Reference manual

SPC58 4B Line - 32 bit Power Architecture automotive MCU z4 core 120 MHz, 2 MBytes Flash, HSM, ASIL-B

Overview

The SPC584Bx is a family of Power Architecture based microcontrollers that targets automotive vehicle body and gateway applications such as:

- Central body controller
- Smart junction box
- Mid and high end gateway

The SPC584Bx belong to a wide family of automotive microcontroller products which offers the scalability needed to implement platform approaches and delivers the performance and features required by increasingly sophisticated body applications.

It is available as single or symmetrical dual core and operates at speeds of up to 120 MHz enabling the customer to adjust the performance and consumption to the application needs. The versatile low power modes available on SPC56 body MCU have been extended with a Smart Standby Wake-up Unit reducing further the average consumption in low power conditions.
A large variety and number of communication interfaces like ISO CAN-FD, Ethernet with AVB are available as well as new features for security (HSM) and safety (ASIL-B) requirements.

It also capitalizes on the nominal available development infrastructure of current Power Architecture devices and is supported with software drivers, operating systems and configuration code to assist with users implementations.

The information in this book is subject to change without notice, as described in the disclaimer. As with any technical documentation, it is the readers' responsibility to ensure they have the most current version of this document.

To locate any published errata or updates for this document, visit the ST Web site at http://www.st.com.

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC584Bx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

Contents

1 Preface

1.1 Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or provide device-specific information.
- Part II includes chapters that describe the functionality of the individual modules on the device.

1.2 Register conventions

Figure 1 and *Table 1* provide the register conventions used throughout this manual.

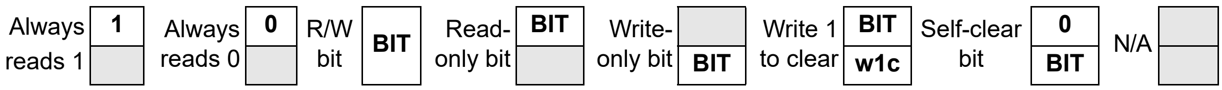

Figure 1. Key to register fields

Table 1. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset values	
0	Resets to zero
1	Resets to one
—	Undefined at reset

1.3 Acronyms and abbreviations

Appendix A: Acronyms and abbreviations lists acronyms and abbreviations used in this document.

1.4 Reference documents

In addition to this reference manual, the following documents provide additional information on the operation of the SPC584Bx:

- IEEE-ISTO 5001™-2012 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture

Information about Power ISA™ Book is available at Power Architecture web site.

2 Introduction

2.1 SPC584Bx microcontroller

The SPC584Bx microcontroller is a new device in the SPC58 family superseding the SPC564Cx and SPC56ECx family. SPC584Bx is built on the legacy of the SPC564Cx and SPC56ECx family, while introducing new features coupled with higher throughput to provide substantial reduction of cost per feature and significant power and performance improvement (MIPS per mW). On the SPC584Bx device, there is one processor core e200z420 and one e200z0 core embedded in the Hardware Security Module.

2.1.1 Core features

The platform consists in one e200z420 CPU operating at up to 120 MHz. It includes enhancements to implement safety (e2e ECC, Core MPU) and increased performance (Local D-RAM as well as Instruction and Data Cache).

The Hardware Security Module (HSM) includes one CPU running at 60 MHz.

All CPUs are compatible with the Power Architecture VLE instruction set, that supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.1.2 Memory hierarchy

The SPC584Bx has three levels of memory hierarchy. At the top level there is a combination of Instruction Cache, Data Cache, and Local Data RAM. The local RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time. The second level of memory is system RAM and flash. These are connected via a 120 MHz, 64-bit wide crossbar. The third level of memory system is the I/O subsystem. All the I/O peripherals are connected together via a 120 MHz 64-bit wide crossbar switch, while peripherals are connected at different frequencies (see the clocking chapter for further details). The reduced speed for the peripherals helps to reduce power.

2.2 Features

On-chip modules within SPC584Bx include the following features:

- One main CPU, dual issue, 32-bit CPU core complexes (e200z4).
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - 64 KB local data RAM for Core_2
  - 8 KB I-Cache and 4 KB D-Cache for Core_2
- 2112 KB (2048 KB code flash + 64 KB data flash) on-chip flash memory
  - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
- 176 KB HSM dedicated flash memory (144 KB code + 32 KB data)
- 128 KB on-chip general-purpose SRAM (+ 64 KB local data RAM: 64 KB included in the CPU)
- Multi channel direct memory access controllers
  - 32 eDMA channels
- One interrupt controller (INTC)
- Dual phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Crossbar switch architecture for concurrent access to peripherals, Flash, or RAM from multiple bus masters with end-to-end ECC
- Hardware security module (HSM) with HW cryptographic co-processor
- System integration unit lite (SIUL)
- Boot assist Flash (BAF) supports factory programming using a serial bootload through the asynchronous CAN or LIN/UART.
- Hardware support for safety ASIL-B level related applications
- Enhanced modular IO subsystem (eMIOS): up to 64 (2 x 32) timed I/O channels with 16-bit counter resolution
  - Buffered updates
  - Support for shifted PWM outputs to minimize occurrence of concurrent edges
  - Supports configurable trigger outputs for ADC conversion for synchronization to channel output waveforms
  - Shared or independent time bases
  - DMA transfer support available
- Body cross triggering unit (BCTU)
  - Triggers ADC conversions from any eMIOS channel
  - Triggers ADC conversions from up to 2 dedicated PIT_RTIs
  - One event configuration register dedicated to each timer event allows to define the corresponding ADC channel
  - Synchronization with ADC to avoid collision
- Enhanced analog-to-digital converter system with:
  - Two independent fast 12-bit SAR analog converters

- One supervisor 12-bit SAR analog converter
- One 10-bit SAR analog converter with STDBY mode support
- Seven deserial serial peripheral interface (DSPI) modules
- Fourteen LIN and UART communication interface (LINFlexD) modules
  - LINFlexD_0 is a Master/Slave
  - All others are Masters
- Eight modular controller area network (MCAN) modules, all supporting flexible data rate (ISO CAN-FD compliant)
- One ethernet controller 10/100 Mbps, compliant to IEEE 802.3-2008
  - IEEE 1588-2008 Time stamping (internal 64-bit time stamp)
  - IEEE 802.1AS and IEEE 802.1Qav (AVB-Feature)
  - IEEE 802.1Q VLAN tag detection
  - IPv4 and IPv6 checksum modules
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard.
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1 and IEEE 1149.7), 2-pin JTAG interface.
- Standby power domain with smart wake-up sequence

2.3 Feature list

Table 2 lists a summary of major features for the SPC584Bx device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on-chip module is given later in this document.

Table 2. Features List

Feature	Description
SPC58 family	40 nm
Number of Cores	1
Local RAM	64 KB Data
Single Precision Floating Point	Yes
SIMD	No
VLE	Yes
Cache	8 KB Instruction
	4 KB Data
MPU	Core MPU: 24 per CPU
	System MPU: 24 per XBAR
Semaphores	No
CRC Channels	2 x 4
Software Watchdog Timer (SWT)	2

Table 2. Features List (continued)

Feature	Description
Core Nexus Class	3+
Event Processor	4 x SCU
	4 x PMC
Run control Module	Yes
System SRAM	128 KB (full standby RAM)
Flash	2048 KB code / 64 KB data
Flash fetch accelerator	2 x 4 x 256-bit
DMA channels	32
DMA Nexus Class	3
LINFlexD	14
MCAN (ISO CAN-FD compliant)	8
DSPI	7
I2C	1
Ethernet	1 MAC with Time Stamping, AVB and VLAN support
SIPI / LFAST Debugger	High Speed
System Timers	8 PIT channels
	1 AUTOSAR® (STM)
	RTC/API
eMIOS	2 x 32 channels
BCTU	64 channels
ADC (SAR)	4
Temp. sensor	Yes
Self Test Controller	Yes
PLL	Dual PLL with FM
Integrated linear voltage regulator	Yes
External Power Supplies	5 V, 3.3 V
Low Power Modes	HALT Mode
	STOP Mode
	Smart Standby with output controller, analog and digital inputs
	Standby Mode

2.4 Packages

The SPC584Bx is available in these production packages: eTQFP64, eTQFP100, eTQFP144, eLQFP176.

2.5 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development. These features include:

- Nexus code execution trace on all CPUs
- Nexus data trace on all bus masters (DMA, Interprocessor bus, CPUs, etc.)
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering

2.6 Block diagram

The figures below show the top-level block diagrams.

Figure 2. Block diagram

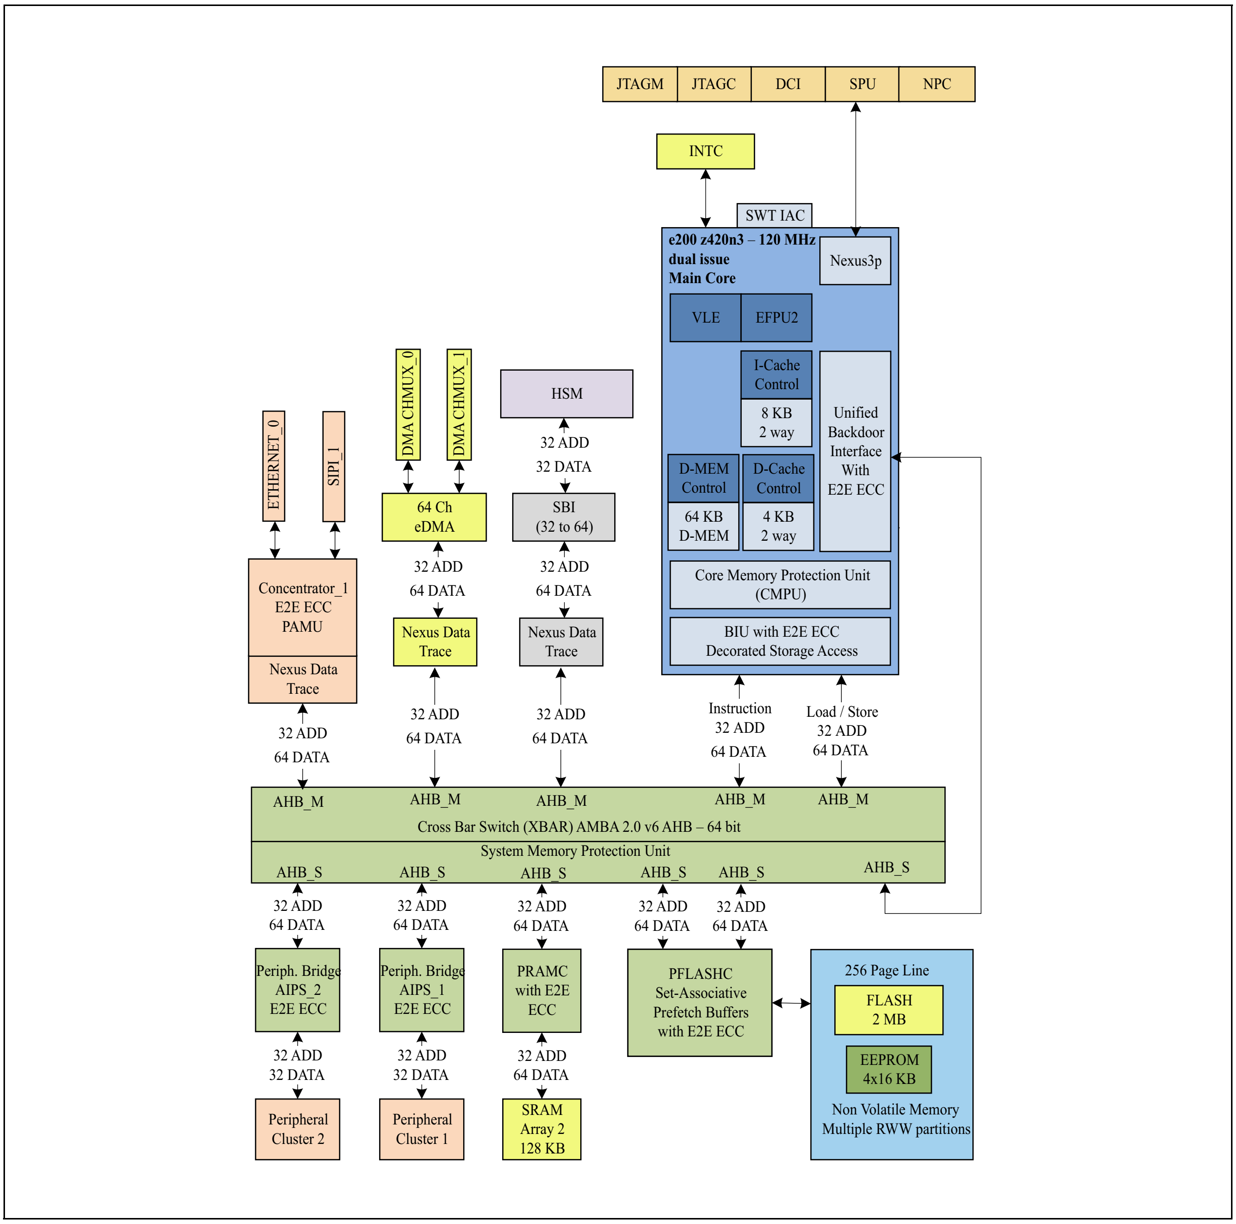

Figure 3. Periphery allocation

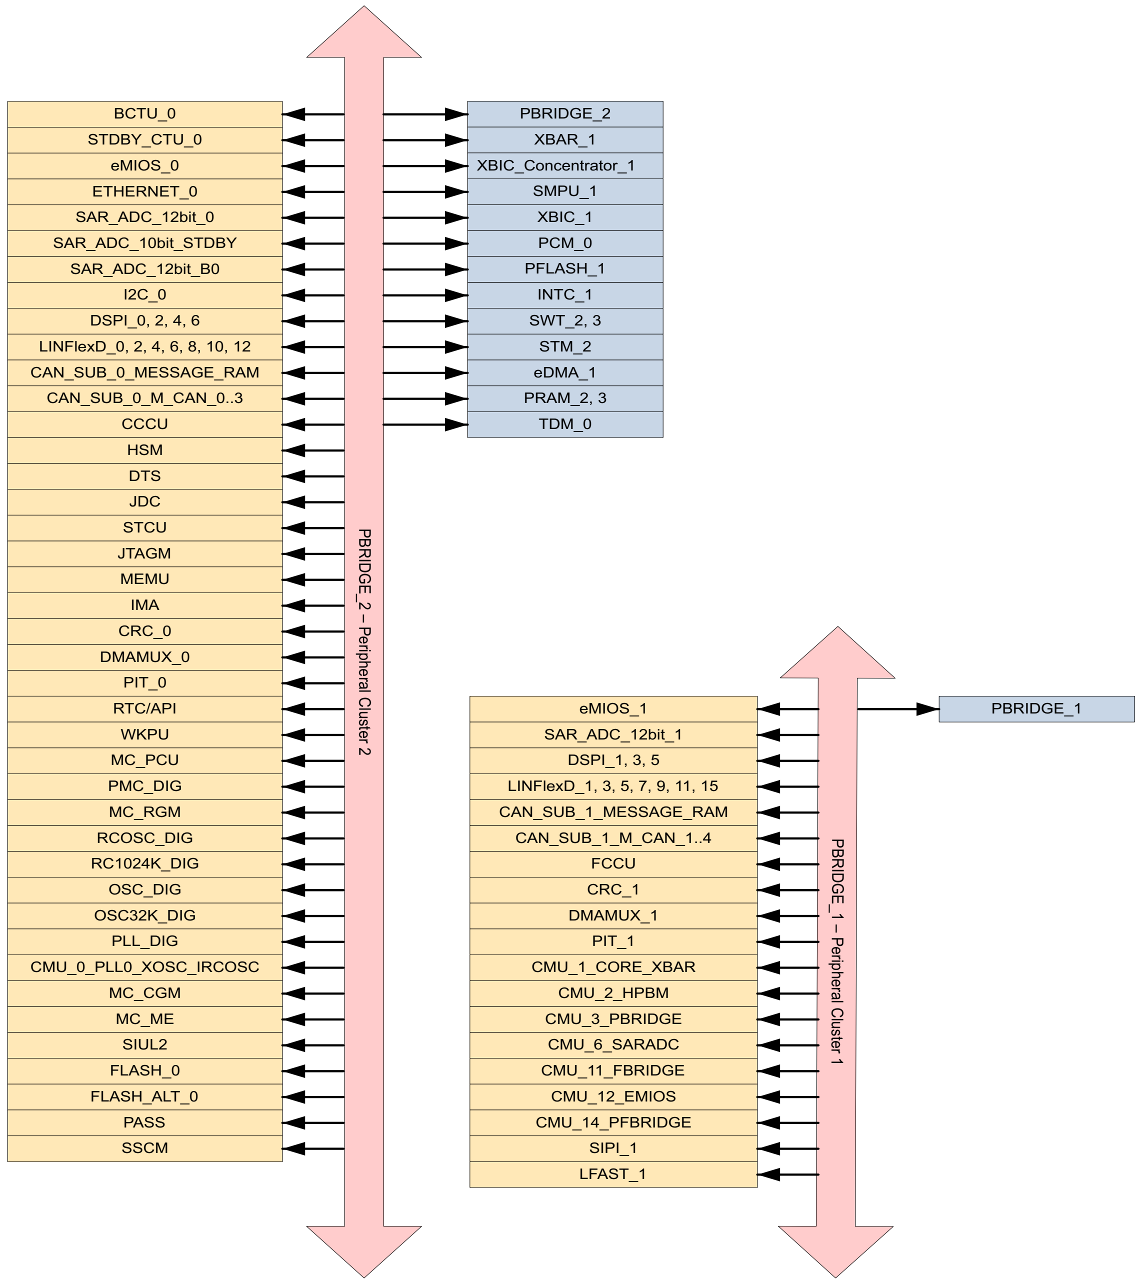


Note: In this diagram, ON-platform modules are shown in orange color and OFF-platform modules are shown in blue color.

3 Embedded memories

3.1 Overview

Features include:

- Onboard SRAM, including system SRAM, and data memory for the processor core
- Onboard system error correction code (ECC) Flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Built-in Flash memory security features including censorship and a programmable Hardware Security Module (HSM)
- Embedded memories in the peripherals[a]:
  - CAN
  - eDMA
  - Ethernet MAC

3.2 SRAM

3.2.1 System SRAM

SPC584Bx device includes 128 KB of general-purpose on-chip ECC SRAM, including 128 KB standby RAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PRCR1 register in the SRAM controller.

- Refer to *Chapter 33: Platform RAM controller AHB (PRAMC_AHB)* for details on configuring the SRAM controller.
- Refer to the Memory Map chapter for the SPC584Bx SRAM map.

3.2.2 Processor core local RAM

SPC584Bx devices include local data RAM (D-MEM) for the processor core to provide enhanced performance.

Refer to the Introduction chapter for processor core local RAM size.

The core RAM supports zero wait-state, single-cycle latency on processor local accesses.

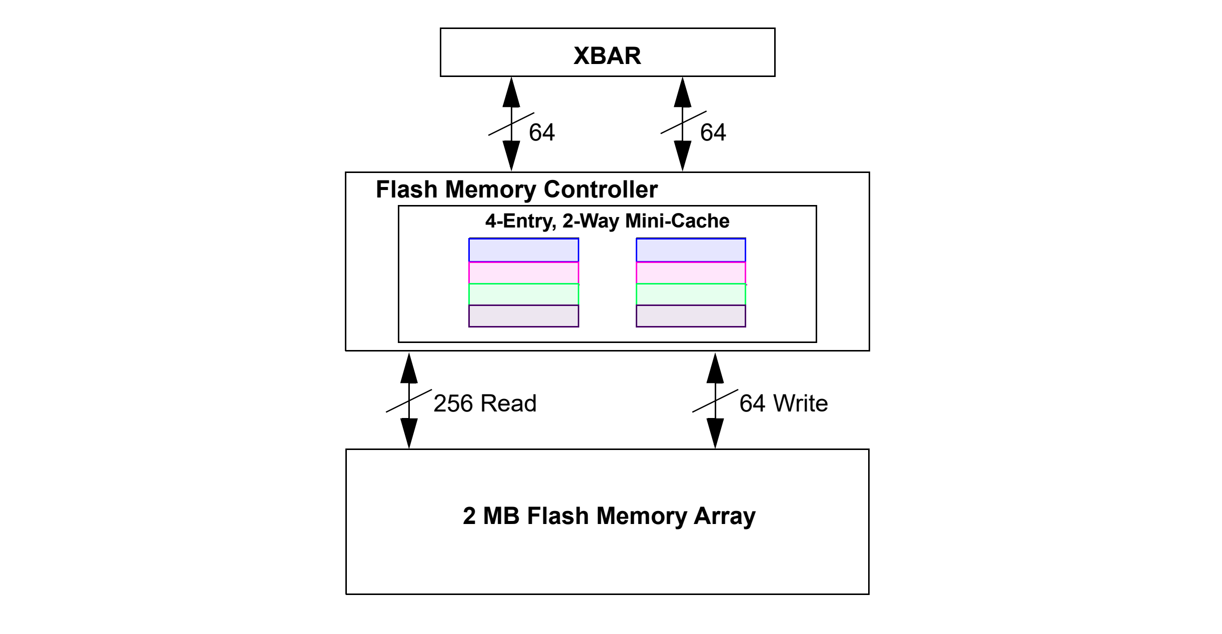
Each area of core RAM is accessible by bus mastering peripheral devices. Refer to the Memory Map chapter for the SPC584Bx SRAM map.

3.3 Embedded Flash memory

Flash memory on SPC584Bx device consists of one Flash memory controller and a Flash memory array module. The Flash controller provides Flash configuration and control functions and manages the interface between the Flash memory array and the device crossbar switch. *Figure 4* shows the memory architecture.

a. Refer to the respective module chapter for details.

Figure 4. SPC584Bx Flash memory block diagram



The remaining sections give the functional details of the Flash controller and Flash array, followed by the memory maps.

3.3.1 Flash memory controller

The SPC584Bx Flash memory controller acts as an interface between the system bus and the Flash memory array.

The Flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers Flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one Flash read page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed Flash memory array access.

The Flash memory controller contains configuration registers that manage Flash functionality such as read buffering in the mini-cache, access control, and read wait state management of the Flash memory.

Refer to the Flash memory controller chapter for details.

3.3.2 Flash memory array

SPC584Bx device includes one single 2 MB Flash memory array, referred to as “main space,” plus an independent 16 KB block of one-time-programmable (OTP) Flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as “UTEST space.”

For code Flash sectors, reads of the embedded Flash memory return a 256-bit page of data that may be buffered in the mini-cache in the Flash memory controller. Programming of the Flash may be done by quad word (128-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

3.3.2.1 Features

- Flash segmentation
  - 16 KB, 32 KB, 128 KB, and 256 KB blocks provided for code or data
  - Four 16 KB blocks provided for EEPROM emulation
  - One 16 KB block and one 128 KB blocks provided for secure code
  - Two 16 KB blocks provided for secure data
  - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with triple bit detection, double and single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.3.2.2 Flash organization

The embedded Flash memory consists of six address spaces in four groupings:

- 16 KB, 32 KB and 128 KB low address spaces
- 16 KB mid address space
- 16 KB high address space
- 256 KB address space

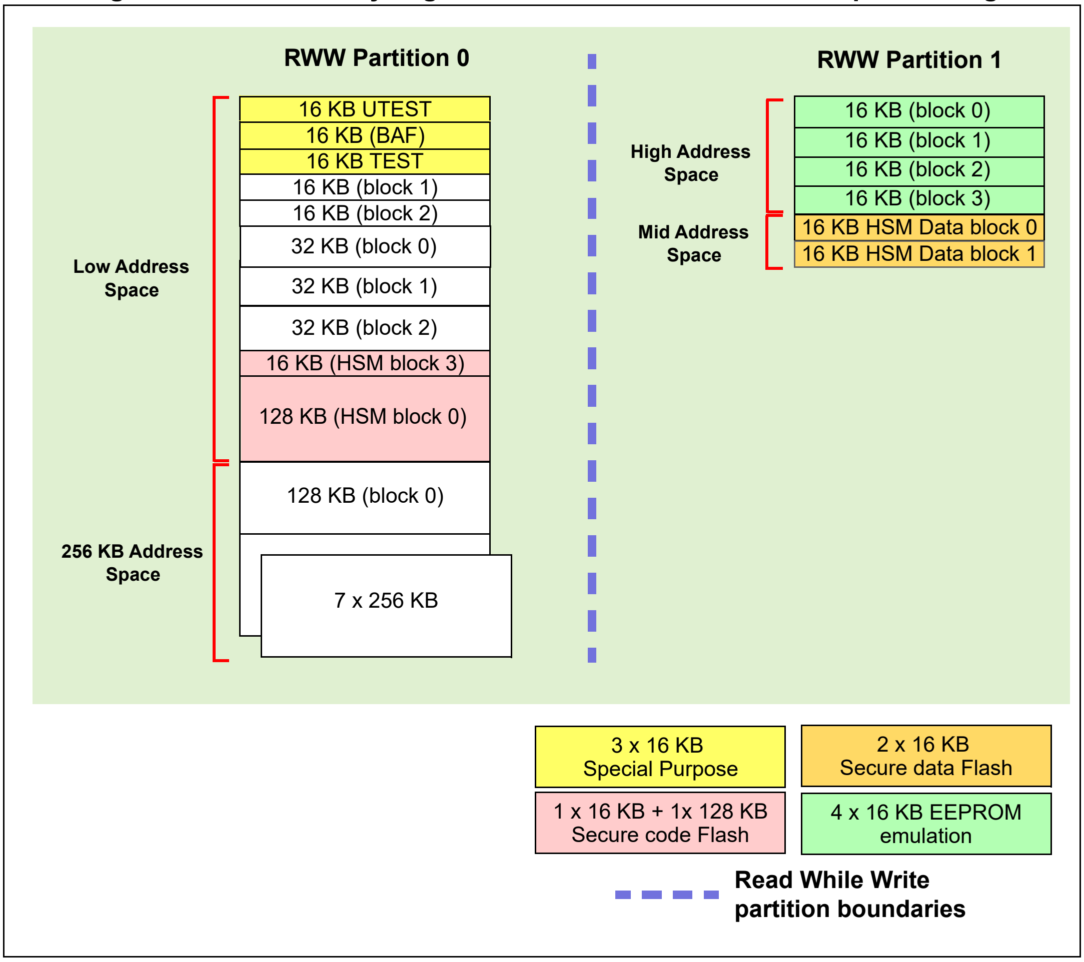
Address space group (low-, mid- or high-address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The Flash module is further divided into two partitions that determine locations for valid Read While Write (RWW) operations. While the embedded Flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously read from the other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

Figure 5 shows the Flash block segmentation and Read While Write partitioning for SPC584Bx devices.

Figure 5. Flash memory segmentation and Read While Write partitioning



Note: Refer to the Memory Map chapter for the SPC584Bx Flash memory map.

3.3.2.3 UTEST memory space

Devices in the SPC584Bx family contain a 16 KB area of one-time-programmable (OTP) Flash memory for storing test information and device configuration data. *Refer to the Memory Map chapter* for the SPC584Bx UTEST memory map.

3.3.2.4 Chip-specific C40FMC Flash register information

Refer to *Chapter 35: Embedded Flash Memory* for chip-specific layouts of the on-chip Flash memory control registers that contain bits used to lock individual Flash blocks from accidental erase or select individual Flash blocks for operations.

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC*)* support. This e2eECC is structurally different from traditional “ECC at memory” functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect or correct errors that have occurred on data stored in the memory, or both. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in *Table 3*.

Table 3. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location

Table 3. ECC comparison of data write-then-read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single or double bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.5 Security features

The SPC584Bx architecture implements a security framework that makes it possible to protect the micro-controller resources from potential attacks.

Note: Detailed information on the SPC584Bx security architecture is published in a separate document and is available on a limited basis to customers who have a non-disclosure agreement (NDA) with STMicroelectronics.

4 Signal Description

4.1 Production packages

The SPC584Bx device is available in these production packages:

- eTQFP64
- eTQFP100
- eTQFP144
- eLQFP176

Case numbers and outline drawings for each package are provided in the *SPC584Bx Microcontroller Data Sheet*.

4.2 Package pinouts/ballouts and pin/ball descriptions

Refer to the *SPC584Bx Microcontroller Data Sheet* and the *SPC584Bx pinout Microsoft Excel® workbook file attached to IO_Definition document*.

The *SPC584Bx pinout* provides signal descriptions and related information for the SPC584Bx device:

- the *I/O Signal Table sheet* contains information on generic pins, including the port pin, SIUL MSCR number, MSCR SSS, function, module, signal description, direction, pad type, and package pin numbers for each I/O pin
- the *Input Muxing sheet* contains the signal multiplexing options
- the *Supply Pins sheet* provides information on power supply and reference voltage pins
- the *Miscellaneous sheet* provides information on system pins (analog, reset, test, debug and trace pins)

The SIUL module is used to multiplex the device input/output pins and the internal input/output ports.

Note: Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination.

5 Memory Map

Table 4 details the device memory map for the SPC584Bx.

All addresses on the SPC584Bx, including those that are reserved, are identified. The addresses represent the physical addresses assigned to each region or module name. A memory access, either read or write, to any region marked as “Reserved” will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Table 4. Overview Memory Map

Start Address	End Address	Description
0x00000000	0x003FFFFF	Reserved
0x00400000	0x0FFFFFFF	Flash memory controller (refer to Table 5)
0x10000000	0x3FFFFFFF	Reserved
0x40000000	0x407FFFFF	System RAM (refer to Table 6)
0x40800000	0x4FFFFFFF	Reserved
0x50000000	0x5FFFFFFF	Processor local RAM (refer to Table 7)
0x60000000	0x9FFFFFFF	Reserved
0xA0000000	0xAFFFFFFF	Security module (refer to Table 8)
0xB0000000	0xF3FFFFFF	Reserved
0xF4000000	0xF7FFFFFF	Peripheral bridge 2 (refer to Table 9)
0xF8000000	0xFBFFFFFF	Peripheral bridge 1 (refer to Table 10)

5.1 Flash memory

Table 5 details the flash memory map for the SPC584Bx.

Table 5. Flash memory map

Start address	End address	Description	1 RWR partition RWW Partition ID
0x00000000	0x003FFFFF	Reserved	
Test & BAF Flash Blocks			
0x00400000	0x00403FFF	16 KB UTEST NVM Block Space(1)	0(2)
0x00404000	0x00407FFF	16 KB BAF block0	0(2)

0x01140000	0x0117FFFF	256 KB Code Flash block5	0
0x01180000	0x011BFFFF	256 KB Code Flash block6	0
0x011C0000	0x0FFFFFFF	Reserved	

1. Refer to for additional details about how the UTest Flash Block is organized
2. Same Flash physical block

5.2 System memory

The following table details the system and stand-by RAM memory map.

Table 6. System and stand-by RAM memory map

Start offset	End offset	Assigned XBAR slave port	Description	Size
0x40000000	0x400A7FFF	Reserved		
0x400A8000	0x400A9FFF	PRAMC_2	System RAM 2 (Standby RAM)	8 KB
0x400AA000	0x400AFFFF		System RAM 2 (Standby RAM)	24 KB
0x400B0000	0x400C7FFF		System RAM 2 (Standby RAM)	96 KB
0x400C8000	0x407FFFFF	Reserved		
0xA0000000	0xAFFFFFFF	—	HSM (refer to *Table 8*)	

5.3 Local memory

Table 7 details the memory map for local RAM processor.

Table 7. Processor local RAM memory map

Start offset	End offset	Description	Used size
0x50000000	0x507FFFFF	Reserved	
0x50800000	0x5080FFFF	Reserved	
0x50810000	0x527FFFFF	Reserved	
0x52800000	0x5280FFFF	D-MEM CPU_2 (1)	64 KB
0x52810000	0x5FFFFFFF	Reserved	

1. Refer to *Table 1082: BAF memory organization* for the “BAF data area and stack” which uses a range of D-MEM CPU_2.

5.4 Security module memory

Table 8 details the memory map for the Hardware Security Module (HSM).

Table 8. HSM memory map

Start offset	End offset	Allocated size	Used size
0xA0000000	0xA0007FFF	32 KB	32 KB
0xA0008000	0xA0009FFF	8 KB(1)	8 KB (Stand-by domain)
0xA000A000	0xAFFFFFFF	Reserved	

1. Enabled during stand-by depending on a DCF bit.

5.5 Peripheral memory

Table 9 and *Table 10* list the memory map of the peripheral region. This region is sub-divided into 16 KB byte regions or 'slots'. A peripheral occupies 1 or more slots.

Within a 16 KB byte peripheral slot, it is normal for the peripheral registers to only occupy part of that 16 KB byte slot - normally from the lowest address upwards. The individual chapters for each block, define all the registers within that contiguous group of registers.

Table 9. Peripheral memory map (PBRIDGE 2)

Start Address	End Address	Peripheral	ON Platform Peripheral Slot[1]	OFF Platform Peripheral Slot[2]	Size[3] [Byte]
0xF4000000	0xF4003FFF	PBRIDGE_2	0		16384

0x01C0	0x01DF	Reserved
0x01E0	0x01FF	Life Cycle slot 0 - ST Production
0x0200	0x021F	Life Cycle slot 1 - Customer Delivery
0x0220	0x023F	Life Cycle slot 2 - OEM Production
0x0240	0x025F	Life Cycle slot 3 - In Field
0x0260	0x027F	Life Cycle slot 4 - Failure Analysis
0x0280	0x029F	Customer Single Bit Correction area (4)
0x02A0	0x02BF	Customer Double Bit Correction area (5)
0x02C0	0x02DF	Customer Triple Bit Detection area (6)
0x02E0	0x02FF	Customer Programmable Detection Area
0x0300	0x0307	DCF Start Record(7)
0x0308	0x036F	Reserved
0x0370	0x0FFF	UTEST DCF Records(8)
0x1000	0x1FFF	Customer OTP data

1. The effective data is 4 bytes, but because of the new DEC ECC scheme, 16 bytes are still reserved.
2. Used to enable the Flash Test Mode when the eFuse protection is not active.
3. Access to this location is conditioned by the Life Cycle.
4. This area is written by ST during production phase with a specific content aimed to generate single bit errors, on behalf of diagnostic at application level of the ECC error correction path.
5. This area is written by ST during production phase with a specific content aimed to generate double bit errors, on behalf of diagnostic at application level of the ECC error detection path.
6. This area is written by ST during production phase with a specific content aimed to generate triple bit errors, on behalf of diagnostic at application level of the ECC error correction path.
7. The SSCM “SHD_DCF_OFFSET” parameter shall be aligned to the start of this area. Note that the UTest Flash block is seen by the SSCM at the following address: 0x0080_0000. The SSCM START RECORD DCF (refer to DCF start record in *Chapter 9: Device Configuration Format (DCF) Records*) must always be programmed at the beginning of this area. Because of the new DEC ECC scheme, the 64b following the START DCF record shall still be programmed in order to let the SSCM complete the DCF parsing (otherwise it would stop when a virgin record is found).

8. Factory can program some UTest DCF records during production test. Consider that the first free location may change. Refer to Sales to retrieve the information for the first free location or directly read the UTest to find it.

6 Functional safety

6.1 Introduction

The SPC584Bx offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL B of ISO 26262. This chapter gives an overview of the safety implementation for the SPC584Bx, and discusses the operation of the safety mechanisms.

6.2 Safety overview

The SPC584Bx has been designed for automotive applications executing safety-relevant tasks that require a fail-silent or fail-indicate MCU. The SPC584Bx supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms but the SPC584Bx generally supports an FTTI of 10 ms.

6.3 Module categorization

The definition of the SPC584Bx safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in *Table 12*.

Table 12. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, Flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules not used to implement any safety related functionality (for example, debug modules), modules which are functionally similar to modules in the categories above but do not provide any embedded safety provisions by default or are not used for safety in a use case scenario. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation. Notice that interference-freedom is guaranteed in both cases.
Other support modules	SuMo	These are modules that, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo’s are the RCCU and Clock Monitoring Unit (CMU).

Table 13 shows module classifications for the SPC584Bx.

Table 13. Module classification

Classification	Modules
ViMos	Core_2 with controllers for I-Cache, D-Cache and local memories, I-Cache, D-Cache and D-Mem arrays, eDMA, DMACHMUX, Concentrator DMA, INTC, XBAR, SRAM controller, System RAM array, Flash memory controller, Flash memory array,System timer, MC_RGM, Dual PLL Digital, XOSC, MC_CGM, MC_ME, Voltage regulator, MC_PMC, STCU2, SSCM, PIT
PeMos	SAR ADC, LINFlexD, DSPI, M_CAN, Ethernet, SIUL2, XBAR_1 (Peripheral), Concentrator Ethernet, LFAST, PBRIDGE*n*
NoSaMos	External memory interface (LFAST, SIPI), HSM, Nexus, JTAG, Concentrator HSM, I2C, WKPU, SPU, STANDBY SAR ADC

Table 13. Module classification (continued)

Classification	Modules
SuMos	CRC units, Temperature Sensors, IRCOSC, CMUs, HVDs, Bandgap reference, IMA, REG_PROT, SWT, FCCU, MEMU

The SPC584Bx implements no specific protection of NoSaMos against Common Cause Failures between them.

6.4 System implementation

6.4.1 General concept

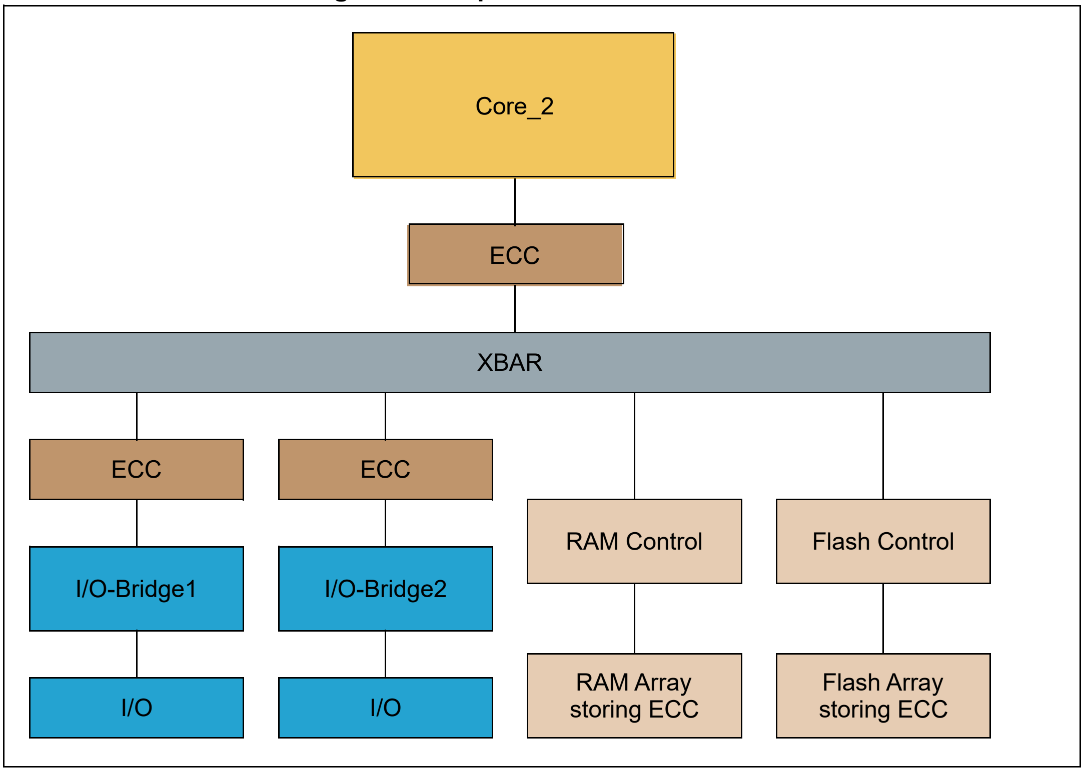
In general, safety integrity is achieved in the following ways:

- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for individual modules. For the periphery, end-to-end ends at the I/O bridges (refer to *Section 6.4.1.1: End-to-End protection on data path*).
- Clock and power, generation and distribution, are supervised by dedicated monitors (refer to *Section 6.4.1.2: Clock and power monitoring*).
- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (refer to *Section 6.4.1.3: I/O peripherals*, and *Section 6.4.1.4: Communication controllers*).
- The Fault Collection and Control Unit (refer to “Fault Collection and Control Unit (FCCU)” chapter for FCCU details) is responsible for collecting and reacting to failure notifications (refer to *Section 6.4.1.5: FCCU and failure monitoring*). MEMU (refer to *Section 6.4.3.4: Memory Error Management Unit (MEMU)*) is responsible for the collection and reporting (to the FCCU) of error events in system memories, and Flash memory, as well as E2E ECC errors caused by the XBAR, or RAM or Flash memory controllers. Error events include ECC corrections and detections as well as faults detected by other embedded monitors.
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (refer to *Section 6.4.2: Common Cause Failure measures*).

6.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected with at least 99% coverage via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a single-error correction, double-error detection (SECDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. *Figure 6* shows a general view of ECC schema.

Figure 6. Simplified view of E2E ECC



Note: Specific implementation for the SPC584Bx varies depending on the special requirements of RAM and Flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters and checked on reads. The ECC correction bits are stored alongside the data in Flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, apart from memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGEs and peripherals can be used redundantly (refer to *Section 6.4.1.3: I/O peripherals*), or other mechanisms may be used to validate peripheral operation.

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) does allow the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address.
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the Flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash controllers; the target is respectively an XBAR slave port, the RAM array, or the Flash module (refer to “Crossbar Switch (XBAR)”, “Flash memory controller”, and “RAM controller (PRAM)” chapters).

6.4.1.2 Clock and power monitoring

6.4.1.2.1 Clock

Clocks in the SPC584Bx are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of lock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

6.4.1.2.2 Power

There are four types of voltage supervisors on the SPC584Bx, Low Voltage Detect (LVD), High Voltage Detect (HVD), Upper Voltage Detector (UVD) and Minimum Voltage Detector (MVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads, and so on) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion) (refer to “Power management” and “Power Control Unit (MC_PCU)” chapters for details on power monitoring).

6.4.1.3 I/O peripherals

To allow a safety application to make redundant use of all I/O peripherals, each peripheral has at least two instances, and each instance is connected to a different PBRIDGE. This means, for example, that if DSPI is provided by the MCU, two DSPI modules (DSPI*n*, DSPI*m*) are included and connected externally through different pins. Internally, DSPI*n* would then be connected to PBRIDGE_0 and DSPI*m* to PBRIDGE_1 and be accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGEs, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops.

Comparison of redundant operation is under the responsibility of the application software, and not the safety hardware mechanism.

6.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and therefore fall under the same safety reasoning as I/O peripherals. Yet we assume that for high bandwidth communication controllers additional software measures are employed that do not require redundant communication peripherals.

The following communication controllers do not contain special safety mechanisms (above what is included in them by their protocol specifications) nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, refer to *Section 6.4.1.3: I/O peripherals*):

- Ethernet
- M_CAN

Typically, software measures for the communication controllers (also called fault-tolerant communication layer) could contain E2E CRC data protection, sender identification, sequence numbering, and an acknowledgement mechanism.

6.4.1.4.1 Disabling of communication controllers

In the event of a dangerous failure, the MCU offers the capability of disabling transmission of individual channels of communication controllers (such as CAN modules). This prevents the transmission of erroneous messages while preserving the capability of communicating over the diagnostic bus. Disabling outputs is controlled by resetting the SIUL2_MSCR*n*[SMC] for the pins that are associated with communication controllers where this feature is needed (refer to the “System Integration Unit Lite2 (SIUL2)” chapter for details on disabling communication signals).

FCCU can drive a fault state on FI[0] with either one of the following two mechanisms:

- Error pin reaction due to a fault
- Software writing FCCU_CFG[FCCU_SET_CLEAR] = 01b

When the FCCU drives FI[0] to a fault state, the SIUL2 disables the output drivers of all pins whose SIUL2_MSCR*n*[SMC] = 0. This disables the possible transmission of erroneous messages. As long as the FCCU drives FI[0] to faulty state, the communication controllers’ Tx pins are disabled and internal pull-up are enabled. As soon as FI[0] is driven to non-faulty state, the communication controllers’ Tx pins are automatically enabled and state of internal pull-up/down restored.

The application should configure SIUL2_MSCR*n*[SMC] for pins that have active mapping of CAN modules (M_CAN) functionality and ensure that pin does not stay in undriven state.

Note: The FCCU uses an internal signal to disable the communication controller transmission, so transmission is disabled even when the FCCU cannot drive the FI[0] pin because the pin is configured as GPIO. Also, if FI[0] is used as error input, externally pulling it down will disable the communication controller transmission if this event drives FCCU to a fault state.

Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, M_CAN) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events.

6.4.1.5 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

6.4.1.5.1 External error indication

Failure of the MCU is signaled to one or two pins, FI[0] (ERROR0) and FI[1] (ERROR1). FI[0] can also serve as an error input mechanism (refer to “Fault Collection and Control Unit (FCCU)” chapter, and “FCCU configuration” section of the “Device configuration” chapter, for details on the fault output signals). Both pins can be multiplexed with other functions with different defaults.

The error indication on pins FI[0] and FI[1] is controlled by SIUL2 and FCCU. The mapping of the FCCU output signals on the relevant pins and the associated electrical characteristics are enabled by the SIUL2_MSCR[*n*] register (refer to table “SIUL2_MSCR0 - SIUL2_MSCR511 field description” in the “System Integration Unit Lite2 (SIUL2)” chapter for signal mapping details). Once the FCCU is mapped onto the pin, the logic level is driven by the FCCU.

FI[0] is controlled by the FCCU at startup by default, but the state of FI[1] is like other I/O signals (refer to table “Pin startup and reset states” in chapter “Signal Description” for default states of FI[0] and FI[1]).

Since it is possible to reset FCCU and SIUL2 independently, the behavior of FI[0] and FI[1] is the result of the combined state of SIUL2_MSCR[*n*] and the FCCU. (refer to section “Reset interface” in chapter “Fault Collection and Control Unit (FCCU)” for FCCU reset details, and chapter “Reset and Boot” for the state of the FCCU relative to the system during different reset phases).

During functional reset, the application shall consider only the PAD PB[11] as FCCU error out. The FCCU EOUT1, that is PC[2], is not enabled during functional reset.

The FCCU_STAT[ESTAT] error status flag can be read to show whether the FCCU is in an error state. This flag can be written by software to either a 1 (fault) or 0 (operational) when the FCCU is in operational state.

FCCU_EINOUT(EINO): The value of this register depends on the state of the pad. If the IBE functionality of the SIUL is enabled, the register bit reflects the physical status of the pin as seen by the input buffer. In case the protocol selected for EOUT interface is a toggling one (Dual rail or Time switching), this may not be true due to synchronization in the safety clock domain.

The register reflects the physical status of the pin from application point of view (external status).

FCCU_STAT(PhysicalErrorPin): This register field indicates the actual status of the Error pin as driven by FCCU to the pad based on different FCCU configurations and state of the failure input channels. The value reported in the FCCU_STAT (PhysicalErrorPin) could be different from what is seen at the pad.

6.4.1.5.2 Failure handling

The FCCU is an autonomous module that is responsible for reacting to failure indicators. A different reaction can be configured for each failure source. Overall failure reaction time requires time for detecting, processing, and indicating the error. During this time, the SPC584Bx could provide wrong results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU.
- Control logic and signals monitored by the FCCU itself (refer to chapter “Fault Collection and Control Unit (FCCU)”).
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Keep in mind that software can also directly influence the state of the F*n* pins.
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERROR*n*
- Disabling the transmission capabilities of communication controllers (CAN, Ethernet. Note that, it is only possible in conjunction with changing the state of the failure indication pins
- No reaction

Software can read the failure source that caused a fault, either before or after a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication will stay in failure mode for a configurable minimum time. If necessary, software can also reset the MCU.

