powered on,..." *Chapter 16: System Integration Unit Lite2 (SIUL2)* *Table 205: SIUL2_MSCR_IOn field description*: – Changed description of ILS bitfield for 00 value from "Automotive" to "Reserved". – ILS bits value 00 is Reserved. *Figure 116: SIUL2 MCU ID Register #1 (SIUL2_MIDR1)*, in the footnote removed the default value of PKG bitfiled. *Section 16.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*, replaced "input/pull-up enabled" with "ZiH". *Figure 127: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*; ILS bit field Reset value is 0b11. *Chapter 20: System Memory Protection Unit (SMPU)* *Section 20.7: Application information*; Dual core application example removed. *Figure 156: Control/Error Status Register 1 (CESR1)*; Reset value for CH02M is 0b0100. *Chapter 24: DMA channel multiplexer (DMACHMUX)* Updated *Figure 217: DMACHMUX triggered channels* *Chapter 25: Clocking* *Table 302: MC_CGM relationship to clocks*, – Deleted "Bridge clock" from Output clock column of CGM_SC_DC1. – Reviewed description of registers CGM_AC12_DC1/2/3. *Table 304: Maximum auxiliary level clock frequencies*, update "Nominal programmed divider max output frequency" value of "Aux Clock 6 Selector". *Figure 220: Clock generation* Added information in Note 3. *Chapter 26: Dual PLL digital interface (PLLDIG)*: *Table 316: PLL0CR field descriptions*: EXPEDIE bitfield description enhanced *Table 318: PLL0DV field descriptions* and *Table 321: PLL1DV field descriptions*: Updated division factors of RFDPHI. *Section 26.6.3: Frequency modulation*, replaced PLLnCR[MFD] with PLL1DV[MFD]. *Section 26.7: Initialization information*: added footnote linked to "procedure". Changed "MC_ME_<mode>" by "<ME_mode>, "MC_ME_" or "ME" by "<ME>" and "MC_CGM_ACn" by "<CGM_ACn>" throughout all this chapter.

Table 1602. Document revision history (continued)

Date	Revision	Changes
25-Apr-2018	2 (cont'd)	*Chapter 27: Clock Monitor Unit (CMU)* *Table 326: CMU_CSR field descriptions* – SFM: added sentences "MDR[MD] ... CSR[SFM]=1" and "Software ... bit". – RCDIV: added sentence "Ensure ... [RCDIV]". – CME: added sentence "CMU_HFREF ... (CSR[CME=1])". *Section 27.5.2: CLKMN0_RMT supervisor*: deleted Note "f_{CLKMN0_RMT} ... *monitoring*". *Chapter 31: LPRC Digital Interface* *Section 31.2: Low Power RC oscillator*, deleted last paragraph concerning LPRCTRIM. *Section 31.3.1.1: Low Power RC Control register (CTL)*, deleted LPRCTRIM bitfield. *Chapter 38: Analog-to-Digital Converters (ADC) Configuration* *Section 38.2.1.1.2: 12-bit SAR ADC B0*: Removed references to SUPERVISOR. *Section 38.2.1: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*; Removed SUPERVISOR refered to 12 bit SAR ADC. *Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Figure 382: SARADC block diagram*, removed "watchdog trigger". *Section 39.3.1: Main features*: – Deleted "Trigger outputs on watchdog threshold crossover events" only for *WDG_trigout_yes.* – Deleted the bullet "Watchdog thresholds crossover". *Section 39.4.5.1: CTU trigger mode*: Replaced JABORT by JABORTCHAIN (was a typo). *Section 39.4.8: Programmable analog watchdog*: Deleted the latest paragraph about "external trigger output port which". *Section 39.5.1.1: Main Configuration Register (MCR)*: Deleted WTRIGOUT bitfiled. *Table 465: CTU modes*: Added comment in the footnote about CTSEN *Table 468: MCR field descriptions*: Replaced SDADC by SARADC in FRZ bitfield description (was a typo). *Chapter 43: Software Watchdog Timer (SWT)* *Section 43.1.1: Overview*: Added Note "The SWT runs over all device ...". *Chapter 44: Periodic Interrupt Timer (PIT)* *Section 44.2.1.6: PIT RTI Timer Control Register (RTI_TCTRL)*: Removed bitfield CHN.

Table 1602. Document revision history (continued)

Date	Revision	Changes
25-Apr-2018	2 (cont'd)	*Chapter 50: LINFlexD* *Figure 960: Master node: DMA Tx FSM (concept scheme)* and *Figure 964: Slave node: DMA Tx FSM (concept scheme)*: Added note "DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.". *Figure 979: LIN Time-Out Control Status Register (LINTCSR)*: Updated HTO reset value by adding a note (1) on bits 26:27. *Figure 985: LIN Control Register 2 (LINCR2)*: Updated IOPE reset value note (3). *Chapter 51: Reset Generation Module (MC_RGM)* *Figure 1053: Peripheral Reset Status Register 7 (RGM_PSTAT7)*, *Table 1071: RGM_PRST7 register field descriptions*: Fixed field name ETHERNET_0_STAT instead of 'PSTAT'. *Chapter 52: Boot Assist Flash (BAF)* *Section 52.3.7: Optionally perform a serial boot*: Updated introduction paragraph. *Chapter 53: System Status and Configuration Module (SSCM)* Updated *Table 1104: Life Cycle slots*, *Table 1105: Life Cycle Slots in Memory* and *Table 1106: Resulting Life Cycle*. Removed "Glossary" section. *Chapter 54: Power management controller digital interface (PMC_Dig)* Updated the access type of all register descriptions as per *Section 54.3: IPS bus interface* "The registers of the PMC_Dig block are accessible (read/write) in each access mode: user, supervisor or test". *Table 1107: Power Management Controller Memory Map*: Added PNREG_S register. *Chapter 56: Mode Entry Module (MC_ME)* *Table 1178: ME_<mode>_MC Field Descriptions*: FLAON bitfield is valid for both Data and Instruction cache *Chapter 62: Sequence Processing Unit (SPU)* For each occurrence of "Calibration and Debug" in the chapter, added "(or Debug and Trace)" *Chapter 66: LVDS Fast Asynchronous Serial Transmission – High Speed Debug* *Table 1326: PLLCR field descriptions*: Updated description of FBDIV