6.4.1.5.3 FCCU failure inputs from other modules

Table 14 shows the different failure input signals of the FCCU.

Table 14. FCCU failure inputs

FCCU channel	Source	Failure	Failure description	HW failure behaviour
0	PMC DIG	TEMP_ERROR	Temperature detector	Pulse signal. No SW intervention needed to clear it.
1	PMC DIG	LVD_ERROR	Voltage out of range from LVDs (non-destructive reset)	Pulse signal. No SW intervention needed to clear it.
2	PMC DIG	HVD_ERROR	Voltage out of range from HVDs (non-destructive reset)	Pulse signal. No SW intervention needed to clear it.
3	PMC DIG	DPMC_DCF_SAFETY_ERR	Digital PMC DCF Safety Error	Persistent till error negation

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
4	PMC DIG	DPMC_VD_BIST	Digital PMC voltage detector BIST	Clear status through FCCU
5	SSCM/ FLASH 0	SSCM_XFER_FLASH_ERR	SSCM transfer error (during the SSCM and STCU DCF loading) + Flash memory initialization error	SSCM gets cleared by SW. fatal error pulse no SW needed. Memory DCF part is persistent till error negation.
6	STCU	STCU_UF	BIST result - wrong signature (STCU Unrecoverable Fault)	Clear status through FCCU
7	STCU	STCU_RF	BIST result - wrong signature (STCU Recoverable Fault)	Clear status through FCCU
8	STCU	STCU_LMBIST_USR_ERR	STCU fault in case MBIST control signals go to wrong condition during user application.	Clear status through FCCU
9	GLUE LOGIC	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG or NPC not in reset or activation of dangerous debug functionality Spurious activation of SSCM	Clear status through FCCU
15	PLATFORM	DMA1 TCD EDC after ECC	DMA1 TCD EDC after ECC	Clear status through FCCU
16	Flash	Flash Reset Error	The pin/flag signals the following unrecoverable errors: – ECC errors on Flash internal reads during configuration loading (startup) – ECC errors on Flash internal reads during fw copy (startup) – Double ECC errors on KRAM during internal self-check routine (always running)	Cleared by reset only

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
17	PLATFORM	SWT3_ResetReq	Reset request from SWT_3. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT3 (after a functional reset)	Cleared by reset only
18	PLATFORM	SWT2_ResetReq	Reset request from SWT_2. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT2 (after a functional reset)	Cleared by reset only
21	MEMU	MEMU_RAM_CE	MEMU RAM correctable error	Clear status in MEMU
22	MEMU	MEMU_RAM_UCE	MEMU RAM uncorrectable error	Clear status in MEMU
23	MEMU	MEMU_RAM_OV	MEMU RAM overflow(1)	Clear status in MEMU
24	MEMU	MEMU_PER_CE	MEMU Peripheral correctable error	Clear status in MEMU
25	MEMU	MEMU_PER_UCE	MEMU Peripheral uncorrectable error	Clear status in MEMU
26	MEMU	MEMU_PER_OV	MEMU Peripheral overflow(2)	Clear status in MEMU
27	MEMU	MEMU_FLS_CE	MEMU Flash correctable error	Clear status in MEMU
28	MEMU	MEMU_FLS_UCE	MEMU Flash uncorrectable error	Clear status in MEMU
29	MEMU	MEMU_FLS_OV	MEMU Flash overflow	Clear status in MEMU
30	IMA	IMA SoC	IMA SoC Active The fault is cleared by disabling IMA (IMA.SLCT.R = 0x0), followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Persistent till error negation
32	PLATFORM / SMPU	SMPU_MONITOR XBAR 1	SMPU XBAR 1 Monitor incorrectly refuses an access	Pulse signal. No SW intervention needed to clear it.

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
34	PLATFORM / SMPU	SMPU ERROR XBAR 1	SMPU XBAR 1 refuses an access correctly.	Pulse signal. No SW intervention needed to clear it.
48	PLATFORM / CORE	DMA 1 TCD Ram feedback checker	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
49	PLL DIG	FM_PLL_0	PLL0 Loss of Lock (Interrupt event)	SW clear required in PLLDIG
50	PLL DIG	FM_PLL_1	PLL1 Loss of Lock (Interrupt event)	SW clear required in PLLDIG
51	CMU	CMU_0_XOSC	XOSC less than IRC, XTAL Pin Floating, EXTAL Pin Floating(3)	Clear status in CMU
52	CMU	CMU_0_PLL0	Sysclk frequency out of range(4)	Clear status in CMU
53	CMU	CMU_Platform	Monitoring internal clocks of comp_subsys(5)	Clear status in CMU
54	CMU	CMU_other	Monitoring internal clocks of other clocks(6)	Clear status in CMU
56	PLATFORM / XBAR 1	XBAR 1 XBIC + XBAR 1 decoder checker	Indication of a hardware fault resulting in corrupted transaction through the XBAR or gaskets	Clear status through FCCU
57	PLATFORM / CORE	CORE 2 D-MEM address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
58	PLATFORM / CORE	CORE 2 D-MEM address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
59	PLATFORM / CORE	CORE 2 I-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
60	PLATFORM / CORE	CORE 2 I-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
61	PLATFORM / CORE	CORE 2 I-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
62	PLATFORM / CORE	CORE 2 I-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
63	FLASH 0	FLASH_REF_ERR	If the current and voltage Read references are out of range, this bit is set to signify that previous reads requested may have been corrupted.	The recommended clear mechanism is device reset
64	PLATFORM / FLASH 1	EDC_ECC_FLASH 1	EDC after ECC for FLASH array - Indication of a hardware fault in the ECC of the Flash memory resulting in corrupted ECC detection/correction.	Clear status through FCCU
65	PLATFORM / FLASH 1	EDC_ECC_FLASH_C 1	EDC after ECC for FLASH controller – Indication of hardware fault in the Flash memory controller resulting in corrupted ECC detection / correction.	Clear status through FCCU
66	PLATFORM / FLASH 1	ENC_ERR_FLASH 1	Flash encoding error – Indication of hardware fault resulting in corrupted Flash memory access.	Clear status through FCCU

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
67	PLATFORM / FLASH 1	ADDR_FDBK_ERR_FLASH_C 1	PFlashC address feedback error - alarm indicating the Flash controller detected a transaction monitor mismatch when compared to the Flash safety feedback outputs	Clear status through FCCU
69	PLATFORM / CORE	CORE 2 I-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
70	PLATFORM / CORE	CORE 2 D-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
71	PLATFORM / CORE	CORE 2 D-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
72	PLATFORM / CORE	CORE 2 D-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
73	PLATFORM / CORE	CORE 2 D-Cache address ERR	Feedback checkers implemented in the platform covering memory address/CS/WE feedback signals	Clear status through FCCU
74	PLATFORM / PRAM 2	ADDR_FDBK_ERR_PRAM 2 + RAM_LWB_ERR	System RAM address feedback + RAM Late-Write buffer mismatch. Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access	Clear status through FCCU

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
75	PLATFORM / PRAM 2	EDC_ERR_PRAM 2	EDC after ECC for RAM (read-modify-write ECC). Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read.	Clear status through FCCU
78	TCU	DFT1	Test circuitry Group x activation	Persistent till reset
79	TCU(7)	DFT2	Test circuitry Group x activation	Persistent till reset
80	TCU	DFT3	Test circuitry Group x activation	Persistent till reset
81	TCU	DFT4	Test circuitry Group x activation	Persistent till reset
84	PLATFORM / CORE	Core 2 Exception	Core Machine check exception indication	Pulse signal. No SW intervention needed to clear it.
89	PLATFORM / PBRIDGE	PBRIDGE_1_e2eEDC_ERR	ECC bits in the PBRIDGE transaction contain an error	Persistent till error negation
91	PLATFORM / PBRIDGE	PBRIDGE_2_e2eEDC_ERR	ECC bits in the PBRIDGE transaction contain an error	Persistent till error negation
92	PLATFORM	Monitor_Concentrator1_ Alarm	Failure of Concentrator 1 Monitor	Clear status through FCCU
93	PLATFORM	Monitor_Concentrator_DMA	Concentrator DMA gasket monitor failure	Clear status through FCCU
94	MC_RGM	Safe Mode(8)	Safe mode entry request from RGM	Persistent till system remains in Safe mode
95	COMPENSATION CELLS	Compensation Disable	Indication of undesired deactivation of pad compensation. Fault may affect a distorted transmissions on I/Os associated. The indication is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm](9)	Persistent till error negation from HW

Table 14. FCCU failure inputs (continued)

FCCU channel	Source	Failure	Failure description	HW failure behaviour
96	GLUE LOGIC	EIN_ERR	Error input pin (from the external world)	Persistent till error negation from HW
101	PLATFORM	DSMC_2 monitor error	DSMC_2 monitor error	Persistent till error negation from HW
106	PLATFORM / CORE	CORE 2 I-MEM ILLEGAL ACCESS	CORE 2 Attempt to access non-existent I-MEM	Clear status through FCCU
107	PLATFORM	Monitor_Concentrator_HSM	Concentrator HSM gasket monitor failure	Clear status through FCCU
108	PLATFORM	Monitor_Concentrator1_ XBIC	Concentrator 1 XBIC monitor failure	Clear status through FCCU

114	PLATFORM	Monitor_Concentrator_DMA	Concentrator DMA gasket monitor failure	Clear status through FCCU

1. Aggregate of RAM Correctable Error overflow flag, RAM Uncorrectable Error overflow flag, RAM Error buffer Overflow Flag
2. Aggregate of Peripheral RAM Correctable Error overflow flag, Peripheral RAM Uncorrectable Error overflow flag, Peripheral RAM Error Buffer Overflow Flag
3. CMU_0_PLL0_XOSC_IRCOSC OLR event + XTAL pin floating + EXTAL Pin Floating
4. CMU_0_PLL0_XOSC_IRCOSC FLL and FHH events
5. CMU_1_CORE_XBAR, CMU_2_HPBM, CMU_3_PBRIDGE FLL and FHH events, CMU_11_FBRIDGE FLL and FHH events, CMU_14_PFBRIDGE
6. CMU_6_SARADC, CMU_12_EMIOS
7. In the event of activation of RF[94] (that is safe mode request), RF[79] is also activated. If the RGM trigger of safe mode is functionally used, during servicing of the response to activation of the RF[79], software should check that the device is not in safe mode to discriminate between an unwanted activation of test circuitry and a safe mode request.
8. In the event of spurious activation of this fault source, RF[79] is activated together with RF[94]. In scenarios where safe mode trigger from RGM is a valid functional use case, the RF[94] should be disabled.
9. Compensation cell reduces the spread of some circuit parameters (slew rate of the output signal and the output impedance) in the IO buffers over temperature, process and voltage. Compensation cell might remain disabled until supplies have reached LVD290 threshold.

6.4.1.6 Operational interference protection

Being a multi-master system, SPC584Bx provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom is guaranteed via a hierarchical memory protection schema including:

- MPUs
- PBRIDGEs
- Register protection

There are two Memory Protection Unit levels included in the SPC584Bx. The Core Memory Protection Unit (CMPU) is a mechanism included in each core to protect address ranges against access by software developed according to lower ASIL. The CMPU is typically used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. The MPUs prevent access of different bus masters to address ranges and are typically used by the safety application to prevent NoSaMos (such as the Performance Core) to access the application’s safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual register to be locked against any manipulation without unlocking.

These safety mechanisms are further described in the chapters System Memory Protection Unit (SMPU), Peripheral Bridge (PBRIDGE) and Registers Protection (REG_PROT).

6.4.1.7 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, F*n*). If the FCCU does not react within a predefined interval as specified in the “FCCU configuration” section of the “Device configuration” chapter, on one of those outputs to the incoming failure indication, the FOSU assumes the FCCU has failed, and causes a destructive reset.

The FOSU does not require any configuration by software.

6.4.2 Common Cause Failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the safety measures. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

There are also configuration registers that, on change, can affect the execution of the MCU's safety function and, simultaneously, disable the respective safety mechanism. These are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing the register protection described above.

6.4.3 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

6.4.3.1 ECC for storage

All storage used in normal operation is protected by ECC with:

- SEC/DED (single bit error correction and double bit error detection) for core, local memory, peripheral RAM
- SEC/DEC/TED (single bit error correction, double bit error correction and triple error bit detection) for Flash memory

The following exceptions exist:

- The caches in the cores are protected by EDC (Error Detection Code), only detecting, but not correcting errors.
- SRAM is protected by SEC/DEC ECC in PRAM controller only during partial writes (RMW operations) otherwise it is protected by E2E-ECC mechanism
- The HSM's AES program extension RAM are not protected by ECC.

A list showing the implementation of RAMs with ECC (including address protection) and for the SPC584Bx is shown in *Table 15*.

Table 15. ECC RAM implementations

Location	Memory	MEMU Classification	ECC	Address is ECC	Muxing Factor	Reacts to uncorrectable error
Core_2	D-MEM	System RAM	SEC/DED(1)	Y	16	Y
	I-Cache	System RAM	EDC	Y	4	Y
	D-Cache	System RAM	EDC	Y	4	Y
	ITAG	System RAM	SEC/DED	Y	4	Y
	DTAG	System RAM	SEC/DED	Y	4	Y
HSM	PRAM	Peripheral	SEC/DED	Y	8	N
	I-Cache	Peripheral	SEC/DED	Y	4	N
	ITAG	Peripheral	SEC/DED	Y	4	N
	C3	None	NO	N	4	N
Ethernet	FIFO RX	Peripheral	SEC/DED	Y	4	Y
	FIFO TX	Peripheral	SEC/DED	Y	4	Y
CAN	CAN	Peripheral	SEC/DED	N	8	Y
DMA	DMA	Peripheral	SEC/DED	Y	4	Y
Platform	SRAM	System RAM	E2E-ECC(2)	Y	8	Y
	Nexus	Peripheral	NO	—	4	N

1. Only when accessed by its own core. During access from other cores it is protected by E2E-ECC.
2. SEC/DEC for partial write operation (RMW), refer to *Section 34.5.13: Safety considerations*.

As shown in *Table 15*, some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback). This is different for storage related to PeMos. PeMos, in general, use an ECC without address error protections and do not include additional measures to detect them. All ECC calculations for RAMs in PeMos are accomplished by logic outside of the RAM, not in the RAM block.

6.4.3.2 All-x words and ECC

There is a special case for valid ECC values in the SPC584Bx. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not valid for memory that is checked by ECC. Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be valid. The Flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be valid.

In case of not valid codeword, All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be always uncorrectable errors. For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, a not valid All-x codeword may result in a correctable error.

Note: For Flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (refer to Chapter 35: Embedded Flash Memory, for more details on Flash memory safety mechanisms).

6.4.3.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU. The MEMU (refer to *Section 6.4.3.4: Memory Error Management Unit (MEMU)*) may filter ECC error notification for known ECC error addresses with same (optional) syndrome (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU, which filters and then forwards unfiltered notifications in an aggregated manner to the FCCU.

6.4.3.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events generated by the ECC logic used to protect system RAMs (in this context they are those RAMs with “System RAM” memory classification as shown in *Table 15*), peripheral RAM, and Flash memory. In addition to storage errors, e2eECC errors caused by XBAR, RAM or flash memory controllers and memory related faults detected during MBIST are also routed to MEMU. When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU.

Refer to the Device Configuration chapter for MEMU connections.

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses with same (optional) syndrome in the table is ensured. For example, if an address with same (optional) syndrome is already stored in the

MEMU's table, correctable errors at that address will no longer be reported to the FCCU

- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (refer to *Chapter 73: Memory Error Management Unit (MEMU)* for more information).

6.4.3.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- The (optional) ECC-syndrome or MBIST bad-bit information in case of SBE
- A configuration specifying whether the ECC unit is attached to a peripheral RAM, to a System RAM or to Flash memory

Not all ECC units provide a syndrome. If an ECC unit does not provide the syndrome, 0xFF is stored in the MEMU error table instead of the syndrome. If an error is signaled, it is compared against all errors known for that storage:

- If no entry of that address with same (optional) syndrome is already in the buffer, it is to be added into the appropriate table depending on the SBE versus UCE indicator
- If there is no free entry left in that buffer, the overflow flag is set

Note: If a previously known error has been marked invalid by software, no comparison against the address will occur.

If a valid entry of that address is in the buffer, and if the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. In case of the same error is reported by ECC which reports the syndrome and additionally by ECC which does not, the reporting order becomes important.

- If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. If ECC which provides the syndrome reports first, the second reporting without syndrome is discarded.
- If ECC which does not provide the syndrome reports first, a second entry with the syndrome is stored in the table.

7 Device configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters
- Links for more information

7.2 Core modules

The HSM module embeds one additional core.

The main platform has one core that performs various computational and control functions: Main Core_2 which uses an e200z420n3 core.

PowerISA 2.06 and implementation-specific SPRs for the e200z215An3 core are listed in *Table 16*. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in *Table 16*.

Table 16. Special Purpose Registers (SPRs)

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No

1. The Debug Status Register can be read using *mfspr RT,DBSR*. The Debug Status Register cannot be directly written to. Instead, bits in the Debug Status Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr DBSR,RS*.
2. Undefined on **POR** assertion, unchanged on **external PORESET** assertion.
3. The Machine Check Syndrome Register can be read using *mfspr RT,MCSR*. The Machine Check Syndrome Register cannot be directly written to. Instead, bits in the Machine Check Syndrome Register corresponding to ‘1’ bits in GPR(RS) can be cleared using *mtspr MCSR,RS*.
4. The 64-bit DVC registers are accessed by using the DVC1,2 spr #s for the lower 32 bits, and the DVC1,2U spr #s for the upper 32 bits.

Table 17 shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately following a system reset.

7.3 System modules

7.3.1 SIUL2 configuration

The System Integration Unit Lite 2 (SIUL2) controls the MCU pad configuration, ports, general-purpose input and output (GPIO) signals and external interrupts with trigger event configuration.

For details please refer *Chapter 16: System Integration Unit Lite2 (SIUL2)*.

Note: All output pins, whose SIUL2_MSCRn[SMC] = 0, disable their output drivers when the device enters SAFE mode while the internal weak pull-up of GPIO is enabled automatically. Coherently, ME_SAFE_MC.PDO must be set to 1 (default value) when disabling the output buffer.
Each other configuration has no effect on output driver of pin, refer to Table 19.

Table 19. Output buffer configuration

ME_SAFE_MC [PDO]	SIUL2.MSCR_IOn[SMC]	DRUN Mode	SAFE Mode
0 (no safe gating of I/O)	0 (output buffer disabled)	Output buffer enabled	Output buffer enabled
0 (no safe gating of I/O)	1 (output buffer enabled)	Output buffer enabled	Output buffer enabled
1 (output buffer driver disabled in SAFE mode)	0 (output buffer disabled)	Output buffer enabled	Output buffer disabled, internal weak pull-up enabled
1 (output buffer driver disabled in SAFE mode)	1 (output buffer enabled)	Output buffer enabled	Output buffer enabled

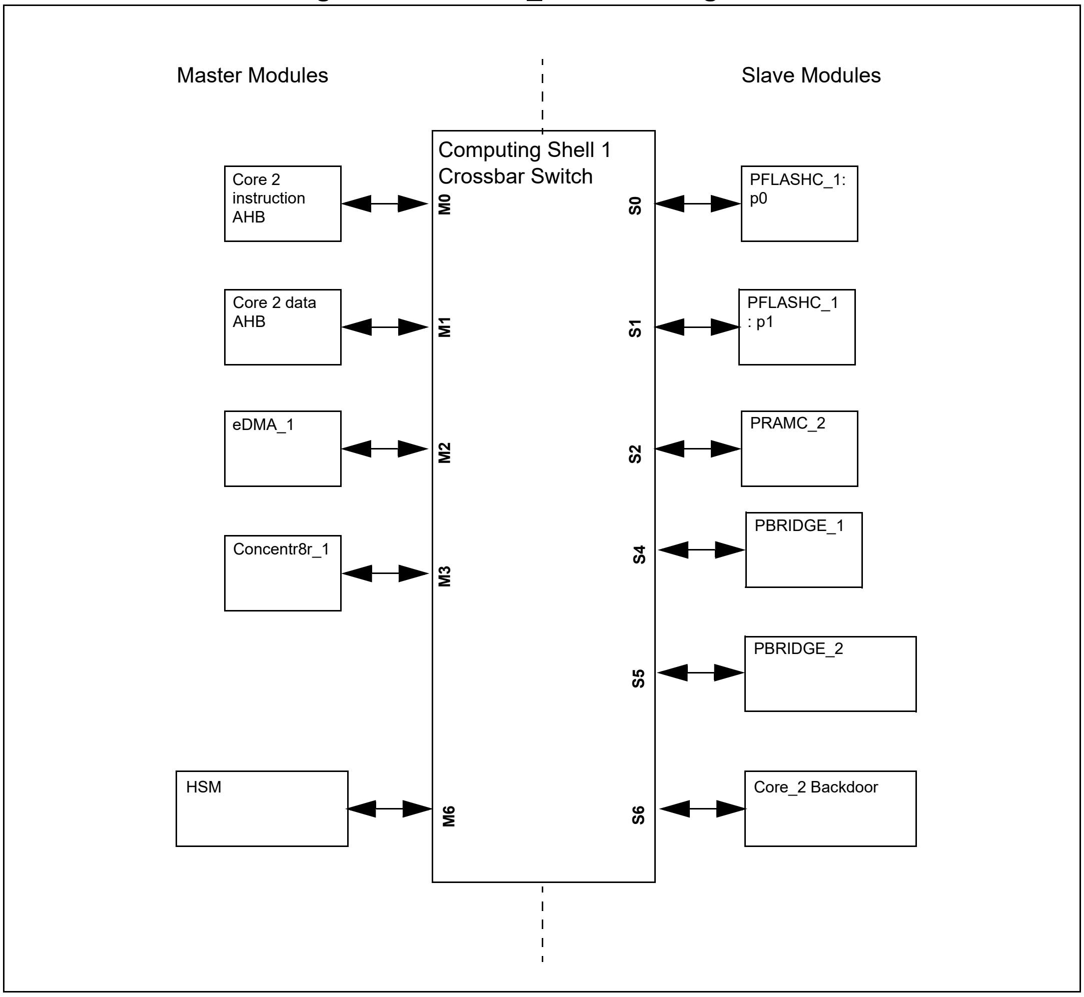
7.3.2 Crossbar switch

This device contains one crossbar switch module.

7.3.2.1 Computing shell 1 crossbar switch (XBAR_1) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, refer to the chapter for that module.

Figure 7. Crossbar_1 switch integration



The following figure shows hardwired connections between Masters and Flash Ports slaves (S0/S1).

Figure 8. Crossbar_1 hardwired connections

7.3.3 System Memory Protection Unit (SMPU) configuration

This chip contains two instances of the System Memory Protection Unit (SMPU):

- SMPU_HSM for the Hardware Security Module
- SMPU for XBAR

The following sections explain how SMPU for XBAR is configured on this chip. See the *Microcontroller Security Reference Manual* for configuration details of SMPU_HSM.

7.3.3.1 SMPU1 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 9. SMPU1 configuration

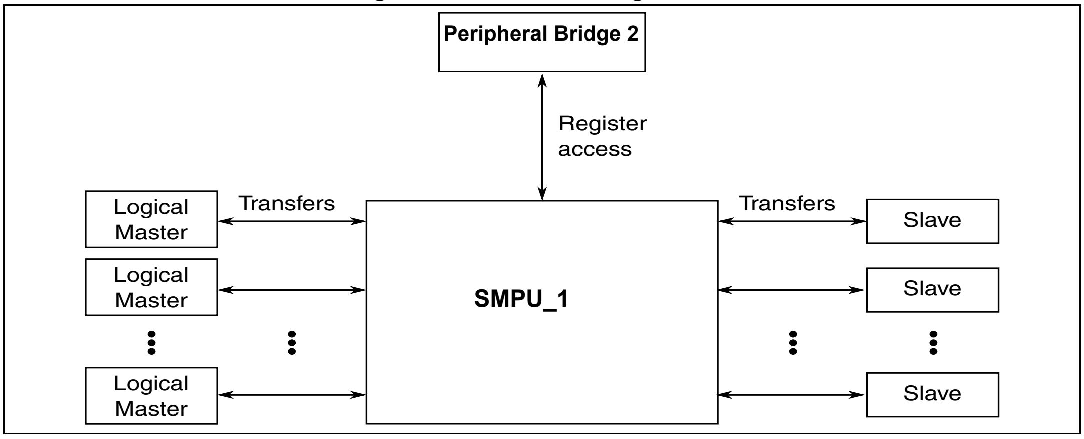

Table 24. Reference links to related information

Topic	Related module	Reference

Master Access Permissions	—	*Section 7.3.3.1.4: Master Access permissions for SMPU1*

7.3.3.1.1 SMPU1 logical bus master assignments

The logical bus master assignments for the SMPU1 are present in Device configuration chapter, *Section 7.3.2.2: AHB Master ID Assignments*.

7.3.3.1.2 Number of region descriptors supported by SMPU1

This instance of the SMPU module supports a maximum of 16 region descriptors.

7.3.3.1.3 RGD_WORD2 formats supported by SMPU1

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.3.1.4 Master Access permissions for SMPU1

The only masters allowed to access the SMPU1 registers are HSM, Core 2. It is also required that the core be in supervisor mode.

7.3.4 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 10. Peripheral bridge configuration

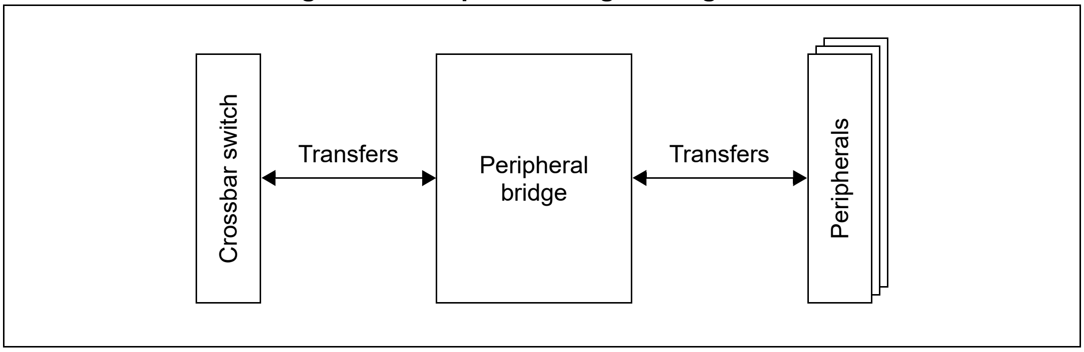

Table 25. Reference links to related information

Topic	Related module	Reference

Clocking	—	*Chapter 25: Clocking*
Crossbar switch	Crossbar switch	*Section 7.3.2: Crossbar switch*

7.3.4.1 Peripheral bridge instantiation

This device contains two identical peripheral bridges.

7.3.4.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See *Chapter 5: Memory Map* for the memory slot assignment for each module.

7.3.4.3 MPR registers

Each of the two peripheral bridges supports up to sixteen crossbar switch masters, each assigned to a MPROT*n* field in the MPRA-B registers. However, fewer are supported on this device. See *Section 7.3.2: Crossbar switch* for details of the master port assignments for this device.

7.3.4.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each assigned to a PACR*n* or OPACR*n* field within the PACRA–H/OPACRA–AF registers. However, fewer peripherals are supported on this device. See *Chapter 5: Memory Map* for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

7.3.5 Interrupt controller (INTC) configuration

7.3.5.1 INTC configurable parameters

The INTC on this chip supports two processors.

7.3.5.2 Interrupt channel map

Table 26 defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 26. Interrupt sources

Number	Description	Register bit
0	Software interrupt flag 0	INTC_1_SSCIR0[CLR]

7.3.5.3 Interrupt latency

The Interrupt system is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

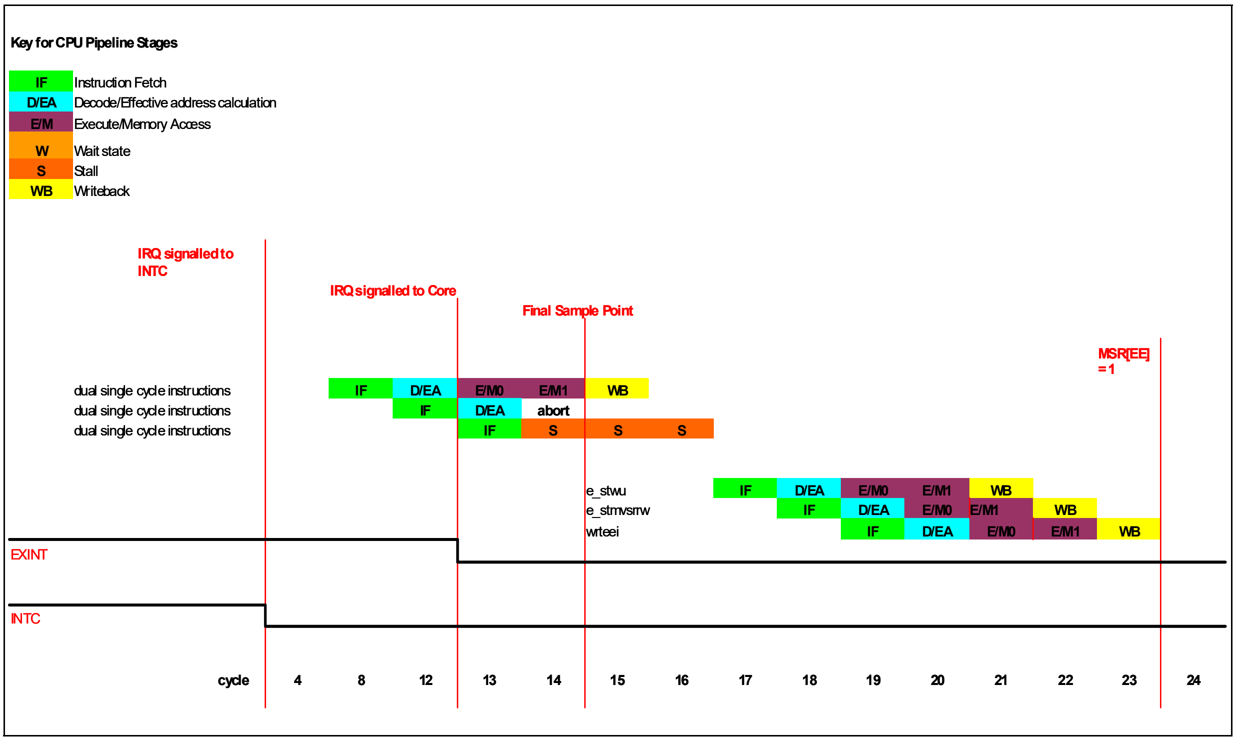
The latency time is difficult to define exactly because it depends on what interrupts the INTC is processing and what the CPU is doing.

In general, the latency time is divided into three subsections:

- INTC Latency
  - 3 clock cycles (INTC clock domain[b]) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency
  - 4 clock cycles (CPU clock domain[b]) from the assertion of the interrupt request from the INTC to the execution of the first instruction
- Software Latency
  - 7 clock cycles (CPU clock domain[b]) to execute the three instructions needed to save essential registers and enable interrupts

b. 120 MHz

Figure 11. Interrupt timing



7.3.6 DMA controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

7.3.7 DMACHMUX configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.3.7.1 DMACHMUX parameters

SPC584Bx has two DMA channel multiplexers.

Each DMACHMUX includes 16 channels.

Table 29 lists the number of DMA channels, always slots and DMA triggers.

Table 29. DMACHMUX controller generics

Signal name description	Description	DMACHMUX_0	DMACHMUX_1
NUMBER_OF_DMA_CHANNELS	Number of DMA channels	16	16
NUMBER_OF_ALWAYS_SLOTS	Module-internal slots which will always do a request	2	2
NUMBER_OF_DMA_TRIGGERS	Number of DMA channels which will be gated with a trigger pulse	3	3

7.3.7.2 DMA channel assignment

Table 30 lists which channels apply to each multiplexer.

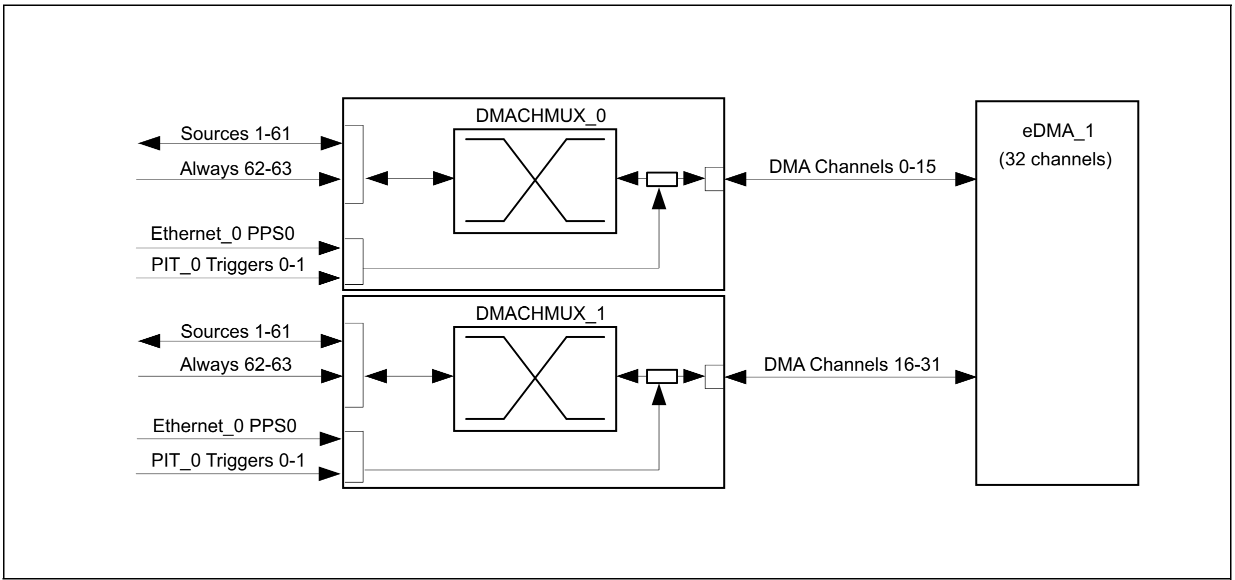
Table 30. SPC584Bx multiplexer and channel list

DMACHMUX instance	eDMA_1 channel
0	0-15
1	16-31

7.3.7.3 DMA channel multiplexing block diagram

The connections of the DMA channel multiplexers to the eDMA are shown in *Figure 13*. One DMACHMUX is instantiated for every sixteen DMA channels.

Figure 13. DMA channel multiplexing



7.3.7.4 DMA request mapping

The mapping of the peripheral DMA requests to the DMACHMUX input sources is shown in *Table 31*.

Table 31. DMAMUX Map

7.3.8 Platform Configuration Module (PCM) configuration

The Platform Configuration Module (PCM) contains three registers. These PCM registers are used for controlling different aspects of the Platform functionality including the Frequency Gasket Configurations of the Intelligent Bus Bridging Gaskets.

The PCM module is mapped to PBRIDGE_2 on platform slot 10. Its base address is 0xF4028000.

7.3.8.1 Platform Configuration Module 0 register (PCM0)

Field	Description
9 EN_HSIZE_MUX_ PRAM	DMC operations HSIZE control for PRAM 2 and 3 Force HSIZE=32 bit for Decorated Memory operations on PRAM as decorated operations compute write checkbits (ECC) on 32-bit word. 0 Any decorated write to SRAM peripherals will be done with native HSIZE of the instruction (8b/16b/32b) 1 Any decorated write to SRAM peripherals will be done with HSIZE=32bit

7.3.9 Wakeup unit (WKPU) configuration

The Wakeup unit supports 24 external sources that can generate CPU exceptions or wakeup events and 2 external sources, driven by PA[4] and PD[15], that can cause non-maskable interrupt requests or wakeup events.

The effect of the signals coming from PA[4] and PD[15] depends on the execution mode.

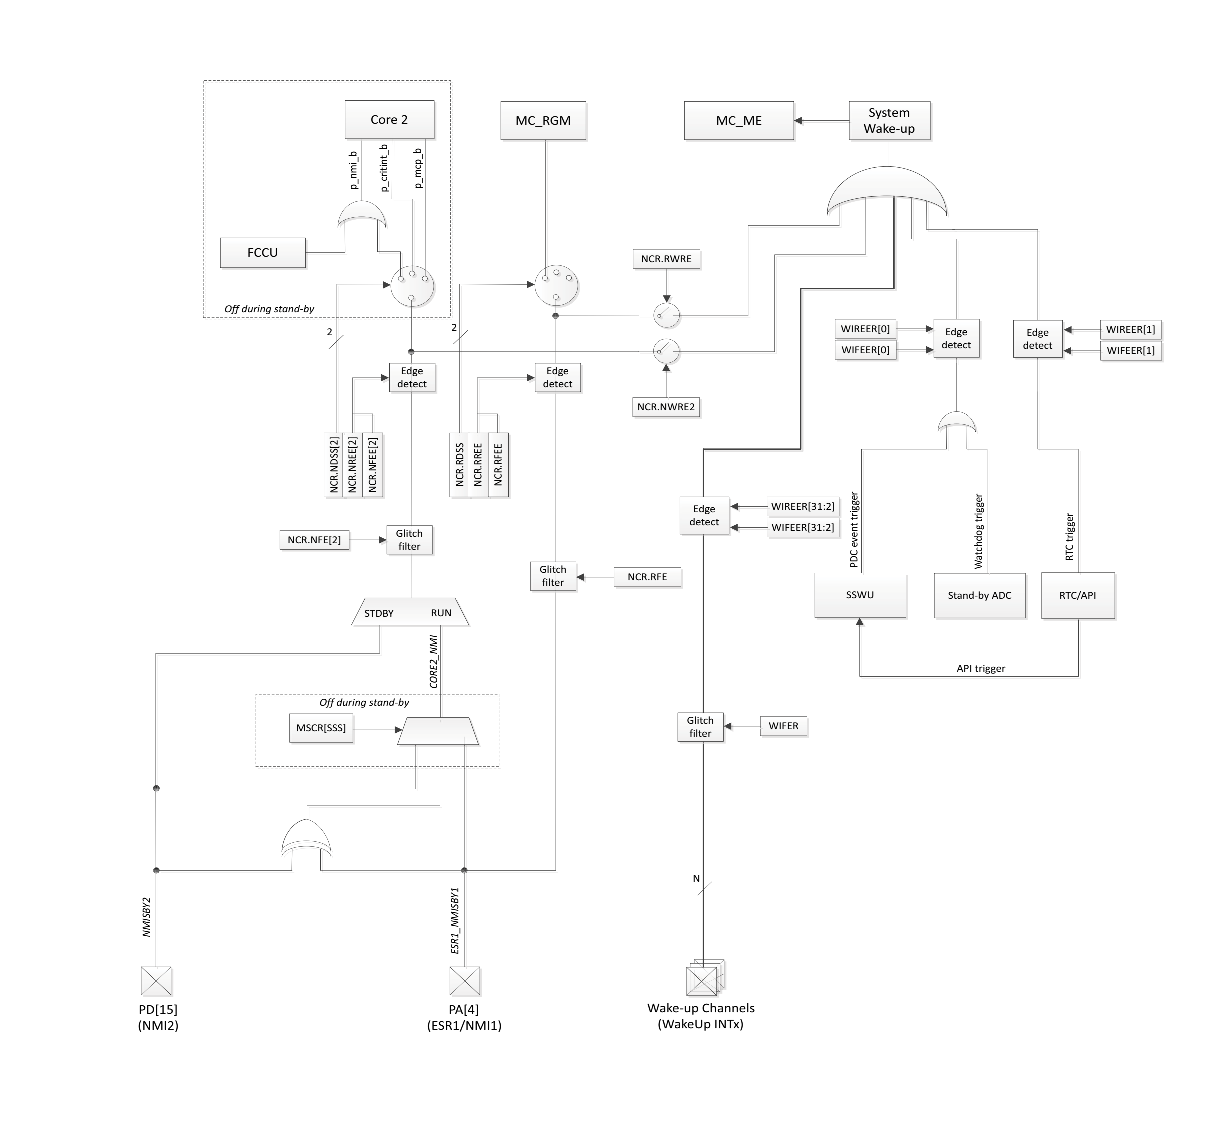
In any run mode, one signal (CORE2_NMI) is input to the core. This signal is the output of one multiplexer, which makes it possible to select (via SIUL2 register) any of the following sources:

- PA[4]
- PD[15]
- Logical XOR'ed of PA[4] and PD[15]

In stand-by mode, the signals driven by PD[15] (NMISBY2) can be used to wake-up the system.

PA[4] can be used to trigger a reset to the whole system.

Figure 17. NMI block diagram SPC584Bx



In *Figure 1622: Wakeup unit block diagram* of *Chapter 80: Wakeup unit (WKPU)*, it has to be noted that only one filter is implemented.

7.3.9.1 Features

The Wakeup unit supports these distinctive features:

- Non-maskable Interrupt support with:
  - 2 NMI source with bypassable glitch filter
  - Independent interrupt destination: non-maskable interrupt, critical interrupt, or machine check request
  - Edge detection
- External wakeup/interrupt support with:
  - 30 wakeup/interrupt sources
  - Analog glitch filter per each wakeup line
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable pull/padkeeper functionality

Note: WIPUER register is used to disable Pad keeper functionality only on a set of interrupt pads (Group_1) and to enable internal pull only on a different set of interrupt pads (Group_2). Group_1 gathers : WKUP8 (PC1) - WKUP9 (PF3) - WKUP15 (PD5) - WKUP18 (PA2) - WKUP24 (PA11) - WKUP25 (PE10)) and Group_2 gathers all other WKUPx.

Note that the actual bit configuration for field WIPUER.IPUEx (x = 8/9/15/18/24/25) is:
1 Pad Keeper is disabled.
0 Pad Keeper is enabled.

- On-chip wakeup support
  - 2 wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status
  - Independent interrupt mask
  - Configurable system wakeup triggering from all interrupt sources

7.3.9.2 Wakeup vector mapping

7.3.10 Crossbar integrity checker (XBIC)

The device implements the following XBIC instances:

- XBIC_Concentrator_1
- XBIC_1

Master and slave assignments are defined as follows:

- XBIC master definition follows the AHB master (see AHB Master ID assignments in *Section 7.3.2.2: AHB Master ID Assignments*).
- XBIC slave definition follows the XBAR slave numbering (see Crossbar_1 switch slave assignments in *Section 7.3.2.1.2: Crossbar_1 switch slave assignments*)

7.3.11 Body Cross Triggering Unit (BCTU) configuration

This section summarizes the Body Cross Triggering Unit (BCTU) configuration in the SPC584Bx device. For a comprehensive description of the BCTU, please refer to the BCTU's dedicated chapter.

7.3.11.1 Module overview

One single BCTU instance (BCTU0) is implemented. It is interconnected to:

- SAR_ADC_12bit_B
- eMIOS
- PIT

The Body Cross Triggering Unit is used to prioritize the trigger events from eMIOS/PIT.

The BCTU synchronizes the ADC conversion with PWM signal coming from eMIOS/PIT (refer to *Table 39*). When the event is programmed to be an ADC trigger, the 7-bit channel number is provided to ADC. This channel number is used to communicate which particular channel has to be converted (refer to *Table 40*).

The BCTU is also used to route the trigger events from eMIOS as a DMA request in case the event is not programmed to be a trigger to ADC.

The supported trigger sources are the following:

- 62 eMIOS channels
- 2 PIT channels

Figure 18. BCTU overview

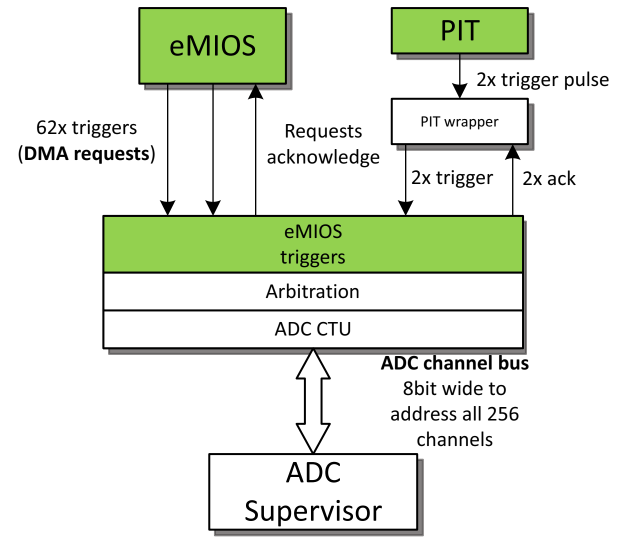

Table 39. BCTU input triggers allocation

Body CTU trigger input	Trigger source	Connected signal
0–22	eMIOS0	eMIOS_0 CH0–CH22
23	PIT_RTI_0	PIT_0 CH1
24–31	eMIOS_0	eMIOS_0 CH24–CH31

7.4 Clocking

See *Chapter 25: Clocking* for a description of the architecture for the system level clocks including clock generation, the clock sources and the peripheral clocks. The chapter also provides configuration details for the Clock Monitor Unit (CMU).

7.5 Memories and memory interfaces

See the following chapters for detailed information on memories and memory interfaces.

Table 42. Reference links to related information

Topic	Related module	Reference
Embedded memories	—	Chapter 3: Embedded memories
System memory map	—	Chapter 5: Memory Map
Platform Flash	—	Chapter 34: Flash memory controller
Platform RAM controller	—	Chapter 33: Platform RAM controller AHB (PRAMC_AHB)
Embedded flash memory	—	Chapter 35: Embedded Flash Memory
Decorated Storage Memory Controller	—	Chapter 37: Decorated Storage Memory Controller (DSMC)

7.5.1 Flash memory controller (PFLASH) configuration

One flash controller and memory array is implemented. The flash controllers provide flash configuration and control functions and manage the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, PFCR2, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See the crossbar switch configuration section for details. See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

Flash memory architecture overview	Flash memory, Flash controller	Section 3: Embedded memories
Flash memory	Flash memory	Chapter 35: Embedded Flash Memory
Flash port assignments	Crossbar switch	Section 7.3.2: Crossbar switch
System memory map	—	Chapter 5: Memory Map

The master assignments are shown in *Table 23: SMPU1 logical bus master assignments*.

7.5.2 Decorated Storage Memory Controller (DSMC)

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR, and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The DSMC is instantiated within the core platform and physically resides between the CPU data AHB bus and the associated crossbar master port.

Due to this architecture choice, the DSMC can access the whole addressing space.

7.6 Analog modules

This section highlights the following analog modules that are implemented on SPC584Bx:

Table 44. Reference links to related information

Module or Subsystem	Device-specific information	Block details
ADC subsystem	*Section 38.1: ADC overview*	*Chapter 38: Analog-to-Digital Converters (ADC) Configuration*
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	*Section 7.6.1: SARADC*	*Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC)*

The temperature sensor is used to measure the temperature of the SPC584Bx device. The temperature sensor has the following outputs:

- Two analog voltages
  - A voltage signal that is linearly increasing with internal junction temperature (PTAT that is proportional to absolute temperature)
  - A voltage signal that is linearly decreasing with internal junction temperature (CTAT that is complementary proportional to absolute temperature)
- Three digital outputs that signal under- or over-temperature operating conditions.

During production testing of the device, the output voltages of the temperature sensor are sampled by SARB of the onboard ADC module at a predefined high temperature and also at a predefined low temperature. These calibration parameters are stored during production test into UTEST Flash memory. See Section UTEST in Chapter Flash Memory.

By converting the two analog outputs of the temperature sensor through ADC, one can find out a constant reference code which does not change with temperature or the ADC reference values. It is also called 'Digital Bandgap Voltage'. See *Section 40.3.2: Equations* *for converting TSENS voltages into constant reference (Digital Bandgap Voltage)* in *Chapter 40: Temperature Sensor*.