Table 1602. Document revision history (continued)

Date	Revision	Changes
25-Apr-2018	2 (cont'd)	*Chapter 73: Memory Error Management Unit (MEMU)* *Section 73.1: Introduction*: Replaced "Peripheral System RAM" by "Peripheral RAM" in the second bullet. *Table 1452: SYS_RAM_UNCERR_ADDR field descriptions*, *Table 1457: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 1462: FLASH_UNCERR_ADDR field descriptions*: Added the sentence "This register must be READ ONLY when its corresponding valid bit is not asserted." to ERR_ADD field description. *Chapter 75: Fault Collection and Control Unit (FCCU)* *Table 1488: FCCU_CFG field descriptions*: updated description of bitfield FCCU_SET_CLEAR. *Figure 1533: FCCU CTRL Key Register (FCCU_CTRLK)* and *Table 1487: FCCU_CTRLK field descriptions*: Changed CTRLK field name to CTRLK_VAL. *Figure 1538: FCCU RF Key register (FCCU_RFK)* and *Table 1495: FCCU_RFK field descriptions*: Changed RFK field name to RFK_VAL. *Figure 1552: FCCU XTMR Register (FCCU_XTMR)* and *Table 1512: FCCU_XTMR field descriptions*: Changed XTMR field name to XTMR_VAL. *Figure 1556: FCCU Delta T Register (FCCU_DELTA_T)* and *Table 1517: FCCU_DELTA_T field descriptions*: Changed XTMR field name to XTMR_VAL. *Chapter 76: Self-Test Control Unit (STCU2)* *Table 1524: STCU2 memory map*: Renamed table title (was register set). *Section 76.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Removed equation number. *Figure 1572: STCU2 Error FM Register (STCU_ERR_FM)*: Set reset value of bits 0:15 to all 0. Removed section "Register map" *Chapter 78: Password and Device Security Module (PASS)* *Table 1552: LCSTAT register field descriptions*: Updated description of LIFE bitfield with value 110 (ST production) *Figure 1599: Password Group n - Lock 0 Status register (LOCK0_PGn)*: Added ATSL field at bit 1 and set undefined reset with figure note. *Table 1556: LOCK0_PGn register field descriptions*: Added ATSL field and its description at bit 1. *Section 78.2.1.4: Challenge Input register (CINn)*: Added the following sentence "Valid password criteria is that it should not be all Zeros or all Ones". *Chapter 93: Tamper Detection Module (TDM)* *Table 2346: TDM_STO_KEYn field descriptions*: Added "See the section...". *Figure 2446: Diary implementation*: Changed Diary_TDR0 size from 256x64 to 256x128 bits.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3	Following are the changes in this version of the Reference manual: *Chapter 5: Memory Map* *Table 8: HSM memory map*: Updated the table. *Table 9: Peripheral memory map (PBRIDGE 2)* Updated size + end offset of MC_CGM and start offset of the following Reserved field. *Table 11: UTest memory map*: Added a footnote, “Factory could program........find it” to the “UTest DCF records” for Start offset of 0x0370. *Chapter 6: Functional safety* *Table 13: Module classification* - NoSaMos: Moved “Concentrator HSM” to ViMos classification. *Table 15: ECC RAM implementations*: Replaced all JTAG occurrences by ITAG *Section 6.4.3.4: Memory Error Management Unit (MEMU)*: Rephrased the first paragraph. *Chapter 7: Device configuration* Made extensive changes in this chapter. *Chapter 8: Reset and Boot* *Section 8.3.1: Power-on and the Reset Generation Module*: Removed “long external reset” from the last paragraph. *Section 8.3.8: PHASE1[FUNC] Phase: temporization and monitoring setup*: added the latest sentence “During this phase, test modules are available.” *Figure 35: Reset Generation Module Reset Sequence*: – Removed a block of “no self test” – Added footnote, “To specify that no self-tests are executed in this case” – Updated the figure Updated footnote, “No self-tests are executed.” *Chapter 9: Device Configuration Format (DCF) Records*: Removed “FlexRay” from the entire chapter. *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* *Section 11.6.4: OPC*: Added second and third bullets to the set of pads behavior *Chapter 15: Core (z420n3) Description* *Section 15.9: Local memories*: Added this section. *Section 15.10: End-to-End ECC support*: Added this section. *Chapter 16: System Integration Unit Lite2 (SIUL2)* *Figure 126: Soc Configuration Register 0 (SIUL2_SCR0)*: – Updated the bit [8] from “ESR0_ASSERT” to “Reserved”. – Added a note for bit [8], “This bit shall be left at '0' default value by application.”

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Section 16.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*: Changed the latest sentence by referring to the device I/O_Definition document. *Table 205: SIUL2_MSCR_IOn field description*: Changed WPDE and WPUE field descriptions. *Chapter 17: Crossbar switch (XBAR)* *Table 214: XBAR memory map*: added MASTER channel n (n = 0 to 7) title and XBAR_MGPCRn registers at 0x0800 +n*0x100 address offsets. *Table 215: XBAR_PRSn field descriptions*: Added description of bitfield M3. *Table 216: XBAR_CRSn field descriptions*: Updated the note of PARK field from “Only select master.......behavior may occur.” to “Only select master.......parking configuration.” *Section 17.3.3: Master General Purpose Control Register (XBAR_MGPCRn)*: added this section. *Chapter 19: Peripheral Bridge (PBRIDGE)* *Section 19.2.3: Peripheral Access Control Register (PACRx)*: Added paragraph “The PBRIDGE registers themselves are mapped into the PACR0 address space and can only be accessed in supervisor mode by trusted bus masters.” *Table 225: Peripheral bridge memory map*: Updated some reserved spaces versus table notes. *Chapter 23: Enhanced Direct Memory Access (eDMA)* *Figure 178: Control Register (eDMA_CR)*: Changed GRP1PRI field reset value to 2’b01. *Chapter 25: Clocking* *Section 25.1: Introduction*: Updated this section and deleted text “as a backup clock”. Updated *Section 25.4: Default clock configuration* “Synchronous IP blocks...PLL or oscillator failure.” Updated *Figure 223: Clock distribution* *Section 25.5.1.6: Loss of clock detection*: deleted the last sentence “Software may enable or disable an optional backup clock in the PLL”. *Section 25.8.1: Loss of PLL/XOSC clock*: Updated this section. *Section 25.8.2: Loss of IRCOSC clock*: Updated this section and deleted text “and backup”. *Table 302: MC_CGM relationship to clocks* – Removed row-headed CGM_AC2_DC0 – Updated row-headed CGM_AC12_DC2 CGM_AC12_SC *Table 304: Maximum auxiliary level clock frequencies*: Added note to EMIOS_CLK. *Chapter 26: Dual PLL digital interface (PLLDIG)* *Section 26.1: Introduction*: Added note with a cross-reference to Clocking chapter for chip-specific implementation details.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Section 26.4: Modes of operation*: – Changed "the operating modes" by "the operating mode" – Changed "The various modes of operation for the PLL are" by "The mode of operation for the PLL is defined below" *Figure 229: Dual PLL digital interface block diagram*: – Updated this figure by adding a divider by 2 in PLL0 block. – "Backup Clock Selection" block is made blue and note added "Backup Clock Selection" block in blue is not implemented". *Chapter 27: Clock Monitor Unit (CMU)* *Section 27.4.1.1: CMU Control Status Register (CMU_CSR)*: Updated the description of RCDIV from, "Ensure clock.......CMU_CSR[RCDIV]." to "Ensure clock......otherwise the operation can lead to a spurious OLR event." *Table 326: CMU_CSR field descriptions*: Updated the descriptions of SFM and CME fields. *Section 27.4.1.5: CMU Interrupt Status Register (CMU_ISR)*: updated Note. *Chapter 28: Clock Generation Module (MC_CGM)* Updated *Section 28.3.1.37: Auxiliary Clock 8 Divider 0 Configuration Register (CGM_AC8_DC0)* Updated *Section 28.3.1.43: Auxiliary Clock 11 Divider 0 Configuration Register (CGM_AC11_DC0)* Removed Section "Divider jitter injection" *Section 28.4.3.1: Fractional divider details*: Added this section. *Chapter 29: OSC digital interface (XOSC)* *Figure 298: XOSC Control register (XOSC_CTL)*: Changed I_OSC field access type to R/w1c (was RW). Added *Section 29.2.4.1: Automatic Level Control (ALC)* *Chapter 31: LPRC Digital Interface* *Section 31.2: Low Power RC oscillator*: Updated the second paragraph starting with "Low power RC oscillator is enabled..." *Figure 301: Low Power RC Control register (CTL)*: Updated the reset value of S_LPRC field to '1'. *Chapter 34: Flash memory controller* *Section 34.5.13.1.1: e2eECC and Flash accesses*: added the latest sentence. *Section 34.5.14: e2eECC on data Flash accesses*: added the latest sentence. *Chapter 35: Embedded Flash Memory* *Section 35.3.2.1: Module Configuration Register (MCR)*: Updated EEE field description. *Table 407: MCR field descriptions*: – Added sentence "Note that EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash" at EEE field description.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	– Improved wording of DWEE in both for code and data memory. *Table 410: MCRE field descriptions*: – Updated description of fields N64KL and N16KL. – Removed the row of field "N256KH". Improved wording for bitfield ADDR in *Table 422: ADR field descriptions*. *Section 35.4.4.1: Error correction code*: Added sentence, "EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash" at the end of the fourth sentence. Added *Section 35.4.4.1.1: Multi-bits error management (more errors than uncorrectable detection capability)*. Updated size of customer OTP area in*Table 405: UTEST block memory map* Sentence in *Section 35.4.1: Reset* has been highlighted with Warning style *Chapter 36: Flash Memory Programming and Configuration* *Section 36.6.2: Creating the tamper detect diary*: – The maximum size of Diary updated from 2 KB to 4 KB. – Multiplied by 2 KB is updated to 4 KB. – Updated the *Example 7: Creating the tamper detect diary* *Example 4: Overriding secure write protection*: Updated paragraph list 2. *Chapter 38: Analog-to-Digital Converters (ADC) Configuration* *Section 38.2.1.1.1: 12-bit Fast SAR ADC*: Updated "analog input channel" for each SARADC instances. *Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Table 467: SARADC digital interface register map*: Removed "Register classification" column. *Section 39.4.4.1: Conversion timings*: Changed SAMPSEL by CTSEL field name. *Table 468: MCR field descriptions*: added note to NSTART, JSTART and PWDN field descriptions. *Table 487: PDEDR field descriptions*: added latest paragraph in PDED field description. *Section 39.4.6: Test channel connection with internal analog channel*: removed temperature sensor and bandgap from the first sentence of the first paragraph. *Section 39.5.1.11: Watchdog Threshold Register n (WTHRHLRn)*: Replaced in 1st note MSB=0 bits numbers by LSB=0 bit numbers. *Chapter 44: Periodic Interrupt Timer (PIT)* *Section 44.2.1.6: PIT RTI Timer Control Register (RTI_TCTRL)*: Removed the bitfield CH. *Section 44.5: Example Configuration for the Lifetime Timer*: Updated *Equation 29:* From, "current_uptime = PIT_LTMR64H << 64" to "current_uptime = PIT_LTMR64H << 32" *Chapter 45: Enhanced Modular IO Subsystem (eMIOS)* *Table 569: EMIOSMCR field descriptions*: Updated note in GTBE field description.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Chapter 46: CAN subsystem* *Table 595: TSCC field descriptions*: – TCP: Removed the note, "With CAN FD..... generation (TSS = '10')." – TSS: Added a new note, "In case of CAN FD..... frames are received." – TSS: Updated the value of 10 from "External timestamp counter value used" to "Reserved". *Table 596: TSCV field descriptions*: – TSC: Updated the content from , "The internal/ external......(both Rx and Tx)." to "The internal.....(both Rx and Tx)." – TSC: Removed, "When TSCC. TSS = '10', TSC reflects .... no impact." *Section 46.3.5.2.3: Data Bit Timing and Prescaler Register (DBTP)*: corrected time quanta max number in the first sentence. *Table 608: XIDFC field descriptions*: corrected max enumerated value of LSE field to 0x7F. *Table 613: RXF0C field descriptions*: corrected max enumerated value of F0WM and FOS fields to 0x7F. *Chapter 49: Deserial Serial Peripheral Interface (DSPI)* *Section 49.3.6: DSPI Status Register (DSPI_SR)*: changed reset value from 0xDEAD_BEEF to 0x0201_0000 *Table 957: DSPI_MCR field descriptions*: added note to HALT field description. *Chapter 50: LINFlexD* *Section 50.2.2: UART mode features*: Updated the 3 latest bullets. *Table 1022: TCD setting: UART - Tx mode*: Removed note at DADDR[31:0]. *Table 1023: TCD setting: UART - Rx mode*: Removed note at SADDR[31:0]. *Table 1024: LINFlexD memory map*: Removed "Register classification" column. *Chapter 51: Reset Generation Module (MC_RGM)* *Table 1067: RGM_PRST3 register field descriptions*: In SAR_ADC_12BIT_B_RST field, added note "In case BCTU_0 is used to trigger SAR_ADC_12BIT_B...." *Section 51.4.7: 'Destructive' reset escalation*: Added footnote to "each 'destructive' reset". *Chapter 52: Boot Assist Flash (BAF)* *Section 52.1: Introduction*: Updated the fourth paragraph. *Section 52.3: Functional description*: Removed section "Production disable activation protocol and implementation". *Section 52.3.7: Optionally perform a serial boot*: Deleted text "All Tx-channels have to be disabled during this phase"