For details, see *Chapter 40: Temperature Sensor*.

7.6.1 SARADC

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for an application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

SPC584Bx includes four (4) independent 12-bit SARADCs and one (1) independent 10-bit SARADC. The 12-bit SARADC_B has access to all external analog input pins, access to the external multiplexed inputs, and has special safety features.

For details, refer to the section Analog-to-Digital Converters (ADC) Configuration.

7.7 Timers

7.7.1 System Timer Module (STM) configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the HPBM_CLK divided by an 8-bit prescale value (1 to 256).

SPC584Bx includes STM with four 32-bit compare channels.

Table 45. System Timer Module (STM) instances

Instance	Description	Number of channels	Number of registers (32-bit)
STM_2	Clocked by HPBM_CLK (Core_2)	4	14

7.7.2 Software Watchdog Timer (SWT) configuration

SPC584Bx includes two SWTs.

Table 46. Software Watchdog Timer (SWT) instances

Instance	Description
SWT2	Clocked by IRCOSC clock; using value of IAC8 register of Core 2 for instruction address compare feature
SWT3	Clocked by IRCOSC clock; not supporting the address compare feature

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Internal 16 MHz RC oscillator clock that is used for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.7.2.1 IAC (Instruction Address Compare)

The IAC feature makes it possible to serve a SWT when the CPU executes an instruction at a specific address location. The purpose is to guarantee that the application regularly executes an instruction within some fundamental section of the code. If this address location is not executed regularly, it implies that a critical error has occurred and the device should be eventually reset.

Not all the SWTs embed the IAC feature: *Table 46* shows for which watchdog the IAC feature is enabled.

If the IAC feature is enabled for a specific SWT, the address to be executed is set by the Instruction Address Compare 8 (IAC8) register, whereas the IAC feature can be activated by the register field SWT_CR[SMD] to one of the following settings:

- 2'b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this 'freezes' changes to the IAC8 register when the SWT is enabled
- 2'b11 for Incremental Address Execution; the IAC8 register can be updated

7.7.2.2 Reset assertion

The SWT can assert a reset when the watchdog timer expires. See *Section 8: Reset and Boot* chapter for details.

7.7.2.3 Default configuration

On SPC584Bx, the SWTs come out of reset with the default reset values summarized in *Table 47*. Minimum timeout value is 256 cycles for SWT0, SWT2, and SWT3. For details, please refer to *Section 52.3.5: Initialization of BAF DCF clients*

Table 47. Register reset values

SWT instance	Register	Reset value
SWT_2	SWT Control Register (SWT_CR)(1)	0xFF00_011B
SWT_2	SWT Time-out (SWT_TO)	0x0003_FDE0
SWT_3	SWT Control Register (SWT_CR)	0xFF00_010A
SWT_3	SWT Time-out (SWT_TO)	0x0005_FCD0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is ‘1’, but the DCI can override that default value by setting it to ‘0’. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT; it cannot enable it.) For details refer to *Section 58.1.3: Operating modes*.

7.7.3 PIT configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Table 48. Reference links to related information

Topic	Related module	Reference
Full description	PIT	*Chapter 44: Periodic Interrupt Timer (PIT)*
System memory map	—	*Chapter 5: Memory Map*

Power management	—	*Chapter 10: Power management*
DMA channel assignments	DMACHMUX	*Chapter 24: DMA channel multiplexer (DMACHMUX)*
BCTU channel assignment	BCTU	*Chapter 41: Body Cross Triggering Unit (BCTU)*

7.7.3.1 PIT instantiation

Table 49. PIT information

PIT module	PIT channels	Description
PIT_0	8 + RTI	The PIT has eight standard channels. All PIT registers are cleared by any reset.
PIT_1	2	PIT1 has chaining mode to implement a 64-bit timer and the timer value is unchanged by a functional reset.

7.7.3.2 PIT/DMA periodic trigger assignments

The PIT generates periodic trigger events to the DMACHMUX. To check the mapping of the PIT channel number with the corresponding DMA channel number, refer to the *Table 32: Periodic trigger to DMA channel mapping*.

7.7.3.3 PIT Registers

The following tables show the implementation of PIT registers in this MCU.

Table 50. PIT_0 memory map

Offset address (hex)	Register name
0x0000	PIT Module Control Register (PIT0_MCR)(1)
0x00E0–0x00E4	Reserved
0x00F0–0x00FC	RTI Timer Channel Registers (PIT0_RTI_LDVAL, PIT0_RTI_CVAL, PIT0_RTI_TCTRL, PIT0_RTI_TFLG)
0x0100–0x017C	Timer Channel [0:7] Registers (PIT0_LDVALn, PIT0_CVALn, PIT0_TCTRLn, PIT0_TFLGn)
0x0180–0x3FFF	Reserved

1. The reset value of MCR is 0x06.

Table 51. PIT_1 memory map

Offset address (hex)	Register name
0x0000	PIT Module Control Register (PIT1_MCR)(1)
0x00E0	PIT Upper Lifetime Timer Register (PIT1_LTMR64H)
0x00E4	PIT Lower Lifetime Timer Register (PIT1_LTMR64L)
0x00F0–0x00F8	Reserved
0x0100–0x011C	Timer Channel [0:1] Registers (PIT1_LDVALn, PIT1_CVALn, PIT1_TCTRLn, PIT1_TFLGn)
0x0120–0x3FFF	Reserved

1. The reset value of MCR is 0x02.

7.7.3.4 PIT clocking

The PIT_0 standard channels are clocked with the peripheral clock (PER_CLK).

The PIT_0_RTI channel clock source is selectable between XOSC and RCOSC via the auxiliary clock selector 9.

The PIT_1 channels are clocked with the peripheral clock (PER_CLK).

Refer to *Figure 453: Block diagram of the PIT* for PIT clock sources description.

7.8 Communication interfaces

7.8.1 Ethernet configuration

7.8.1.1 Ethernet interface selection

On this chip, the Ethernet interface depends on the SIUL2_SCR0 settings (in the SIUL2), as shown in *Table 52*.

Table 52. Ethernet interface selection

SIUL2_SCR0[Ethernet_MODE]	Interface used by the Ethernet
0	RMII
1	MII

7.8.1.2 Ethernet timestamp snapshot trigger

The Ethernet interface includes an internal 64-bit time base counter to support IEEE 1588 Precision Time Protocol (PTP) timestamps.02

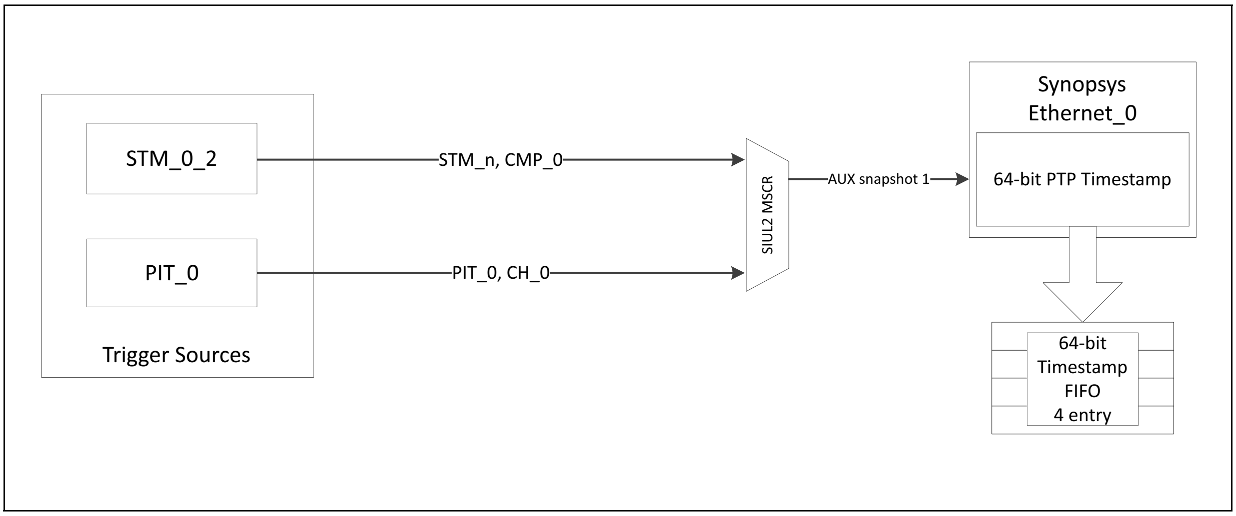
To synchronize other system events to the Ethernet PTP time base snapshot feature is available to capture the Ethernet time base on different system events into a four-entry-deep

FIFO. Details about the snapshot feature is available in *Section 47.3.9: IEEE 1588 Timestamps*.

The selection of the various trigger sources is done in the SIUL2 module by configuration of the corresponding MSCR registers. The details about the signal configuration are available in I/O Signal Table.

The system implementation of the snapshot feature is shown in *Figure 19*.

Figure 19. Ethernet Snapshot feature integration

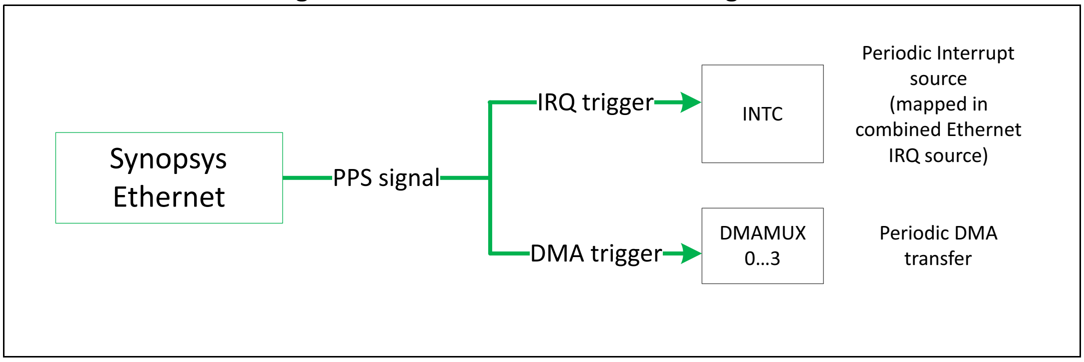


7.8.1.3 Ethernet Pulse-Per-Second output (PPS)

The Ethernet interface module includes a programmable time reference signal which can be used to trigger several system events. Details about the Pulse-Per-Second feature are available in *Section 47.3.9.4: Reference Timing Source*.

The system implementation of the PPS feature is shown in *Figure 20*.

Figure 20. Ethernet PPS feature integration



7.8.2 CAN subsystem configuration

Two CAN subsystems are implemented:

- CAN subsystem 0 (M_CAN type)
- CAN subsystem 1 (M_CAN type)

Please refer to *Chapter 46: CAN subsystem* for details.

7.8.2.1 CAN nodes

Table 53 lists the different CAN nodes for both CAN subsystems.

Note: All CAN instances are supporting ISO CAN FD mode.

Table 53. CAN bus controllers

Subsystem	Peripheral bridge instance	Shared message RAM size (words)	Type	Instance	ISO CAN FD support up to 64 data byte[(1)]	Debug on CAN support	Clock calibration[(2)]
CAN subsystem 0	PBRIDGE_2	3968	M_CAN	CAN_SUB_0_M_CAN_0	Yes	No	Yes
				CAN_SUB_0_M_CAN_1	Yes	Yes	Yes
				CAN_SUB_0_M_CAN_2	Yes	Yes	Yes
				CAN_SUB_0_M_CAN_3	Yes	No	Yes
CAN subsystem 1	PBRIDGE_1	3968	M_CAN	CAN_SUB_1_M_CAN_1	Yes	No	No
				CAN_SUB_1_M_CAN_2	Yes	No	No
				CAN_SUB_1_M_CAN_3	Yes	No	No
				CAN_SUB_1_M_CAN_4	Yes	No	No

1. M_CAN revision 3.2.0
2. Clock calibration based on M_CAN_1 messages for CAN subsystem 0.

7.8.3 DSPI configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

Table 54. Reference links to related information

Topic	Related module	Reference
Full description	DSPI	*Chapter 49: Deserial Serial Peripheral Interface (DSPI)*
System memory map	—	*Chapter 5: Memory Map*
Clocking	—	*Chapter 25: Clocking*
Signal Multiplexing	Port control	*Chapter 4: Signal Description*
System Module	System Integration Unit Lite	*Chapter 16: System Integration Unit Lite2 (SIUL2)*
DMA Channel Assignments	Direct Memory Access multiplexer	*Chapter 24: DMA channel multiplexer (DMACHMUX)*

7.8.3.1 DSPI instantiation

This device contains seven DSPI modules. *Table 55* shows the instantiation information for each module.

Table 55. DSPI instantiation

DSPI Module	CTARs	TX FIFO Depth	RX FIFO Depth	PCS Signals	Data Serialization Support
DSPI0	8	4	4	Link to External I/O Signal excel table	—
DSPI1	8	4	4		—
DSPI2	8	4	4		—
DSPI3	8	4	4		—
DSPI4	8	4	4		64
DSPI5	8	4	4		64
DSPI6	8	4	4		—

7.8.3.2 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all '1's.

7.8.3.3 Serialized timed I/O

The timer sources and injection pin inputs to be DSPI serialized downstream outputs are selected through the SIUL2 and MSCR registers. Inversion of these signals is also handled in the SIUL2. Refer to *Chapter 16: System Integration Unit Lite2 (SIUL2)*, for details.

7.8.3.4 DSPI HT external trigger

External hardware triggers are not supported.

7.8.3.5 DSPI ITSB mode

For the ITSB trigger, the internal DSPI trigger (TRGPRD in DSICR1) is used. Use of external trigger is not supported.

7.8.3.6 DSPI registers

The absolute addresses of DSPI modules registers in this MCU are provided in *Chapter 5: Memory Map*.

7.8.3.7 DSPI clocking

Refer to the SPC584Bx Datasheet for the DSPI Baud rates.

7.8.4 LinFlexD

7.8.4.1 LINFlexD configurations

SPC584Bx has 14 instances of LINFlexD. Table 56 lists the configuration for each instance.

Table 56. LINFlexD configurations

Description	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3	LINFlexD_4	LINFlexD_5	LINFlexD_6	LINFlexD_7	LINFlexD_8	LINFlexD_9	LINFlexD_10	LINFlexD_11	LINFlexD_12	LINFlexD_15
Number of filters implemented	16	0												
Number of Tx DMA channels	1 (TX_CH_NUM = 0)(1)													
Number of Rx DMA channels	1 (RX_CH_NUM = 0)(2)													
LIN operation mode	Master/Slave (slave = 1)	Master (slave = 0)												
Value of auto-synchronization	1	0												

1. Number of TX DMA channels = 2**TX_CH_NUM where ** stands for exponentiation.
2. Number of RX DMA channels = 2**RX_CH_NUM where ** stands for exponentiation.

7.8.4.2 LINFlexD implemented registers

Table 57 shows the registers implemented for each LINFlexD instance on the SPC584Bx chip.

Table 57. LINFlexD register comparison map

Register description	Address offset (hex)													
	LINFlexD_0	LINFlexD_1	LINFlexD_2	LINFlexD_3	LINFlexD_4	LINFlexD_5	LINFlexD_6	LINFlexD_7	LINFlexD_8	LINFlexD_9	LINFlexD_10	LINFlexD_11	LINFlexD_12	LINFlexD_15

7.9 Reset and Boot modules

7.9.1 BAF configuration

7.9.1.1 Search boot header and boot options

Refer to *Section 8.3.12.2.3: SW boot record search (BAF search)* in the *Chapter 8: Reset and Boot*.

7.9.1.2 LINFlexD and MCAN pins configuration

Table 58 shows the device pin configurations for LINFlexD_0/2 and CAN_SUB_0_M_CAN_1/2 modules.

Table 58. LinFlexD and MCAN pin configuration

Pads	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received	Serial Boot Mode after a valid LINFlexD message received
	Function	Pad Configuration	Function	Function
PA[10]	MCAN_2 Tx	(1) Output:— Push/Pull medium drive no pullup/pulldown	MCAN_2 Tx	LINFlexD_2 Tx
PA[11]	LINFlexD_2 Rx and MCAN_2 Rx	Input:— high-Z hysteresis CMOS level	MCAN_2 Rx	LINFlexD_2 Rx
PB[10]	MCAN_1 Tx	(1) Output:— Push/Pull medium drive no pullup/pulldown	MCAN_1 Tx	LINFlexD_0 Tx
PB[9]	LINFlexD_0 Rx and MCAN_1 Rx	Input:— high-Z hysteresis CMOS level	MCAN_1 Rx	LINFlexD_0 Rx

1. Pad is set to output configuration as described in the table. Output buffer is enabled for the whole duration of the BAF serial boot.

7.9.2 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the SPC584Bx device. For a comprehensive description of the SSCM, please refer to the SSCM's dedicated chapter.

7.9.2.1 SSCM instantiation

There is one SSCM instance in the SPC584Bx device. The SSCM is part of the reset and boot sub-system.

7.9.2.2 Device-specific features

The device specific reset values for the SSCM_MEMCONFIG register are shown in *Table 59*.

Table 59. SSCM_MEMCONFIG reset values

Field	Field definition	Value
JPIN	JTAG Part ID	10'h110(1)
MREV	Minor Revision	4'h0(2)

1. This value will change for each major revision of the device.
2. This value will change for each minor revision of the device.

Table 60 shows the address locations that the SSCM uses to search for startup information.

Table 60. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET)	0x0040_0000
Location of the Boot Assist code in Flash (BAF)	0x0040_4000
Specifies the locations which are searched for a valid HSM boot header (starting from the lowest address)	0x60_C000 0x61_0000

7.10 Safety modules

7.10.1 CRC

Table 62 lists the number of contexts available for the current CRC computation of multiple data streams of CRC.

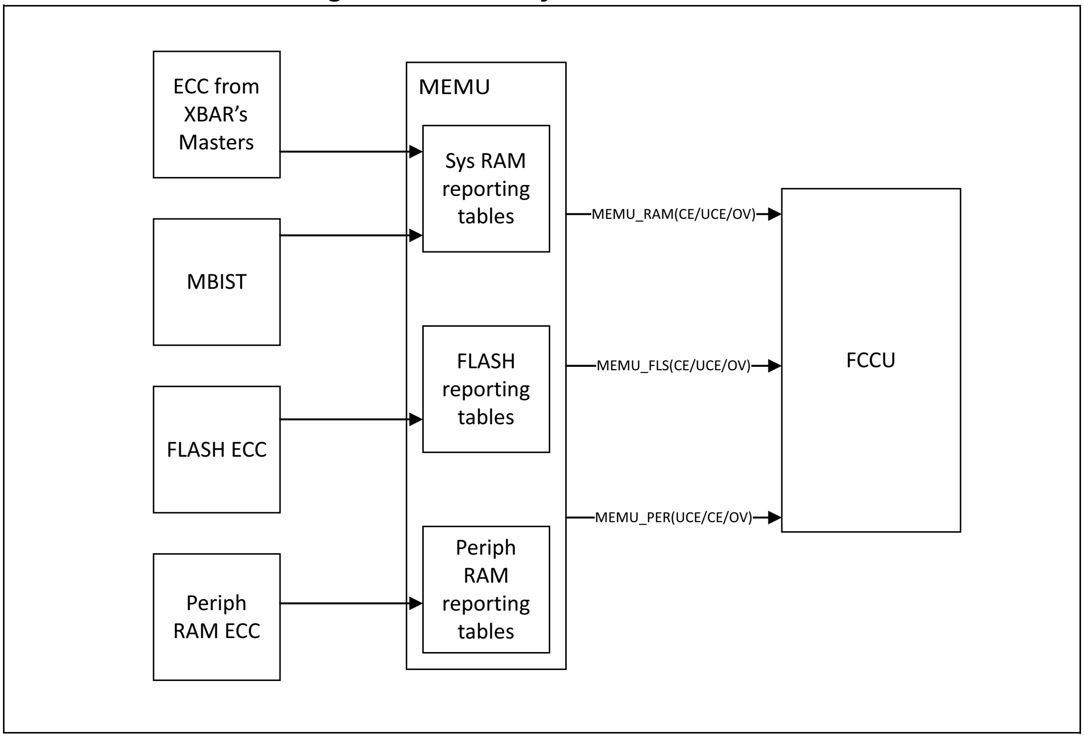
Table 62. CRC contexts

Signal name	Description	CRC_0	CRC_1
CRC_CNTX_NUM	Number of contexts available for the current CRC computation of multiple data streams.	4	4

7.10.2 MEMU configuration

7.10.2.1 MEMU system connections

Figure 21. MEMU system connections



7.10.2.2 MEMU error sources

Table 63 shows the MEMU error sources for each instance configured on this chip.

Table 63. MEMU error sources

Instance	Value
Number of system RAM unique error sources	73
Number of peripheral RAM unique error sources	16
Number of flash memory unique error sources	2

7.10.2.3 Reporting tables implementation

There are 3 categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting
- Peripheral RAM error reporting

Each category of error reporting has two tables associated with it, these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 64. Number of entries in each reporting table

Error Source	Number of entries in correctable error reporting table	Number of entries in uncorrectable error reporting table
Flash	20	1
System RAM	10	1
Peripheral RAM	2	1

7.10.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from one of the three categories, Flash, System RAMs or Peripheral RAMs. In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Note: z4c stands for Core_2 in the following tables.

Table 65. Corresponding error sources for system RAM OFLW0 register

Source number	OFLW0 bit-field position (bit)(1)	Error sources
6	25	z4c Data AHB
7	24	z4c Instruction AHB
8	23	z4c Data TCM (DMEM)
9	22	—
10	21	z4c Data Cache

7.10.2.6 Indirect Memory Access (IMA) configuration

The IMA refers to the alteration of memory data values during system development and test activities. This section provides details about what memory locations can be accessed, either via processor core access or via the IMA module, and how they are configured. For details on IMA see *Chapter 74: Indirect Memory Access (IMA)*.

Note: See the SPC584Bx Microcontroller Security Reference Manual for the HSM IMA details.

7.10.2.7 SRAM Arrays accessible by processor cores

All the SRAM arrays in *Table 72* can be accessed by the core (Core_2).

Table 72. SRAM with processor Core access

Block	Function	SPC584Bx		
		Words	Bits	ECC Bits

7.10.3.3 FOSU parameters

The FOSU_COUNT, or FOSU timeout response time, is 1000 IRCOSC clock cycles.

7.10.4 Register protection (REG_PROT) configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software-controlled and can be dynamically reconfigured at runtime or made effective until device reset.For a detailed explanation, see the *Chapter 77: Register Protection (REG_PROT)*.

1. The clock domain for CAN memories is supplied by PFBRIDGE_CLK. In case of offline MBIST which runs at speed (120 MHz), then CAN memories works at 30 MHz (CGM_SC_DC4 = 4 by default, thus PFBRIDGE_CLK = SYS_CLK/4). To test the CAN memories at the maximum frequency (120 MHz when PFBRIDGE_CLK = SYS_CLK/1), the online MBIST has to use programming CGM_SC_DC4 = 1.
2. HSM and FLASH online MBIST are not accessible when lifecycle is customer delivered/OEM/IN FIELD (SSCM_LCSTAT[LC]=CUST_DELIV/PROD_OEM/IN_FIELD).

Table 93 lists the MBIST registers in STCU2 with their available fields.

Table 93. MBIST registers in STCU2 with available fields

MBIST register	Fields available
STCU_MBS1	MBS31 – MBS0
STCU_MBS2	MBS34 – MBS32
STCU_MBE1	MBE31 – MBE0
STCU_MBE2	MBE34 – MBE32
STCU_MBS1SW	MBSSW31 – MBSSW0
STCU_MBS2SW	MBSSW34 – MBSSW32
STCU_MBE1SW	MBESW31 – MBESW0
STCU_MBE2SW	MBESW34 – MBESW32
STCU_MBUFM1	MBUFM31 – MBUFM0
STCU_MBUFM2	MBUFM34 – MBUFM32

Note: Refer to the Self-Test Control Unit (STCU2) chapter for a description of the registers programming and to the DCF client table for the description of the available DCF. The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. By default, STCU2 is not bypassed. This means that if offline self tests are not programmed, the hard-coded WDG of the STCU2 will be anyway activated. As a consequence, the startup time of the device will be increased accordingly to the WDG timeout value.

7.11 Security modules

7.11.1 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based on several resources like the Flash R/W access, or the debugger JTAG port. Up to four levels of password protection can be implemented for each resource.

Note: The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See *Chapter 78: Password and Device Security Module (PASS)* for further details.

7.11.1.1 PASS_LOCK*n*_PG*n* register bit mapping

Each password group defined in the DCF records has a set of four LOCK*n* registers association with it: PASS_LOCK*n*_PG*n.* The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note: The mapping of various LOCK register bits to flash blocks in the SPC584Bx microcontroller is very similar to the LOCKx registers implemented in the FLASH, but not identical. The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

Bit	Register field	Flash block name	Read lock region

7.11.1.2 PASS Module DCF Records

The records required to configure the initial values for the PASS module password group registers are shown in *Table 94*. These values provide the following capabilities:

- Set flash memory to censored/uncensored state (censorship also depends on lifecycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part

2. See *Section 7.11.1.1: PASS_LOCKn_PGn register bit mapping* for values.

7.11.2 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a type of flash memory erase protection mechanism that forces software to program a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), that is, write once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

See the *Chapter 79: Tamper Detection Module (TDM)* for further details on the TDM, including the DCF clients and two additional memory-mapped registers.

7.11.2.1 Diary Base Address (DBA) DCF client

DBA DCF client holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations. This DCF client is described in the TDM chapter.

7.11.2.2 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. This DCF client is described in the TDM chapter. The mapping is shown below.

DCF Client Address: 0x0001 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 26. Tamper Region Override (TO) DCF client

The mapping of the Tamper Region Override Enable (TOE*n*) DCF client is as follows:

Table 95. TO[TOE*n*] field mapping

Field	TDR
TOE0	0
TOE1	1
TOE2	2
TOE3	3
TOE4	4
TOE5	5

This DCF client is more fully described in the TDM chapter

7.11.2.3 OTPEN*n* DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPEN*n* DCF clients.Each mapped bit is associated with a specific flash block. A “1” bit value indicates a block is OTP.

The mapping is shown in *Figure 27* - *Figure 30*.

Figure 30. TDR*x*_LOCK3/OTPEN3 DCF client

7.11.2.4 TDRx_LOCKn DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A "1" in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDM_LOCKn DCF client bits to flash blocks is identical to the OTPEN*n* mapping and is shown in *Figure 27* - *Figure 30*. Any available flash block can be mapped to any tamper protection region.

7.11.2.5 DCF client details

Table 96 contains the DCF client information.

Table 96. Tamper Detection Module (TDM) DCF clients

DCF CS[14:0]	DCF Address [16:10]	DCF Address [9:2] (Binary)	DCF Client Description	No. of Valid Bits	No. of DCF Records

000_0000_0001_0000	0000000	00101010	TDR5_LOCK2	32	1
000_0000_0001_0000	0000000	00101011	TDR5_LOCK3	32	1
000_0000_0001_0000	0000000	00101100 - 1111111	Reserved		

1. OTP DCF clients have the same structure and mapping as the write-protect bits of the flash and PASS module LOCK DCF clients. A value of ‘1’ in an OTP bit indicates a block is programmable only once. Note that a block cannot be reconfigured as non-OTP after it has been configured as OTP.
2. There are no flash memory blocks mapped to the OTPEN3 DCF client.

8 Reset and Boot

8.1 Introduction

This chapter describes the reset and boot phase, from the time a power on or reset is applied, till the completion of the Boot Assist Flash (BAF) code.

After reset, Core_2 is woken-up, HSM may be woken-up (refer to details in *Chapter 9: Device Configuration Format (DCF) Records*).

The following memory elements are involved in the boot-up process:

- UTEST flash memory
- TEST flash memory
- Boot Assist Flash (BAF)

8.1.1 TEST flash memory block

The TEST flash memory block contains Device Configuration Format (DCF) records used to hold trim values and other variables, as well as general device configuration information.

The trim values are for:

- Adjusting low-voltage and high-voltage detect circuit trip points
- Temperature sensor adjustments
- Power-on reset voltage trip point
- Analog-to-digital adjustments
- Internal RC oscillator (IRCOSC) trim values
- Power management configuration, for the devices supporting different regulation schemes

Note: The DCF records are written by the device manufacturer and programmed into TEST flash memory during production testing. Further programming of the TEST flash is disabled at the end of the factory test cycle.

8.1.2 UTEST flash memory block

The UTEST flash memory block also contains DCF records. Some UTEST DCF records are written by the factory and programmed during production testing. Others are written by the end user and programmed at the same time application code is programmed into the flash memory. UTEST DCF records are used to set up various control and configuration registers, including the Self-Test Control Unit (STCU2) and default memory configuration.

8.1.3 Boot Assist Flash

The Boot Assist Flash (BAF) contains factory code to facilitate the device boot-up procedure.

Refer to *Chapter 52: Boot Assist Flash (BAF)* for further details on this procedure.

8.2 Modules used in reset sequence

The modules involved in the SPC584Bx reset sequence are:

- Power Management Controller (PMC)
- Reset Generation Module (MC_RGM)
- Mode Entry Module (MC_ME)
- System Status and Configuration Module (SSCM)
- Self-Test Control Unit (STCU2)

8.2.1 Power Management Controller

The Power Management Controller (PMC) controls and monitors:

- Its own supply voltage
- The supply voltages to all the high- and low-voltage detect circuits
- The trip points for all the high- and low-voltage detect circuits
- The power supplies and reference voltages to the Analog-to-Digital Converter
- The major power supplies to the SPC584Bx

8.2.2 Reset Generation Module

The Reset Generation Module (MC_RGM) is a complex state machine that begins sequencing the SPC584Bx through the initial steps of the reset process. The MC_RGM does not execute program code, it is a state machine that centralizes the different reset sources and manages the reset sequence. Reset sources are organized into two categories: destructive and functional.

Refer to *Figure 31* for more information on the MC_RGM reset sequence.

8.2.2.1 Destructive resets

A destructive reset source is related to a critical error or dysfunction, usually caused by a hardware malfunction. When a destructive reset event occurs, software recovery is not possible and the contents of memory are assumed unknown. A full device reset sequence starting from PHASE0 is therefore applied to the device, ensuring a safe startup state for both digital and analog modules.

Examples of destructive resets are:

- Power-on reset
- Low voltage detection
- Reset escalation (when too many functional resets occur simultaneously)

8.2.2.2 Functional resets

A functional reset source is related to a less critical error or dysfunction usually not associated with hardware malfunction. When a functional reset event occurs, a partial reset sequence is applied to the device starting with PHASE1[FUNC]: most digital modules are reset normally and the state of analog modules, specific digital modules (for example, debug and flash memory modules) and system memory content is preserved.

Examples of functional resets are:

- External reset
- Machine check
- Software reset from mode entry
- Boundary scan instructions

8.2.3 Mode Entry module

The Mode Entry module (MC_ME) is responsible for configuring the execution mode, including the delivery of reset vectors to all the SPC584Bx cores.

8.2.4 System Status and Configuration Module

During the reset phase, the SSCM reads the DCF records in the TEST and UTEST flash memory areas in order to distribute within the device the pre-assigned configuration.

The DCF records are primarily for setting up the memory, configuring the Self-Test Control Unit (STCU2), and providing initial device configuration values.

The SSCM continues with the reset or boot-up sequence by locating boot vectors for the boot core and, if enabled for the HSM CPU. The start addresses are written into the Mode Entry Module (MC_ME) registers, which, in turn, will pass them to the proper CPU at the end of the reset phase.

8.2.5 Self-Test Control Unit

The Self-Test Control Unit (STCU2) is a self-contained module that runs a Memory Built-In Self-Test (MBIST). The DCF record can be used to select which individual tests are run for MBIST and disable tests for modules and memory elements that are not going to be used in user applications, thus shortening device boot-up time.

8.3 Reset sequence

The power-up reset sequence always begins with the application of power and follows different sequences depending on the condition of the SPC584Bx device and whether various modes are enabled from settings in the DCF records. For instance, the SPC584Bx device enters Serial Boot mode (the Serial Boot Loader receives startup code and begins program execution) if a valid boot header file is not found (conditioned by the Life Cycle value).

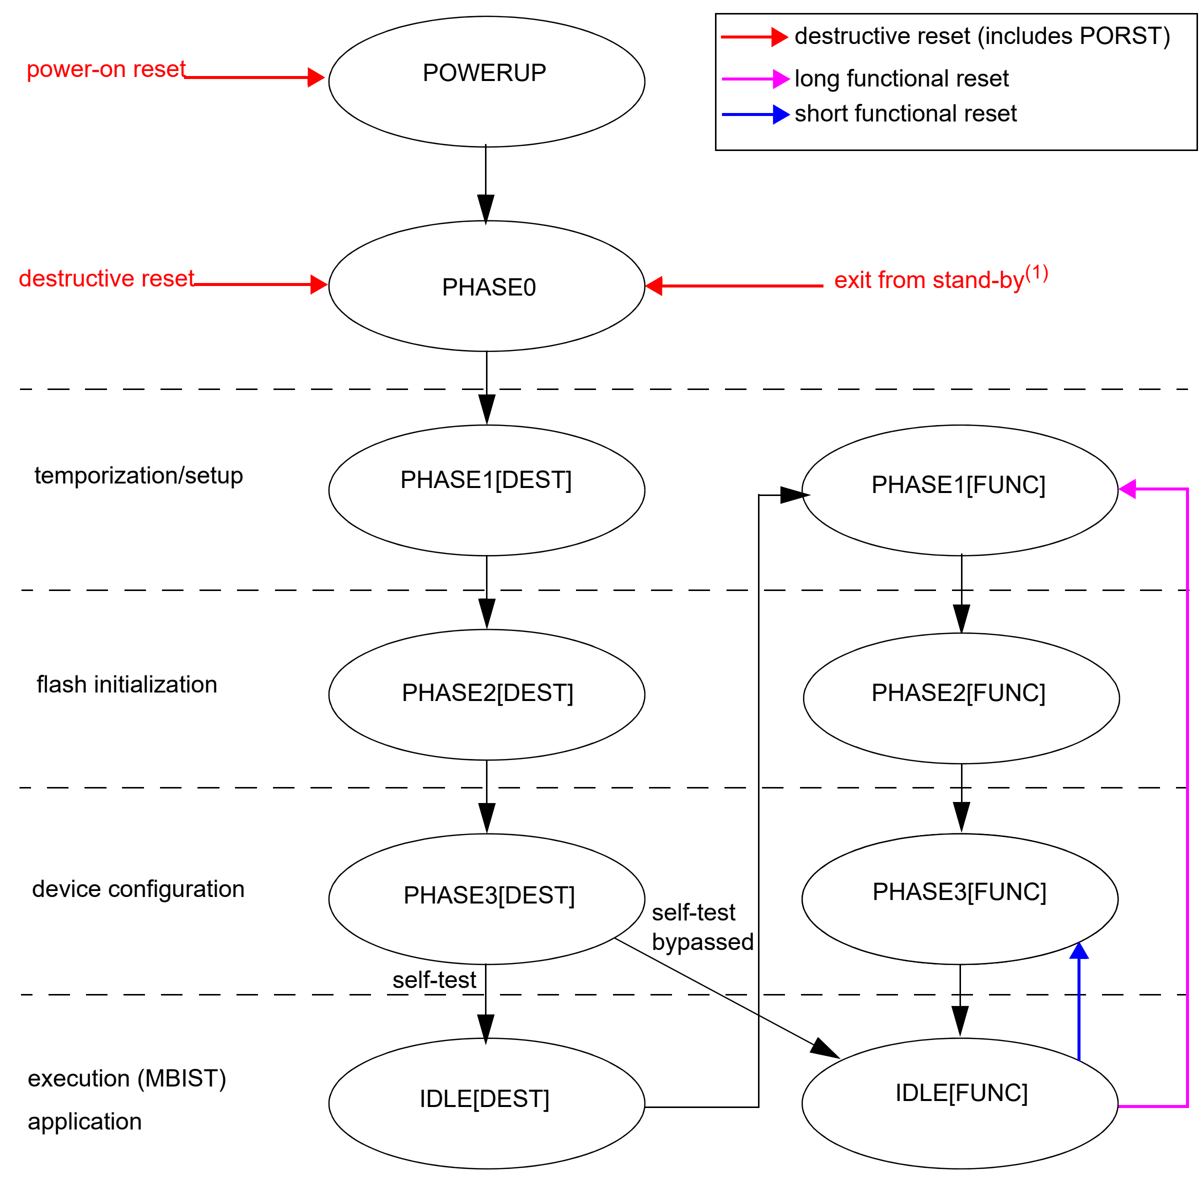
8.3.1 Power-on and the Reset Generation Module

When power is applied to the SPC584Bx, the Reset Generation Module (MC_RGM) advances the device through a series of steps shown in *Figure 31*.

The Reset Generation Module (MC_RGM) starts the System Status and Control Module (SSCM), which continues the boot-up process after the MC_RGM enters the IDLE state.

The STCU is reset on any power-on, destructive reset.

Figure 31. Reset Generation Module Reset Sequence



1. No self-tests are executed.

								Short functional reset	
						functional reset			
	destructive reset								

1. RESET only during POR.
2. Depending on flash configuration.
3. FCCU remains ON during functional reset; it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST].
4. The STCU remains idle during functional reset; it is instead reset on long external reset.
5. Can be triggered by SW. Please refer to *Chapter 76: Self-Test Control Unit (STCU2).*
6. MEMU is reset whenever STCU is reset.

8.3.2 Power-up phase: power stabilization

When a power-on reset event occurs (initial application of power), the reset generation module (MC_RGM) causes the device to enter the power-up phase of the reset sequence (refer to *Figure 31*). The only method to enter the power-up phase is from a power-on reset event.

The device remains in the power-up phase until the Power Management Controller module (PMC) determines that all power supplies are in their respective operational ranges.

The supplies for initial configuration are:

- VDD_LV: low voltage supply for digital module.
- VDD_HV_FLA: high voltage supply for flash module.
- VDD_LV_FLA: low voltage supply for flash module.
- VDD_HV_IO_MAIN: high voltage supply associated with system pins (PORST, TEST Mode), including power management unit.

Peripheral supplies such as , VDD_HV_IO_ETH or VDD_HV_ADV do not gate the power-up process. The low- and high-voltage detect circuits for these and other power supplies are managed by the PMC, which provides enable and status bits for these voltage detection circuits.

The PMC sends a signal to the Reset Generation Module when power stabilization has been achieved. The Reset Generation Module then advances to the PHASE0 state (refer to *Figure 31*). During the power-up phase, the PMC does the following:

- Drives to a logic ‘0’ all VDs (voltage detectors) signals monitored by the Power Management Control (PMC) module.
- Monitors its own power supply voltage (VDD_HV_PMC) to determine that the applied voltage is within a specified range.
- Monitors the core power supply voltage (VDD_LV_CORE) to determine that the applied voltage is within a specified range.
- Monitors the low- and high-voltage detect circuit power supply voltage to determine that the applied voltage is within a specified range.
- Holds the outputs of the internal low- and high-voltage detect circuits at a ground state until the PMC determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Enables all low- and high-voltage detect circuits once all power supplies are at their functional levels.
- Begins to monitor the various power supplies using the high- and low-voltage detect circuits.
- Provides status information to the Reset Generation Module (MC_RGM) indicating whether or not power is properly applied.

To exit power-up and enter PHASE0:

- All enabled destructive resets must be processed.
- All power supplies must be at their functional voltages.
- The PMC must signal the MC_RGM that all power supplies are at the required levels.

8.3.3 PHASE0 Phase: analog supply initial configuration

This phase is entered:

- On exit from power-up phase.
- On PORST pin falling edge detection except for the initial power-up sequence.
- Immediately from PHASE2[DEST], PHASE3[DEST], IDLE[DEST], PHASE1[FUNC], PHASE2[FUNC], PHASE3[FUNC] or IDLE[FUNC], on the occurrence of a PORST falling edge event other than power-on reset.

During PHASE0:

- All digital modules are reset, including safety, security, and test modules.
- All trimming bits for analog modules are reset.
- Startup of the internal analog modules (IRCOSC, FUSE, Flash memory, and I/Os) begins:
  - PMC determines that proper voltages are applied.
  - I/O pins are ensured correctly configured: outputs are driven to known levels, inputs ignored.

To exit PHASE0 and enter PHASE1[DEST]:

- All enabled destructive resets must be processed.
- Gating PHASE0 must be released.
- All processes initiated in PHASE0 must be completed. This generally includes startup of the internal analog modules: PMC, IRCOSC, and I/Os.

Note: The core voltage must rise above upper threshold to exit PHASE0. This ensures significant hysteresis on low voltage supply avoiding spurious low voltage detection during the power-up process.

8.3.4 PHASE1[DEST] Phase: temporization and monitoring setup

This phase is entered on exit from PHASE0.

During PHASE1[DEST]:

- Initial configuration of the watchdog to monitor the reset sequence
- Temporization for reset signal propagation in case of reset

Test modules are available during PHASE1[DEST], but their functionality is limited by the security module.

All PHASE1[DEST] tasks must be completed before entering PHASE2[DEST].

8.3.5 PHASE2[DEST] Phase: flash initial configuration

This phase is entered on exit from PHASE1[DEST].

During PHASE2[DEST]:

- Reset is released to the flash memory module by the Reset Generation Module.
- The flash memory module starts its initial configuration process.
- The flash memory initialization is performed by a state machine internal to the flash module.
- The SWT starts monitoring flash memory configuration execution so that a reset occurs in the event of configuration failure.

Note: SWT is hardware configured to generate destructive reset in case of flash memory failure during flash boot process. In this case the software can read the cause of the reset by the MC_RGM_DES.F_FIF flag. On boot completion, the watchdog event is converted to generate an FCCU fault only.

All PHASE2[DEST] tasks must be completed before entering PHASE3[DEST].

8.3.6 PHASE3[DEST] Phase: device configuration

This phase is entered on exit from PHASE2[DEST].

During PHASE3[DEST], the System Status and Configuration Module (SSCM) starts by retrieving the Device Configuration Format (DCF) record from the TEST and UTEST flash memory areas, and uses the configuration and initialization information therein to:

- Configure the Self-Test Control Unit (STCU2) and the initial memory map of the device.
- Transfer reset vectors for the various cores to the Mode Entry Module (MC_ME). This information enables tests that the STCU runs and also provides the memory map setup information so that the STCU can test memory.
- Write trim values for analog modules including the Analog-to-Digital Converter, low- and high-voltage detect circuits, and the temperature sensor to their respective registers.

The DCF record programmed into the TEST flash memory area is written by the manufacturer. The portion of the DCF record programmed into the UTEST flash memory is usually written by the customer, although there is a default DCF record programmed into both the TEST and the UTEST flash memory areas during device production testing.

The DCF record also provides configuration information for the following:

- Trimming of the analog modules (for example, voltage regulator, voltage detectors, I/Os, and oscillator)
  - Trim values are in DCF records in the TEST flash memory area
  - Trim values are determined during production test and programmed into the TEST flash memory area
  - Security configuration
- Application configuration bits:
  - Watchdog configuration
  - Safety execution directives (self-test, MBIST)
  - Boot Assist Flash options
  - Oscillator startup during reset sequence configuration

To exit PHASE3[DEST]: All processes that need to be completed in PHASE3[DEST] must be finished.

This phase depends on actual trim values, especially those used for safety execution directives. This device configuration is maintained until the next internal power-on reset. Each time a destructive reset event occurs, the SSCM takes values from the DCF record and writes them to the applicable registers.

During this phase, the internal STCU watchdog is started and is only cleared after completion of STCU configuration.

If self-test execution is the configuration information from the DCF record requests, the device moves to IDLE[DEST] and the STCU2 begins self-test. At the end of the test, the

STCU2 asserts a functional interrupt causing the Reset Generation Module to move to PHASE1[FUNC]. If self-test execution is not requested, the device moves directly to IDLE[FUNC]. The Reset Generation Module determines whether self-test execution is enabled or not by examining an entry in the DCF record stored in the UTEST flash memory.

Note: When self-test execution is not requested, it is possible to maintain the device in PHASE3[DEST] by forcing the PORST pin low. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.

8.3.7 IDLE[DEST] Phase: self-test execution

This phase is entered upon exit from PHASE3[DEST] if the execution of self-test is enabled.

During the IDLE[DEST] phase:

- Dedicated watchdog is configured to monitor self-test execution completion within expected time. The length of this phase is variable depending on the self-test requirements.
- The Self-Test Control Unit (STCU2) executes all tests specified by the DCF information retrieved in PHASE3[DEST].
- The self-test engine updates the self-test completion flag and triggers an associated functional reset on completion of self-test.

The length of this phase is variable depending on the self-test requirements.

Note: When the SSCM is decoding the Device Configuration field, it sets and clears various flags in STCU registers and memory that can later be examined by the SSCM to determine which self-test directives must be run.

Exiting IDLE[DEST] and moving to PHASE1[FUNC]:

- The IDLE[DEST] phase is automatically exited when the self-test code generates a functional reset on completion.
- The functional reset causes the reset generation module to move to the PHASE1[FUNC] phase.

Note: In the case of unrecoverable fault detected during the execution of the offline BIST, the STCU requests a destructive reset and device re-enters PHASE0[DEST].

In the case of a permanent fault, when the reset escalation is reached, the hardware keeps the device in PHASE0[DEST] until a Power On Reset occurs.

Whereas in the case of a transient fault, the software can read the cause of the reset by reading the MC_RGM_DES.F_SUF flag.

8.3.8 PHASE1[FUNC] Phase: temporization and monitoring setup

This phase is entered either:

- On exit from IDLE[DEST].
- Immediately from PHASE2[FUNC], PHASE3[FUNC], or on IDLE[FUNC] when a non-masked external or functional reset event occurs, providing the source of the reset event has not been configured to trigger a ‘short’ reset sequence.

During PHASE1[FUNC]:

- Initial configuration of the watchdog to monitor reset process.
- Temporization for reset signal propagation in case of reset.

To exit PHASE1[FUNC] and enter PHASE2 [FUNC]:

- All enabled, non-shortened functional resets must be processed.
- All processes started in PHASE1[FUNC] must be completed.
  - Initial configuration of the watchdog to monitor reset process.
  - Temporization for reset signal propagation in case of reset.

During this phase, test modules are available.

8.3.9 PHASE2[FUNC] Phase: flash initial configuration

This phase is entered on exit from PHASE1[FUNC].

During the PHASE2[FUNC] phase:

- The reset signal is released to the flash memory.
- Flash initialization and configuration begins using a state machine that is internal to the flash memory module.
- A watchdog monitors flash initialization to ensure a reset in case of flash memory configuration failure.

The reset state machine exits PHASE2[FUNC] and enters PHASE3[FUNC] on verification that all processes started in PHASE2[FUNC] are completed.

8.3.10 PHASE3[FUNC] Phase: device configuration monitoring

PHASE3[FUNC] is entered:

- On exit from PHASE2[FUNC].
- Immediately from IDLE[FUNC] when an enabled, short functional reset event occurs.

During PHASE3[FUNC], configuration information contained within the UTEST flash memory sector is checked against information extracted during PHASE3[DEST] and written to the Self-Test Control Unit (STCU2). In case of mismatches, a dedicated boot fault is triggered within the FCCU which, if enabled, can cause a system reset. The purpose of PHASE3[FUNC] is to verify that the DCF information transferred to the STCU, MC_ME and other modules, in PHASE3[DEST], was performed correctly and has not been corrupted.

The Reset Generation Module exits PHASE3[FUNC] and enters the IDLE[FUNC] on verification of the following:

- All processes started in PHASE3[FUNC] are completed.
- PORST pin is not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened functional reset event.

After all PHASE3[FUNC] internal actions have been completed, it is possible to maintain the device within PHASE3[FUNC] by forcing the PORST pin low. This can be used for debugging purposes in order to connect through the JTAG port to the internal debugger.

8.3.11 IDLE[FUNC] Phase

This is the Reset Generation Module's final phase of the reset sequence. It is entered either on exit from PHASE3[DEST] (if self-test was not enabled) or at the completion of PHASE3[FUNC]. When the IDLE[FUNC] phase is reached, the MC_RGM releases control of the system to the System Status and Control Module. The SSCM, which started in

PHASE3[FUNC], (or in PHASE3[DEST] in case no self-test was enabled) runs and waits for a signal from the MC_RGM indicating that the MC_RGM is now in the IDLE state. The MC_RGM then waits for new reset events that can trigger a reset sequence. The SSCM continues with the system boot-up sequence.

8.3.12 System start-up

At the start-up, only one processor (from now on called Boot CPU) and, if available and enabled, the Security Module CPU wake up.

8.3.12.1 Boot CPU reset vector

After the reset phase is completed, the Boot CPU starts executing at the value forced onto its reset vector. The reset vector is driven by the ME peripheral, according to the value stored into the CADDR register.

The value of the CADDR register depends on whether the reset is generated as a consequence of a wake-up reset event (restart from Stand-by) or any other event. The Flash status (powered on or off) also concurs to select the reset vector value.

In case the reset is not due to a wake-up event, the CADDR registers for the Boot CPU are written by the SSCM, according to the system startup configuration, which is stored in Flash and read by the SSCM from the Flash during the reset.

In case the reset is due to a wake-up event, the ME reads the CADDR reset vectors from the RGM, which had saved a copy of the CADDR registers in its internal latches, which resides in the low-power domain.

8.3.12.2 Boot CPU start-up

The Boot CPU startup configuration comprises of the following settings:

- BAF configuration DCF. It is used to decide whether the BAF code (stored by the manufacturer in the Flash BAF block) will be skipped or executed. The BAF start address is also set within the same DCF.
- Application boot records (programmed by the customer). It is used to set the customer application entry point after reset or after the BAF execution (if enabled).

The target for this device is to let the customer choose whether either the BAF code shall be started after the reset phase or directly the customer application, using the same sales part number.

The BAF configuration DCF shall be permanently written into the UTest block.

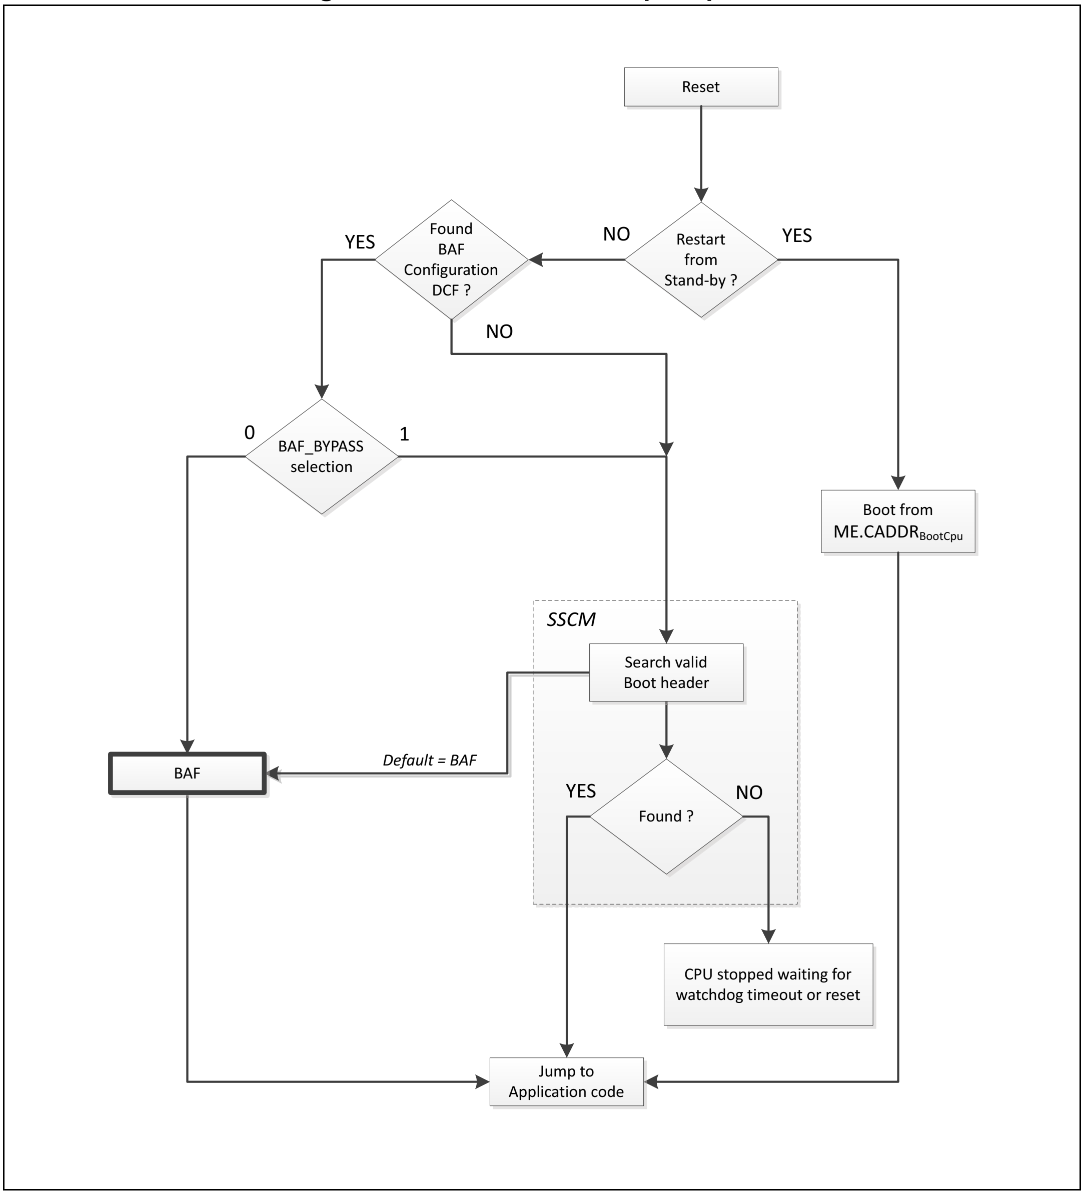
If the BAF configuration DCF is not programmed, the default value for the reset start address depends on the Life Cycle.

If the BAF configuration DCF is programmed, its value determines whether the CPU will start directly from the BAF code (programmed by ST in the Flash BAF block) or at the application entry point defined by the customer.

The application entry point can be retrieved both in HW (by the SSCM or ME, depending on the fact the system restarts from Stand-by or not (refer to *Section 8.3.12.1*) or in SW (by the BAF). In both cases, the application entry point is retrieved by searching for a valid Boot Record, which shall be programmed by the customer in one of the pre-determined Flash memory locations looked at by the SSCM or the BAF code. Next sections provide more details about the Boot Record structure and search operation.

8.3.12.2.1 Start-up flow chart

Figure 32. Boot CPU start-up sequence



8.3.12.2.2 HW boot record search (SSCM search)

If the programmed value of the BAF configuration DCF skips the BAF, then the SSCM module looks for a valid software entry point, called SSCM boot record. The SSCM boot record is organized as shown in the *Table 98*. The “Application start address” value will be passed to the CADDR register of MC_ME, which is used to set the CPU start address (reset vector) after the reset phase.

Table 98. Boot record structure searched by the SSCM

Offset	Field description	
0x4	Application start address	
0x0	SSCM Boot Record Tag (0x5A)	Reserved

The SSCM searches for a valid boot record at the addresses specified in *Table 99*. A boot record is considered valid if it contains the value 0x5A in the "Boot Record Tag" field.

The "Search Order" column specifies which location is searched first.
The SSCM stops the search as soon as a valid boot record is found.

Table 99. SSCM boot record search locations

Search order	Address	Location	SSCM configuration parameter
0 (First)	0x00FC_0000	Flash 16 KB Code Block 1	RCHW_LOC_0
1	0x00FC_4000	Flash 16 KB Code Block 2	RCHW_LOC_1
2	0x00FC_8000	Flash 32 KB Code Block 3	RCHW_LOC_2
3	0x00FD_0000	Flash 32 KB Code Block 4	RCHW_LOC_3
4	0x00FE_0000	Flash 128 KB Code Block 0	RCHW_LOC_4
5	0x0100_0000	Flash 256 KB Code Block 1	RCHW_LOC_5
6 (Last)	0x0040_4000	Flash 16 KB BAF block	RCHW_LOC_6

Depending upon the fact that a valid SSCM boot record is found and the content of the SSCM boot record, three scenarios can happen:

1. If a valid Boot Record is programmed by the customer, then the application is executed after the reset from the specified entry point address.
2. If no valid Boot Record is programmed by the customer, then the default BAF Boot Record is retrieved and the BAF code is executed after the reset.
3. If no valid Boot Record is found, then the BAR code is executed after the reset. This situation happens only during ST production stage.

Note: When the device is shipped to the customer, the slot number 6 is programmed with a valid SSCM Boot Record, which points to the BAF code. This is the default start address for the SSCM Boot CPU when no other valid Boot Record are programmed or found. The content of the slot number 6 cannot be changed.

8.3.12.2.3 SW boot record search (BAF search)

The BAF is executed if:

- the BAF configuration DCF does not bypass the BAF code.
- the BAF configuration DCF does bypass the BAF code and no valid Boot Record is programmed by the customer.

The latter case happens because before the unit is delivered to the customer a valid SSCM boot record pointing to the BAF code is programmed at the location number 6. This boot record will point to the BAF entry point. Because the boot record number 6 is the last one being searched by the SSCM, this means that, if no other boot record is programmed, the software will start from the BAF. Notice that the location of the boot record number 6 is placed within the BAF block itself, making it not erasable and not over-programmable (the BAF block is OTP).

When the BAF code is executed after the reset sequence is completed, a valid application Boot Record for the application entry point is searched. The mechanism is the same executed by the SSCM: a set of fixed locations are analyzed and, if a valid boot record is found, then, at the end of the BAF code, the CPU will start executing from the application entry point.

Note that the valid boot record is identified by a different tag: 5Ah for the SSCM; A5H for the BAF. This will make it possible to program the same boot record locations and launch the application directly after the reset or after the BAF code execution. *Table 100* shows the BAF boot record structure.*Table 102* shows the addresses of the location searched by the BAF code. *Figure 33* shows a flow chart of the whole reset sequence, including the BAF search for a valid boot header.

Table 100. Boot record structure searched by the BAF

Offset	Field description	
0x4	Boot CPU (CPU_2) Reset vector	
0x0	BAF Boot Record Tag (0xA5)	CPU enable flags (refer to *Table 101*)

Table 101. CPU enable flags

16-19	20-23	24-27	28	29	30	31
0000	0000	0000	0	0	0	CPU_2

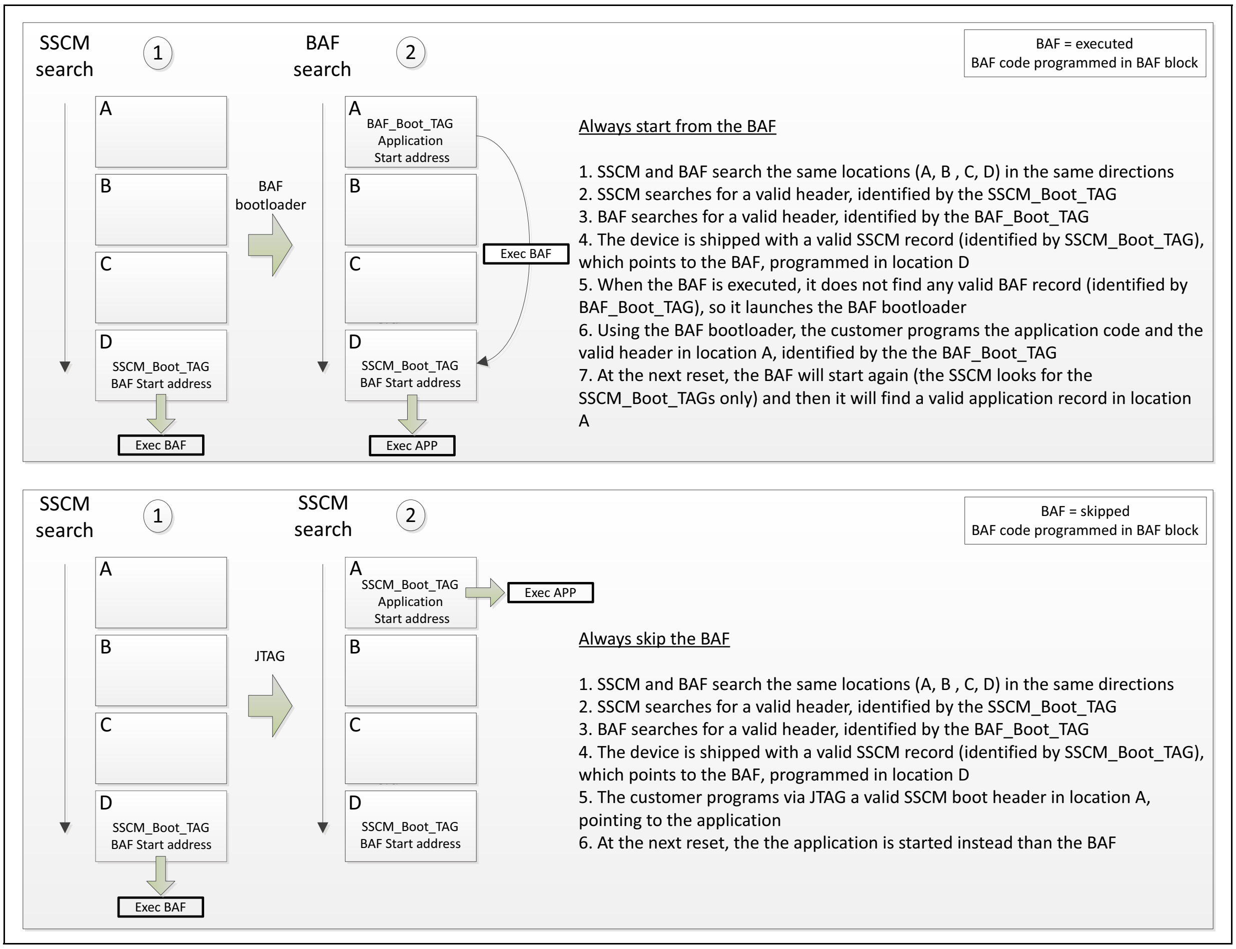
Table 102. BAF boot record search locations

Search order	Address	Location
0 (First)	0x00FC_0000	Flash 16 KB Code Block 1
1	0x00FC_4000	Flash 16 KB Code Block 2
2	0x00FC_8000	Flash 32 KB Code Block 3
3	0x00FD_0000	Flash 32 KB Code Block 4
4	0x00FE_0000	Flash 128 KB Code Block 0
5 (Last)	0x0100_0000	Flash 256 KB Code Block 1

8.3.12.2.4 HW and SW boot header search summary

The following picture summarizes the mechanism adopted to search for a valid boot header with the SCCM or the BAF code, or both.

Figure 33. Valid boot header search



Note: for sake of simplicity, the picture shows only 4 boot record positions.

8.3.12.3 Security Module CPU start-up

The Security Module CPU is also woken up after a reset. The Security Module CPU receives the start address as described in *Section 8.3.12.2.2: HW boot record search (SSCM search)*.

The SSCM looks for a valid boot header record and then direct the Security Module CPU to the application start address specified within the record.

8.3.12.3.1 HSM restart from Stand-by

In case of restart from stand-by, then the application entry point is conditioned by the Flash status (powered on or off) and by two DCF:

1. a DCF (to be placed in UTest under the customer control) determines whether the security module should also restart after Stand-by[c].

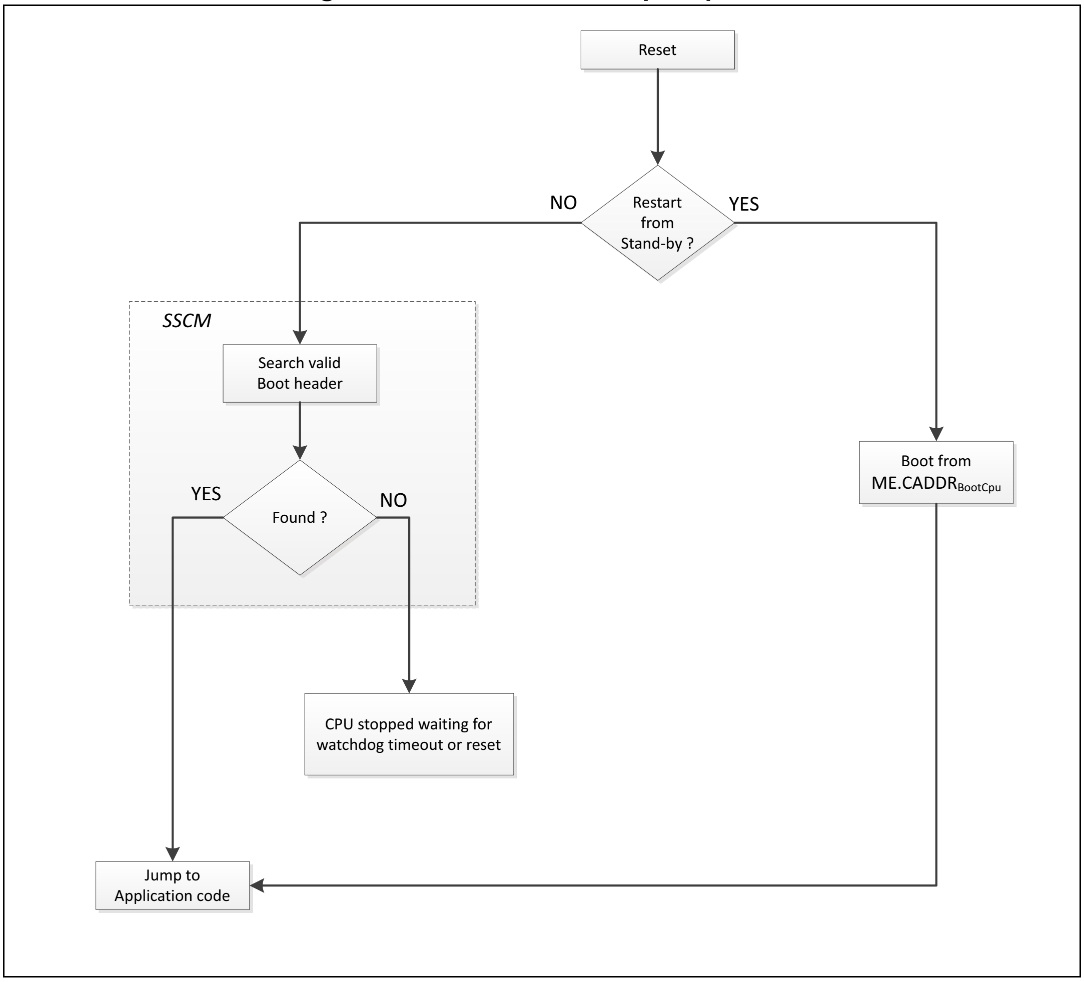
---

c. If the HSM is flagged by this DCF to not restart, then also the HSM Standby RAM can be turned off during Stand-by

2. a DCF (to be placed in UTest under the customer control) is used to inhibit the possibility to let the Flash powered off after a restart from Stand-by. If the restart is from Stand-by, the Flash is powered off, and the DCF client allows this scenario, then the Boot CPU restarts from the address stored into the corresponding ME.CADDR register. Otherwise, the Boot CPU restarts following the same flow as per a non stand-by reset.

8.3.12.3.2 Start-up flow chart

Figure 34. HSM CPU start-up sequence



8.3.12.3.3 Boot vector search

The Security Module start vector is searched by the SSCM in a similar way as described in the chapter for the Boot CPU (HW SSCM search).

The SSCM stops the search as soon as a valid boot record is found within one of these locations.

Table 103. SSCM boot record search locations

Search order	Address	Location
0 (First)	0x0060_C000	Flash 16 KB Code Block0
1	0x0061_0000	Flash 128 KB Code Block0

8.3.12.4 Restart from Stand-by RAM with the Flash powered off

This feature makes it possible to wake-up the micro-controller from the Stand-By mode and let the Boot CPU restart directly from the RAM, while the Flash is powered off.

Note: For security reason, the possibility to keep the Flash powered off in any execution modes shall be gated by a DCF.

In case of restart from stand-by with the Flash powered-off, only the Boot CPU shall be woken up. Other CPUs shall be kept under reset. The restart after Stand-by from RAM is made possible by using the Mode Entry registers:

- ME_CCTL*n* => to set up the processor status (ON/OFF) for each mode.
- ME_CADDR*n* => to set up the processor reset vector.
- ME_<mode>_MC => to set up whether the Flash is ON or OFF.

Note: The registers related to the HSM CPU can be modified by the HSM only.

8.3.12.5 Start-up summary

Table 104. Start-up summary

Start from	Flash status	Security Module CPU (1)	Boot CPU	Other CPUs (2)
Power-on / Destructive reset	ON	It starts from the address provided by SSCM	Depending on the BAF configuration DCF setting, it starts from the BAF or from the address provided by SSCM	They can be woken-up with a ME mode change
Functional reset	ON	It starts from the address provided by SSCM	Depending on the BAF configuration DCF setting, it starts from the BAF or from the address provided by SSCM	They can be woken-up with a ME mode change

1. If existing and enabled.
2. For MCUs with multiple application processors.

8.3.13 Waking-up other CPUs

The process of waking-up the other CPU is handled by writing some registers within the ME module and triggering a Mode Change.

If the BAF code is executed, it reads form the Boot Header record the information regarding which CPU shall be woken up and at which address shall they start from, and then applied a Mode change to enable them.

If the BAF code is not executed, it is responsibility of the user code to properly write the ME module registers and trigger a mode change in order to wake up the other CPUs form the intended addresses.

8.3.14 BAF Bootloader

The BAF code includes a way to upload via CAN or UART some code into the system RAM and execute it. The possibility to execute the Bootloader is conditioned by the Life Cycle status, which regulates what can or cannot be done according to the stage of the micro-controller. If the Bootloader is allowed by the Life Cycle, then it is executed whenever the Boot CPU, executing code in the BAF, does not find a valid boot header file in flash memory. This mode uses a defined protocol to receive a program over a serial port via LINFlexD or CAN. The Boot CPU then jumps to the first instruction of the uploaded program and begins execution.

The BAF bootloader code includes the following steps:

1. Configure LINFlexD or M_CAN module and external pins
2. Wait for START WORD
3. Receive START WORD
4. Receive START ADDRESS
5. Receive DOWNLOAD SIZE
6. Receive CODE
7. Branch to START ADDRESS

Note: There is a software watchdog timer that is started by the BAF code. If a program is not received before the watchdog timer timeout, a reset occurs.

9 Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record is 64 bits long. It consists of a pointer to the location of a register internal to the device and the respective data.

Note: Because the Flash memory programming resolution is 128 bits then 2 DCF records must be written within 1 Flash programming operation.

There are two broad categories of DCF records: TEST DCF Records and UTEST DCF Records.

- TEST DCF records are programmed by the MCU manufacturer. They are used mainly to:
  - Program registers involved in trimming trip points for voltage comparators
  - Adjusting analog to digital voltage supplies
  - Trim oscillator frequencies
  - Enable RAM repair

Note: The TEST DCF Records are programmed into TEST Flash during production and cannot be modified. TEST Flash is not visible to the user.

- UTEST DCF records can be either:
  - Factory programmed during production testing (see “UTEST Flash memory map” table in the Memory Map chapter).
  - User programmed when application code is written into the Flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the factory UTEST DCF records. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) runs during the boot sequence, enable the HSM, assign Flash memory blocks to specific tamper detect regions, assign memory blocks as OTP and assign Flash blocks to be associated with specific password groups.

Note: DCF records are HW processed by SSCM during reset.

Soft DCF records are SW processed by BAF code execution. Please see Section 52.3.5.1: ‘Soft’ DCF clients in *Chapter 52: Boot Assist Flash (BAF).*

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective Flash memories.

9.2 DCF clients

DCF clients are 32-bit hardware registers inside a module that receives and stores the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written and may have special writing constraints like ‘Write Once’ or only allowing bits to be written from ‘1’ to ‘0’ or vice versa.

A list of DCF clients is shown in *Table 107*. (TEST DCF Record Only clients are not shown as these are not accessible by the user).

The DCF Records select the target DCF client via a 30-bit field in the DCF Record consisting of:

- A 15-bit Chip-Select field: each module that includes DCF clients is assigned a Chip Select during chip definition.
- A 15-bit Address field: the address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64 bits) entries programmed in a reserved area of OTP UTEST Flash memory beginning at 0x0040_0300. Take care to write 128 bits which is the ECC granularity (complete with a dummy DCF if needed). Address alignment is also on 128 bits.

Warning: Over Program Protection will generate an unrecoverable ECC error if only one DCF record (64 bits) is written.

Caution: Once a stop record is detected, the SSCM will stop scanning for further records.

The structure of a DCF Record is shown in *Figure 35*.

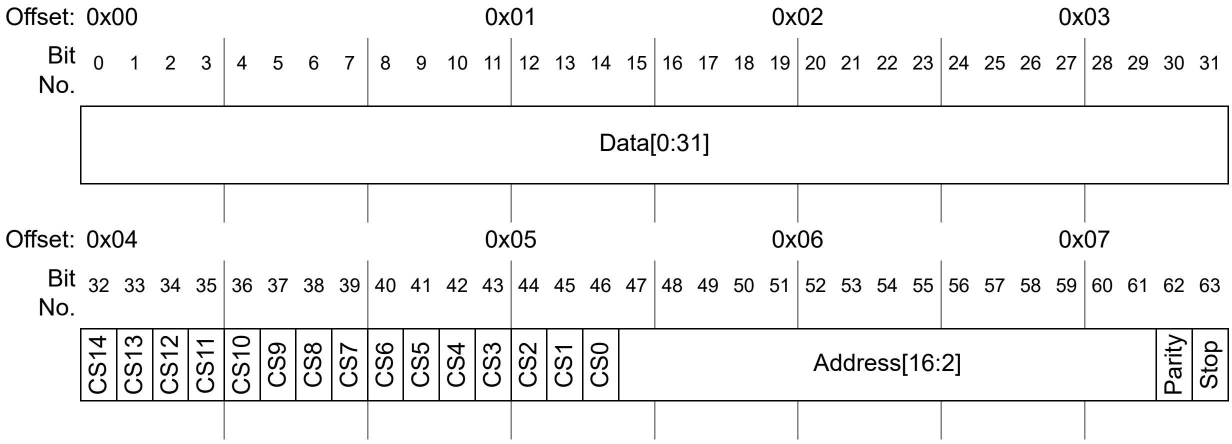


Figure 35. DCF record structure

Table 105. DCF record field description

Field	Description
0:31 Data[0:31]	32 bits of data to be written to the DCF Client.
32:46 CS*n*	Chip Select n. **Note:** Only assert one chip per DCF record to select the target module for the DCF client. All other Chip Selects should be negated. 1 Chip select is asserted. 0 Chip Select is negated.
47:61 Address[16:2]	Address of the DCF client within the selected module. **Note:** Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62 Parity	Parity Bit for the DCF Record. **Note:** This bit is NOT implemented for DCF Clients written from UTEST.
63 Stop	This bit indicates the end of the list of DCF Records. **Note:** The Erased state of Flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list. 1 End of the list. 0 NOT the end of the list.

The following structure must be present:

- The first record must be a start record.
- DCF records containing configuration data must immediately follow the start record with no blank records between an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a bit in the DCF record (stop record).

Each record is 64 bits long. *Figure 36* shows the DCF start record.

Caution: The start record must be placed at the beginning of the DCF area in UTEST Flash memory to indicate that the following data records must be processed.

Figure 36. DCF start record

0x00 0:31	0x04 32:63
0x05AA55AF	0x00000000

During system boot, while the reset signal is asserted, the SSCM reads the device configuration records and writes the data to the appropriate internal module registers. Many operational aspects of the device are therefore already configured when the reset signal is released and normal device operation begins.

Some device configuration records are calculated during production testing and programmed into the TEST Flash memory area. Other DCF records are developed by the user and programmed into the UTEST Flash area.

The stop bit designates the last device configuration record in a set of records. If it is set to ‘1’ within a DCF, then this DCF is the last one being read during the reset phase. A DCF can have the stop bit set to ‘1’ in two modes:

a) The Flash memory location of a DCF is not programmed (that is all the bits are set to ‘1’).

b) A DCF is programmed and the stop bit is set to ‘1’.

When the device is shipped from the factors, some DCF records are already programmed and the Flash memory location after the last DCF is left unprogrammed to make it possible to add additional DCF records.

Due to the Flash programming memory resolution, which is 2-times the length of a DCF record, in case an odd number of DCF shall be written but additional DCF should be programmed later on, then a dummy DCF should be written to pad the last 64 bits of the programming data.

A dummy DCF can be one of the following:

a) The same DCF record written within the 128 bits (that is the DCF record is written two times).

b) A DCF record with an invalid Chips Select (refer to the *Table 107* for a list of used Chip Selects).

The padded DCF must have the stop bit set to ‘0’ in order to be able to add new DCF records.

The general format of the stop record is shown in *Figure 37*. Only the stop bit needs to be ‘1’ in order to form a stop record, all other bits are ignored. An unprogrammed location in UTEST Flash is interpreted as a stop record.

Figure 37. DCF stop record

0:31	32:62	63
Reserved	Reserved	1

If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 106*.

Table 106. Series of DCF records in UTEST Flash memory

<table>
<tr><th>ADDR offset</th><th colspan="4">DATA</th></tr>
<tr><td>0x00</td><td colspan="4">0x05AA55AF</td></tr>
<tr><td>0x04</td><td colspan="3">0x00000000</td><td>STOP=0</td></tr>
<tr><td>0x08</td><td colspan="4">WDATA[31:0]</td></tr>
<tr><td>0x0C</td><td>CS[14:0]</td><td>ADDR[16:2]</td><td>PRTY</td><td>STOP=0</td></tr>
<tr><td>0x10</td><td colspan="4">WDATA[31:0]</td></tr>
</table>

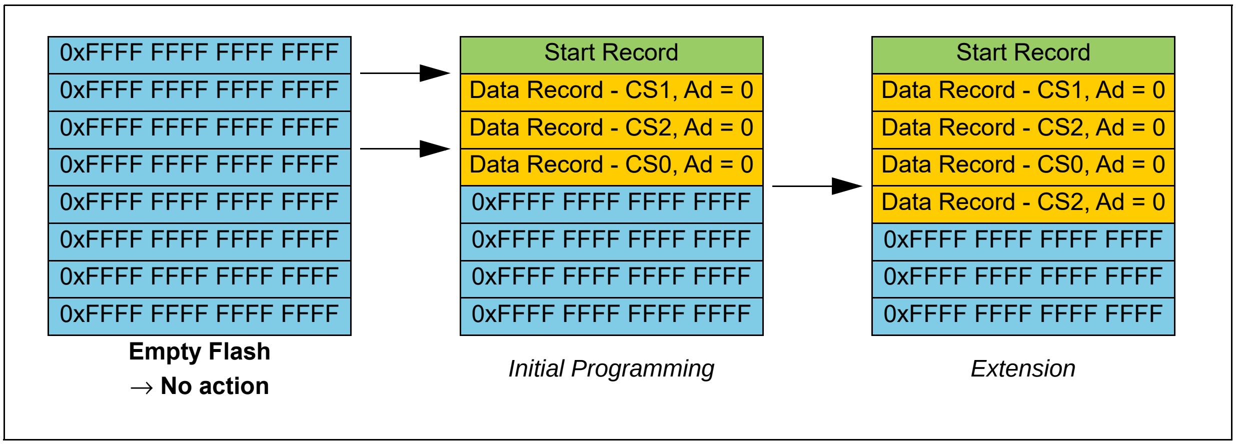
Table 106. Series of DCF records in UTEST Flash memory (continued)

ADDR offset	DATA			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8*n* + 0x0	Reserved			
8*n* + 0x4	Reserved			STOP=1
8(*n*+1) + 0x0	—			
8(*n*+1) + 0x4				

Caution: There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored.

Records programmed in several sessions is shown in *Figure 38*, appending new records to the end of the list each time.

Figure 38. Appending DCF records



It is possible for several DCF Records to write to the same DCF client. The later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST Flash memory area (refer to UTEST Flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory and the user may add USER DCF records from the first unprogrammed location following the factory programmed UTEST DCF records.

When programming UTEST DCF records, the records must start at the first address in the UTEST Flash memory area and be continuous: one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST Flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module.

9.4 DCF client table

A list of DCF clients is shown in *Table 107*. Various attributes of the DCF clients are listed in these tables:

- DCF Chip Select [14:0]: the CS field is a 15-bit field with each bit acting as a module select signal for the internal modules. Only one bit in this field should be set in a DCF record.
- DCF address [16:2]: the 15-bit ADDR field specifies an internal address for a DCF client. These addresses are only used by the SSCM when interpreting DCF records and writing data to specified modules.
- DCF Client Description: the name of the DCF clients.
- Reset value of DCF client: the reset value of DCF client before being written by the SSCM with the associated DCF record.
- IPS read: this column specifies whether or not a DCF client can be read by user software after the release of reset.
- DCF client special strategy: registers are designated as DCF clients if they need to be written with a DCF record. Other features that must be designated for DCF clients include different write strategies listed below. The following list defines the special strategies:
  - None: no special DCF strategy is used.
  - Write Once: a DCF client can only be written once. The DCF client ignores subsequent writes.
  - Triple Voted: DCF clients have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows for ‘bit-flip’ error tolerance without changing the DCF client output data.
  - Write 0 only: a bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a logic 1 is ignored.
  - Write 1 only: a bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a logic 0 is ignored.
- DCF order dependency in Flash memory
  - DCF order dependency in Flash memory: this column details whether or not there are special conditions on the location of a particular DCF record in Flash memory.

10 Power management

10.1 Overview

SPC584Bx microcontrollers include a robust power management infrastructure that enables applications to select among various operational and low-power modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave reset. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Clock Generation Module (MC_CGM)
- Mode Entry Module (MC_ME)
- Power Management Controller (PMC)
- Power Management Controller Digital Interface (PMC_DIG)
- Smart Standby Wake-up Unit (SSWU)

This chapter describes these modules in brief. For complete details, refer to the respective module chapters.

The MC_PCU provides a status register and a submodule, the PMC_dig (Power Management Control Digital Interface), provides an interface to configure and control internal voltages.

The MC_CGM generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement low power modes.

The MC_ME module controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application.

The PMC module contains all the internal voltage regulator and monitors of the device: refer to *Section 10.1.3: Power management controller overview*.

The PMC_DIG module is the digital interface of the PMC, and contains all the registers to control the PMC during reset and power mode changes.

The SSWU Unit provides services to schedule sequence of tasks executed without CPU intervention. This is aimed at reducing further power consumption during standby.

The SPC584Bx has two types of modes, SYSTEM modes and USER modes.

SYSTEM modes:

- SYSTEM modes are entered automatically on system events or on application request.
- The SYSTEM modes are: RESET, SAFE, TEST and DRUN.

USER modes:

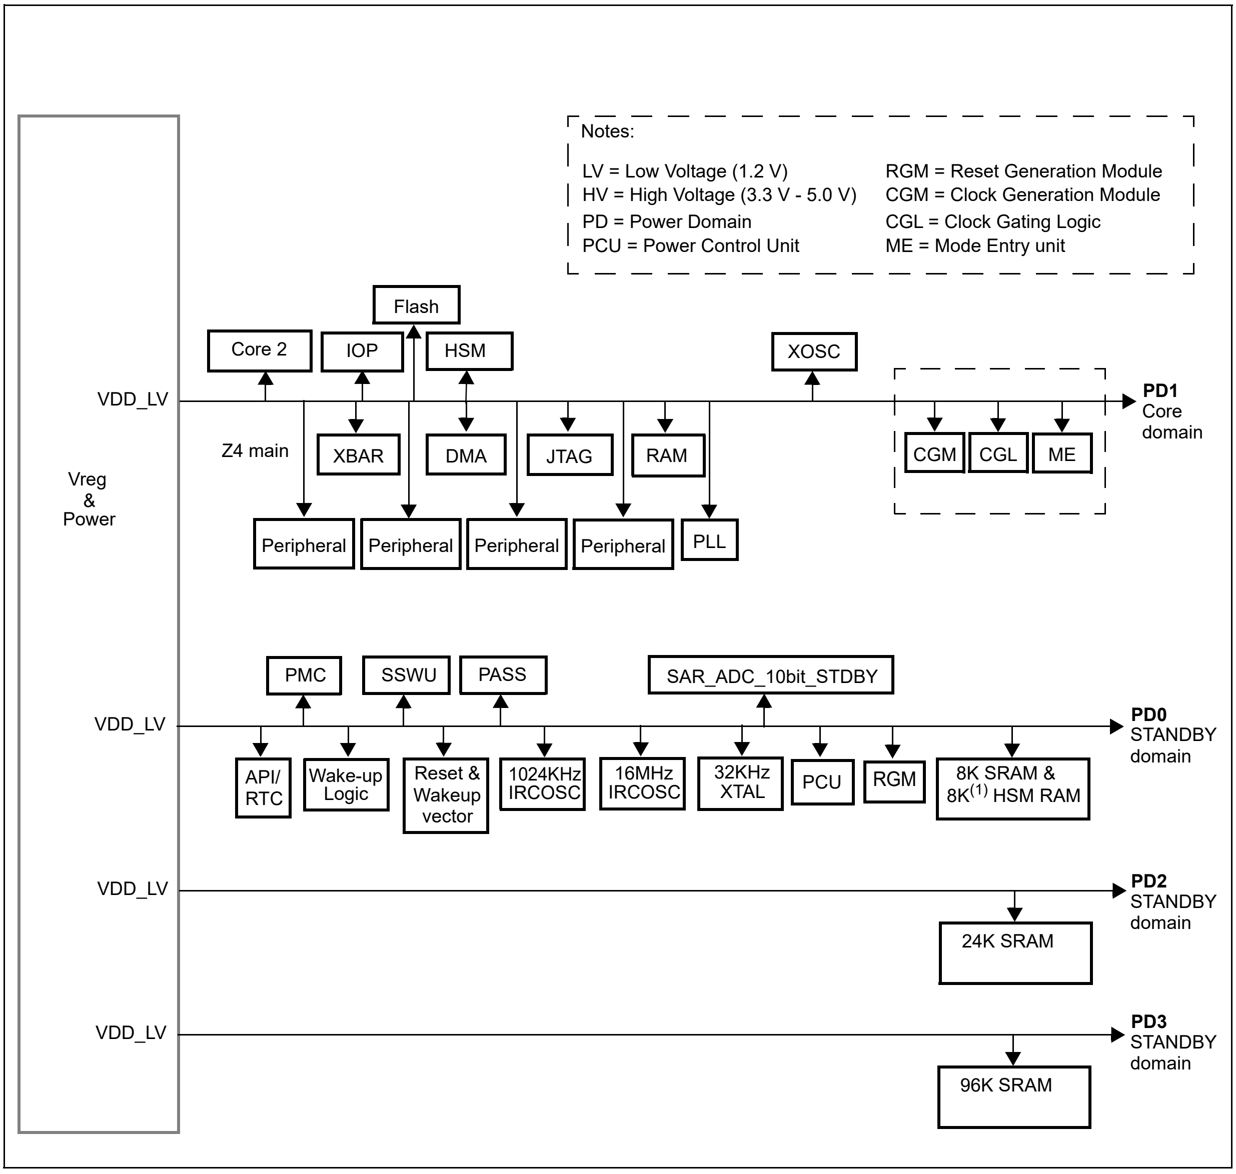
- USER modes control performance and consumption during normal application operation. The modes are organized according to the performance provided
- The USER modes are RUN0-3, HALT, STOP and STANDBY.
- Each mode is entered by writing a dedicated register protected by a key, to avoid unwanted transition

Please refer to the Magic Carpet Mode Entry Module chapter for modes details.

10.1.1 Power management framework

The power management framework supports a variety of configuration options. Refer to *Figure 45* for more details. SPC584Bx implements a unique core voltage power domain. There are no separate functional power domains.

Figure 45. Device power management framework



1. Enabled during stand-by depending on a DCF bit

10.1.2 Power management supply description

Table 114 provides an overview of the PMC supply signals.

Table 114. Device power management controller external signals

Name	Type	Description
VDD_HV_ADR_S	Reference	Voltage reference of ADC SAR module
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_FLA	Supply	Supply pin for Flash
VDD_HV_IO_MAIN	Supply	High voltage power supply for I/O
VDD_HV_IO_ETH	Supply	Ethernet I/O supply
VDD_LV	Supply	Low voltage power supply for the core area generated by internal regulator
VSS	Ground	Ground supply for the device / I/O. This is covering both VSS_LV and VSS_HV in case of exposed pad device.
VSS_HV_ADR_S	Reference	Ground reference of ADC SAR module
VSS_HV_ADV	Supply	Ground supply for the ADC modules

Caution: There are constraints on some input voltages relative to other input voltages. Refer to the device data sheet for detailed information.

10.1.3 Power management controller overview

The power management controller unit (PMC) contains all the device internal voltage regulators and all the voltage monitors. The supported regulators are:

- Internal regulator
  - An internal high power regulator (HPREG) using an external NPN bipolar as the ballast device (Refer to the SPC584Bx datasheet for the bipolar part number).
  - An internal digital regulator (DREG).
- Low-power regulator
  - When the device is in STANDBY, the supply is provided by the internal LPREG and the HPREG/DREG is off, with a reduced maximum driving capability.
- Auxiliary and clamp regulators
  - For fast current transients, auxiliary and clamp regulators are used in both HPREG and DREG modes to improve the load regulation by compensating voltage overshoots and under-shoots.

Please refer to the data sheet for the electrical characteristics of the regulators and the monitors and the list of external components required. The list and functionality of the monitors are described further in this chapter.

Figure 46 describes the top level block diagram of power management unit.

Figure 46. Power management controller block diagram overview

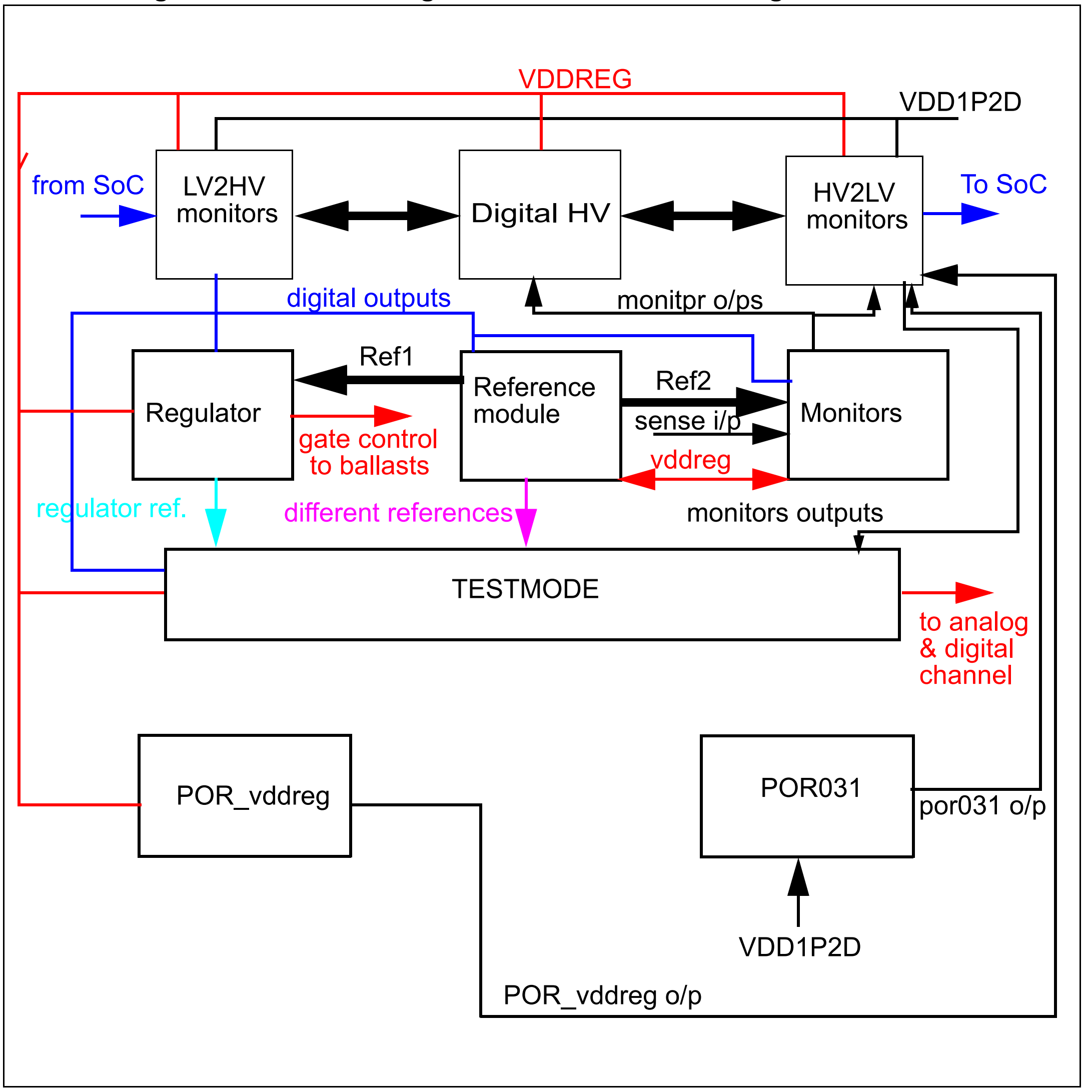


Figure 47. Voltage Monitor Coverage(1)(2)

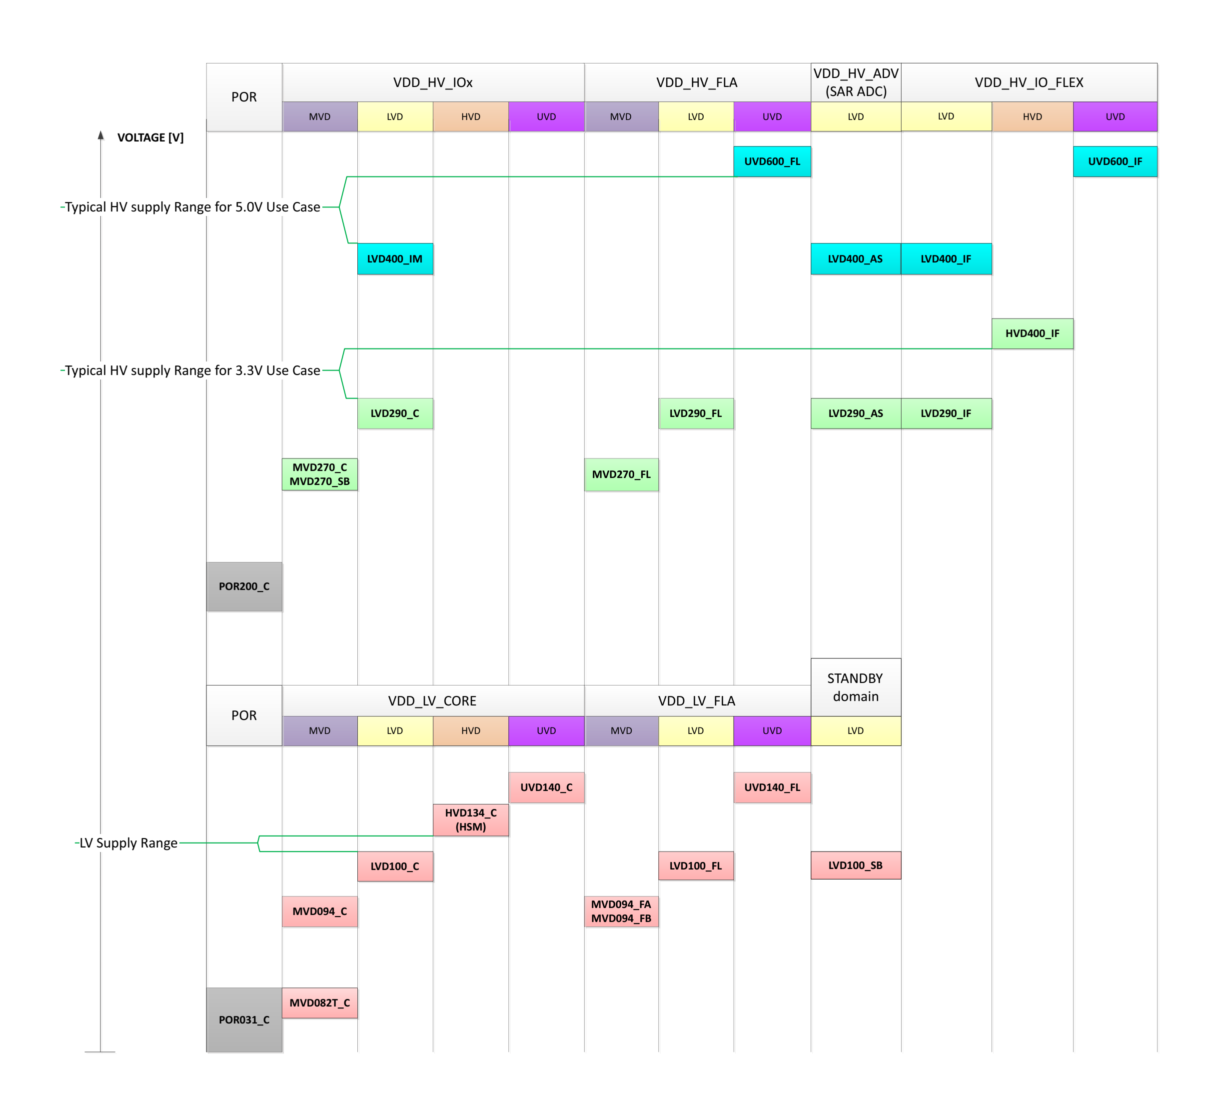


1. Refer to *Table 115* for VDs descriptions
2. Voltage levels for all VDs are given in the data sheet

VDD_HV_IO is redundant, ensuring that single pin failure does not prevent device from functioning correctly. Full specification may not be guaranteed.