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Chapter 53: System Status and Configuration Module (SSCM)* *Figure 1070: HSM and User Option Status Register (UOPS)* and *Table 1099: UOPS field descriptions*: – Added fields FL_RUN, BAF_FA and FL_STDBY and their respective descriptions. – Changed HSB bit field length to 3 bits and updated its description. *Section 53.3.3: Boot mode functionality*: Updated Standby-Boot section. *Chapter 54: Power management controller digital interface (PMC_Dig)* Removed “FlexRay” from the entire chapter. *Section 54.5.27: Miscellaneous CTRL REG (MISC_CTRL_REG)*: – Changed Bit 31 to RESERVED with a footnote. – Changed Bit 29 to Reserved – Added a footnote to Bit 28 *Table 1111: REE_LV0 field descriptions* and *Table 1121: REE_HV0 field descriptions*: Changed “REE” by “RES” in REE_XX field descriptions. *Table 1112: RES_LV0 field descriptions* and *Table 1121: REE_HV0 field descriptions*: Changed “RES” by “REE” in RES_XX field descriptions. *Section 54.5.53: User BIST Time1 and Time0 Register (BIST_TIME10)*: Changed Bit 3 and Bit 19 to RESERVED. *Section 54.5.54: User BIST Time3 and Time2 Register (BIST_TIME32)*: Changed Bit 3 and Bit 19 to RESERVED. *Section 54.5.55: User BIST Time6 and Time5 Register (BIST_TIME65)*: Changed Bit 3 and Bit 19 to RESERVED. *Section 54.9: Flash interface (DCF client usage)*: Added 2 paragraphs relative to monitors reactions. *Section 54.10: Voltage monitor BIST programming*: Updated this section. *Chapter 56: Mode Entry Module (MC_ME)* *Section 56.4.1: Mode transition request*: – Added a note, “If CMU reveals....... executed correctly”. – Added a second note. *Table 1178: ME_<mode>_MC Field Descriptions*: Removed table footnote in XOSCON field description. *Chapter 58: Debug and Calibration Interface (DCI)* *Section 58.1.3.5: SWT control*: Added note “Debugger should...the SWT.” *Chapter 59: JTAG Controller (JTAGC)* *Table 1233: 6-bit JTAG instructions*: Code instruction “111100” is set to reserved. *Chapter 61: JTAG Data Communication (JDC)* *Figure 1246: Module Status Register (JDC_MSR)*: Corrected register access to read/write.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Chapter 64: Debug Zipwire* *Section 64.8: Debug SIPI module*: Removed "FLEXAY" from this section. *Chapter 65: Debug Serial Interprocessor Interface (SIPI)* *Section 1.6.2: Payload and frame format*: Added Note at the end of the section. *Table 1310: Payload size of LFAST channel frame*: Added footnote. *Figure 13: Data allocation*: Added 32-bit data allocation *Chapter 66: LVDS Fast Asynchronous Serial Transmission – High Speed Debug* *Table 1321: TMCR field descriptions*: Updated description of bitfields CLKTST and LPON. *Table 1325: PICR field descriptions*: updated description of bitfield PNGREQ *Table 1328: UNSTCR field descriptions*: updated description of bitfield USNDRQ *Table 1326: PLLCR field descriptions*: – Corrected typo in FBDIV. – Updated the description of FBDIV. *Chapter 72: Cyclic Redundancy Check (CRC) Unit* *Figure 2: CRC Configuration Register n (CRC_CFGn)*: Swapped reset values versus function of n in the figure footnote of POLYG reset. *Chapter 73: Memory Error Management Unit (MEMU)* *Table 1452: SYS_RAM_UNCERR_ADDR field descriptions*: Removed to "This register is not writable when the corresponding VLD bit is zero." *Table 1457: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 1462: FLASH_UNCERR_ADDR field descriptions*: deleted the sentence "This register is not writable when the corresponding VLD bit is zero.)" *Table 1459: FLASH_CERR_STSn register field descriptions*: Updated description of bitfield BAD_BIT to replace 0xFF by 0xFFFF *Chapter 74: Indirect Memory Access (IMA)* *Table 1466: E2EECSR0 field descriptions*: Corrected register name in title. *Chapter 75: Fault Collection and Control Unit (FCCU)* *Table 1486: FCCU_CTRL field descriptions*: Added field numbers *Figure 1532: FCCU Control Register (FCCU_CTRL)*, *Figure 1543: FCCU IO Control Register (FCCU_EINOUT)* and *Figure 1553: FCCU MCS Register (FCCU_MCS)*: Changed some reset bit values to "0/1" with a cross-reference to the Device configuration chapter. *Table 1485: FCCU memory map*: Removed "Register classification" column. *Figure 1537: FCCU RF Status register n (FCCU_RF_Sn)*: Removed "Refer to for the errors description." from table footnote 1. *Table 1504: FCCU_STAT field descriptions*: – Added a note to PhysicErrorPin field description. – Updated this table.