VDD_LV is redundant, ensuring that single pin failure does not prevent the device from functioning correctly.

10.1.3.1 1.2 V safety/spike regulator specification

SPC584Bx implements a 1.2 V safety/spike regulator. This regulator can be used to handle fast application current variation that cannot be fully handled by an external regulator.

10.2 Low power mode support

The SPC584Bx microcontroller supports low power modes.

Dedicated logic prevents uncontrolled activation of low-power mode. This is implemented using protected sequence from ME.

Inadvertent entry into low power mode is prevented by triple voting of the control flops, both SW readable and otherwise.

10.2.1 Low power mode (HALT/STOP/STANDBY)

Low power mode may be used to control the ECU during the IDLE phase, as in a partial networking system or when the key has been turned off and periodic tasks, like contact monitoring, must be maintained.

Note: STANDBY mode behaves very differently from HALT/STOP modes. For more details, refer to Section 55.4.4.1: STANDBY Mode transition and Section 56.4.2.8: STANDBY0 Mode.

The device implements the equivalent of an idle or power-down mode through STANDBY, STOP and HALT mode configuration.

The entry into a low power mode is requested by the application code while the exit is triggered by a hardware event (internal, for instance RTC/API, or external, for instance Wake-up signal) or by the SSWU which detected a wake-up condition.

A combination of mode control and clock control (clock source selection but also peripheral clock gating) allows the user to configure the low power modes according to his application needs.

In STOP/HALT mode, peripheral modules can be enabled/disabled using the control described in the ME section. For example, it is possible to keep two CAN modules, eMIOS module and a few requested pins active. For alternate configurations, other modules can be enabled/disabled using the control described in the ME section. External interrupt request channels and external wake-up channels can be made active to wake-up the device in alternative to peripherals interrupts.

All pins associated to the active modules are functional.

Control of the pins is defined by user during run time. A wake-up line is associated to each selectable module.

One of the available modules can be configured to perform the wake-up task. For example, with all but one CAN modules on the chip set completely to power down mode and only one is configured for wake-up message receive (any of the modules can be configured to perform this task).

All CAN modules can be independently configured to receive messages and respond to wake-up messages.

Basically the low power modes allow to control the clock and the state of all peripherals (analog and digital) but also select the mode of the flash module as well as select and enable/disable clock sources like PLL or oscillator.

10.2.1.1 ECU in SLEEP mode versus Contact Monitoring

Most Body ECU are requested to support a SLEEP mode which is activated while the car is stopped and switched off.

The activity to be maintained during the SLEEP mode depends on the application, while a BCM has to ensure the periodic contact monitoring task, a simple Junction Box may just monitor the battery voltage.

So in most cases a Body ECU remains supplied and active in SLEEP mode, therefore SPC584Bx offers a versatile module, called Smart Standby Wake-up Unit, to handle in STANDBY mode, though without CPU intervention, the periodic event monitoring tasks.

More details about those advanced low power modes are described in the SSWU and ME specific chapters.

10.3 Flash power requirements

During start-up operation, the flash module operates from an untrimmed regulator, which has a slightly larger variation than the ideal case. During this start-up phase, the flash can still be read, but it must be read at a slower rate. While operating in this slower read mode, the flash can operate at a much reduced voltage.

Following completion of the start-up phase the regulator is in its trimmed condition, and subsequently the flash module reference current has also been trimmed. Therefore when entering normal operation the flash can be read in the normal access manner and support the full flash specification.

10.4 Device trimming

During the initialization phase the device defaults to a pre-determined state for each of the LVDs, HVDs and the internal regulators. As the flash becomes available the differential read process allows the trimmed data to be available for trimming the internal LVDs, HVDs and regulators.

Please refer to *Section 10.6* for further details.

10.5 Supply monitoring (POR and LVDs)

The function of the POR and LVD circuits is to hold the device in reset regardless of how slow the supply voltage rise is, until the point at which the POR and LVDs are released.

The POR and LVD circuits function correctly even if the input voltage is non monotonic.

10.5.1 Power-on reset (POR)

The PMC implements two internal power-on reset circuits:

- POR031_C monitors the voltage on the 1.2 V input supply. It is monitoring the VDD_LV_CORE pin. The POR031_C asserts a reset when the input supply is below defined values.
- POR200_C monitors the voltage on the 5.0 V - 3.3 V input supply. It is monitoring the VDD_HV_IO_MAIN pin. The POR trip point is high enough to make sure all the LVD circuits are functional.

Refer to *Chapter 8: Reset and Boot* for PORST/ESR0 pin functionality.

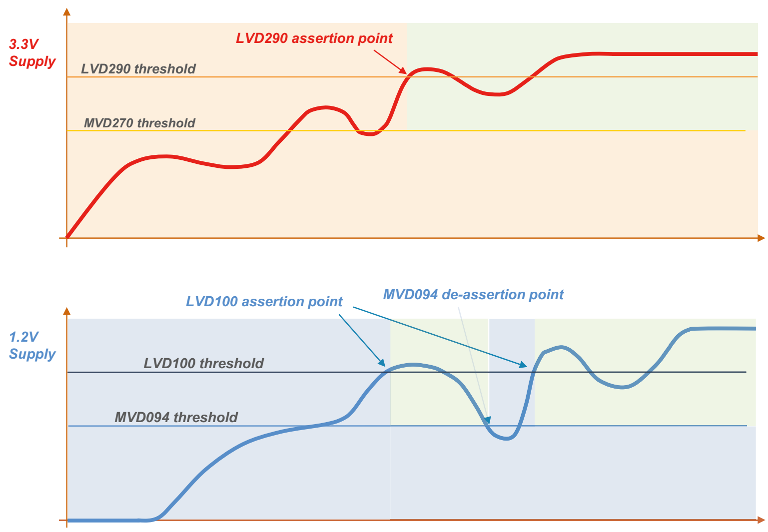
10.5.2 Behavior of device LVD / HVD

Although there is an option to disable the LVD and HVD following reset (refer to *Section 10.5.3*), they are capable of being used in a ‘monitor’ only mode and also capable of generating a safe / interrupt event. *Figure 48* illustrates the behavior of these internal LVD /

HVD circuits during the power on phase, through device initialization and subsequently in ‘normal’ run / operating mode.

The LVDs/HVDs can also be configured after device initialization preventing reset to happen when supply crosses the LVD threshold, effectively providing a higher voltage operating range. It is the responsibility of the application to ensure that the device remains in the functional range.

Figure 48. Internal LVD and HVD in configuration example during power-up



10.5.3 Voltage detections (MVDs, LVDs, HVDs, UVDs)

The internal LVD circuits, monitor when the voltage on the corresponding supply is below the defined values and either assert a reset or an interrupt. The LVDs also support hysteresis in the falling and rising trip points.

10.5.3.1 LVD and HVD implementation

- All LVDs and HVDs are capable of generating either an RGM and/or FCCU event and/or interrupt event.
- All LVDs and HVD configured for reset generation can cause functional or destructive reset. MC_RGM PHASE0 is not exited until all destructive reset conditions are cleared.
- The appropriate bits in the PMC registers are set by LVD and HVD events. Please refer to Power management controler digital interface chapter (PMC_Dig).
- The LVDs and HVDs control is protected by the register protection scheme. Therefore it is configurable as long as the scheme is followed. Refer to *Chapter 77: Register Protection (REG_PROT)*.
- SPC584Bx implements REE (Reset event enable) DCF records to allow to associate “configurable” LVDs/HVDs to a RESET event. This is a write mechanism managed by SSCM during device initialization. When RESET event is selected through REE DCF record, it cannot be disabled by software programming of PMC REE register. When RESET event is not selected through REE DCF record, LVDs/HVDs trigger event reaction depends on the programming of the PMC REE/RES/IE/FEE registers. Refer to *Chapter 9: Device Configuration Format (DCF) Records*.
- When the LVD or the HVD is enabled for destructive reset generation and a subsequent trigger event is detected, the external PORST pin is driven low.

Note: The full list of voltage monitors is provided in Table 115. The functionality and configurability are reported in Figure 49 and Table 116.

Note: MVDs/UVDs are not configurable.

10.6 Power sequence

The following sections describe the power sequence and the relation between the different supplies during power-up and power-down.

The device is considered to be in a power sequence (or POWERUP state) when it is either not supplied or partially supplied. An internal power-on signal is used to identify POWERUP state. This signal is released high on exit of power sequence. The power-on signal is a combination of the LVDs monitoring the following supplies:

- VDD_LV
- VDD_HV_IO
- VDD_HV_FLA

The actual threshold use for each LVD is dependent on the configuration of the device. This is configurable by hardware (flash option bits content) or by software (LVD event configuration through register interface). Once power-on signal has been asserted, device configuration is reset to default power-up configuration.

10.6.1 Power-up sequence

In this section it is assumed that all supplies are low when entering the power-up sequence. Brown-out and power down sequences are managed in specific sections.

10.6.1.1 POWERUP state

At the beginning of power-up, the internal power-on signal remains low due to internal parasitics diodes. As soon as minimum threshold is reached on VDD_LV and VDD_HV supply, the internal power-on signal is forced low until power-up LVDs reach upper not trimmed threshold (refer to SPC584Bx datasheet).

The different supplies can rise independently as long as the constraints described in the SPC584Bx datasheet are met.

During power-up, all functional terminals are maintained into a known state as described in the SPC584Bx datasheet.

10.6.1.2 POWERUP exit

The POWERUP state can be exited when both VDD_LV and VDD_HV are above the internal LVD thresholds.

10.6.1.2.1 VDD_LV conditions and LVD trimming/enabling sequence

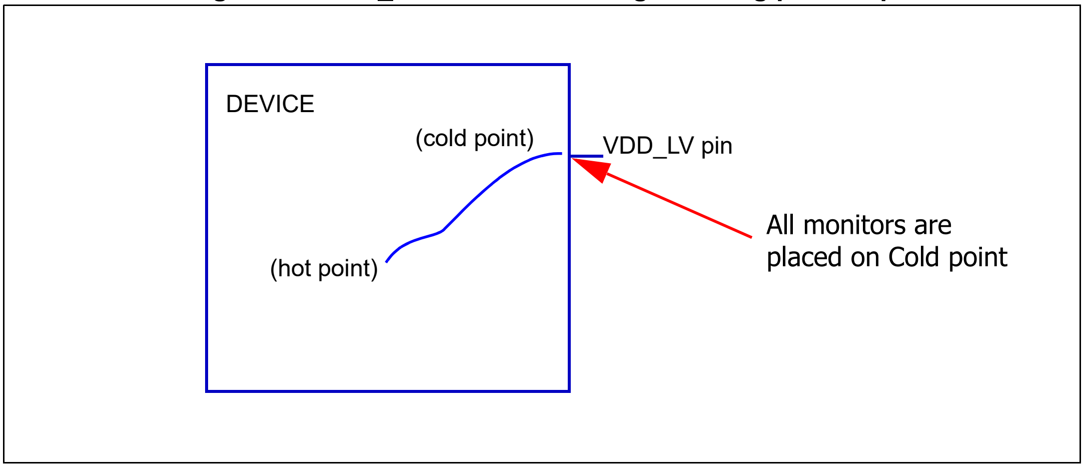
During POWERUP, only the following low voltage VDs are enabled:

- MVD082T_C , MVD094_C , MVD094_FA, MVD094_FB , UVD140_C , UDV140_FL

The VDD_LV conditions to exit POWERUP are the following:

- MVD094_C, MVD094_FA, MVD094_FB upper threshold is crossed

Figure 50. VDD_LV monitored voltages during power-up



After the POWERUP exit conditions (low voltage, high voltage conditions) have been verified, the internal power-on signal is released to all analog modules.

The internal RC oscillator module (IRCOSC) starts initialization and provides clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and LVD100_C is masked. Only MVD094_C remains active.

MVD094_C and LVD100_C share the same reference. This difference provides margin with respect to maximum internal resistive drop and hysteresis addressing external supply.

The device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST] and PHASE3[DEST].

Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST]. Trimming of LVDs/HVDs are stored as internal DCF records. They are read by SSCM at low voltage, using the differential flash read accesses and applied to each LVDs/HVDs module. After analog delay ($t_{LVDTRIM}$) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold, the SSCM proceeds with the reset sequence, eventually running full speed accesses to the flash to read the option bits required to complete device configuration.

The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

When LVD100_C and LVD290_C are masked by the application using the flash user option bits, the device should rely on PORST signal to detect a voltage failure during power-up. The device must wait for PORST to be released high before proceeding with the power-up sequence.This may increase the amount of time necessary to complete the reset sequence.

Figure 51 provides an example of VDD_LV and VDD_HV power-up sequence before and after the monitor trimming.

Figure 52 provides an example of VDD_LV power-up sequence before and after the monitor trimming including UVD and HVD monitors.

Figure 51. Example of VDD_LV power-up sequencing

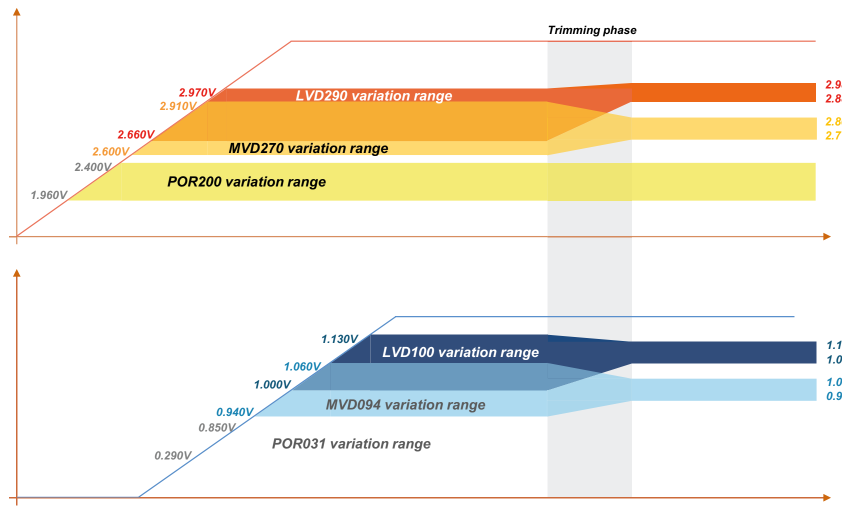


Figure 52. Threshold variation during power-up sequence on VDD_LV supply

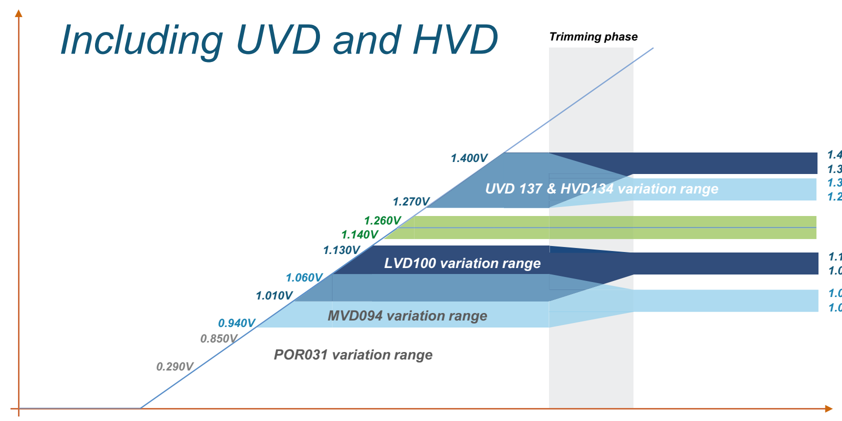


10.6.1.2.2 VDD_HV conditions and LVD trimming/enabling sequence

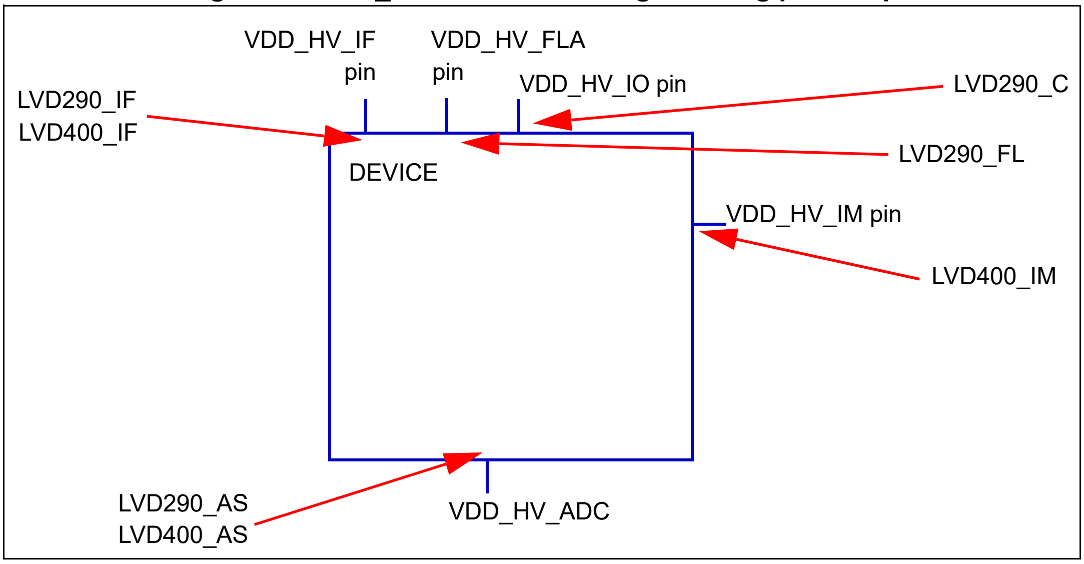
During POWERUP, the following high voltage MVDs are enabled:

- MVD270_C
- MVD270_FL

The VDD_HV conditions to exit POWERUP are the following:

- LVD290_C
- LVD290_FL

Figure 53. VDD_HV monitored voltages during power-up



The IRCOSC module starts initialization and provides the clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles.

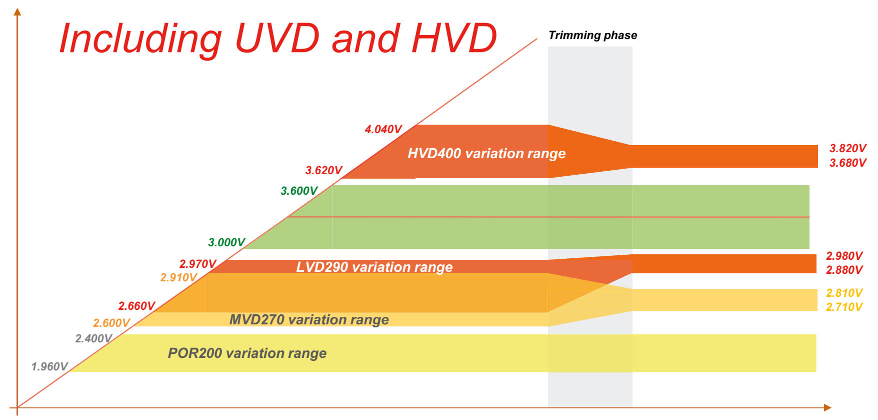
Device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST], PHASE3[DEST].

LVD/HVD modules are trimmed at the beginning of PHASE3[DEST]. Trimming is done by SSCM at low voltage, using the differential flash read accesses. After trimming is completed, SSCM waits for PMC acknowledgement before proceeding with reset sequence.

Configurable LVD/HVD modules are optionally enabled at the end of PHASE3[DEST].

Figure 54 provides the threshold variation of VDD_HV LVDs monitor during power-up sequence from POWERUP before and after trimming.

Figure 54. Threshold variation during power-up sequence on VDD_HV supply



The device needs to fulfill all conditions described in this section to recover.

10.6.2 Power-down sequence

In case LVDs/HVDs are configured to generate destructive reset , either LVD is below threshold or HVD is above threshold, the device enters PHASE0 phase.

Power-down sequence is actually entered as soon as the threshold of MVD094 and MVD270 is crossed. The device enters the POWERUP state. The internal power-on signal is asserted.

On power-on signal assertion, all modules reach their safe state.

Device supplies may then proceed to drop down to ground either through device leakage or external pull-down. During power-down, all supplies should comply with supply constraints.

10.6.3 Brown-out management

During brown-out, the device re-enters the POWERUP phase as soon as the threshold of either MVD094 or MVD270 is crossed. The internal power-on signal is asserted.

Note: The device will correctly start independently from any residual voltage.
At any rate there are corner cases on which the residual voltage above a certain limit can cause the MCU to get stuck indefinitely at the startup during the reset and boot phase. So to have a clean power-on sequence, it is recommended to satisfy the following two constraints at the same time once the device is exposed to brown-out: VDD_HV < 1.5V, VDD_LV < 0.4V.
For more details, refer to “Recommended power-up sequence” section in the Application note, SPC58xx hardware design guideline (AN4880).

Below MVD270 *threshold, the device is under POWERUP state. Above the* MVD270 *threshold, the device is into a RESET state as defined by Voltage monitor or external PORST pin or active state when all have been released.*

On internal power-on signal assertion, all analog modules reach their safe state.

10.6.4 Low voltage requirement during crank

The device can continue operation to the minimum input voltage during crank.

In order to proceed with execution during cranking and prevent device reset, it is important to correctly configure the high voltage LVDs.

During device switch-off the external LVDs monitoring may not be activated quickly enough (external assertion of the PORST pin) and hence the –10% level is crossed before POR is asserted. Malfunction is possible in this case, but reliability is not impacted. In particular the flash is not corrupted.

Internal LVDs that monitor the supply ensure that the flash content is protected.

11 Smart Stand-by Wake-up Unit (SSWU)

11.1 Overview

The Smart Standby Wake-Up Unit (SSWU) is aimed at further reducing the device power consumption by scheduling, on an RTC time basis, a sequence of user-programmable tasks, which are executed in STANDBY Mode without the CPU intervention.

These tasks are programmed in order to allow the following operations in STANDBY:

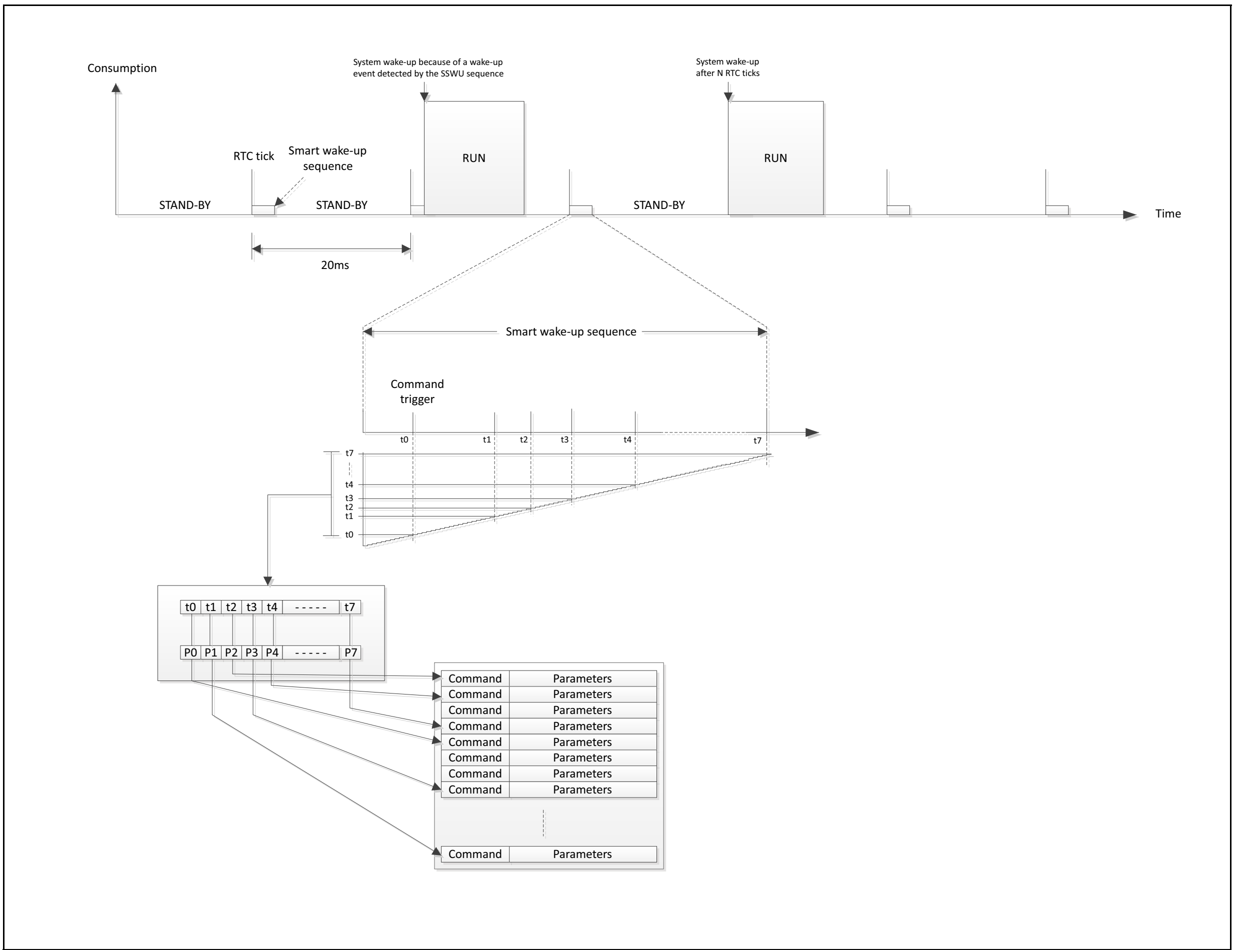
- Control output level
- Analog comparator versus voltage threshold or range
- Digital input state detector: In addition, it is possible to schedule a system wake-up based on a user-defined time interval.

The next sections explain the whole concept in details.

11.2 Functional description

Figure 55 shows the SSWU functionality.

Figure 55. Smart Wake-Up Sequence Functionality



The module is able to maintain the system mostly in stand-by and is eventually woken up based on the acknowledge of predifined wake-up event, which basically can be of two types:

- a time based wake-up event (WKUP1 line event)
- an asynchronous wake-up event (WKUP0 line event) detected during the SSWU sequence, which is periodically started based on the RTC tick (programming API period)

The time based wake-up event type is generated by the API/RTC IP, which can be programmed to generate it after a certain number of timer ticks.
The second asynchronous wake-up event type is generated by the SSWU block itself, as explained in the next sections.

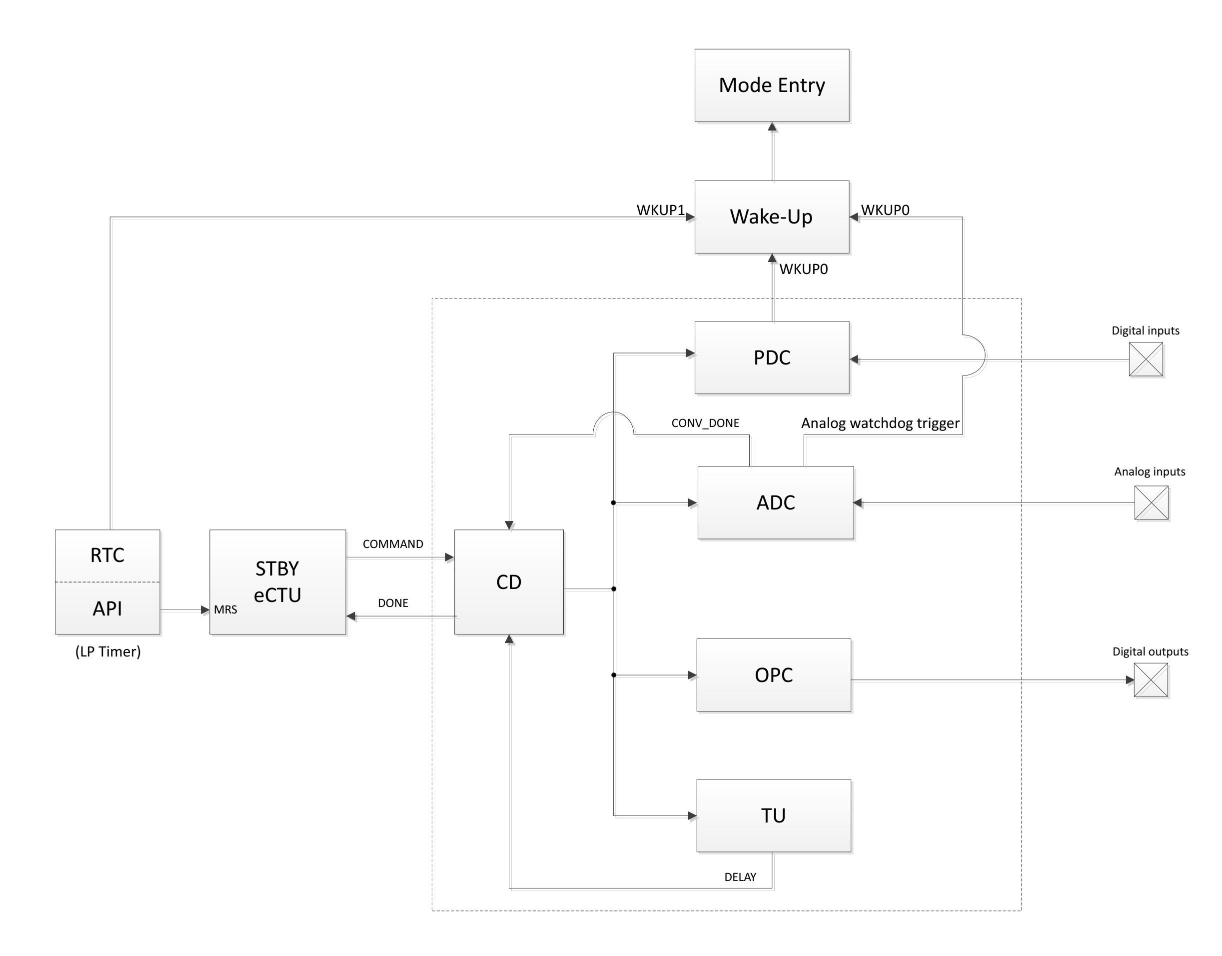
The SSWU sequence is a series of “commands” (plus some command-dependent parameters) generated by the Stand-by eCTU block based on a certain pre-programmed time schedule (t0, t1, etc., in the *Figure 55*). For each scheduled time event, it is possible to assign a command to be executed. As explained later on, it is possible to assign a sub-sequence of commands, which can be displaced with a programmable time delay. Each command is then interpreted by a command decoder, which is dispatching them to the target client.

11.3 Architecture

Once the device is in STANDBY Mode, a minimum set of IPs will be periodically woken-up. This allows a pre-programmed sequence of measurements to run, limiting the power consumption to the minimum requested for a body application.

Figure 56 shows the block diagram of the SSWU architecture.

Figure 56. Smart Wake-up Architecture



Hereafter is a list of the blocks in the picture.

- RTC = Real Time Clock
- STBY eCTU = Stand-by Enhanced Cross Triggering Unit
- CD = Command Decoder
- ADC = Analog Digital Converter (client)
- PDC = Port Digital Comparator (client)
- OPC = Output Pin Control block (client)
- TU = Timer Unit (client)

Hereafter is a brief description of each block, which is explained in details in the following chapters.

The RTC/API timers block is always powered-on in STANDBY and generates a time tick based on the low power clock source (LPRC or OSC32K) selected.

The RTC timer (mapped on the WKUP1 line) allows to periodically exit from STANDBY. The API timer (mapped on the WKUP0 line), instead, drives the starting of SSWU mechanism (refer to *Section 11.4*).

The Stand-by eCTU (Enhanced Cross Triggering Unit) is used to schedule the execution of a set of pre-programmed commands: it is the "engine" of the SSWU sequence.

The CD (Command Decoder) is used to decode the command generated by the Stand-by eCTU and dispatch them to the following client blocks:

- The ADC (Analog Digital Converter) is a dedicated, low-power analog to digital converter, used to generate an API wake-up event (WKUP0) in case the converted value is above or below a certain threshold.
- The OPC (Output Pin Control block) block is used to set the output level of a digital port pin, in order to let the customer open/close some external switches.
- The PDC is used to trigger an API wake-up event (WKUP0) when the level of a pin is a certain value for a specific time.
- The TU is used to generate a programmable delay between different Stand-by eCTU command executed within the same command sequence.

The Wake-up unit collects the wake-up triggers (eventually provided by the ADC or PDC client) and generates a wake-up event (WKUP0) for the Mode Entry block.

The Mode Entry block is then responsible to change the system execution mode (from STANDBY to Run).

In STANDBY mode, only RTC is powered on, while all other blocks are off. At the RTC tick, the hardware switches on the 16 MHz IRCOSC and wakes up the other blocks.

11.4 Clocking

Figure 57 shows the SSWU clocking architecture.

The RTC evolves with the low power clock, which can be selectable between 32 kHz or 128 kHz.

Note: The 1024 kHz clock signal from slow internal RC oscillator (LPRC) is divided by 8 before applied as 128 kHz clock to RTC.

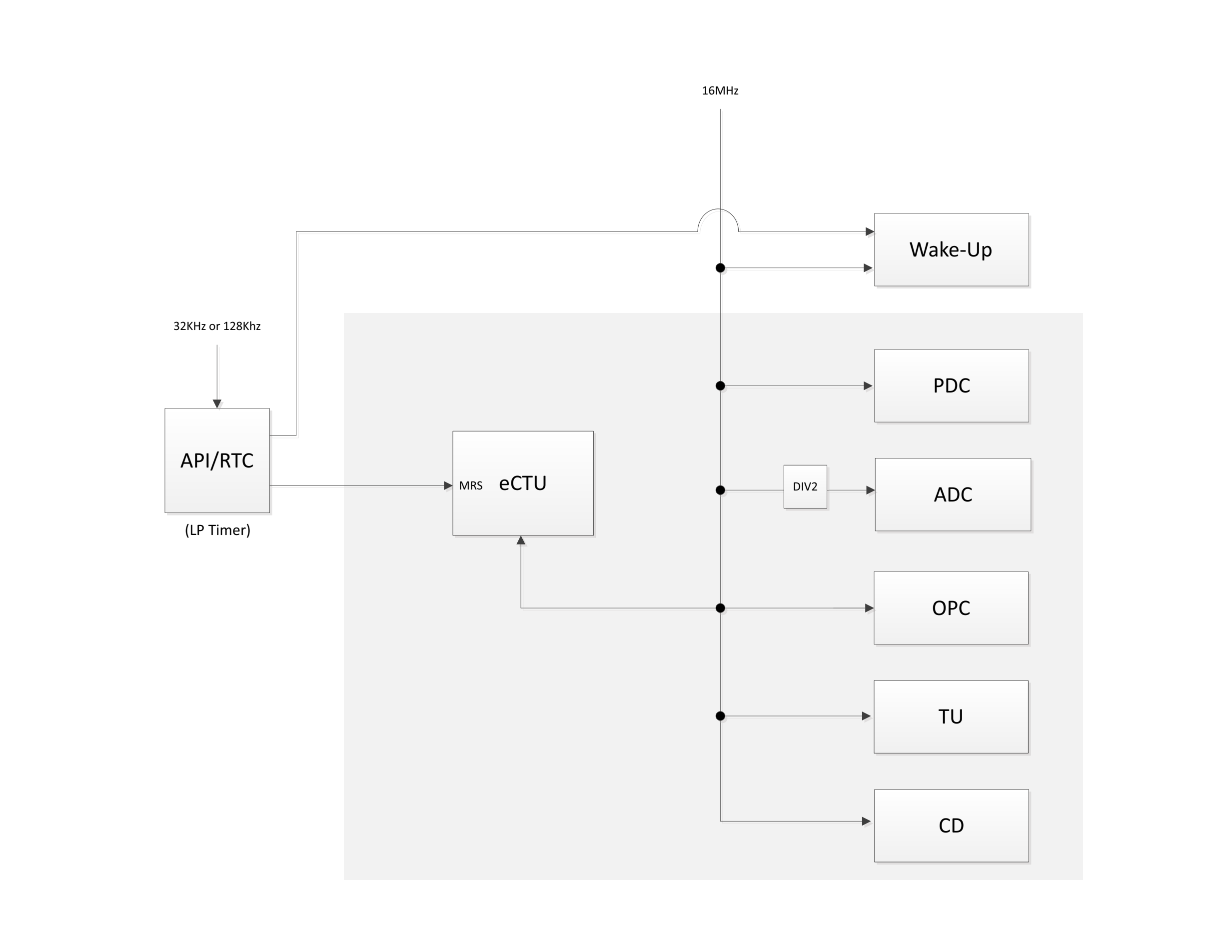
The SSWU IPs evolves with the internal 16 MHz IRCOSC.

A prescaler is embedded in the TU block in order to let the customer program the delay resolution (refer to *Section 11.6.6: TU*).

Note: Even if IRCOSC is configured off in STANDBY through the ME_STANDBY0_MC register, it will be automatically turned-on once SSWU is activated. The IRCOSC will be automatically turned off after SSWU Stop command is executed.

The ADC IP runs at 8MHz (IRCOSC clock divided by 2).

Figure 57. SSWU clock architecture



11.5 Memory map and register descriptions

11.5.1 Memory map

This section provides the memory map of the SSWU. For double buffering and synchronization refer to *Section 11.5.13: Double buffered registers*.

Field	Description
24 CTU_FSM_RESET	CTU state machine reset when written ‘1’. Writing a one has effect on the module, but it always reads as zero. **Note:** It is possible that CTU state machine is waiting for end of SSWU command, and due to any fault, it does not arrive. Therefore, this bit should be used to reset the CTU state machine before each standby entry.
27 CGRE	Clear GRE (1)

Table 134. CTUCR field descriptions (continued)

Field	Description
28 FGRE	Flag GRE [(1)]
30 GRE	General Reload Enable [(1)] 0 disabled 1 enabled
31 TGSISR_RE	TGS Input Selection Register Reload Enable. Is set by the user and reset automatically when its reloaded.

1. Refer to *Section 11.5.13* for details.

11.5.13 Double buffered registers

Some registers of the SSWU are double buffered. When MRS is set, the data programmed in a register on register interface clock domain is transferred to the SSWU kernel clock domain. To avoid error condition due to a MRS signal that arrives when a write operation is not fully completed, the following 2 bits are used:

1. GRE (General Reload Enable)
2. FGRE (Flag General Reload disable)

The reload of all double-buffered registers is enabled by setting the GRE bit in the CTU Control Register in order to guarantee the consistency of all double-buffered registers. The user must ensure that the trigger command list is updated before MRS occurs. If the update is not performed, the previous values of all double-buffered registers remain active.

All the double-buffered registers use the same bit (GRE) to enable the reload when the MRS occurs. This bit is used to signal that the user has updated the registers and so a reload can be performed without any problem. The MRS bit is R/S (Read/Set). If the bit is 1 the reload can be performed, while if this bit is 0, the reload is not performed. A correct reload resets this bit. It is also possible to reset this bit by software setting CGRE (Clear GRE) bit. This bit can be reset in a software way but, anyway, it is reset when GRE bit is at zero.

In order to verify if a reload error occurs, FGRE (Flag GRE bit in the CTU Control Register) bit is used. When one of the double-buffered registers is written, FGRE flag is set to 1 and it is reset by a correct reload. When the MRS occurs while FGRE = 1 and GRE = 1, a correct reload is performed (because all intended registers have been updated before the MRS occurs).

- If FGRE = 1 and GRE = 0, a reload is not performed, the error flag (MRS_RE) is set (in this case at least one register was written but the update has not been ended before the MRS occurrence).
- If FGRE = 0, it is not necessary to perform a reload because all the double-buffered registers are unchanged.
- If GRE = 1 with FGRE = 0, a MRS_RE is generated on the next master reload.

TGSISR_RE bit is used to synchronize TGSISR register. When the user set TGSISR_RE, the value written in the TGSISR register is used.

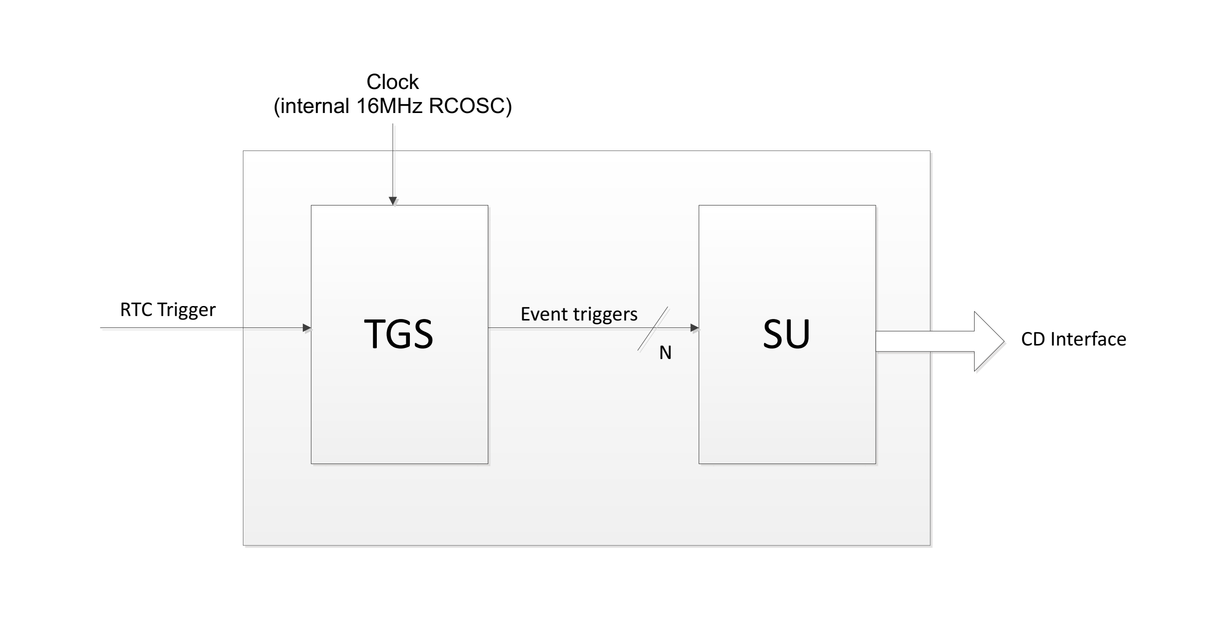
11.6 SSWU module descriptions

11.6.1 Stand-by eCTU

Figure 73 shows the Stand-by eCTU block diagram. Basically it is composed of two blocks:

- TGS (Trigger Generator Sub-unit), which is responsible to generate a set of triggers based on some pre-programmed time schedules
- SU (Scheduler Unit), which receives the trigger and starts the associated command sequence

Figure 73. Stand-by eCTU Block Diagram



The figure shows that the output of the Stand-by eCTU is directed to the CD interface. The CD block of the SSWU decodes the CTU command and dispatches it to the various clients (OPC, PDC, ADC, TU).

11.6.1.1 TGS block

Figure 74 shows the Stand-by eCTU architecture and functionality.

As shown in the figure, the TGS contains a 16-bit counter unit (evolving with the internal slow clock) and a set of comparators (TxCRV). Each comparator determines one time event point (tx in *Figure 55*).

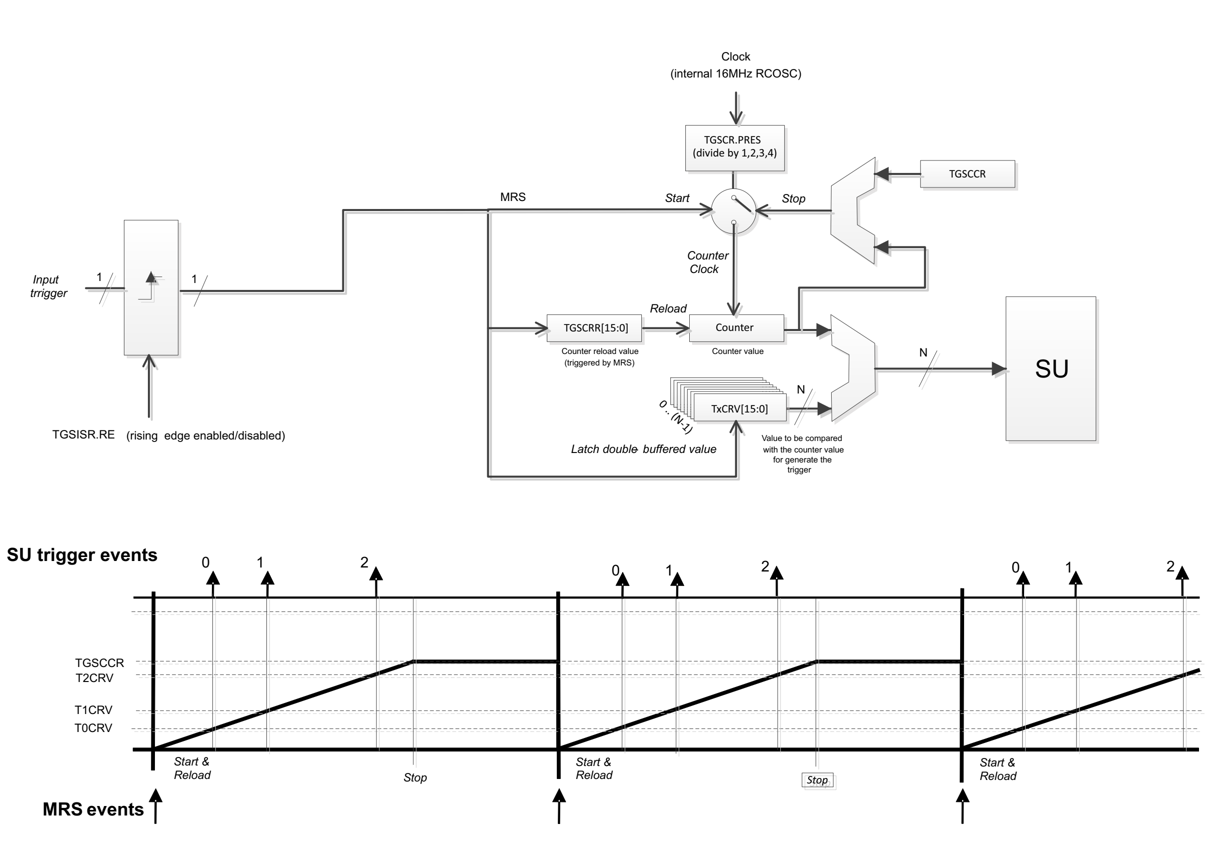
The MSR (Master Reload Signal) is used to reset and start the counter. The reset value is stored in the TGSCRR register. The MRS is generated via HW trigger (RTC tick).