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	*Table 1508: F2A_STATUS field descriptions*: – Changed the table title from F2AF_STATUS to F2A_STATUS – Description of value 0xFF of bitfield FAFS: replaced word “critical” by word “recoverable” *Section 75.6.8: FCCU RF Enable Register n (FCCU_RF_En)*: Deleted text “for debugging purposes”. *Section 75.6.13: FCCU Status Register (FCCU_STAT)*: Deleted text “for debugging purposes”. Deleted text “This register is for test/ debug purposes” from the following sections: – *Section 75.6.14: FCCU NA Freeze Status Register (N2AF_STATUS)* – *Section 75.6.15: FCCU AF Freeze Status Register (A2FF_STATUS)* – *Section 75.6.16: FCCU NF Freeze Status Register (N2FF_STATUS)* – *Section 75.6.17: FCCU FA Freeze Status Register (F2A_STATUS)* *Table 1522: FCCU_EOUT_SIG_ENn field descriptions*: Added a table footnote to enumerated value 0 description in EOUTEN[31:0] field descriptions. *Chapter 76: Self-Test Control Unit (STCU2)* *Section 76.4.2: Reset management*: Added a third sentence. *Section 76.4.8.1: Initialization sequence*: Updated second bullet with a second sentence. *Table 1524: STCU2 memory map*: Updated MBIST registers with k = 0 to 34. *Table 1525: STCU_RUN field descriptions*: Updated MBSPLLEN field description. *Table 1526: STCU_RUNSW field descriptions*: Updated MBSWPLLEN field description. *Table 1528: STCU_CFG field descriptions*: Updated CLK_CFG field description. *Table 1530: STCU_WDG field descriptions*: Updated WDGEOC field descriptions. *Table 1546: STCU_MB_CTRLk field descriptions*: Updated PTR field description. *Figure 1583: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*: Updated offset values with k = 0 to 34. *Section 76.6: Use cases and limitations*: Added paragraph: “The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.”. Removed following register sections: – STCU2 Offline MBIST 3 Status Register (STCU_MBS3) – STCU2 Offline MBIST 3 End Flag Register (STCU_MBE3) – STCU2 Online MBIST 3 Status Register (STCU_MBS3SW) – STCU2 Online MBIST 3 End Flag Register (STCU_MBE3SW) – STCU2 MBIST 3 Unrecoverable FM Register (STCU_MBUFM3) – STCU2 Offline MBIST 4 Status Register (STCU_MBS4) – STCU2 Offline MBIST 4 End Flag Register (STCU_MBE4) – STCU2 Online MBIST 4 Status Register (STCU_MBS4SW) – STCU2 Online MBIST 4 End Flag Register (STCU_MBE4SW) – STCU2 MBIST 4 Unrecoverable FM Register (STCU_MBUFM4)