When the counter reaches one of the values programmed in the TxCRV comparators, an internal trigger is generated to the SU block. Note that is it possible to program TGSCCR register so that the counter will be stopped as soon as it reaches a certain value.

The waveform in *Figure 74* shows an example of three SU trigger generations, based on T0CRV, T1CRV, and T2CRV comparators. Note that, the TGS internal counter is started by a MRS event and reloaded with the '0' value. Also the TGSCCR register is used to stop the counter when it reaches the value programmed in this register.

Caution: When the SSWU sequence is generated with several SU triggers, the user must insure the SSWU command is finished before triggering a new one.

Figure 74. TGS Architecture and Functionality (triggered mode)



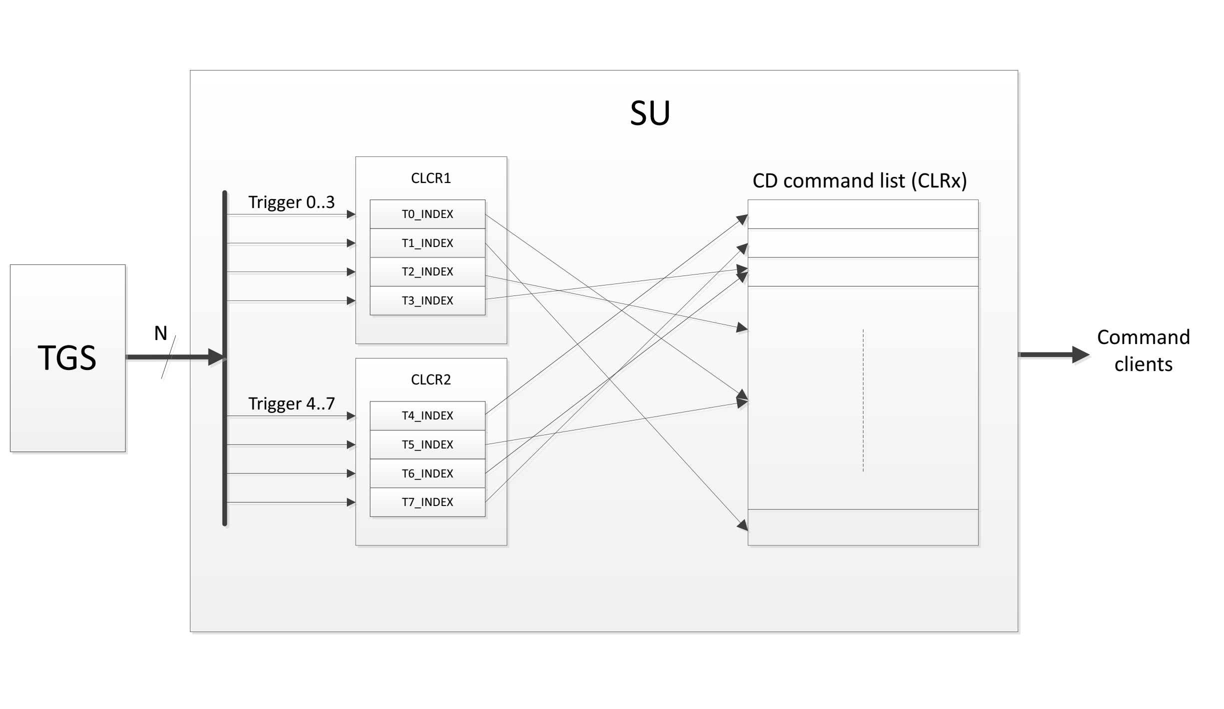
11.6.1.2 SU block

Figure 75 shows the SU block functionality. Its function is to receive the internal SU trigger and activate a sequence of commands, pre-programmed in a command table [d].

In fact, each trigger from the TGS block is associated to a programmable pointer, which determines, within the SU command table, the begin of the sequence of commands.

d. The command table length is 32

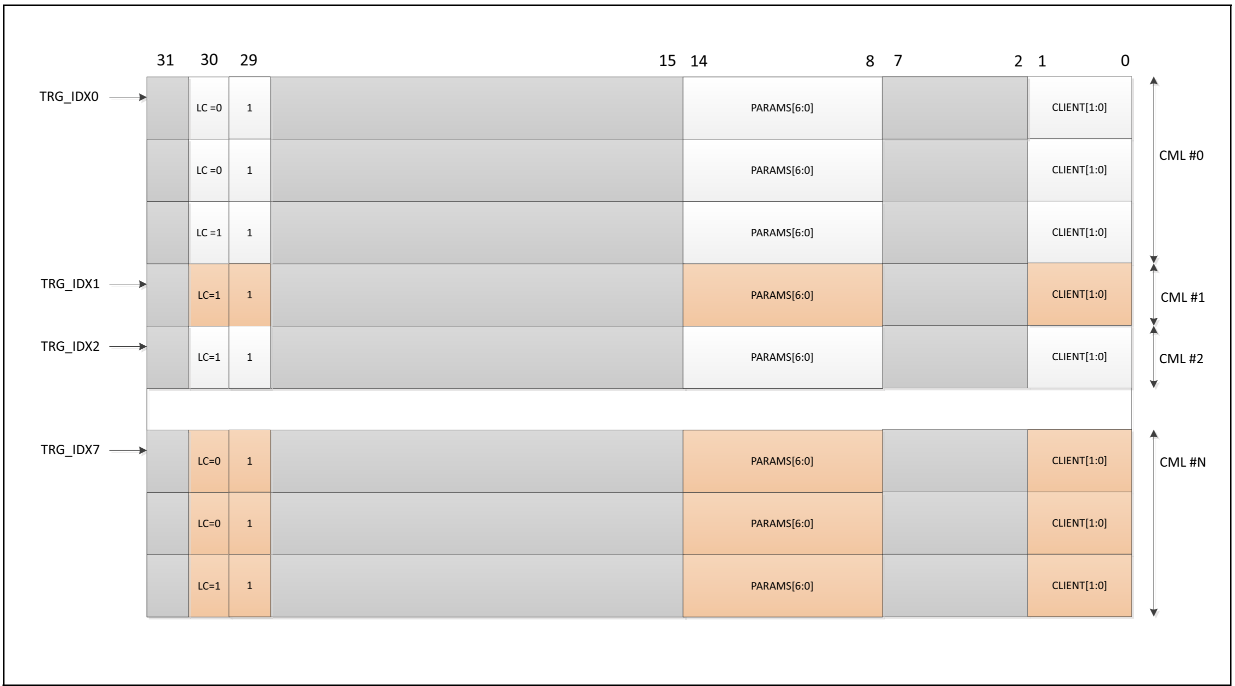
Figure 75. SU Functionality



11.6.1.3 Stand-by eCTU command structure

The command structure is specified in *Figure 76*.

Figure 76. SU Command Structure



Hereafter is a description of the command fields.

- LC (last Command): this flag is used to specify whether the command being executed is the last of the sequence started by a SU trigger. *Figure 76* shows several examples: the command sequence triggered by TRG_IDX0 is composed of 3 commands, while the sequence triggered by TRG_IDX1 is actually one single command.
- EC (bit 29): always set to 1
- PARAMS: specify the command parameters
- CLIENT: specify the client ID

Starting from the first command to be executed, as programmed in the pointer associated to a specific SU trigger, each command is executed after the previous one is completed. The “LC” command flag determines whether the current command is the last one to be executed for the sequence of commands being executed.

11.6.1.4 Stand-by eCTU command sequence summary

As a summary, the command sequence is driven by:

- the TGS sequence of triggers, where each SU trigger is generated on a programmable time-basis,
- the SU command sequence, activated by a SU trigger.

The Stand-by eCTU commands are executed in a row till the one marked as "LC = 1". The Stand-by eCTU executes the next command as soon as it is acknowledged that the previous command was completed. This is represented in *Figure 56* by the DONE feedback signal from the CD block to the Stand-by eCTU block.

The execution time between each command depends on the command itself.

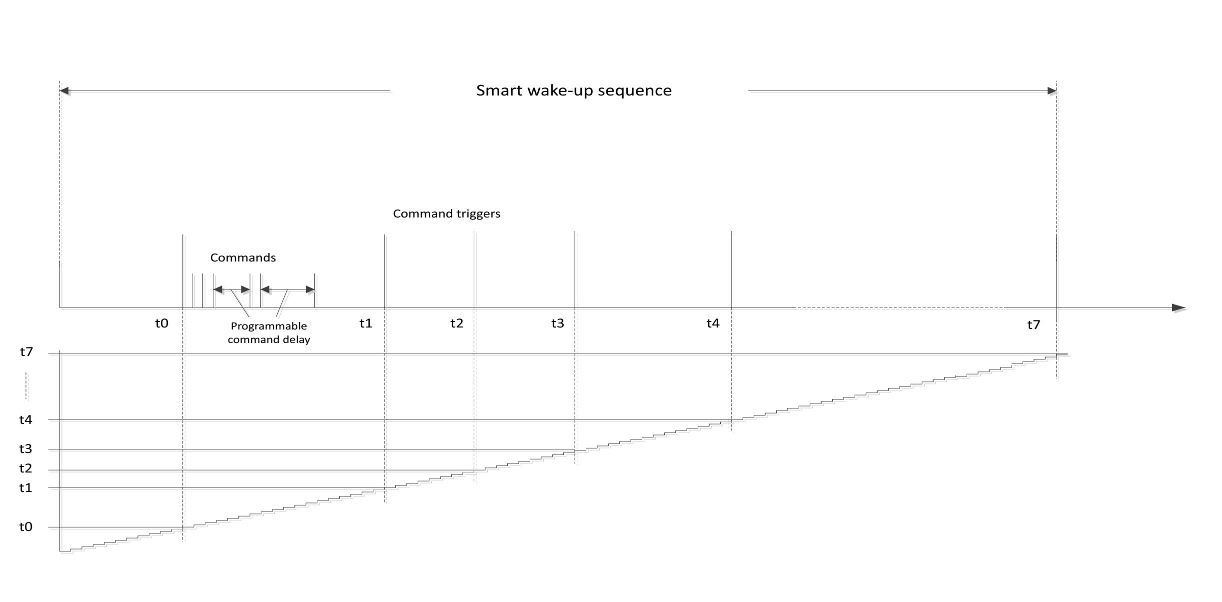
A command associated with an ADC conversion lasts till the ADC has acknowledged the Stand-by eCTU that the conversion was completed. This is represented in *Figure 56* by the CONV_DONE feedback signal from the ADC block to the CD block.

Other commands (for example, the one used to set a digital port pin level) have no “intrinsic” duration. Because of this, the “TU” block has been introduced, in order to be able to set a programmable delay between “immediate” commands. This is represented in *Figure 56* by the DELAY feedback signal from the TU block to the CD block.

As a result, shown in *Figure 77*, the time when a command shall be executed can be controlled in two ways:

- the value of the TxCVR comparators (t0, t1, etc. in *Figure 77*)
- the TU delay times (“programmable command delay” in *Figure 77*)

Figure 77. Programmable Command Delay



11.6.2 CD (Command Dispatcher)

The Stand-by eCTU commands contain two main fields:

- CLIENT
- PARAMS

The information in these two fields is decoded by the CD block and dispatched to the target clients (refer to *Table 135*).

The PARAMS field of the command is interpreted according to the type of client being activated.

Table 135. Smart Wake-up Sequence command

CLIENT[1:0]	Block	PARAMS[6:0]
0	ADC	Refer to *Table 136*

Table 139. TU Commands

PARAMS bits	Field name	Value	Description
[6:0]	DELAY	Any	Programmable delay

11.6.2.1 PDC channel handling

The SSWU is able to drive 14 PDC channels: PDC0-PDC4, PDC7-PDC16, PDC5 and PDC6 are reserved. The PDC channel number is selected by the PDC command parameter (refer to *Table 138*).

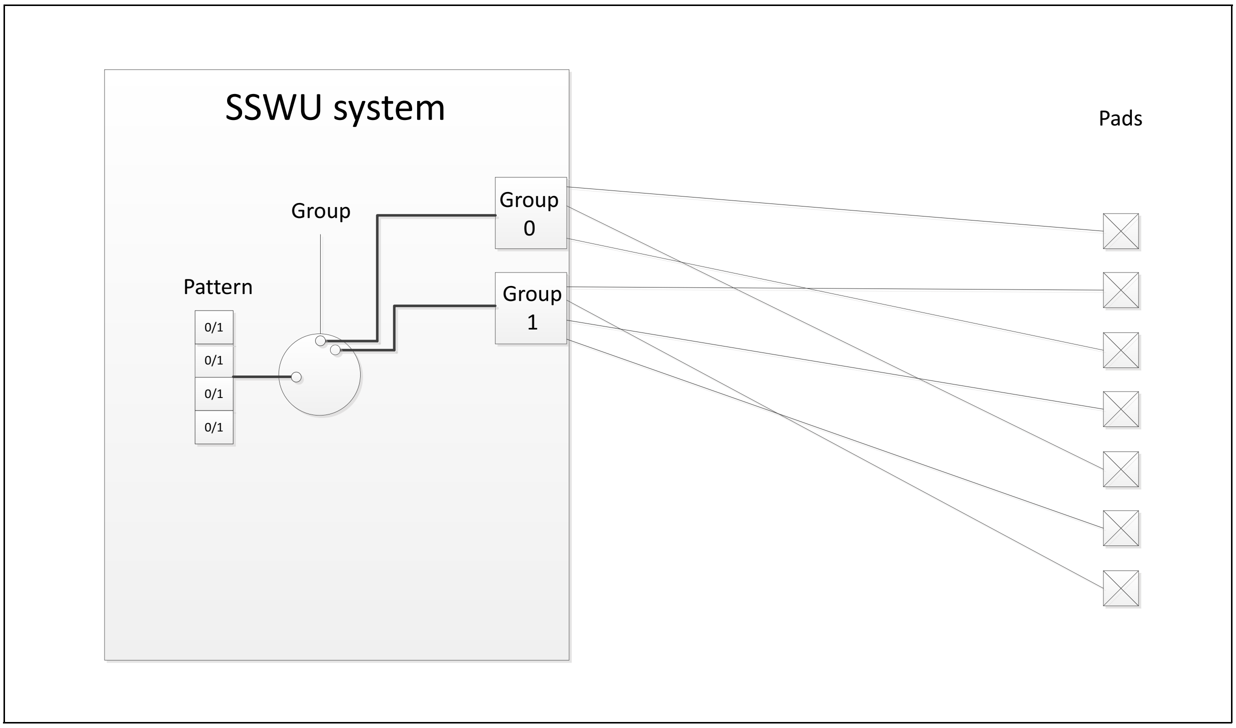
The connection between each PDC channel and the corresponding pad is hard-wired as specified in the Microsoft Excel pinout file (I/O Signal Table).

11.6.2.2 OPC channel handling

The SSWU is able to drive up to 7 OPC channels. OPC0 is reserved.

The channels are divided into 2 groups of 4 channels each. The “GROUP” command parameter is used to select the group of channels to be operated (refer to *Table 137*). The 4 channels belonging to the selected group are driven in parallel: the 4 channels will be set according to the value specified in the “PATTERN” command parameter. The connection between each OPC channel and the corresponding pad is hard-wired as specified in the Microsoft Excel pinout file (I/O Signal Table).

Figure 78. SSWU OPC connections



11.6.3 ADC

The ADC block is a reduced, low-power version of the Successive Approximation Register Analog-to-Digital Converter called 10-bit SARADC_STDBY. Its main functionality is to compare the converted value towards a watchdog, and trigger a wake-up event in case the value is out of the intended range.

The watchdog thresholds (low and upper limits) are linked (that is pre-programmed during the RUN mode) to each ADC channel, so that a specific channel has its own threshold limit.

The ADC configuration comprises:

- 24 internal channels
- 4 different watchdog threshold values
- 8 external channels

More details about the ADC configuration are given in the *Chapter 38: Analog-to-Digital Converters (ADC) Configuration*.

11.6.3.1 ADC Channel Selection

The selection of internal or external channel group is done through the PARAMS[6] bit.

In case the internal channel group is selected (PARAMS[6] = 0), the internal channel number depends on the value specified by the PARAMS[5:0] bits. Because the internal channels are statically connected to a specific analog input pin, the channel selection is also a selection vs. which analog input pins will be used (refer to *Section 7.3.12: SSWU configuration*).

In case the external channel group is selected (PARAMS[6] = 1), the value of PARAM[5:0] represents the external channel number, starting from the offset 128, for example if

PARAM[5:0] = 0, then the external channel 128 is selected; if PARAM[5:0] = 1, then the external channel 129 is selected, and so on (refer to *Section 7.3.12: SSWU configuration*). The selected external channel number is then re-mapped on an internal channel through the ECMICR registers, which contains a set of fields, one for each external channel, where the linked internal channel can be specified. This association has to be done before entering into the stand-by mode. In this way, it is possible to link different external channels to the same internal channel.

11.6.3.2 ADC Watchdog Threshold Selection

A voltage measurement threshold (upper and lower limit) can be selected for each channel. The WTHRHRLx registers define a pool of watchdog threshold values, which can be referenced for each channel through the ICWSELx and ECWselx registers for the internal or external channel respectively.

In case the same analog input pin is used to measure the same voltage range with the same voltage threshold, then an internal channel is used (PARAMS[6] = 0). In this case, the external channels are grouped in slice of 8 channels. Each slice is selected by PARAMS[5:3] and can be associated to an internal channel. PARAMS[2:0] selects which external channel is used, among the 8 channel of a slice.
In this scenario, the configuration is:

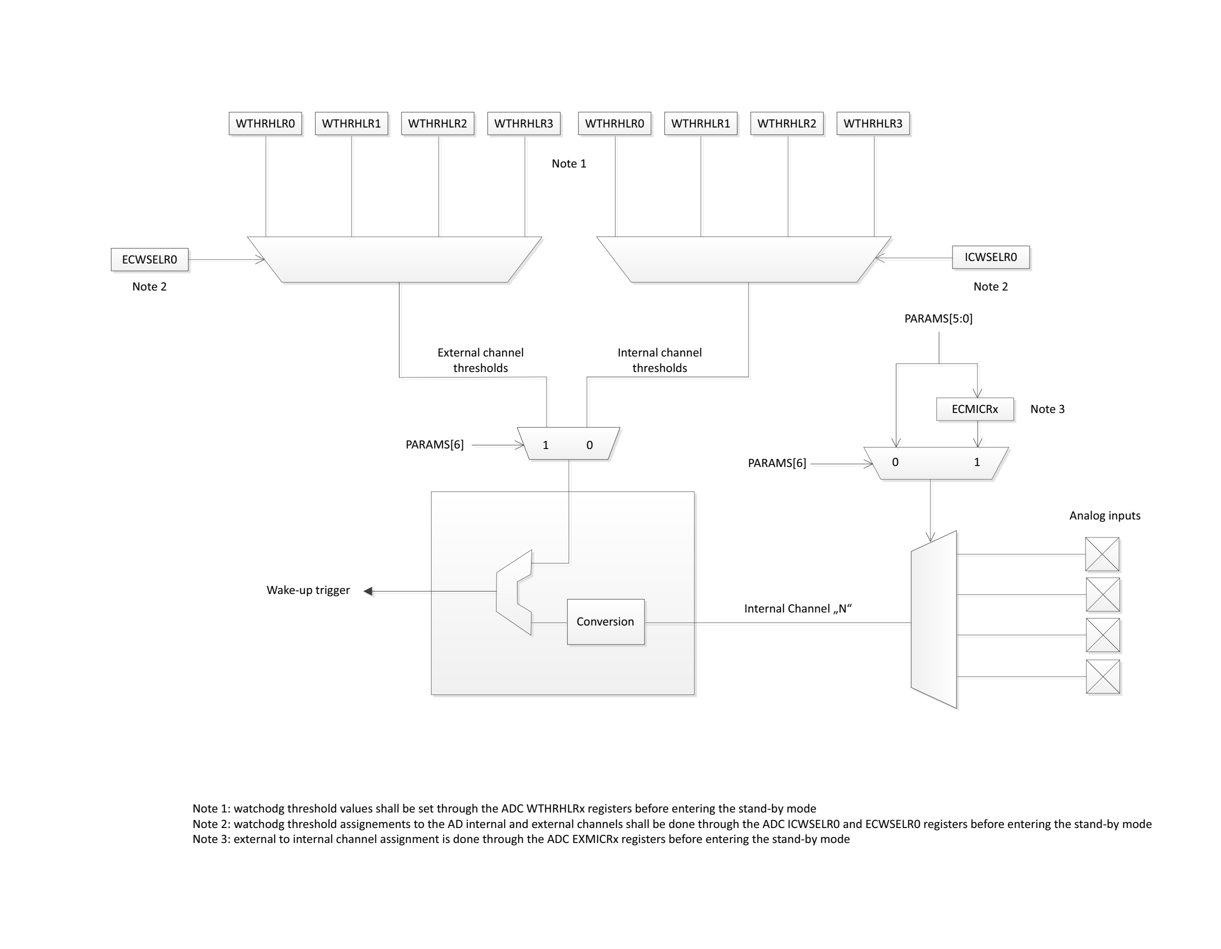
- the internal channel value is fixed by the PARAMS[5:0] value
- the threshold is chosen by setting the ICWSEL register before entering the stand-by mode

In case the same analog input pin is used to measure the different voltage range with the same voltage threshold, then an external channel is used (PARAMS[6] = 1). In this scenario, the configuration is:

- the external channel value is fixed by the PARAMS[5:0] value
- the threshold is chosen by setting the ECWSEL register before entering the stand-by mode
- the internal channel (the pin to be used) linked to the chosen external channel is defined by the ECMICR register

Figure 79 represents in graphical form the above description.

Figure 79. ADC channel selection



11.6.4 OPC

The OPC block is used to drive the 7 digital output pins to a desired level.

The intended functionality is to open/close external switches.

The Stand-by eCTU command parameter contains the OPC channel and level.

The OPC channels are controlled in groups of 4 channels, but, it is possible to mask any one of these channels, in order to retain the value set in RUN mode on any pad not intended to be used for the SSWU.

The mechanism to achieve this is to use the SIUL SCR bits to mask the OPC channel driving to the pad (refer to *Section 16.2.2.11: Soc Configuration Register 0 (SIUL2_SCR0)*). In order to drive an OPC channel, the SW shall configure the associated SCR bit before entering in stand-by mode.

The set of pads used to control external logic during the Stand-by have the following behavior:

- Upon entering the stand-by mode, the pad values corresponding to OPC channels are maintained.
- That means if the pad is used for OPC functionality during STANDBY mode, then on the subsequent STANDBY mode entry, the PAD value is restored to the value during the previous STANDBY mode exit.
- However, if the PAD is not used for OPC functionality during STANDBY, then the same value as in RUN mode is maintained upon entering STANDBY mode.
- SIUL_SCR0.OPC_MASK configuration for any OPC channel should remain same during the application. Otherwise, the value on OPC channel on STANDBY entry may have some undesired transitions.
- During stand-by mode, it is possible to change the value of those pads thanks to OPC programming.
- Upon exiting from stand-by, the value of the pads connected to OPC channels can also be maintained. This avoids glitches during the transition between stand-by and run mode. For this purpose, the SIUL2_SCR0 register must be programmed before entering stand-by.

Note: Note that the pads value and direction can still be changed during the RUN mode, but this requests to write a bit within the SIUL_SCR0 register to “1”. Before entering the standby mode the SIUL_SCR0 bit shall be programmed to "0".

11.6.5 PDC

The PDC block is targeted to measure the level of a set of 14 pins and to generate a system wake-up event when the level is acknowledged at a specified level and, optionally, for a certain time.

Two commands are needed for the PDC:

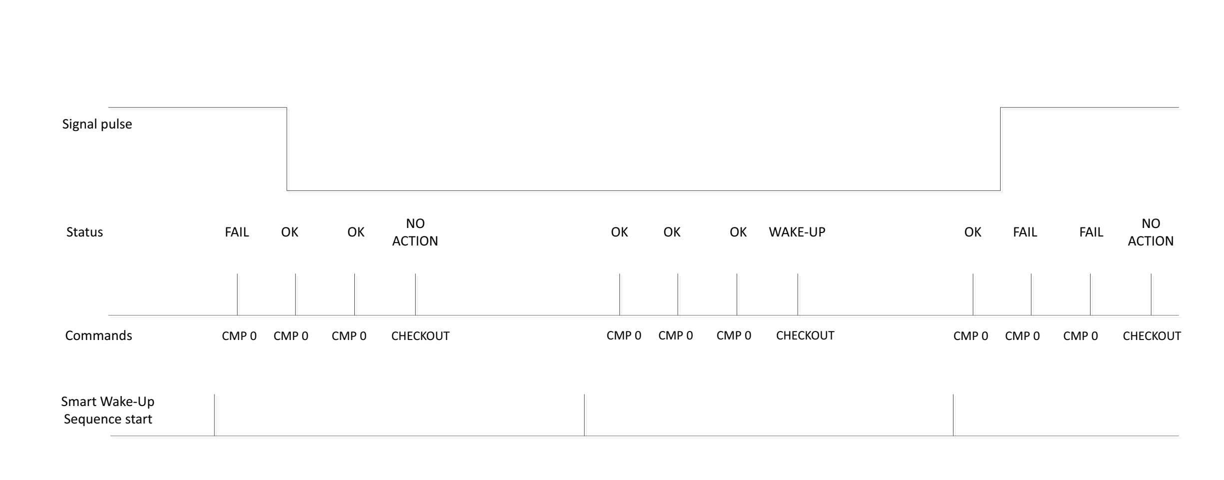
- CMP 0/CMP 1: to compare a pin level versus a 0 or 1
- CHECKOUT: to trigger a wake-up in case the result of the CMP commands for that specific pin executed from the beginning of the Smart Wake-up Sequence is always OK

For each pin, the PDC will latch the comparison results, which will report whether the target value was always matched (whenever a PDC, CMP0/1 command is launched) or not.

When checkout command is launched for a specific pin, it will trigger a wake-up event only if the target level was steadily acknowledged along all the comparisons done for that pin.

Figure 80 summarizes the above description.

Figure 80. Smart Wake-up Sequence PDC



11.6.6 TU

The TU block is used to create a programmable delay between the command execution. It needs only one command with the delay value programmed as a parameter.

The delay parameter is intended as number of IRCOSC periods (so that when TU = 1, then the delay is 1 clock cycle; TU = 2, then the delay is 2 clock cycles; and so on). The clock cycle can be adjusted with a linear prescaler, which is programmed through SSWU_CTRL_REG register of PMC_Dig module during the RUN mode, and whose value is preserved through the stand-by mode. The prescaler has a division factor from 1 to 128 (7 bits). Combining the TU parameter and the prescaler, the delay ranges from 62.5 ns (Clock period = 62.5 ns, PARAMS[6:0] = 1, prescaler = 1) up to 1.016 ms (Clock period = 62.5 ns, DELAY = 127, TU_{PRESC} = 128).

Note: TU_{PRESC} is defined in the SSWU_CTRL_REG. Please refer to Chapter 54: Power management controller digital interface (PMC_Dig).

Caution: The two commands which can cause wakeup (ADC-ADC or ADC-PDC or PDC-PDC) shall not be executed one after another without inserting a TU delay command.

11.6.6.1 SSWU STOP Command

In case the TU parameter (delay time) is set to 0, this is decoded as a command request to stop the whole SSWU sequence.

11.7 SSWU Configuration example

11.7.1 Description

In this scenario, the device stays in STANDBY and, every 32 msec, starts following the SSWU operations sequence:

- suddenly set OPC1 pin to '1'
- after 200 µsec, set OPC1 pin to '0'
- perform an ADC conversion (configuring an ADC threshold to wakeup the device)
- set a TU command for stopping the SSWU sequence

Device wakes-up from STANDBY only in case of ADC threshold overcoming.

11.7.2 Registers configuration

Following a pseudo-code that explains how to configure all the SSWU registers and all others IPs that are interconnected with it in order to get the overall STANDBY scenario

11.7.2.1 SSWU registers Configuration

```
//First command list
SSTDBY_CTU_0.CLR[0].R = 0x60001001; //set OPC1(PB9) pins to '1'

//Second command list
STDBY_CTU_0.CLR[2].R = 0x20000001;   //set OPC1(PB9) pins to '0'

STDBY_CTU_0.CLR[3].R = 0x20000C00; //convert internal channel  (AN82/PB10)

STDBY_CTU_0.CLR[4].R = 0x60000003; //add a delay of 0usec to stop the
sequence

STDBY_CTU_0.CLCR1.B.T0_INDEX = 0;   // trigger0 points to CLRN[0]
STDBY_CTU_0.CLCR1.B.T1_INDEX = 2;   // trigger0 points to CLRN[2]

STDBY_CTU_0.THCR1.R = 0x00001111;   // trigger0-1 enable
STDBY_CTU_0.TCRN[0].R = 0x00000001; // trigger0 generated quite immediately
STDBY_CTU_0.TCRN[1].R = 0x00000C80; // trigger1 generated 200us after the
API event

STDBY_CTU_0.TGSISR.R = 1;  // ctu_trg_in[0] (API) Rising edge Enable

STDBY_CTU_0.CTUCR.B.TGSISR_RE = 1;   // TGS Input Selection Register Reload
Enable

STDBY_CTU_0.CTUCR.B.GRE = 1;     // General Reload Enable
STDBY_CTU_0.CTUCR.B.CTU_FSM_reset = 1; // reset CTU FSM before
                                       // next stand-by entry
```

11.7.2.2 Other IP registers configuration

Following IPs should also be configured in order to complete the entire STANDBY scenario:

```
---------------------------------------------
Clock and Mode Entry configuration
---------------------------------------------

MC_ME.ME.R = 0x0000FFFF;         // Enable all modes

// Set RUN Configuration Registers
MC_ME.RUN_PCN[1].R=0x000000FE;       // Peripheral ON in every running mode
MC_ME.LP_PCN[1].R=0x00002500;

MC_ME.PCTL15.B.RUN_CFG=1;        // SIUL2
MC_ME.PCTL114.B.RUN_CFG=1;       // ADC_STDBY
MC_ME.PCTL242.B.RUN_CFG=1;       // STDBY_CTU_0

MC_CGM.AC0_DC2.R = 0x80000000;   // enable ADC_CLK
MC_CGM.AC0_DC4.R = 0x80000000;   // enable ECTU_CLK

//Enter DRUN to act the previous configurations
MC_ME.MCTL.R = 0x30005AF0;       // DRUN Mode & Key
MC_ME.MCTL.R = 0x3000A50F;       // DRUN Mode & Key

while(MC_ME.GS.B.S_MTRANS);      // Waiting for end of transaction
while(MC_ME.GS.B.S_CURRENT_MODE != 0x3);   // ME_GS Check DRUN mode has
successfully been entered

---------------------------
WKPU configuration
---------------------------

//Configure wakeup line 0 (SSWU wakeup event)
WKPU.WRER.R = 1;                 // Wakeup Request Enabled
WKPU.WIREER.R = 1;               // Rising Edge Event Enabled

---------------------------------------------
SAR_ADC_10bit_STDBY configuration
---------------------------------------------

SAR_ADC_10BIT_STDBY.MCR.B.OWREN = 1; // SAR ADC 0 overwrite enable set
SAR_ADC_10BIT_STDBY.MCR.B.MODE = 0; // Normal Mode
SAR_ADC_10BIT_STDBY.ICNCMR2.B.NCE_CH82 = 1; //sets channels 82 to be
converted in SARADC_10bit_standby (see table in ADC Config)
SAR_ADC_10BIT_STDBY.MCR.B.CTU_MODE = 1; // Trigger mode is selected
SAR_ADC_10BIT_STDBY.MCR.B.CTUEN = 1;    // CTU enabled
```

```
SAR_ADC_10BIT_STDBY.MCR.B.PWDN = 1; // SAR ADC 0 automatic power
                                   // up by SSWU during stand-by

//ADC_STANDBY_CH0 = Internal Channel 82:
SAR_ADC_10BIT_STDBY.WTHRHLRN[0].B.THRH = 0x333; // select high THRHLR0
treshold = 4V
SAR_ADC_10BIT_STDBY.ICWSELR11.B.WSEL_CH82 = 0;  // select THRHLR0 treshold
for CH88
SAR_ADC_10BIT_STDBY.ICWENR2.B.WEN_CH82 = 1;  // enable watchdog for CH82
SAR_ADC_10BIT_STDBY.WTIMR.B.MSKWDG0H = 1;   // enable high THRHLR0 treshold
interrupt

---------------------------
STANDBY configuration
---------------------------

PMCDIG.MISC_CTRL_REG.B.LPRCREG_ENB = 0;    // Enable LPRC in running modes

---------------------------
API/RTC configuration
---------------------------

RTC_API.RTCC.R = 0x80009001;    // Counter Enabled, API Enabled, LPRC
prescaled by 8 @128KHz used, Trigger enabled
RTC_API.APIVAL.R = 0x00001000;  // API period =32.25msec
```

Caution: For SSWU, ADCSAR must be used in CTU_TRIGGER mode.

11.7.2.3 Activate SSWU sequence

Once all previous register configurations have been configured, it just needs to perform STANDBY Mode entering, in order to get the desired scenario.

```
//Mode Entry Module (MC_ME): Enter STANDBY Mode
MC_ME.ME_STANDBY0_MC.IRCON.B = 0; /* Switch off IRCOSC during standby */
MC_ME.MCTL.R = 0xD0005AF0;       /*! Write Mode and Key | MC_ME.MCTL */
MC_ME.MCTL.R = 0xD000A50F;  /*! Write Mode and Key inverted | MC_ME.MCTL */
```

12 Security

All SPC58 family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations while other more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off; they require significant involvement for implementation. Consequently, they provide an important opportunity to define the security level of the device.

12.1 Basic security

All SPC584Bx devices have the following basic set of security features.

- Device security feature based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
  - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection
  - SRAM and caches initialized to a constant value after reset (power-on reset, when in a test mode, when not booting from internal flash memory); MBIST functionality used in case of power-on and destructive resets to initialize RAMs selected via configuration in UTEST flash; BAF software routines to initialize RAMs when not booting from internal flash memory
- Monitoring of operating conditions
- Unique ID for each device: each SPC584Bx device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device
- Secure watchdog timer
- Debugger access control

12.2 Advanced security

Depending on the device configuration, the following features are available:

- Customer programmable Hardware Security Module (HSM): a dedicated security subsystem that includes a processor core, dedicated SRAM, an encryption module, and exclusive access to secure areas of device flash memory; HSM runs code independently from the main device processor cores and can be used to implement advanced security and monitoring functions
- Advanced debugger access control
- Boot modes:
  - Trusted/secure boot support
  - Handshake with BAF supported

12.3 Detailed security information

Details of most of the SPC584Bx security features are published in a separate *SPC584Bx Microcontroller Security Reference Manual*, which is only available to qualified customers.

13 Debug and Trace

This chapter discusses the device-specific information for the debug modules. This device implements a high-speed serial Nexus trace auxiliary port. In addition, the LFAST module, a high speed calibration interface, is supported for run control and memory access. The LFAST signals are alternate functions on the device's JTAG pins. The device starts up in JTAG mode and the tool can request that the JTAG interface be converted to the LFAST high-speed interface. All standards used have freely available specifications for tool developers.

13.1 Core debug support

Internal debug support in the e200z420n3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug mode, such that no code runs. This allows debuggers to perform operations such as edit of overlay memory prior to user code execution.

For details, refer to *Chapter 57: e200z420n3 Core Debug Support*.

13.2 Run control and memory access

Run control is any operation required to control device operation. Run control includes starting and stopping the processor's execution of code, as well as accessing memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both Boundary Scan and Debug modes. It is based on the IEEE 1149.1 and IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can either be fed directly from the JTAG pins or the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross-triggering of events from the device. The SPU can access some of the DCI run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the $\overline{\text{EVTI}}$ pins. Furthermore, the SPU can use system triggers to cause many different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

13.2.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug features. The DCI module includes the device JTAG Controller and the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tools or software
- Port-sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all the CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Simultaneous operation for debug features

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. *Table 141* summarizes the sources and destinations of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the device. For example, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU, and inputs to the Cores, HSM and NXMC.

Table 141. DCI signals

Signal	Cores	HSM	NXMC	NPC	JTAGM	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	I	—	O	I/O	—
$\overline{\text{EVTI}}$[1]	—	—	—	—	O	I/O	—
$\overline{\text{EVTO}}$[0]	O	O	O	—	I	I/O	—
$\overline{\text{EVTO}}$[1]	—	—	—	—	I	I/O	O
Core debug event	I	—	—	—	—	—	—
DCI cross triggering	O	—	—	—	—	—	—

The DCI sends the system debug signal, ipg_debug, to the following modules. For details regarding module functionality during system debug, refer to the individual module chapter.

- CAN
- DSPI
- eDMA
- eMIOS
- FCCU
- I2C
- LINFLEX
- NXMC
- PIT
- SARADC
- SSCM
- STM
- SWT

13.2.2 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG Controller.

13.2.3 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

13.2.4 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows both JTAG and software access to two registers. These two registers are the challenge/response password authorization registers used by the Hardware Security Module (HSM).

13.2.5 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

13.2.5.1 SPU Level1 Input Mux Configuration registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0–7) are described in the following tables. The L1SEL0 register fields are described in the following table.

Table 142. L1SEL0 register field descriptions

13.2.5.2 Tool interface

This device includes an alternate calibration interface for high-speed run control and advanced software control. This calibration interface is based on the LFAST interface. The LFAST based calibration has the ability to perform all of the functions that JTAG supports, only at a faster speed. The MCU implements the slave module, and the pins for the LFAST interface are multiplexed onto the same pins as the JTAG pins. Initially, the device powers up with the JTAG module in control of the pins. Under tool commands, the LFAST interface can be enabled and the pins become LFAST signals. Once the LFAST interface has been activated, all run control and other JTAG operations are converted in the MCU from LFAST messages into JTAG control operations of the JTAG Controller. The interface is supported entirely in hardware for both LFAST and JTAG modes, with no software or system overhead required to support interface traffic.

Table 150. Reference links to related information

Related module	Reference
JTAG Master (JTAGM)	*Chapter 63: JTAG Master (JTAGM)*
LFAST Module (Debug LFAST)	*Chapter 66: LVDS Fast Asynchronous Serial Transmission – High Speed Debug*
Development Tool Semaphore (DTS)	*Chapter 67: Development Trigger Semaphore (DTS)*

13.2.6 JTAG Master (JTAGM)

The JTAG Master (JTAGM) acts as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or through software.

The data transferred to this module is transformed to produce TCK, TMS, TDI, and TRST outputs and to accept TDO inputs. The module allows these five signals to connect to the JTAGC as if the JTAG data were coming from an external tool. The JTAGM generates all required JTAG scan chains to allow software and high-speed serial communication access to all JTAG-mapped resources.

13.2.7 Debug LFAST

The high-speed calibration interface provides up to a 320 Mbit/s interface between a calibration tool and the device. The calibration interface uses the LFAST as the physical layer between the tool and the JTAGM for access to debug resources. In addition, an LFAST switch allows direct access to read and write memory via the SIPI_DEBUG module. The calibration LFAST is configured for slave-only operation and is meant to be used as a calibration interface to provide higher (than JTAG) speed debug and calibration operations.The calibration LFAST interface supports full duplex operation, where the available bandwidths for upstream and downstream traffic are independent.

13.2.8 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There is a variety of ways that this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data-acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus auxiliary port.

13.3 Debug over CAN

As well as supporting debug via JTAG and LFAST interfaces, the device supports the use of a CAN interface for debug. This allows debug of application hardware where access to the dedicated JTAG/LFAST interface signals is not easily available. The debug over CAN mechanism is intended to provide basic debug functionality with some reduction in bandwidth and features compared to the use of the dedicated JTAG or LFAST interfaces.

Use of the CAN interface for debug purposes requires the use of some M_CAN, eDMA and JTAGM resources. Some initialization of these resources via software is required, but once this initialization has completed, debug over CAN is possible without any further software overhead.

As the debug over CAN scheme generates internal JTAG messages based on received CAN data, all JTAG clients and included debug resources are accessible. Basic device trace capability is also possible by configuring the device trace hardware to stream to a device overlay/trace RAM, which can be read later using debug over CAN.

The debug over CAN scheme supports the following features:

- Supports operation through CAN_SUB_0_M_CAN_1 or CAN_SUB_0_M_CAN_2 interfaces
  - Makes use of M_CAN debug enhancements
  - Debug message selected by filter configuration SFEC/EFEC=111
- Allows debug of hardware where JTAG access is not available
- Debug traffic carried over application CAN bus
- Debug traffic on CAN coexists with application traffic
- No software overhead after initialization
- flexible selection of CAN identifiers for debug use
- Access to all JTAG debug facilities, includes CPU run control

13.4 Nexus Trace interface

This interface allows Nexus protocol information to be transmitted at high speed.

The trace information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single port, of information from multiple trace clients within the MCU. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client; generally, it can be individually enabled (both the type of message and the client). *Table 151* shows a few examples of Nexus messages. All messages can be enabled to include a timestamp.

Table 151. Nexus message types

Message Type	Description
Program trace	Nexus program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership trace	Ownership trace provides information on process identification changes.

Table 151. Nexus message types (continued)

Message Type	Description
Watchpoint trace	Watchpoint messages are generated any time a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device identification	The device identification message allows information about the MCU to be transmitted upon startup to allow tools to identify the target system MCU type.
Debug status	Debug status messages provide additional information that may be needed to reconstruct software execution, such as whether the device has entered Debug or Low-power mode.
Data acquisition	Data acquisition messages are an optional feature that allows software control of information to be transmitted.
error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

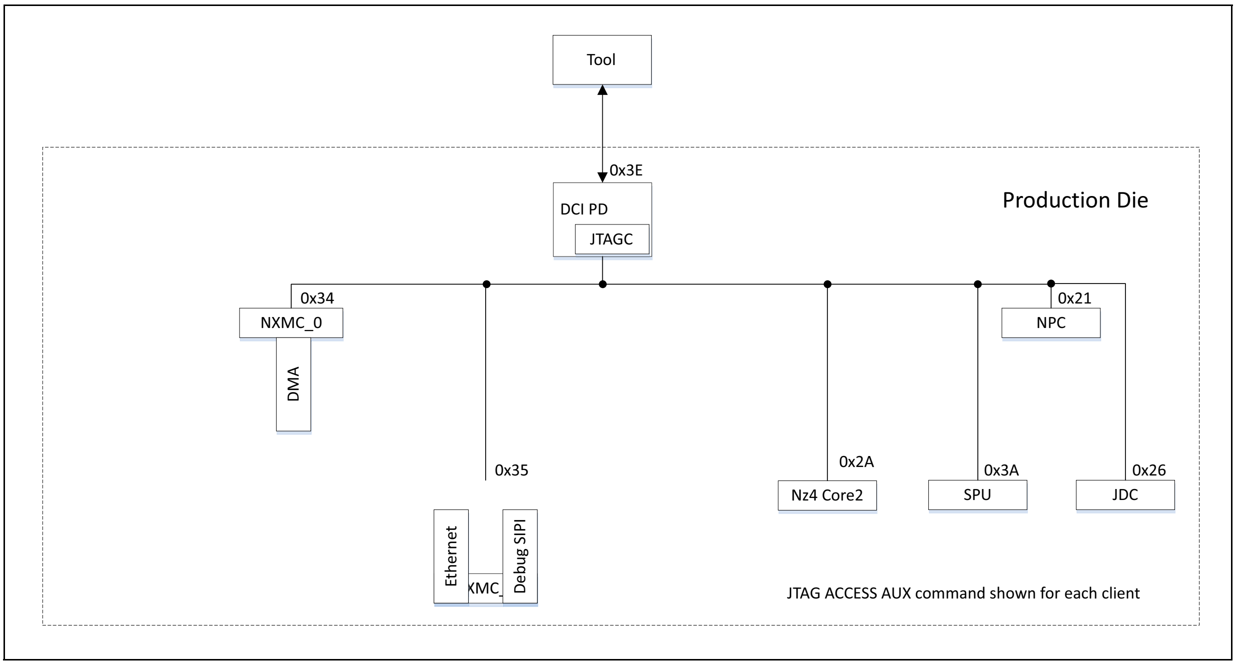
The Nexus blocks do not have memory-mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 152. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Production Die		
Cores	CORE_ENABLE	0x7C (10 bits)
NXMC	NEXUS_ENABLE	0x0 (4 bits)
NPC		
SPU		

All of the internal JTAG modules are accessed through a single JTAG connection to the device.

Figure 81. JTAG hierarchical view



13.4.1 Nexus Port Controller (NPC)

The Nexus Port Controller controls the usage and sharing of the Nexus Auxiliary Port between Nexus clients. The Nexus Auxiliary Port is accessed by:

- The N3 block of the CPU
- The DMA master port NXMC client
- The Ethernet
- The SIPI_DEBUG

The NPC is placed in disabled mode upon exit of reset. Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. Once the NPC is enabled, if message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

13.5 Nexus clients

Nexus supports the transmission of information from multiple trace clients within the device.

Table 153. Reference links to related information

Related module	Reference
e200z420n3 Nexus Support	*Chapter 70: e200z420n3 Nexus 3 Module*
Nexus Crossbar Multi-Master Client (NXMC)	*Chapter 71: Nexus Crossbar Multi-Master Client (NXMC)*

13.5.1 e200z420 Nexus 3

The e200z420n3 Nexus 3 module provides real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

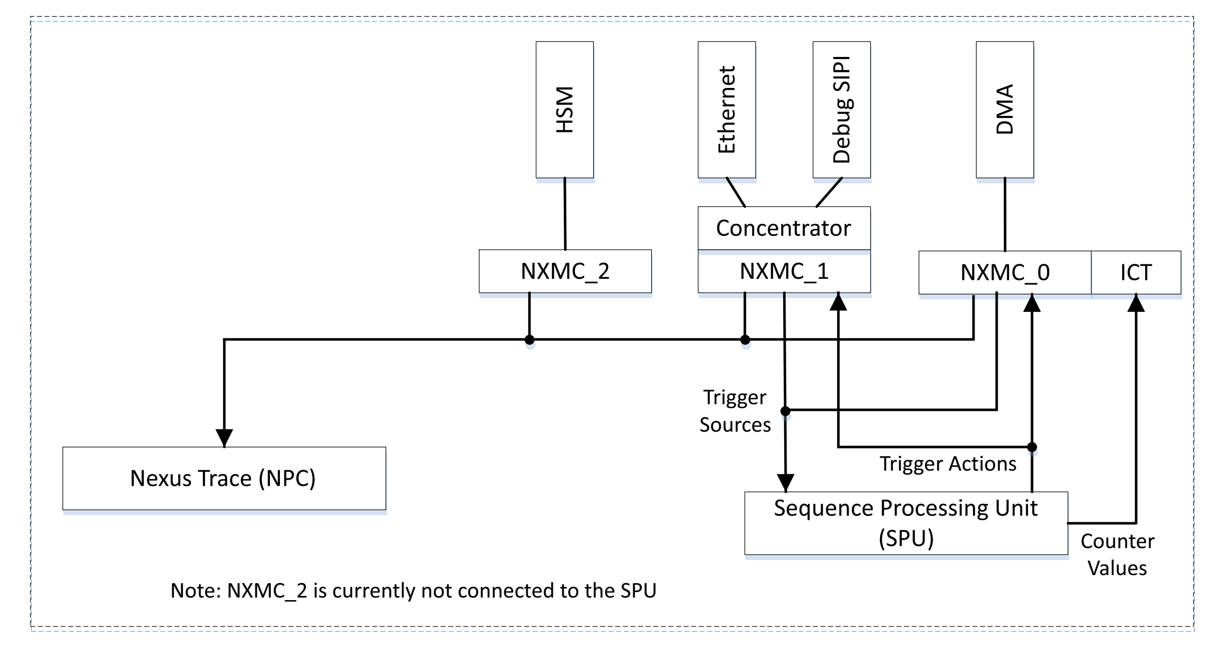
13.5.2 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Three NXMCs are implemented, out of which only two interact with the SPU. Trace messages transmitted over the Nexus interface include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four in total: two from each NXMC) for events from the SPU.

The *Figure 82* shows a block diagram illustrating the NXMC integration.

Figure 82. NXMC integration block diagram



The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 154. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
direct master	eDMA Controller	0b1100	0b0001
XBAR Client 1 Concentrator	Debug SIPI	0b1101	0b1000
	Ethernet_0		0b1010
direct master	HSM	0b1000	0b0000

14 e200z4d Core Complex Description

The SPC584Bx has one e200z420n3 core that performs various computational and control functions. This core is used for general computational functions.

This chapter provides overviews of the e200z420n3.

14.1 Overview of the e200z420n3 core

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

The e200z420n3 are dual-issue, 32-bit Power VLE compliant designs with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

The e200z420n3 cores implement the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document. The base *PowerISA 2.06* fixed-length 32-bit instruction set is not directly supported.

The e200z420n3 processor cores integrate a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

A Nexus Class 3+ module is integrated into each e200z420n3 processor core.

A Memory Protection Unit is integrated in each e200z420n3 processor core.

14.2 Features

The following is a list of some of the key features of the e200z420n3 processor cores:

- Dual issue, 3[2-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
  - Return Address Stack
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit System buses
- Local Data Memories (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z420n3 core: 64 KB DMEM
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
  - e200z420n3 core: 8 KB ICache, 4 KB DCache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Performance Monitor APU supporting execution profiling
- Nexus Class 3-plus Real-time Development Unit
- Power management
  - Low power design with extensive clock gating
  - Power saving modes: doze, nap, sleep, wait
  - Dynamic power management of execution units, caches and Local memories
- Testability
  - Synthesizeable, MuxD scan design
  - ABIST/MBIST for arrays

14.3 Microarchitecture summary

The e200z420n3 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/ EA Calc, Execute 0/ Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. *Figure 83* shows a block diagram of the e200z architecture.

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. The integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

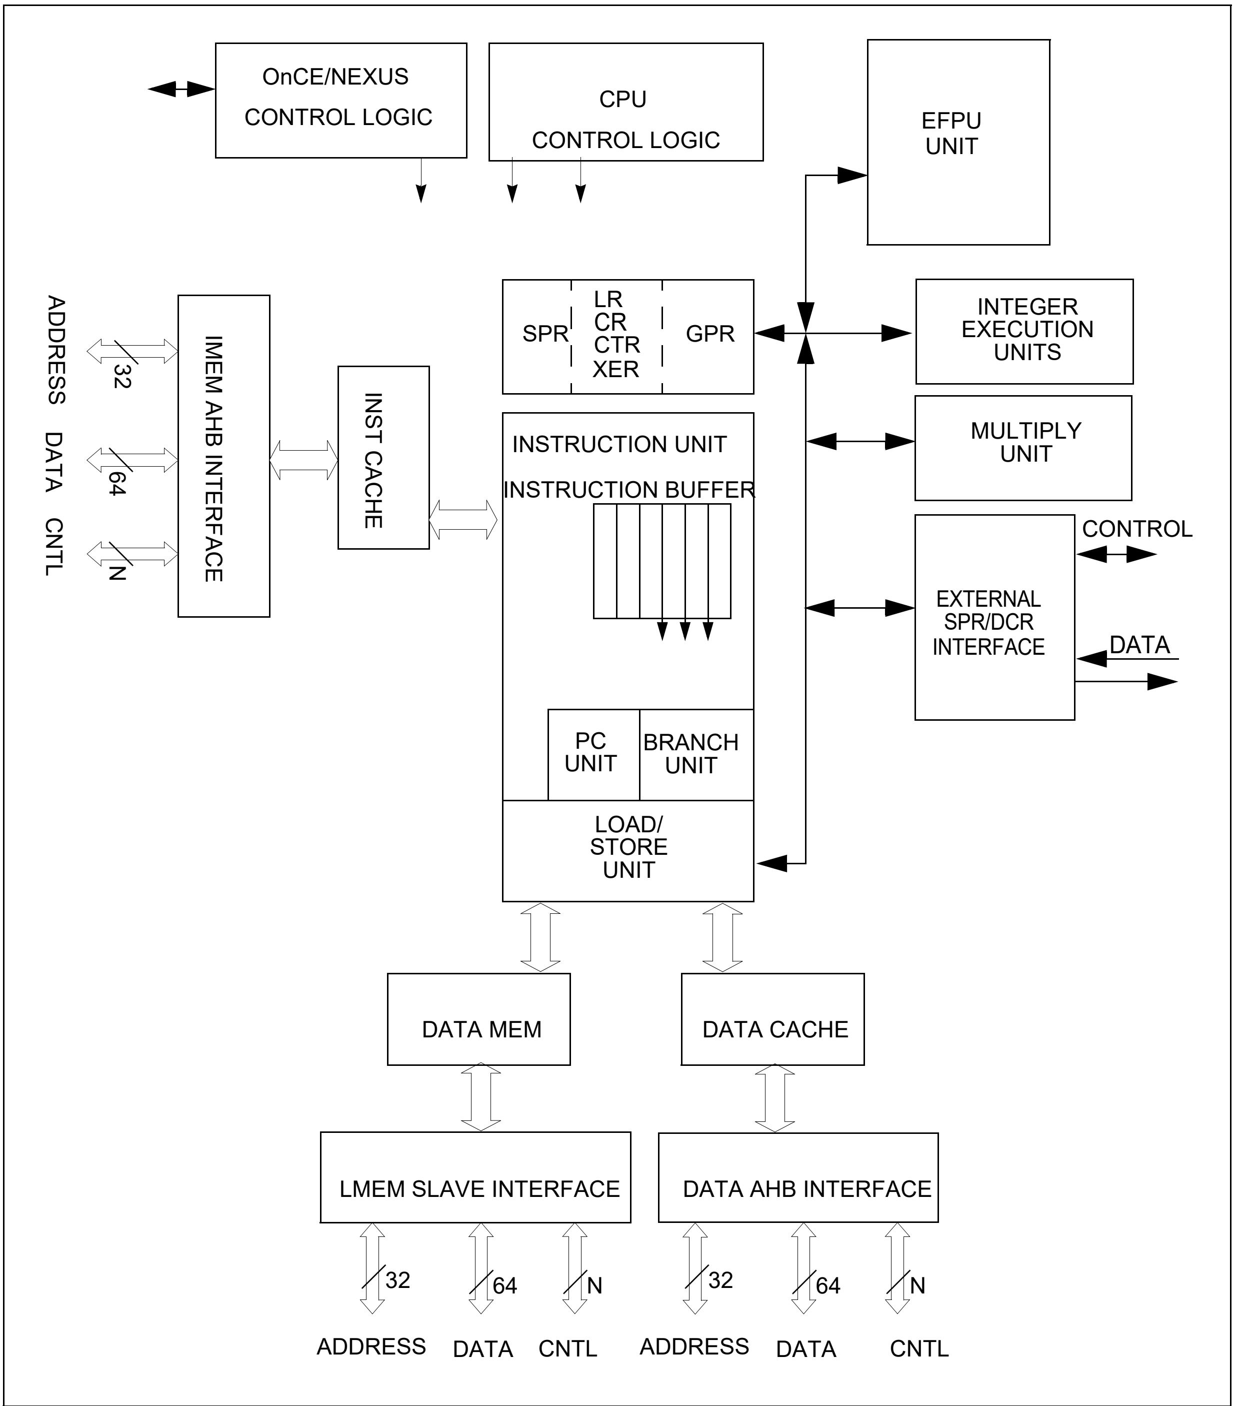
The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Figure 83. e200z block diagram



Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

14.3.1 Instruction unit features

The features of the e200z420n3 Instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to 8 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

14.3.2 Integer unit features

The e200z420n3 integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero's function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

14.3.3 Load/Store unit features

The e200z420n3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

14.3.4 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier
- Programmable Memory Attributes
- Entry Invalidation Protection
- Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

14.3.5 Cache features

The features of the Caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
  - e200z420: 8 KB ICache, 4 KB DCache
- Write through Support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Supports Way locking
- Supports Write allocation policies
- Supports multi-bit EDC with Correction/Auto-invalidation capability for the I and D caches
- Hardware Debug Cache Invalidate Support for the Data Cache
- Software and Hardware Debug access to cache tag, status and data storage via dedicated control registers

14.3.6 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Data Memories (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z420n3: 64 KB DMEM
- Supports zero wait-state access relative to cache hit timings
- Supports multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

14.3.7 e200z420n3 system bus features

The features of the e200z420n3 System Bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

15 Core (z420n3) Description

15.1 Overview of the Core (z420n3)

Core (z420n3) is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general purpose registers (GPRs). The Core (z420n3) core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The Core (z420n3) processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

Core (z420n3) contains an 8 KB Instruction Cache, and a 4 Kbyte Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit is also included which supports protections of various instruction and data memory areas.

15.2 Register Model

This section describes the registers implemented in the Core (z420n3) core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

Core (z420n3) extends usage of the General Purpose Registers to support EFPU APU operations operating on the 32-bit GPR registers.

Figure 84 and *Figure 85* show the complete Core (z420n3) register set, all of which are accessible in supervisor mode. *Figure 86* and *Figure 87* show the subset of registers which are accessible while in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 84. Core (z420n3) Supervisor Mode Programmer's Model SPRs

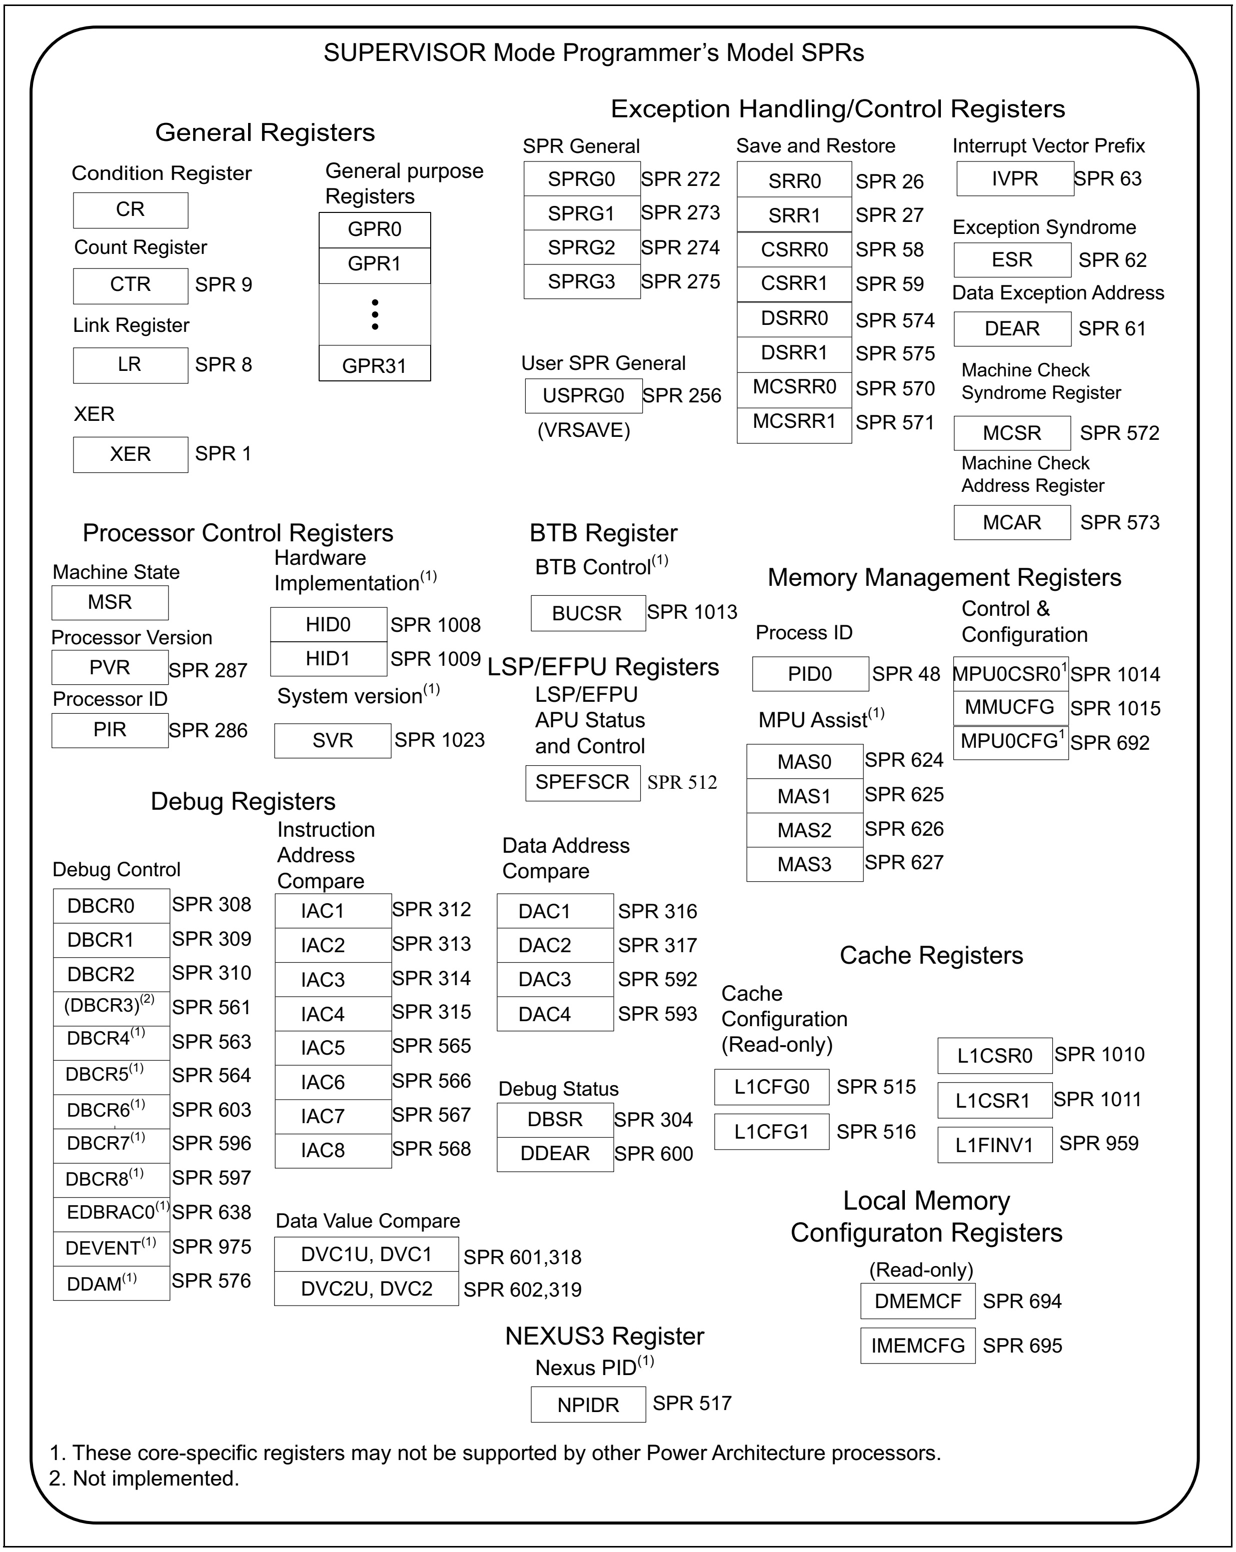


Figure 85. Core (z420n3)Supervisor Mode Programmer's Model DCRs and PMRs

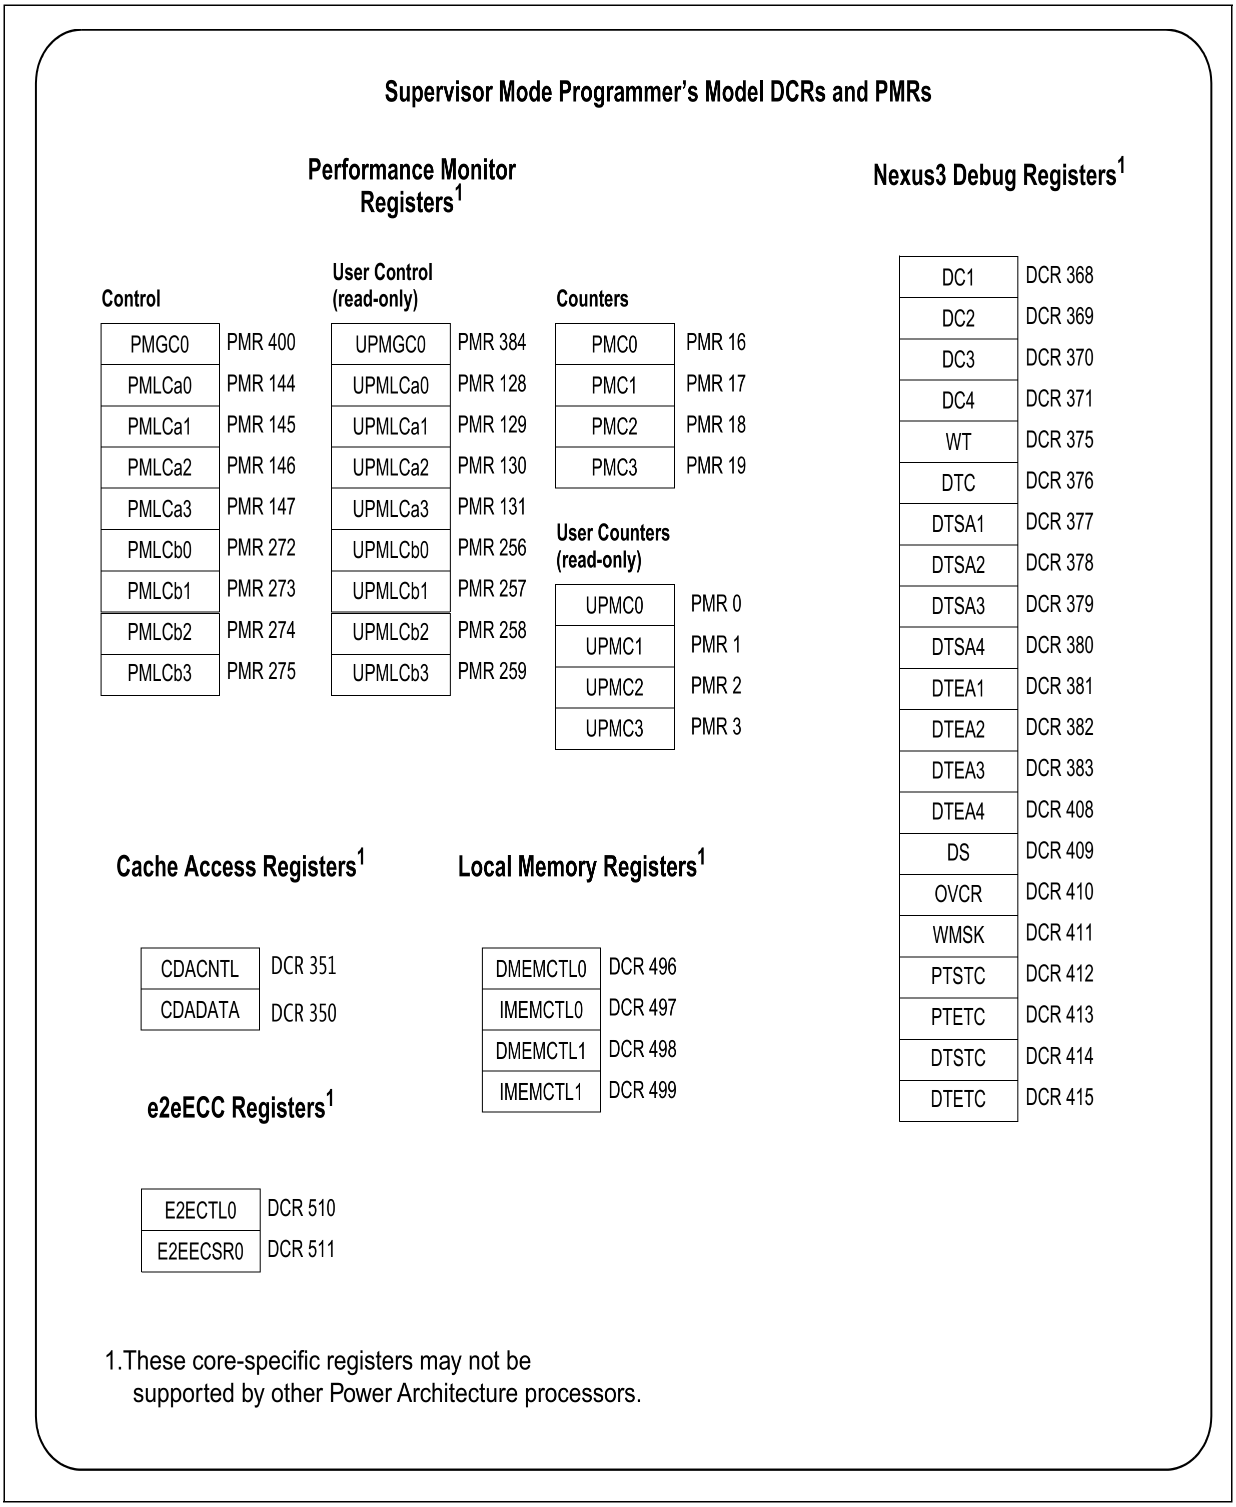

Figure 86. Core (z420n3) User Mode Programmer’s Model SPRs

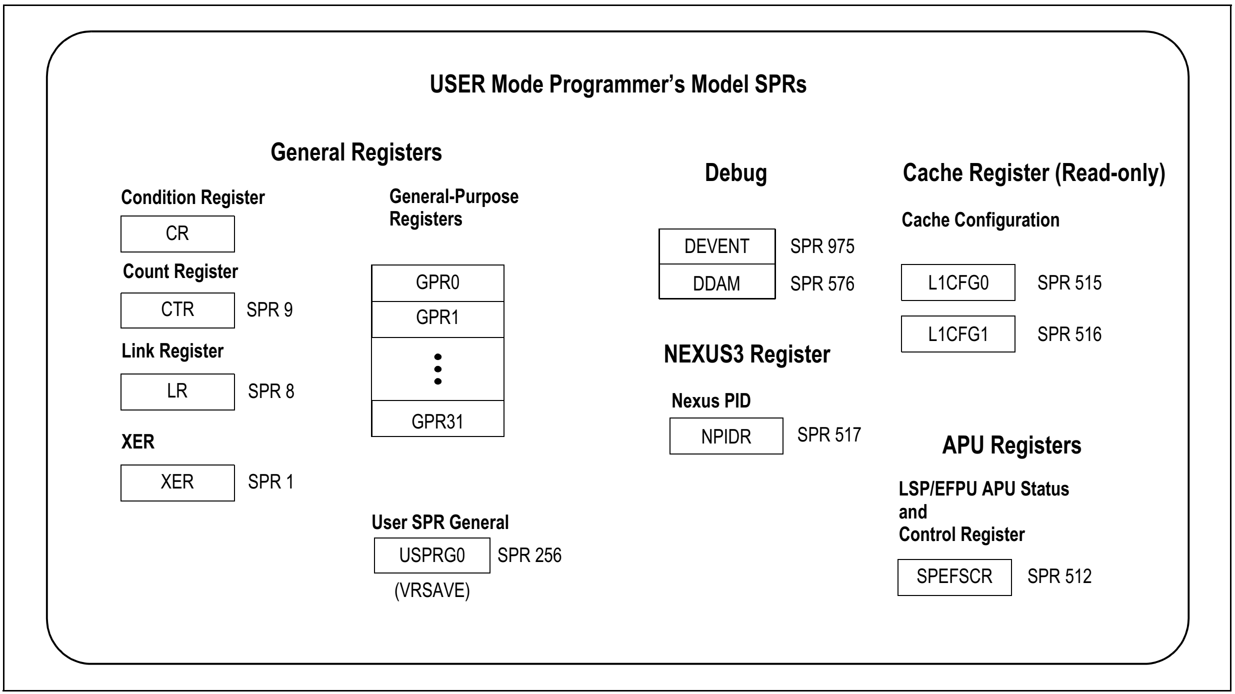

Figure 87. Core (z420n3) User Mode Programmer’s Model PMRs

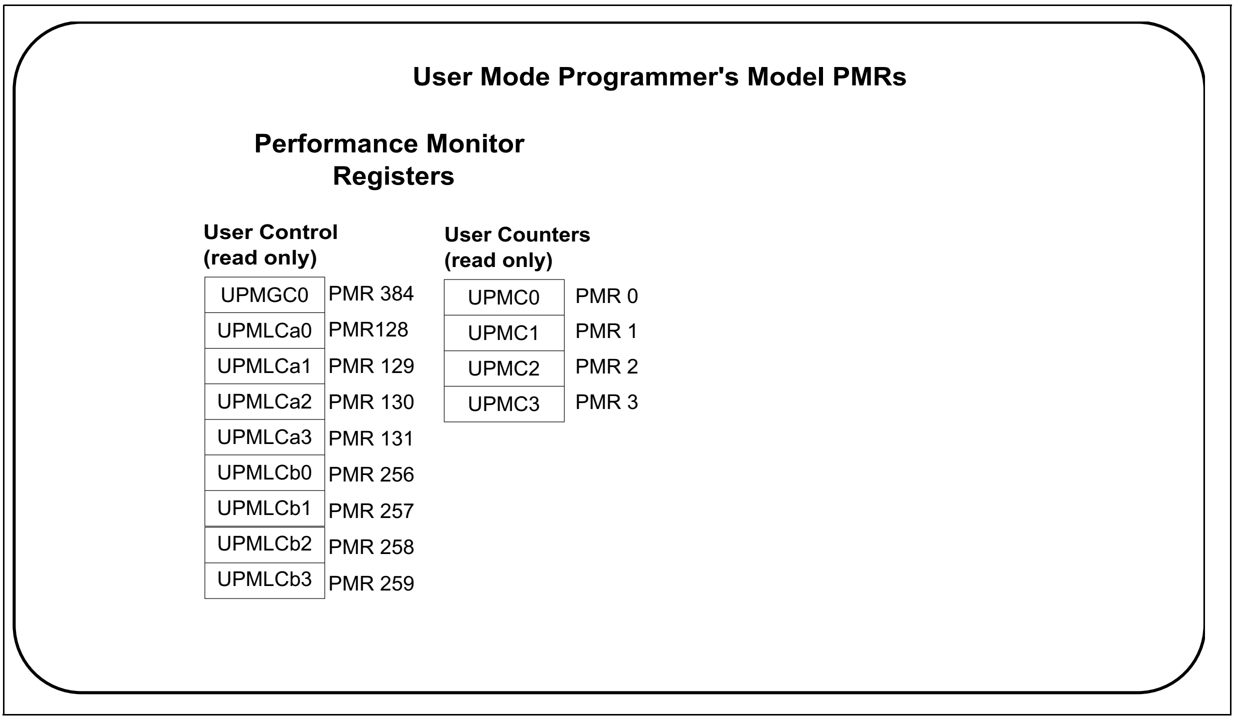

15.3 Dual Issue Operation

The instruction issue unit attempts to issue a pair of instructions each cycle to the execution units. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions which cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

Table 155 shows the Core (z420n3) concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue.

Table 155. Concurrent Instruction Issue Capabilities

Class of Instruction	branch	load/store	scalar integer	scalar float	vector integer non-MAC	vector integer MAC	special
branch	—	yes	yes	yes	yes	yes	—
load/store	yes	—	yes	yes	yes	yes	—
scalar integer	yes	yes	yes(1)	yes	yes	yes(2)	—
scalar float	yes	yes	yes	—	yes	yes	—
vector integer non-MAC	yes	yes	yes	yes	—	—	—
vector integer MAC	yes	yes	yes(2)	yes	—	—	—
special	—	—	—	—	—	—	—

1. excludes multiply or divide class instructions occurring in both issue slots
2. excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions

15.4 Reservation Instructions and Cache Interactions

The Zen core treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx.**, **sthcx.**, and **stwcx.**) accesses as though they were cache inhibited, and forces a cache miss. A reservation access is always issued to the bus.

15.5 Signal Processing Extension / Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point uses the SPEFSCR register. The SPEFSCR register is implemented as special purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in *Figure 88*.

0	FINXS	FINVS	FDBZS	FUNFS	FOVFS	0	SOV	OV	FG	FX	FINV	FDBZ	FUNF	FOVF	0	FINXE	FINVE	FDBZE	FUNFE	FOVFE	FRMC
0 1 2 3 4 5 6 7 8 9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30 31

SPR - 512; Read/Write; Reset - 0x0

Figure 88. DSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in *Table 156*.

Table 156. EFPU Status and Control Register

Bits	Name	Description
0:9	—	Reserved
10	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF=1), but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1), but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
11	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
12	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
13	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
14	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
15	—	Reserved
16	SOV	Summary integer overflow Defined by LSP APU.
17	OV	Integer overflow Defined by LSP APU.
18	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.

Table 156. EFPU Status and Control Register (continued)

Bits	Name	Description
20	FINV	Embedded Floating-point Invalid Operation / Input error The FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0.
21	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24	—	Reserved
25	FINXE	Embedded Floating-point Inexact Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF=1) but Floating-point Overflow exceptions are disabled (FOVFE=0), or if the result of a Floating-point instruction results in underflow (FUNF=1 or FUNFH=1) but Floating-point Underflow exceptions are disabled (FUNFE=0), and no Floating-point Data exception occurs.
26	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction.
27	FDBZE	Embedded Floating-point Divide by Zero Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction.
28	FUNFE	Embedded Floating-point Underflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction.

Table 156. EFPU Status and Control Register (continued)

Bits	Name	Description
29	FOVFE	Embedded Floating-point Overflow Exception Enable 0 = Exception disabled 1 = Exception enabled If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction.
30:31	FRMC	Embedded Floating-point Rounding Mode Control 00 = Round to Nearest 01 = Round toward Zero 10 = Round toward +Infinity 11 = Round toward -Infinity

15.6 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.6.1 Cache Overview

The Core (z420n3) processor supports a 8 Kbyte 2-way set-associative instruction and 4 Kbyte 2-way set associative data cache with a 32-byte line size. The caches improve system performance by providing low-latency data to the Core (z420n3) instruction and data pipelines, which decouples processor performance from system memory performance.

Instruction and data addresses from the processor are used to index the cache array. If the access address matches a valid cache tag entry, the access hits in the cache.

15.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache as well as providing general control over disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in *Figure 89*.

WID	0	WDD	0	0	DCWA	0	DCECE	DCEI	DCLOC	0	DCEA	DCLOINV	0	DCABT	DCINV	DCE
0 1	2 3	4 5	6	7 8 9 10 11	12	13 14	15	16	17 18	19 20 21 22 23 24	25 26	27	28	29	30	31

SPR - 1010; Read/Write; Reset - 0x0

Figure 89. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 bits are described in *Table 157*.

Table 157. L1CSR0 Field Descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable. 0 = The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 = The corresponding way instruction cache is not available for replacement by instruction miss line fills. Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache.
2:3	—	Reserved(1)
4:5	WDD	Way Data Disable. 0 = The corresponding way in the data cache is available for replacement by data miss line fills. 1 = The corresponding way in the data cache is not available for replacement by data miss line fills. Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache.
8:11	—	Reserved(1)
12	DCWA	Data Cache Write Allocation Policy 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled When enabled is a write misses the cache the cache line is loaded into cache before writing data.
13:14	—	Reserved(1)
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits. This includes writes due to store hits as well as writes due to cache line refills. DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE=0.

Table 157. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
17:18	DCLOC	Data Cache Lockout Control 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error. **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of error conditions.
19:24	—	Reserved(1)
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 1x Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation When written to a ‘1’ in conjunction with writing DCINV to a ‘1’, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value.
28	—	Reserved(1)
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 157. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
30	DCINV	Data Cache Invalidate 0 No cache invalidate 1 Cache invalidation operation When written to a ‘1’, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value.
31	DCE	Data Cache Enable 0 Cache is disabled 1 Cache is enabled When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE.

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in *Figure 90*.

0–14	15	16	17–18	19–24	25–26	27	28	29	30	31
0	ICECE	ICEI	ICLOC	0	ICEA	ICLOINV	0	ICABT	ICINV	ICE

SPR - 1011; Read/Write; Reset - 0x0

Figure 90. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 bits are described in *Table 158*.

Table 158. L1CSR1 Field Descriptions

Bits	Name	Description
0:14	—	Reserved(1)
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits. ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE=0.

Table 158. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
17:18	ICLOC	Instruction Cache Lockout Control 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error. **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of error conditions.
19:24	—	Reserved(1)
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 1x Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation When written to a ‘1’ in conjunction with writing ICINV to a ‘1’, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value.
28	—	Reserved(1)
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 158. L1CSR1 Field Descriptions (continued)

Bits	Name	Description
30	ICINV	Instruction Cache Invalidate 0 No cache invalidate 1 Cache invalidation operation When written to a ‘1’, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value.
31	ICE	Instruction Cache Enable 0 Cache is disabled 1 Cache is enabled When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE.

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the Core (z420n3) L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in *Figure 91*.

CARCH	CWPA	CFAHA	DCFISW	0		DCBSIZE	DCREPL	DCLA	DCECA	DCNWAY	DCSIZE
0 1	2	3	4	5	6	7 8	9 10	11	12	13 14 15 16 17 18 19 20	21 22 23 24 25 26 27 28 29 30 31
00	1	0	1	0	0	00	11	0	1	00000001 (2 way)	00000000100 (4 KB)

SPR - 515; Read-only

Figure 91. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in *Table 159*.

Table 159. L1CFG0 Field Descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 - The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 - The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 - The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 - The data cache supports invalidation by Set and Way via L1FINV0

Table 159. L1CFG0 Field Descriptions (continued)

Bits	Name	Description
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 - The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11- The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 - The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 - The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 - The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 - The size of the data cache is 4 Kbyte

15.6.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the Core (z420n3) L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in *Figure 92*.

0	ICFISW	0	ICBSIZE	ICREPL	ICLA	ICECA	ICNWAY	ICSIZE
0 1 2 3	4	5 6	7 8	9 10	11	12	13 14 15 16 17 18 19 20	21 22 23 24 25 26 27 28 29 30 31
0000	1	0 0	00	11	0	1	00000001 (2 way)	00000001000 (8 KB)

SPR - 516; Read-only

Figure 92. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 bits are described in *Table 160*.

Table 160. L1CFG1 Field Descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 - The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 - The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 - The instruction cache implements a FIFO replacement policy

Table 160. L1CFG1 Field Descriptions (continued)

Bits	Name	Description
11	ICLA	Instruction Cache Locking APU Available 0 - The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 - The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 - The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 - The size of the instruction cache is 8 Kbyte

15.6.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

15.6.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided however for a Dcache line invalidation operation requested by an external hardware debugger to occur. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available DCache access cycle.

15.6.8 Cache Invalidate by Set and Way

Core (z420n3) supports cache set/way invalidation under software control. The caches may be invalidated by set and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

15.6.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in *Figure 93*.

Bits 0–6	Bit 7	Bits 8–20	Bits 21–26	Bits 27–29	Bits 30–31
0	CWAY	0	CSET	0	CCMD

SPR - 1016; Read/Write; Reset - 0x0

Figure 93. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in *Table 161*.

Table 161. L1FINV0 Field Descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8:20	—	Reserved for set extension
21:26	CSET	Cache Set Specifies the cache set to be selected
27:29	—	Reserved for set/command extension
30:31	CCMD	Cache Command 00 = The data contained in this entry is invalidated 01 = Reserved 1x = Reserved

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error.

15.6.8.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in *Figure 94*.

0–6	7	8–19	20–26	27–29	30–31
0	CWAY	0	CSET	0	CCMD

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 959; Read/Write; Reset - 0x0

Figure 94. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in *Table 162*.

Table 162. L1FINV1 Field Descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:29	—	Reserved for set/command extension
30:31	CCMD	Cache Command 00 = The data contained in this entry is invalidated 01 = Reserved 1x = Reserved

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error.

15.6.9 Cache EDC/ECC Protection

Cache protection is supported for both the tag and data arrays of each cache. Tag arrays of both instruction and data caches support error detection and correction. Each doubleword in the data arrays of the ICache and for each word in the data arrays of the DCache, have single and double bit error detection.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error, to protect against internal addressing failures.

Tag ECC and data EDC checking is controlled by the $L1CSR0_{DCECE}$ and $L1CSR1_{ICECE}$ control fields. When error checking is enabled, checking is performed on each cache access.

For cache lookups due to instruction fetching, normal loads, or normal stores, if an uncorrectable tag ECC error is detected on any portion of the accessed tags, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, an error is also signaled.

Store hits to the Dcache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the Dcache during otherwise idle cycles once two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur, and one or more syndrome bits to be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled, or both may occur, depending on the error action control setting in the appropriate cache control register.

15.6.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the Icache and Dcache has a lockout indicator composed of a redundant set of lockout bits which can be selectively set when certain errors occur in either the tag or data portion of the cache line. Use of the lockout function and control over error conditions which cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines which encounter selected tag ECC or data EDC errors on normal cacheable instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Lockout indicators may be cleared by software performing a cache invalidation operation (setting $L1CSR\{0,1\}_{[D,I]CINV}$) in conjunction with a cache lockout indicator invalidation (setting

L1CSR{0,1}$_{[D,I]CLOINV}$). Three stored redundant lockout bits are provided to allow for single and double-bit parity errors to be detected on the lockout indicators themselves.

When operating in machine check mode, if lockout controls are enabled via L1CSR{0,1}$_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception. If correction/auto-invalidation is instead enabled, on each cache lookup operation, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by re-writing all lockout bits to the asserted state, and no machine check is generated.

Lockout bit parity errors are ignored for non-cacheable accesses in either error action mode. In addition, to avoid certain exception conditions and for consistency with error reporting, non-cacheable accesses and specialized load/store accesses do not set LO bits; instead, cache contents are ignored for those errors since the cache is bypassed. A future cacheable normal access will perform the lockout function if required.

15.6.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting EDC/ECC errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1$_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant EDC/ECC check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If L1CSR0$_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant EDC/ECC check bits inverted in the data array for each word loaded. Additionally, inverted bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the EDC/ECC bit errors, a cache invalidation or an invalidation of the lines which have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV[0,1] invalidation operation.

15.7 Exceptions

As specified by the PowerISA 2.06 architecture, interrupts can be either precise or imprecise, synchronous or asynchronous, and critical or non-critical. Asynchronous exceptions are caused by events external to the processor’s instruction execution; synchronous exceptions are directly caused by instructions or an event somehow synchronous to the program flow, such as a context switch. A precise interrupt architecturally guarantees that no instruction beyond the instruction causing the exception has (visibly) executed. Critical interrupts are provided with a separate save/restore register pair (CSRR0/CSRR1) to allow certain critical exceptions to be handled within a non-critical interrupt handler. Machine check interrupts are also provided with a separate save/restore register pair (MCSRR0/MCSRR1) to allow machine check exceptions to be handled within a non-critical or critical interrupt handler. Debug interrupts are also provided with a separate save/restore register pair (DSRR0/DSRR1) to allow debug exceptions to be handled within a critical, non-critical, or machine check interrupt handler.

Interrupts implemented in Zen and the exception conditions that cause them are listed in *Table 163*.

Table 163. Exceptions and Conditions

Interrupt Type	Interrupt Vector Offset Value	Causing Conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	1) Reset
Critical Input	0x00(1)	**p_critint_b** is asserted and MSR_{CE}=1.
Machine check	0x10	1) **p_mcp_b** transitions from negated to asserted 2) ISI or Bus Error on first instruction fetch for an exception handler 3) EDC/ECC Error signaled on cache or Local Memory access 4) External bus error 5) Stack limit check failure
Machine check (NMI)	0x10	1) Non-Maskable Interrupt.
Data Storage	0x20	1) Access control
Instruction Storage	0x30	1) Access control
External Input	0x40(2)	Interrupt Controller interrupt and MSR_{EE}=1
Alignment	0x50	1) **lmw**, **stmw** not word aligned 2) **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3) dcbz
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$=1, MPU
EFPU Data Exception	0xA0	
EFPU Round Exception	0xB0	
TBD	0xC0-0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.7.1 Exception Syndrome Register

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

Bits	0–3	4	5	6	7	8	9–11	12	13	14	15	16–23	24	25	26	27–29	30	31
Field	0	PIL	PPR	PTR	FP	ST	0	0	0	BO	0	0	SPV	0	VLEMI	0	0	0

SPR - 62; Read/Write; Reset - 0x0

Figure 95. Exception Syndrome Register

The ESR bits are defined in *Table 164*.

Table 164. ESR Bit Settings

Bit(s)	Name	Description	Associated Interrupt Type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception (For Core (z420n3), PIL is used for both illegal and unimplemented instructions)	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	--	Reserved	—

26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

15.7.2 Machine State Register

The Machine State Register defines the state of the processor. The Zen MSR is shown in *Figure 96*.

0:5	6	7:12	13	14	15	16	17	18	19	20	21	22	23	24:25	26	27	28	29	30	31
0	0	0	0	CE	0	EE	PR	0	ME	0	0	DE	0	0	IS	DS	0	PMM	RI	0

Read/ Write; Reset - 0x0

Figure 96. Machine State Register (MSR)

The MSR bits are defined in *Table 165*.

Table 165. MSR Field Descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	—	Reserved
7:12	—	Reserved
13	—	Reserved
14	CE	Critical Interrupt Enable 0 - Critical Input interrupts are disabled. 1 - Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 - External Input interrupts are disabled. 1 - External Input interrupts are enabled.

Table 165. MSR Field Descriptions (continued)

Bit(s)	Name	Description
17	PR	Problem State 0 - The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 - The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 - Asynchronous Machine Check interrupts are disabled. 1 - Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 - Debug interrupts are disabled. 1 - Debug interrupts are enabled.
23	—	Reserved
24	—	Reserved
25	—	Reserved
26	—	Reserved
27	—	Reserved
28	—	Reserved
29	PMM	PMM Performance monitor mark bit. System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the Performance Monitor registers PMLCa n, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt - This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken
31	—	Reserved

15.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 97*.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
MCP	IC_DPERR	0	DC_DPERR	EXCP_ERR	IC_TPERR	DC_TPERR	IC_LKERR	DC_LKERR	0		NMI	MAV	MEA	U	IF	LD	ST	G	0		STACK_ERR	IMEM_PERR	DMEM_RDPERR	DMEM_WRPERR	0		BUS_IRERR	BUS_DRERR	BUS_WRERR	BUS_WRDSI	0

SPR - 572; Read/Clear; Reset - 0x0

Figure 97. Machine Check Syndrome Register (MCSR)

Table 166 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write ‘1’ to clear”. Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME}=1.

Table 166. Machine Check Syndrome Register (MCSR)

Bit	Name	Description	Exception Type[(1)]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved		—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Icache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the Dcache for certain situations. May also be set on locked line refill error.	Async Mchk	—
10:11	—	Reserved		—
11	NMI	NMI input pin	NMI	—

Table 166. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV=1,MEA=1 indicates that the MCAR contains an effective address and MEA=0 indicates that the MCAR contains a physical address	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an ECC error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an ECC error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved		—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved		—

Table 166. Machine Check Syndrome Register (MCSR) (continued)

Bit	Name	Description	Exception Type(1)	Recoverable
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved		—

1. The Exception Type indicates the exception type associated with a given syndrome bit

   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a "1" to the bit position(s) to be cleared.

   - "Status" indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a "1" to the bit position(s) to be cleared.

   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a "1" to the bit position.

   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME}=1. If MSR_{ME}=0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a "1" to the bit position(s) to be cleared.

15.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the Interrupt Vector Prefix register (IVPR) to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 98*.

Vector Base (bits 0–23)	0 (bits 24–31)

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 63; Read/Write

Figure 98. Interrupt Vector Prefix Registers (IVPR)

The IVPR fields are defined in *Table 167*.

Table 167. IVPR Register Fields

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.7.5 Interrupt Definitions

15.7.5.1 Critical Input Interrupt (Offset 0x00)

A Critical Input exception is signalled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 168 lists register settings when a Critical Input interrupt is taken.

Table 168. Critical Input Interrupt—Register Settings

Register	Setting Description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME— FE0 0 DE—/0(1)	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13]**) || 2'b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.7.5.2 Machine Check Interrupt (Offset 0x10)

The Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome register (MCSR) to record the source(s) of machine checks, and a Machine Check Address register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 169*.

Table 169. Machine Check Interrupt - Register Settings

<table>

</table>

1. Clearing of DE is optionally supported by control in HID0.

15.7.5.3 Data Storage Interrupt (Offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 170 lists register settings when a DSI is taken.

Table 170. Data Storage Interrupt—Register Settings

<table>
<tr><th>Register</th><th colspan="3">Setting Description</th></tr>

ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x30		

15.7.5.5 External Input Interrupt (Offset 0x40)

An External Input exception is signalled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 172 lists register settings when an External Input interrupt is taken.

Table 172. External Input Interrupt—Register Settings

Register	Setting Description
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.
SRR1	Set to the contents of the MSR at the time of the interrupt

15.7.5.6 Alignment Interrupt (Offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** not word aligned.
- The operand of **lwarx** or **stwcx.** not word aligned.
- The operand of **lharx** or **sthcx.** not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

Table 173 lists register settings when an alignment interrupt is taken.

Table 173. Alignment Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—

MCSR	Unchanged		
DEAR	Set to the effective address of a byte of the load or store access causing the violation.		
Vector	$IVPR_{0:23}$ || 0x50		

15.7.5.7 Program Interrupt (Offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

core will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- Instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

core will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR}=1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions which specify a SPRN value with $SPRN_5$=1 (even if the SPR is undefined).

core will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause a illegal instruction program exception.

Table 174 lists register settings when a Program interrupt is taken.

Table 174. Program Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt

MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x60		

15.7.5.8 System Call Interrupt (Offset 0x80)

A System Call interrupt occurs when a System Call (**se_sc**) instruction is executed and no higher priority exception exists.

Table 175 lists register settings when a System Call interrupt is taken.

Table 175. System Call Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the instruction *following* the system call instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE— EE 0 PR 0	FP 0 ME— FE0 0 DE—	FE1 0 IS 0 DS 0 PMM 0 RI—
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x80		

15.7.5.9 Debug Interrupt (Offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM}$=1 (internal debug mode) and MSR_{DE}=1).

Table 176 lists register settings when a Debug interrupt is taken.

Table 176. Debug Interrupt—Register Settings

Register	Setting Description		
DSRR0[(1)]	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP. Set to the effective address of the next instruction to be executed *following* the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
DSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0[(2)] EE—/0[(2)] PR0	FP 0 ME— FE0 0 DE 0	FE1 0 IS 0 DS 0 PMM 0 RI—

2. conditional based on control bits in HID0
3. Note that multiple DBSR bits may be set

15.7.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signalled to the processor through the assertion of system-defined signals.