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	For all available MBIST registers: – Added note, "Refer to..... number of NMCUT available in this device." – Added note to all fields from 0:30, "The availability of this field is based on......Device configuration chapter" *Section 76.4.8.2: MBIST scheduling*: removed STCU_MBE3/4 and STCU_MBE3SW/4SW inside this section. *Section 76.4.9: CRC*: Added note at the end of the section "The CRC calculated depends on the specific sample and not only the self-test configuration programmed." *Section 76.6.1: Offline self-test sequence*: removed STCU_MBS3/4, STCU_MBS3/4 and STCU_MBE3/4 registers inside this section. *Section 76.6.2: Online self-test Sequence*: removed STCU_MBUFM3/4, STCU_MBS3SW/4SW and STCU_MBE3SW/4SW registers inside this section. *Chapter 78: Password and Device Security Module (PASS)* *Section 78.1.2: Features* – Removed bullet "Production Disable control". – Removed section "External signal description". *Section 78.2: Memory map and register definition:* Removed section "Production Disable". *Section 78.2.1.5: Password Group n - Lock 0 Status register (LOCK0_PGn):* Removed paragraph about production disable. *Table 1559: LOCK3_PGn register field descriptions*: Added note to all RLx field descriptions. *Section 78.4.5.2.4: **Fuse Bypass Password compare***: – Removed text "of the Flash page contain different data not related to Fuse Bypass" at the end of the first sentence. – Removed "as the most significant 32 bits" in the second sentence. *Section 78.4.2: Debug Interface Access*: Removed "and production Disable" from the first paragraph. *Table 1563: Debug Interface Enable Truth table*: Removed Production Disable mode row. *Table 1564: Flash Memory Read Protection truth table*: Removed the second table. *Chapter 80: Wakeup unit (WKPU)* *Section 80.1.2: Features*: – Changed "configurable pullup" by "configurable pull". – Added a note referring to the Device Configuration chapter. *Section 80.3.2.5: Wakeup Request Enable Register (WRER)*: Added a note "Any wakeup pad..." *Section 80.3.2.8: Wakeup/Interrupt Filter Enable Register (WIFER)*: Added a Note, "Glitch filter must be enabled in case the wake-up sources are used to exit from Standby." *Section 80.3.2.9: Wakeup/Interrupt Pull Enable Register (WIPUER)*: – Updated the text from, "This register ...... value of 1" to "This register...... SIUL2_MSCR_IO_n.WPDE-WPUE bits."

Table 1602. Document revision history (continued)

Date	Revision	Changes
09-Apr-2020	3 (cont'd)	– *Table 1592: WIPUER field descriptions*: Replaced "Pullup" to "Pull" in the complete table. – Added a table note referring to the Device Configuration chapter on "Description" heading. *Chapter 81: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Section 81.4.6: RTC Compare Value Register (RTC_RTCVAL)*: – Added a note "If RTC interrupt is enabled (RTCIE), it is required after each RTC counter match to reload the RTCVAL via software, to re-enable the interrupt again." – Updated note.
13-Apr-2021	4	Following are the changes in this version of the document: Editorial changes throughout the document Updated the sub-title of the document. *Chapter 2: Introduction* *Figure 3: Periphery allocation*: updated "XBIC_Concentrator_0, 1" to "XBIC_Concentrator_1". *Chapter 3: Embedded memories* *Section 3.2.1: System SRAM*: updated the text from, "The SRAM can be configured....PFCR1.....controller." to "The SRAM can be configured... PRCR1.....controller." *Chapter 6: Functional safety* *Table 14: FCCU failure inputs*: – Updated Failure Description for FCCU channel 17-18 – Updated failure description for FCCU channel 30 – Updated the "Failure description" column of "COMPENSATION CELLS" Updated *Section 6.4.3.1: ECC for storage* *Table 15: ECC RAM implementations*: – updated column-head from memory classification to MEMU classification – added footnote for column-headed ECC for System RAM for location Platform – updated MEMU Classification for location HSM – updated column-headed ECC for Nexus for location Platform *Chapter 7: Device configuration* Updated this chapter. *Chapter 8: Reset and Boot* *Table 97: Module status during reset phases*: – removed note from Module "System watchdog" – updated row-headed SWT

Table 1602. Document revision history (continued)

Date	Revision	Changes
13-Apr-2021	4 (cont'd)	Updated *Section 8.3.5: PHASE2[DEST] Phase: flash initial configuration* *Figure 31: Reset Generation Module Reset Sequence*: added line "self-test bypassed" between PHASE3[DEST] and IDLE[FUNC]. *Section 8.3.2: Power-up phase: power stabilization*: updated the section. *Table 99: SSCM boot record search locations*: updated the location of column for Flash 16 KB. *Table 102: BAF boot record search locations*: updated the location of column for Flash 16 KB *Chapter 9: Device Configuration Format (DCF) Records* *Table 107: DCF client list*: added *2.* *Chapter 10: Power management* *Figure 49: Voltage monitors functionality*: Updated the figure. *Section 10.6.3: Brown-out management*: – added text to note "At any rate there are....." – added reference to the Application note. *Chapter 16: System Integration Unit Lite2 (SIUL2)* Updated *Section 16.2.2.1: MCU ID Register #1 (SIUL2_MIDR1)*: *Chapter 15: Core (z420n3) Description* Added *Section 15.9.2.3: DMEM Control Register 1 (DMEMCTL1)* *Chapter 17: Crossbar switch (XBAR)* *Section 17.3.1: XBAR Priority Registers Slave (XBAR_PRSn)*: – added text "Once the RO.....initiating the write" – added note "No two available.... will not be updated" – removed text "The XBAR_PRSn register is read-only...." *Chapter 18: Crossbar Integrity Checker (XBIC)* *Table 220: XBIC_EIR field descriptions*: In the second note, replaced "SMPU logical bus master assignments" with "AHB Master ID Assignments". *Chapter 25: Clocking* *Section 25.5.1.6: Loss of clock detection*: removed the last sentence "Software may enable or disable an optional backup clock in the PLL". *Table 304: Maximum auxiliary level clock frequencies*: – updated the third note from DSPI_CLK to DSPI_CLK0/1. – added note "DSPI_CLK frequency should always be greater than or equal to 1.25 times PBRIDGE_CLK" to DSPI_CLK1. *Chapter 26: Dual PLL digital interface (PLLDIG)* *Section 26.4.1: Normal mode with reference, PLL0 or both PLLs enabled*: added in Note cross-ref to *Section 26.7: Initialization information*.

Table 1602. Document revision history (continued)

Date	Revision	Changes
13-Apr-2021	4 (cont'd)	Removed section "Register classification for safety requirements" *Section 26.5.2.1: PLL0 control register (PLL0CR)*, *Section 26.5.2.4: PLL1 control register (PLL1CR)*: updated note for field LOLIE. *Chapter 27: Clock Monitor Unit (CMU)* *Section 27.4.1.5: CMU Interrupt Status Register (CMU_ISR)*: updated Note *Chapter 33: Platform RAM controller AHB (PRAMC_AHB)* *Section 33.2.1: Registers description*: added this section title. *Chapter 35: Embedded Flash Memory* *Table 405: UTEST block memory map*: added note to offset 0x140 *Section 35.3.2.4: Lock 0 register (LOCK0)*, *Section 35.3.2.5: Lock 1 register (LOCK1)*, *Section 35.3.2.6: Lock 2 Register (LOCK2)*, *Section 35.3.2.7: Lock 3 Register (LOCK3)*, *Section 35.3.2.8: Alternate Lock 0 register (LOCK0A)*,*Section 35.3.2.9: Alternate Lock 1 register (LOCK1A)*, *Section 35.3.2.10: Select 0 register (SEL0)*, *Section 35.3.2.11: Select 1 register (SEL1)*, *Section 35.3.2.12: Select 2 register (SEL2)*, *Section 35.3.2.13: Select 3 register (SEL3)*: text modified as follow "once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared" in the bit-field description *Table 407: MCR field descriptions*: Description text modification, removed Tpabt /Teabt parameters *Section 35.4.7.1: Array Integrity Self Check* and *Section 35.4.7.2: Margin Read*: Description for enable of Single and double error correction fixed. *Table 410: MCRE field descriptions*: changed coding of N32KL ('10' assigned to One 32KB sector in Low Space) Updated *Figure 362: Erase of blocks (example)* Updated *Figure 365: Array Integrity Check of blocks (example)* *Chapter 36: Flash Memory Programming and Configuration* *Figure 370: Sample DCF record for secure write protection*: updated the value of the figure. *Section 36.1: Selection of Flash memory blocks for erase*: replaced LOCKx with SELx in this section. *Chapter 38: Analog-to-Digital Converters (ADC) Configuration* *Section 38.1: ADC overview*: Updated "four 12-bit SAR ADCs" to "three 12-bit SAR ADCs. *Section 38.2.1: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*: Updated "four independent 12-bit" to "three independent 12-bit". *Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Section 39.5.1.11: Watchdog Threshold Register n (WTHRHLRn)*: Replaced in 1st note LSB=0 bits numbers by MSB=0 bit numbers. *Chapter 43: Software Watchdog Timer (SWT)* Removed section "External signal description".