A System reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 177 lists register settings when a System Reset interrupt is taken.

Table 177. System Reset Interrupt—Register Settings

Register	Setting Description
CSRR0	Undefined.
CSRR1	Undefined.

Table 177. System Reset Interrupt—Register Settings (continued)

15.7.5.11 Embedded Floating-point Data Interrupt (Offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and a EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

Table 178 lists register settings when a EFPU Floating-point Data interrupt is taken.

Table 178. Embedded Floating-point Data Interrupt—Register Settings

Register	Setting Description		
SRR0	Set to the effective address of the excepting EFPU instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt

15.7.5.13 Performance Monitor Interrupt (Offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- $PMLCax_{CE}$ = 1; that is, for the given counter the overflow condition is enabled.
- $PMCx_{OV}$ = 1; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 180 lists register settings when an performance monitor interrupt is taken.

Table 180. Performance Monitor Interrupt—Register Settings

Register	Setting Description		
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.		
SRR1/ DSRR1(1)	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE—/0(2) EE 0/—(3) PR 0	FP 0 ME— FE0 0 DE—/0(4)	FE1 0 IS 0 DS 0 PMM 0 RI—

Register	Setting Description
DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0x70

1. DSRR0/1 are used if $PMGC0_{UDI}$ = 1'
2. CE is cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLRCE}$ = 1
3. EE is not cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLREE}$ =0
4. DE is cleared if $PMGC0_{UDI}$ = 1'

15.8 MPU

15.8.1 MPU Overview

The Core (z420n3) Memory Protection Unit (MPU) provides the capability of protecting regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints

Software managed by **mpure** and **mpuwe** instructions

15.8.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MPU Assist registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with a **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with a **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

15.8.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

Figure 99. MPU Read Entry Instruction (mpure)

mpure **mpure**

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

15.8.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

Figure 100. MPU Write Entry Instruction (mpuwe)

mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

15.8.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the Core (z420n3).

Figure 101. MPU Synchronize Instruction (mpusync)

15.8.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the Core (z420n3) MPU design. The MMUCFG register is shown in *Figure 102*.

0	RASIZE	0	PIDSIZE	NMPUS	NTLBS	MAVN
0 1 2 3 4 5 6 7	8 9 10 11 12 13 14	15 16 17 18 19 20	21 22 23 24 25	26 27	28 29	30 31

SPR - 1015; Read-Only

Figure 102. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 181*.

Table 181. MMUCFG Field Descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000- This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 - PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 - This version of the MMU implements one MPU structure: a fully-associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 - This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 - This version of the MMU implements Version 3.1 of the MMU Architecture

15.8.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the Core (z420n3) MPU. The MPU0CFG register is shown in *Figure 103*.

0	1–7	8–11	12–15	16	17	18	19–22	23–25	26–28	29–31
FASSOC	0	MINSIZE	MAXSIZE	IPROT	0	UAMSKA	0	SHENTRY	DENTRY	IENTRY

SPR - 692; Read-Only

Figure 103. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in *Table 182*.

Table 182. MPU0CFG Field Descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 - Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size 0x0 - Smallest region size is 1 byte Note: due to the use of access address matching, the effective smallest region size is 8 bytes
12:15	MAXSIZE	Maximum Region Size 0xB - Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 - Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 - Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 - Indicates that MPU0 contains 6 shared entries
26:28	DENTRY	Number of Data Entries 0x4 - Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 - Indicates that MPU0 contains 6 dedicated Instruction entries

15.8.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in *Figure 104*.

0–15	16	17	18	19	20	21	22–23	24	25	26	27	28	29	30	31
0	BYPSR	BYPSW	BYPSX	BYPUR	BYPUW	BYPUX	0	DRDEN	DWDEN	IDEN	0	TIDCTL	0	MPUFI	MPUEN

SPR - 1014; Read/ Write; Reset - 0x0

Figure 104. MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0CSR0 bits are described in *Table 183*.

Table 183. MPU0CSR0 - MPU0 Control and Status Register 0

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses 0 - No Bypass of MPU protections for Supervisor Read accesses 1 - Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
17	BYPSW	Bypass MPU protections for Supervisor Write accesses 0 - No Bypass of MPU protections for Supervisor Write accesses 1 - Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses 0 - No Bypass of MPU protections for Supervisor Instruction accesses 1 - Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
19	BYPUR	Bypass MPU protections for User Read accesses 0 - No Bypass of MPU protections for User Read accesses 1 - Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).
20	BYPUW	Bypass MPU protections for User Write accesses 0 - No Bypass of MPU protections for User Write accesses 1 - Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G).

Table 183. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
21	BYPUX	Bypass MPU protections for User Instruction accesses 0 - No Bypass of MPU protections for User Instruction accesses 1 - Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI).
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable 0 - MPU debug events are disabled for data read accesses 1 - MPU debug events are enabled for data read accesses This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events.
25	DWDEN	Data Write Debug Enable 0 - MPU debug events are disabled for data write accesses 1 - MPU debug events are enabled for data write accesses This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events.
26	IDEN	Instruction Debug Enable 0 - MPU debug events are disabled for instruction accesses 1 - MPU debug events are enabled for instruction accesses This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG=1. When enabled, instruction accesses are not blocked from generating MPU debug events.
27	—	Reserved
28	TIDCTL	TID usage Control 0 - TID comparisons performed normally 1 - no TID comparisons are performed for matching while in Supervisor mode When TIDCTL is set to ‘1’, the TID match is disabled (forced match) in Supervisor mode.
29	—	Reserved

Table 183. MPU0CSR0 - MPU0 Control and Status Register 0 (continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate 0 - No flash invalidate 1 - MPU1 invalidation operation When written to a ‘1’, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to ‘0’. Writing a ‘1’ while an invalidation operation is in progress will result in an undefined operation. Writing a ‘0’ to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. Note that entries which have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable 0 - MPU is disabled 1 - MPU is enabled This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG=1 if in EDM and hardware owns MPU Debug entries.

15.8.9 MPU Assist Registers (MAS)

The Core (z420n3) uses four special purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 105*. Fields are defined in *Table 184*.

Field	VALID	IPROT	SEL	0	RO	DEBUG	INST	SHD	0	ESEL	0	UAMSK	UW	SW	UX/UR	SX/SR	IOVR	GOVR (1)	1	1	I	0	G (1)	0
Bits	0	1	2–3	4	5	6	7	8	9–11	12–15	16	17–19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 624; Read/ Write; Reset - Unaffected

Figure 105. MPU Assist Registers 0 (MAS0)

1. This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1

Table 184. MAS0 —MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 - This MPU entry is invalid 1 - This MPU entry is valid
1	IPROT	Invalidation Protect 0 - Entry is not protected from invalidation 1 - Entry is protected from invalidation

Table 184. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 - Reserved, no access 01 - Reserved, no access 10 - Select MPU 11 - Reserved, no access
4	—	Reserved
5	RO	Read-Only 0 - This MPU entry is writable 1 - This MPU entry is Read-only When set to ‘1’, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs.
6	DEBUG	Debug Control for Entry 0 - This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 - This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access.
7	INST	Instruction Entry 0 - This MPU entry is used for matching data accesses only 1 - This MPU entry is used for matching instruction accesses only When SHD=0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD=1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry.
8	SHD	Shared Entry Select 0 - The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 - The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected. This bit is used to control selection of the Shared portion of the region descriptor table.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

Table 184. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
17:19	UAMSK	Upper Address Mask Control 000 - No upper address bits are masked, address matching uses all 32 address bits for accesses 001 - The most significant access address bit is forced to zero before matching 010 - The two most significant access address bits are forced to zero before matching 101 - The upper 5 access address bits are forced to zero before matching 11x - Reserved, do not use This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly.
20	UW	User Mode Write Permission 0 - No User mode Write permission 1 - User mode has Write permission Determines User mode Write (W) permission when INST=0. Ignored when INST=1.
21	SW	Supervisor Mode Write / Read Permission 0 - No Supervisor mode Write permission 1 - Supervisor mode has Write permission Determines Supervisor mode Write (W) permission when INST=0. Ignored when INST=1.
22	UX/UR	User Mode Execute / Read Permission 0 - No User mode Execute/ Read permission 1 - User mode has Execute/ Read permission Determines User mode Execute (X) permission when INST=1, or User mode Read (R) permission when INST=0.
23	SX/SR	Supervisor Mode Execute / Read Permission 0 - No Supervisor mode Execute/ Read permission 1 - Supervisor mode has Execute/ Read permission Determines Supervisor mode Execute (X) permission when INST=1, or Supervisor mode Read (R) permission when INST=0.
24	IOVR	Cache-Inhibit attribute Override 0 - No override of I attribute by entry 1 - Entry I bit overrides I attribute Determines whether this matching entry overrides the I bit settings of other matching entries and the Cache-Inhibited region configuration signals
25	GOVR/—	G attribute Override 0 - No override of G attribute by entry 1 - Entry G bit overrides G attribute Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
26	—	Reserved
27	—	Reserved

Table 184. MAS0 —MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
28	I	Cache Inhibited 0 - This region is considered cacheable 1 - This region is considered cache-inhibited This attribute may be overridden by the cache-inhibited region configuration input settings.
29	—	Reserved
30	G/—	Guarded 0 - Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 - All loads and stores to this region are performed without speculation (i.e. they are known to be required) This attribute may be overridden by the guarded region configuration input settings. This bit is not implemented in dedicated instruction entries, and is ignore in shared entries with INST=1.
31	—	Reserved

The MAS1 register is shown in *Figure 106*. Fields are defined in *Table 185*.

0	TID	0	TIDMSK
0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31

SPR - 625; Read/ Write; Reset - Unaffected

Figure 106. MPU Assist Register 1 (MAS1)

Table 185. MAS1 —Descriptor Context and Configuration Control

Bit	Name	Comments, or Function when Set
0:7	—	Reserved
8:15	TID	Region ID bits This field is compared with the current process ID of the access address. A TID value of 0 defines an entry as global and matches with all process IDs.

Table 185. MAS1 —Descriptor Context and Configuration Control (continued)

Bit	Name	Comments, or Function when Set
16:23	—	Reserved
24:31	TIDMSK	Region ID mask 0xxxxxxx - TID[0] comparison to PID0[0] not masked 1xxxxxxx - TID[0] comparison to PID0[0] is masked x0xxxxxx - TID[1] comparison to PID0[1] not masked x1xxxxxx - TID[1] comparison to PID0[1] is masked xx0xxxxx - TID[2] comparison to PID0[2] not masked xx1xxxxx - TID[2] comparison to PID0[2] is masked xxx0xxxx - TID[3] comparison to PID0[3] not masked xxx1xxxx - TID[3] comparison to PID0[3] is masked xxxx0xxx - TID[4] comparison to PID0[4] not masked xxxx1xxx - TID[4] comparison to PID0[4] is masked xxxxx0xx - TID[5] comparison to PID0[5] not masked xxxxx1xx - TID[5] comparison to PID0[5] is masked xxxxxx0x - TID[6] comparison to PID0[6] not masked xxxxxx1x - TID[6] comparison to PID0[6] is masked xxxxxxx0 - TID[7] comparison to PID0[7] not masked xxxxxxx1 - TID[7] comparison to PID0[7] is masked This field controls whether bits within the TID to PID[0] comparison are masked for determining a range match. When a bit is masked, the value of that TID and PID0 bit is ignored for matching purposes.

The MAS2 register is shown in *Figure 107*. Fields are defined in *Table 186*.

Figure 109. MPU Assist Registers Summary

15.9 Local memories

Note: Instruction memory (IMEM) is not present in this device.

15.9.1 Local instruction and data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added to the next generation processor cores. These memories provide for low latency access (zero wait-state) similar to an instruction or data cache, but do not suffer from the overhead of cache miss or cache Writethrough operations. Instead, they provide “tightly coupled” storage.

15.9.2 Local memory control and configuration

DMEM and IMEM local memory configuration is provided by a set of privileged read-only SPRs which are accessed using **mfspr** instructions. DMEM and IMEM local memory is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the Core (z425n3) local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 110*.

DMEM BASE ADDR	0	DECUA	DECA	0	DMSIZE	0
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19	20	21	22	23	24 25 26 27 28 29	30 31
CURRENT DMEM BASE ADDRESS VALUE	0	1	1	0	010000 (64 KB)	00

SPR - 694; Read-only; Privileged

Figure 110. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 188*.

Table 188. DMEMCFG0 Field Descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** low order bits of this field are driven to 0's when the DMEM size is > 4 Kbyte
20	-	Reserved
21	DECUA	DECUE - DMEM Error Correction Update Available 0 - Error Correction Update is not available 1 - Error Correction Update is available for correction of a correctable single-bit error detected on a read access DECUA indicates an error scrubbing function for the DMEM is available.
22	DECA	DECUE - DMEM Error Correction Available 0 - Error Correction is not available 1 - Error Correction is available DECA indicates an error correction function for the DMEM is available.
23	-	Reserved
24:29	DMSIZE	DMSIZE - DMEM Size 010000 - The size of the DMEM is 64 Kbyte.
30:31	-	Reserved

15.9.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCECE	DSECE
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16	17 18	19	20	21	22	23	24	25	26	27 28	29	30	31

DCR - 496; Read/Write; Reset(1) - 19‘b0 || p_dmem_rstcfg[8,6:7,0] || 4‘b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 111. DMEM Control Register 0 (DMEMCTL0)

1. reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 189. DMEMCTL0 Field Descriptions

Bits	Name	Description
0:16	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
17:18	-	Reserved
19	DBYPCB	DBYPCB - DMEM Bypass Cache Bypass CPU accesses 0 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port 1 - Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses which target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input.
20	DBYPAT	DBYPAT - DMEM Bypass Atomic CPU accesses 0 - Atomic CPU accesses do not bypass the DMEM CPU port 1 - Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems which support reservation or decoration functionality (or both), since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input.

Table 189. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
21	DBYPDEC	DBYPDEC - DMEM Bypass Decorated CPU accesses 0 - Decorated Load and Store CPU accesses do not bypass the DMEM CPU port 1 - Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems which support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input.
22	DECUE	DECUE - DMEM Error Correction Update Enable 0 - Error Correction Update is disabled 1 - Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be re-written with the corrected data. (Write accesses perform this correction automatically during partial-width writes.) DECUE can be used to provide an error scrubbing function for the DMEM. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input.
23	-	Reserved
24	DBAPD	DBAPD - DMEM Base Address Port Disable 0 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 - The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses. This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses.
25	DPEIE	DPEIE - DMEM Processor Error Injection Enable 0 - Error Injection is disabled 1 - A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]). DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE=0.
26	DICWE	DICWE - DMEM Imprecise CPU Write Enable 0 - Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 - Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only). DICWE may allow for increased partial-width write performance when set.

Table 189. DMEMCTL0 Field Descriptions (continued)

Bits	Name	Description
27:28	DSWCE	DSWCE - DMEM Slave port Write Check/Correct Enable 00 - Slave write data is not checked or corrected for errors. 01 - Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 - Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 - Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or double word writes are not checked or corrected for errors. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs.
29	DDAUEC	DDAUEC - DMEM Disable Address Use in Error Check 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input.
30	DCECE	DCPECE - DMEM CPU Port ECC Enable (CPU port) 0 - End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1- End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input.
31	DSECE	DSECE - DMEM Slave port Error Checking Enable (Slave port) 0 - End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 - End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** this field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input.

15.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally-sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses which target DMEM address range, regardless of whether the access may bypass the DMEM based on settings in DMEMCTL0 $_{DBYPCB,}$ DBYPATF, DBYPDEC.

30:31	DURAC0	DURAC0 - DMEM User Read Access Control for Quadrant 0 00 - User-mode CPU read accesses are allowed to quadrant 0 of DMEM 01 - User-mode CPU read accesses are not allowed to quadrant 0 of DMEM 10 - User-mode CPU read accesses are conditionally allowed to quadrant 0 of DMEM based on memory protection logic 11 - Reserved **Note:** Individual control fields are provided for four equal sized sections of DMEM regardless of DMEM size. A single control field is used for each access based on the upper two address bits used to index into the DMEM. DURAC0 is used when these two bits = 2‘b00

15.10 End-to-End ECC support

This section describes End-to-End Error detection and correction capability (e2eECC) enhancements the Core (z425n3) to address additional diagnostic capabilities for the next generation of embedded designs.

15.10.1 e2eECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) which are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

0																												IDAC	IECCEN	DDAC	DECCEN
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR - 510; Read/Write; Reset - 0x0 || p_e2e_rstcfg[0:3]; Privileged

Figure 113. e2eECC Control Register 0 (E2ECTL0)

Table 191. E2ECTL0 Field Descriptions

Bits	Name	Description
0:27	-	These bits are reserved
28	IDAC	IDAC - Instruction Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Instruction AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 - End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 - End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	DDAC - Data Disable Address Checking 0 - Use of access address is enabled in checkbit and syndrome generation. 1 - Use of access address is disabled in checkbit and syndrome generation. This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion are not used for checkbit/syndrome generation for Data AHB accesses. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 - End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 - End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** this field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

Enabling of e2eECC operation is performed by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a one. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for non-zero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the E2ECTL0$_{[I,D]ECCEN}$ control bits.

The E2ECTL0$_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.10.1.2 End-to-end ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address or checkbit error on external bus write cycles, and then may read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus.

Note that Nexus3 accesses do not cause error injection or capturing of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 114 shows the layout of E2EECSR0.

0				RCHKBIT								0				WRC	INVC	0				WCHKBIT/CHKINVT							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 114. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 192. E2EECSR0 Field Descriptions

Bits	Name	Description
0:3	-	These bits are reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	-	These bits are reserved

Table 192. E2EECSR0 Field Descriptions (continued)

Bits	Name	Description
16:17	WRC	Write Control 00 - No write checkbit substitution is performed by this control bit 01 - Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 - Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11- Reserved **Note:** checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 - No error injection is performed by this control bit 01 - Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 - Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 - Reserved **Note:** checkbit substitution has priority over Error injection
20:23	-	These bits are reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits /Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 - Checkbit is driven normally 1 - Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

16 System Integration Unit Lite2 (SIUL2)

16.1 Introduction

16.1.1 Overview

The System Integration Unit Lite2 (SIUL2) provides control over all the I/O ports on this device and supports 14 ports with up to 16 bits of bidirectional, general-purpose input and output signals. It supports 24 external interrupts with trigger event configuration. *Figure 115* is the block diagram of SIUL2 and its interfaces to other system components for this device.

The SIUL2 provides the GPIO ports on the device.

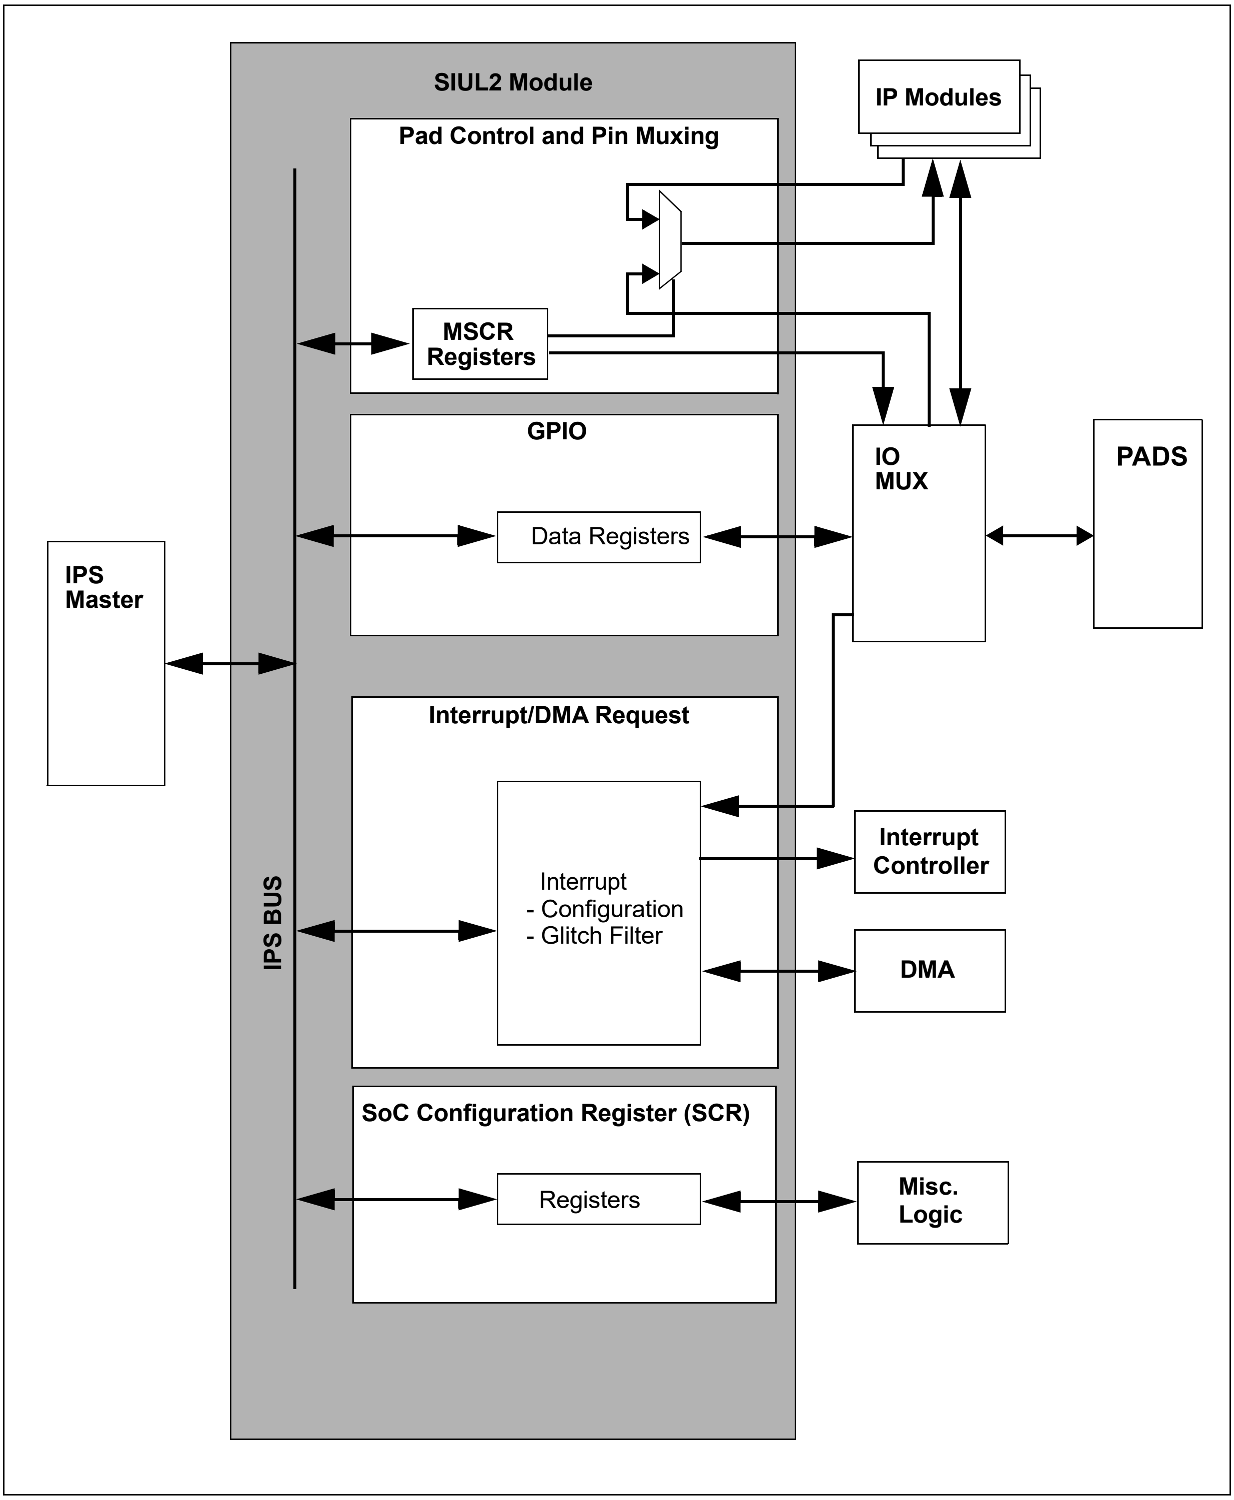
- When configured as output, you can write to the internal GPDO register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from the internal GPDI register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the driven value on the associated I/O pad.

In order to assist in software development, there are different access mechanisms to the GPIO data registers. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation:

- Access to two 16-bit ports in one access
- Read/Write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access

There are 24 external interrupts and 32 DMA inputs to the SIUL2 that map to EIRQ pins on the device. The interrupt/DMA sources can be configured to have a digital filter to reject short glitches on the inputs.

Figure 115. SIUL2 block diagram[e]



e. For pinout details, refer to the SPC584Bx pinout Microsoft Excel file attached to the IO_Definition document.

16.1.2 Features

The SIUL2 supports these distinctive features:

- Up to 14 GPIO ports with data control[f]
  - Drive data to up to 16 independent I/O channels
  - Sample data from up to 16 independent I/O channels
- Two 16-bit registers can be read/written with one access to a 32-bit port if needed.
- External interrupt/DMA request support with:
  - 4 system interrupt vectors for 24 interrupt sources (24 connected to EIRQ pins for this device) with independent interrupt mask
  - 24 programmable digital glitch filters (one for each EIRQ)
  - Independent DMA channels for each EIRQ pin
  - Edge detection

Details about the electrical parameters and setting of functional pads can be found in the SPC584Bx pinout Microsoft Excel file attached to the IO_Definition document. These are used to configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control of JTAG pins
- Internal weak pull control
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration
- TTL, CMOS and Automotive input levels

16.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0(SIUL2_DIRER0)
- SIUL2 DMA/Interrupt Request Select Register 0(SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0(SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0(SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0(SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

Details about the protected registers at specific addresses can be found in *Chapter 77: Register Protection (REG_PROT)* and *Chapter 7: Device configuration*.

f. For pinout details, refer to the SPC584Bx pinout Microsoft Excel file attached to the IO_Definition document.

16.2 Memory map and register description

This section provides a detailed description of all registers accessible in this module.

16.2.1 Memory map

Table 193 gives an overview of the SIUL2 registers implemented.

Note: Reserved registers will be read as 0, write will have no effect. If supported and enabled in this MCU, a transfer error will be issued when trying to access completely reserved register space. A 8-bit or 16-bit access to an "only 32-bit supported access register" gives a transfer error. Unimplemented register accesses give transfer error, that is due to register not being present.

For SIUL2_MSCR_MUX_512-SIUL2_MSCR_MUX1023, only 32/16-bit accesses are supported (8-bit writes do not occur and read zeros).

16.2.2 Register descriptions

This section describes in address order all the SIUL2 registers.

16.2.2.1 MCU ID Register #1 (SIUL2_MIDR1)

This register contains identification information about the device.

In case of HPREG configuration, the reset values are:

- QFP176: 0x584244xx
- QFP144: 0x584234xx
- QFP100: 0x584224xx
- QFP64: 0x584204xx

In case of DREG configuration, the reset values are:

- QFP176: 0x584246xx
- QFP144: 0x584236xx
- QFP100: 0x584226xx
- QFP64: 0x584206xx

Note: The “x” value in the reset values above listed depends on the minor device silicon version.

16.2.2.3 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set irrespective of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) is enabled. The EIF bit remains set until cleared by software or through the servicing of a DMA request. The EIF bits are cleared by writing a ‘1’ to the bits. A write of ‘0’ has no effect.

This register contains the interrupt flags.

Figure 118. SIUL2 DMA/Interrupt Status Flag Register (SIUL2_DISR0)

Table 196. SIUL2_DISR0 field descriptions

Field	Description
8:31 EIF[23:0]	External Interrupt Status Flag x This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

16.2.2.4 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

Field	Description
8:31 EIRE[23:0]	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR

16.2.2.5 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

Figure 124. SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)

Table 202. SIUL2_IFMCR*n* field descriptions

Field	Description
28:31 MAXCNT	Maximum Interrupt Filter Counter setting (MAXCNTx) Filter Period = TCK*MAXCNTx + n*TCK where (n = -1 to 3) MAXCNT can be 0 to 15 (for MAXCNT<3 filter will behave as all PASS filter) TCK is the Prescaled filter clock period, which is the IRC clock prescaled to IFCP value, specified in SIUL2_IFCPR T(IRC): Basic filter clock period 62.5 ns (f = 16 MHz) Note that filter delay is 2 system clock cycles more than filter period. In general, Filter Period and Filter delay are not integer multiple of TCK because input to Filter is asynchronous whereas output is synchronous with respect to the TCK. T(DELAY) = (1 to 5) * TCK + MAXCOUNT * TCK. The SW is to expect the worst filter delay value

16.2.2.10 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register configures a clock prescaler that selects the clock for all digital filters. The prescaler is applied to the input clock to the SIUL2, which is the system PBRIDGE clock counter in the SIUL2. Refer to *Chapter 25: Clocking* for information on clocking.

Offset: 0x00C0 Access: User read/write

Table 203. SIUL2_IFCPR field descriptions

Field	Description
28:31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15.

16.2.2.11 Soc Configuration Register 0 (SIUL2_SCR0)

The ETHERNET_0_MODE bit is used to select between the Media Independent Interface (MII) and the Reduced Media Independent Interface (RMII) mode for the Ethernet.

MASK_OPCn is used to prevent the SSWU OPC channel n to drive the pad during standby.

PADn_MUX_SEL is used to maintain the pad value at standby exit (PADn_MUX_SEL = 0)

Note: PADn_MUX_SEL must be set to 1 to be able to change the pads value and direction after stand-by while system is in the RUN mode.

Offset: 0x0100 Access: User read/write

16.2.2.12 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO*n*)

Refer to *Section 16.2.3: Multiplexed Signal Configuration Registers* for an introduction to the MSCRs.

This section defines the I/O pin MSCRs. These registers select the output function on the associated I/O pin. The I/O MSCRs control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, and safe-mode operation of the associated I/O pin.

Note: Not all pads have all bits, such as only some pads have hysteresis. Refer to the I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document.

Note that when an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs, and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

All bits and fields in the I/O MSCRs are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The MSCR reset state is detailed in the I/O Signal Table of the SPC584Bx pinout Microsoft Excel file attached to the IO_Definition document.

Figure 127. I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO*n*)

Table 205. SIUL2_MSCR_IO*n* field description

Field	Description
2:3 OERC	Output Edge Rate Control Specifies the output impedance, drive strength and slew rate of the associated pin. Refer to output Impedance columns in the I/O Signal Description Table for the applicable edge rates for each I/O pin on the device. The I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) are attached to the IO_Definition document. Refer to the device Data Sheet for the electrical characteristics of the weak, medium, strong, and very strong pad types **Note:** OERC[2] programming is required for forward compatibility. 00 Weak drive 01 Medium drive 10 Strong drive 11 Very Strong drive
6:7 ODC	Output Drive Control Specifies the type of output drive control for the associated pin. 00 Output buffer disabled 01 Open-drain 10 Push-pull 11 Open-source
8 SMC	Safe Mode Control Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. Resets to 0 except for PB[11] ERROR0 pin which resets to 1. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Does not disable

Table 205. SIUL2_MSCR_IO*n* field description (continued)

Field	Description
10:11 ILS	Input Level Selection Specifies the logic family for the associated pin, which determines its logic switching levels. Refer to the device Data Sheet for the electrical characteristics of the I/O pad input buffer types. Refer as well to the IO_Definition Microsoft Excel file. 00 Reserved 01 TTL (CMOS for LP pads) 10 LVDS 11 CMOS
12 IBE	Input Buffer Enable Enables the associated pin's input buffer. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. If pin has analog input-only functionality: when WPDE and WPUE are both enabled that pin is configured with Strong pulldown. On all other pins (including analog bidirectional) this configuration means neither a pullup nor a pulldown. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. If pin has analog input-only functionality: when WPDE and WPUE are both enabled that pin is configured with Strong pulldown. On all other pins (including analog bidirectional) this configuration means neither a pullup nor a pulldown. 0 Disabled 1 Enabled
16 INV	Invert The output selected by the corresponding MSCR SSS field can be inverted before it is driven on the I/O pin with the INV bit. **Note:** Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection. 0 The output selected by the SSS field is not inverted before being driven to the pin 1 The output selected by the SSS field is inverted before being driven to the pin
28:31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. Refer to the *Section 16.2.3.1* and *Section 16.2.3.2*.

Table 206. I/O MSCR Reset State Exceptions

Port	Critical Function	SMC	WPDE	WPUE
PA[4]	—	0	0	
PA[5]	JCOMP	1		
PA[6]	TCK	1	1	0
PA[7]	TMS	1	0	1

PE[12]	—	0	0	
PF[13]	—	0	0	
PI[14:15]	—	0	0	
PK[12:15]	—	0	0	
PM[0:8]	—	0	0	

1. When JTAG is enabled (JCOMP asserted) during reset, the TDO pin is pulled up during reset, but Hi-Z after. If JTAG is disabled, the TDO pin defaults to input/pull-up during and after reset.

16.2.2.13 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_MUX*n*)

Refer to *Multiplexed Signal Configuration Registers* for an introduction to the MSCRs.

This section defines the multiplexed input selection MSCRs. These registers select the input source for IP blocks on the device that have inputs from multiple sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

Offset: 0x240 + *n* * 0x4 (*n* = 512 to 1023) Access: User read/write

Table 207. SIUL2_MSCR_MUX*n* field descriptions

Field	Description
16 INV	Invert The input source signal selected by the corresponding SSS field for this MSCR can be inverted before it connects to the destination input with the INV bit. 0 SSS selected input signal is connected directly to the destination input 1 SSS selected input signal is inverted before it is connected to the destination input
28:31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. Refer to *Section 16.2.3.1* and *Section 16.2.3.2*.

16.2.2.14 GPIO Pad Data Output Registers (SIUL2_GPDO*n*)

These registers can be used to set or clear a single GPIO pad with a byte access. For mapping of ports to GPDO registers, refer to the I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document. Note that the GPDO registers do not apply for ports PA[5], PA[6] and PA[7]. The PA ports are JTAG pins with no GPIO. Writes to the GPDO register corresponding to these ports have no effect.

Note: For the exact number of registers, refer to the SPC584Bx pinout Microsoft Excel file attached to the IO_Definition document.

Field	Description
7 PDI	Pad Data In This bit stores the value of the external GPIO pad associated with this register. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

16.2.2.16 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write. Note that the PGPDO registers do not apply for ports PA[5], PA[6] and PA[7]. These PA ports are JTAG pins with no GPIO. Writes to the PGPDO register corresponding to these ports have no effect.

Note: The SIUL2_PGPDO registers access the same physical resources as the SIUL2_PDO and SUIL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

Offset: 0x1700 + n*0x2 (n=0 to 12) Access: User read/write

Field	Description
0:15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit indexes define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

16.2.2.17 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read. Note that the GPDI registers do not apply for ports PA[5], PA[6] and PA[7]. These ports are JTAG pins with no GPIO. The GPDI values corresponding to these ports always read a value of zero.

Field	Description
0:15 MASK	Mask Field Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0 The associated bit value in the MPPDO[x] field is ignored 1 The associated bit value in the MPPDO[x] field is written
16:31 MPPDO	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location is coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO). The x and y bit indexes define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x * 16) + y]

16.2.3 Multiplexed Signal Configuration Registers

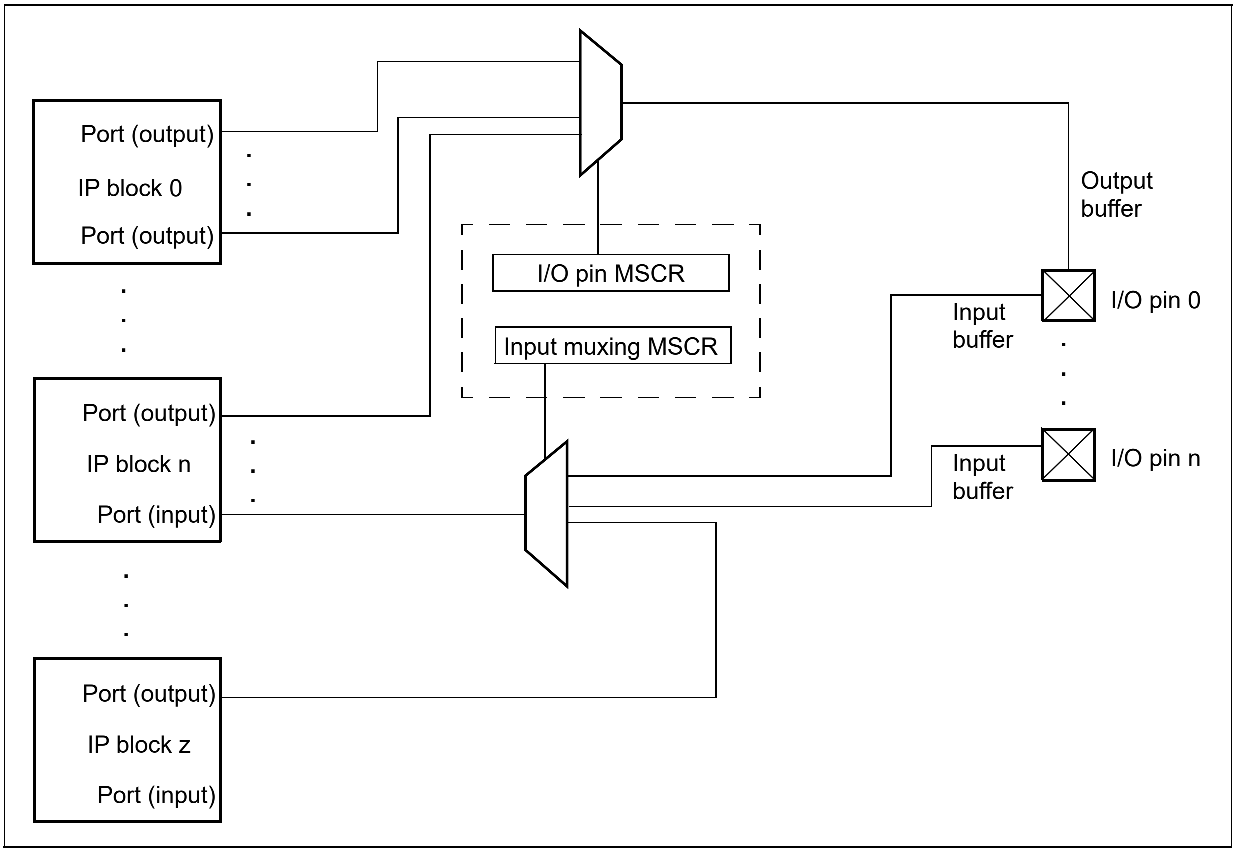
The MSCRs control the I/O pin function and electrical properties for each pin on the device, and are used to select the input signal for IP blocks on the device that have multiple input sources. There is a dedicated MSCR register for each I/O pin on the device. Each MSCR register is independent of the others, except in the case of an LVDS configuration, where two MSCR registers must be configured together in this mode. When LVDS is configured, CMOS pad is disabled (ibe and obe = 0) and when LVDS is not configured, (either of two MSCRs not configured for lvds) then the lvds pad is disabled (lvds_ibe and lvds_obe = 0).

The MSCRs are divided into two sets:

- I/O pin control registers, refer to *I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*
- Multiplexed input selection registers, refer to *Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_MUXn)*

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in *Figure 134*.

Figure 134. MSCR I/O pin and IP block port connectivity



16.2.3.1 Chip-pin MSCR assignments and related information

For device pin MSCR register definitions, refer to the SPC584Bx I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document.

16.2.3.2 Module-port MSCR assignments and SSS values

For each internal module port that is or can be configured as an input and has more than one possible source. Refer to the SPC584Bx I/O Signal Description and Input Multiplexing Tables (Microsoft Excel file) attached to the IO_Definition document. The Input Multiplexing Table shows the assigned MSCR, and the SSS values and their corresponding source signals.

16.3 Functional description

16.3.1 General

This section provides a complete functional description of the SIUL2.

16.3.2 Pad control

The SIUL2 controls the electrical characteristics of the pads on the device through the MSCR registers. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2.

The required controls are:

- Slew rate control
  - This is needed to offer improved EMC performance.
  - Support for a fast and slow slew rate.
- Output Impedance Control
  - 4 output impedances, drive strength and slew rates supported.
- Internal weak pull capability
  - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
  - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Safe Mode behavior configuration
- Open drain/source enable
  - Needed to support different pads muxed (for example mux IIC, with non open drain pads).
- Pin Function Assignment
  - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

16.3.3 General purpose input or output pads (GPIO)

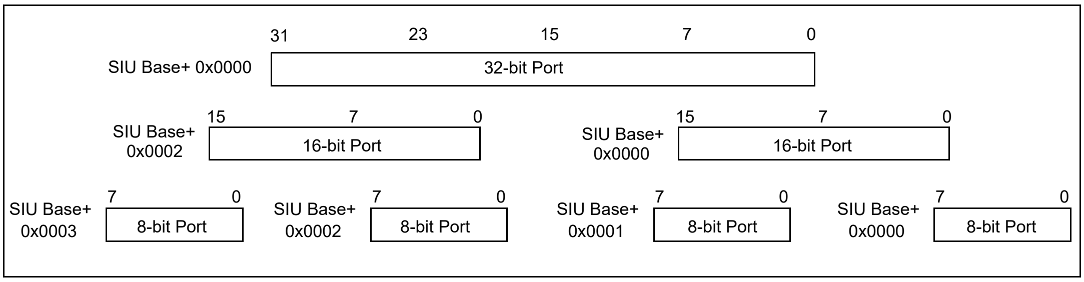
The SIUL2 allows each pad to be configured as either a General Purpose Input Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 202 GPIO pads (205 pads less 3 reserved for JTAG) organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in *Figure 135*, all port accesses are identical with each read or write being performed only at a different location to access a different port width.

Figure 135. Data Port example arrangement showing configuration for different port width accesses



This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note: In case the bidirectional operation impacts some performances (for example ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to “Input Only”.

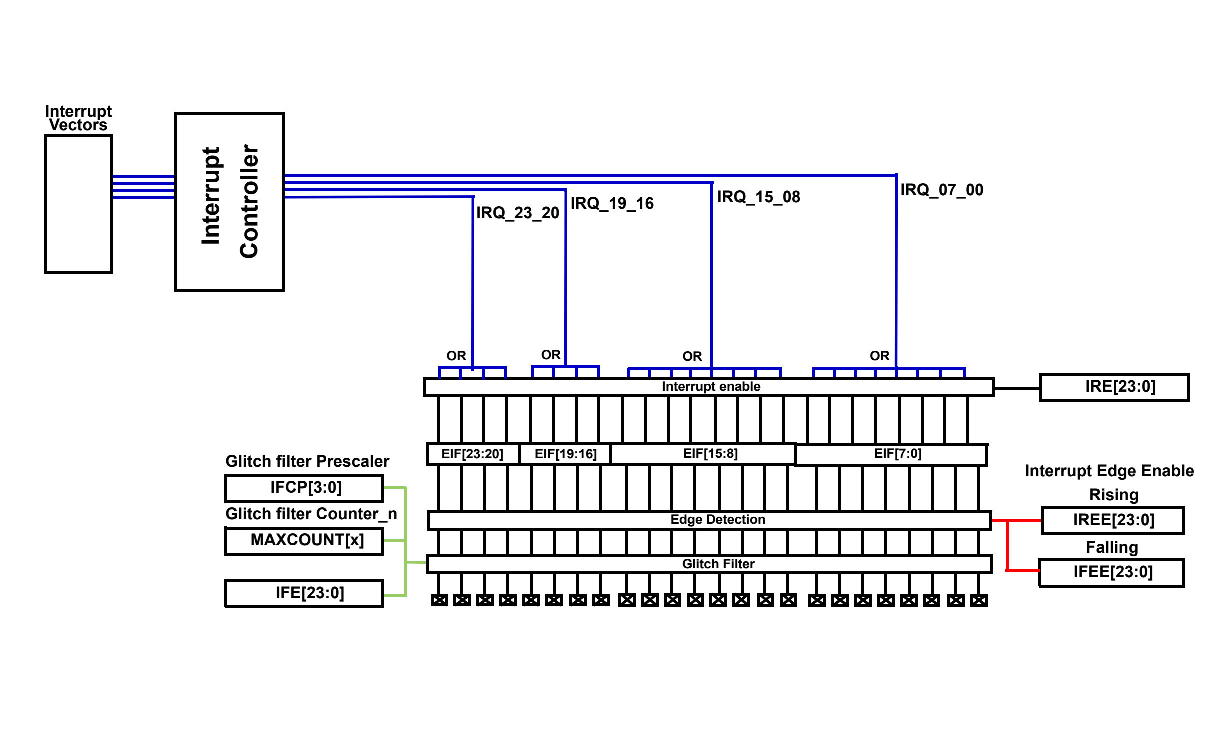
16.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports 24 external interrupts which are allocated to EIRQ pins on the device.

The SIUL2 supports 4 interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support eight or four external interrupt sources from the device pads.

Refer to *Figure 136* for an overview of the external interrupt implementation.

Figure 136. External interrupt pad diagram



All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of user of the software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

16.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
  – Clear the ODC bits to do disable output.
  – Set the IBE bit to enable the pin’s input buffer.
  – If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note: MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.

Note: Not all EIRQ pins have DMA capability. Refer to Section 16.2.2.5: DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0).

- Select the desired glitch filter setup for the pins by writing the following:
  – Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  – Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
  – Then enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

Note: The glitch filter clock runs on the internal RC oscillator clock whereas the SIUL logic runs on the PBRIDGEx clock. The IRC clock is at a fixed frequency of 16 MHz. The PBRIDGEx clock can on higher clock (refer to the Clocking chapter)

The glitch filter is enabled on IRC clock, so make sure at least one IRC clock occurs after enabling it before trying to detect glitchless events.

- Write to EIFn bits in DISR0 to as desired to clear any flags (for DMA it is self clearing).
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

16.3.4.2 External interrupt management

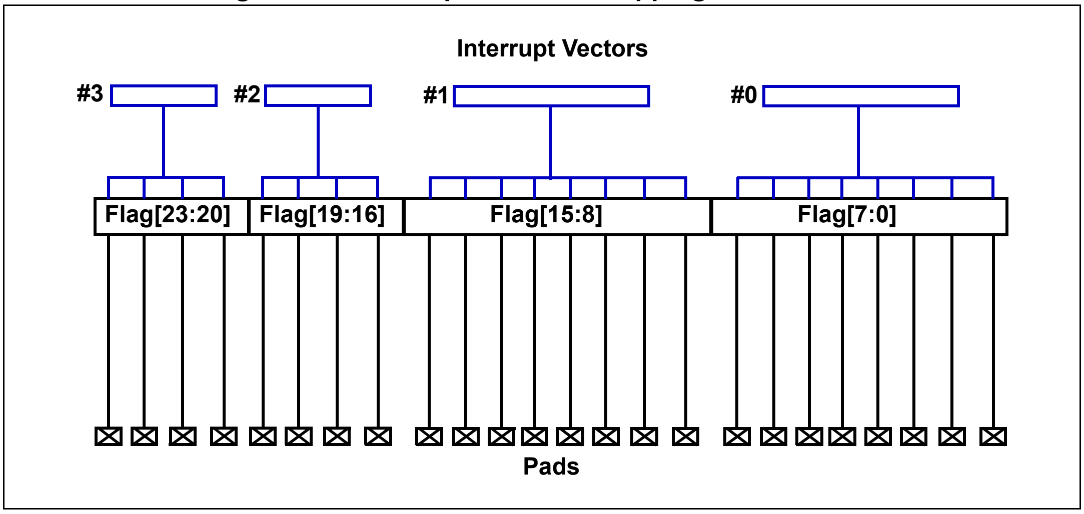
Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (SIUL2_DIRER0). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

The SPC584