Table 1602. Document revision history (continued)

Date	Revision	Changes
13-Apr-2021	4 (cont'd)	*Chapter 46: CAN subsystem* *Figure 518: CAN subsystem generic block diagram*: updated the "Peripheral Bridge" blocks to "PFBRIDGE". *Chapter 47: Ethernet* *Figure 646: MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK)*: updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Figure 647: MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)*: updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Chapter 48: Inter-Integrated Circuit (I2C)* Updated *Figure 868: Flow-Chart of DMA mode master receive* *Section 48.4: Memory map and register definition*: added *Section 48.4.2: Registers definition* sub-section and updated registers sections numbering. *Chapter 49: Deserial Serial Peripheral Interface (DSPI)* *Section 49.4.6.3: Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)*: added a second note. Removed section "Register classification for safety" *Section 49.4.12.10: Receive FIFO Drain interrupt or DMA Request*: – added 3 notes. – replaced 'fill' by 'drain' in the first Note. *Chapter 50: LINFlexD* *Section 50.4: Memory map and register description*: added note that refer to the LinFlexD configuration of the Device Configuration chapter. *Table 1024: LINFlexD memory map*: removed note that refer to the Device Configuration chapter and all cross-references to this note. *Table 1049: DMATXE field descriptions*: field editorial changes to remove the table note. *Table 1050: DMARXE field descriptions*: field editorial changes to remove the table note. *Chapter 51: Reset Generation Module (MC_RGM)* Updated *Section 51.1.3: Reset sources* Updated *Section 51.4.2: 'Destructive' resets* *Chapter 54: Power management controller digital interface (PMC_Dig)* Removed all the occurrences of "FlexRay" from the chapter. Updated *Section 54.3: IPS bus interface* *Table 1161: BIST_CTRL field descriptions*: updated description for row-headed NCFEN.

Table 1602. Document revision history (continued)

Date	Revision	Changes
13-Apr-2021	4 (cont'd)	*Chapter 56: Mode Entry Module (MC_ME)* Updated row-headed PDO in *Table 1178: ME_<mode>_MC Field Descriptions* Updated *Section 56.4.2.3: SAFE mode* Updated *Section 56.4.3.16: Pad switch-off* *Chapter 58: Debug and Calibration Interface (DCI)* Updated *Section 58.1.3.5: SWT control* *Chapter 63: JTAG Master (JTAGM)* Updated row-headed IIE in *Table 1298: JTAGM_MCR register field descriptions* Updated *Table 1300: JTAGM_DOR0 register field descriptions* Updated *Table 1301: JTAGM_DOR1 register field descriptions* Updated *Table 1302: JTAGM_DOR2 register field descriptions* Updated *Table 1303: JTAGM_DOR3 register field descriptions* *Chapter 64: Debug Zipwire* *Section 64.8: Debug SIPI module*: removed the text "Flexray (when available)". *Chapter 65: Debug Serial Interprocessor Interface (SIPI)* Updated the chapter *Chapter 66: LVDS Fast Asynchronous Serial Transmission – High Speed Debug* *Figure 1334: LFAST frame structure*: added "(bits)" to "Payload size" and "Frame size" columns headers. *Table 1316: Header payload sizes*: added "(bits)" to "Payload size" and "Frame size" columns headers. *Table 1334: RIISR field descriptions*: updated ICPFF. *Figure 1366: Rx Loopback mode* to *Figure 1371: Tx LVDS Loopback (external) mode with automatic frame generation*: added note regarding CSR. *Chapter 67: Development Trigger Semaphore (DTS)* *Section 67.4.1.1: DTS output enable register (DTS_ENABLE)*: Added DTS_EN_B field. *Chapter 72: Cyclic Redundancy Check (CRC) Unit* *Table 1440: CRC unit memory map*: removed the "Register classification column" *Chapter 74: Indirect Memory Access (IMA)* Updated *Figure 1504: Cache Debug Access Control register (CDACNTL)* Updated *Figure 1505: Cache Debug Access Data register (CDADATA)* Updated *Section 74.2.2.1: e2eECC Error Control/Status register 0 (E2EECSR0)*

Table 1602. Document revision history (continued)

Date	Revision	Changes
13-Apr-2021	4 (cont'd)	*Chapter 75: Fault Collection and Control Unit (FCCU)* *Section 75.6.1: FCCU Control Register (FCCU_CTRL)*: updated the bullet "configure the glitch filter present on location given by FILTER_POSITION parameter" to "configure the glitch filter present on EIN0 input (FCCU failure input #96)" and replaced text "(FCCU_RF_Sn[RFSx] where y = FILTER_POSTN)" to "FCCU failure input #96". Updated *Figure 1516: FCCU block diagram* Updated row-headed "REG intf" for *Table 1476: FCCU submodules* Updated row-headed OPR for *Table 1486: FCCU_CTRL field descriptions* *Chapter 76: Self-Test Control Unit (STCU2)* *Section 76.4.9: CRC*: updated the note "The expected value of the CRC depends on multiple internal critical signals and can differ among different samples." *Table 1530: STCU_WDG field descriptions*: updated description for WDGEOC. *Section 76.5.5: STCU2 PLL Configuration Register (STCU_PLL_CFG)*: added a note, "f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz." *Section 76.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: added the note to "The expected value of the CRC depends on multiple internal critical signals and can differ among different samples." *Chapter 80: Wakeup unit (WKPU)* *Section 80.3.2.9: Wakeup/Interrupt Pull Enable Register (WIPUER)*: updated the note from "This register shall be left at '0' default value" to "WIPUER bits related to those bonded LP pads that are used to wake-up the device from STANDBY Mode, should be left at 0 default value". *Chapter 81: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Figure 1634: RTC/API block diagram*: Added "32 kHz SXOSC" to the figure.
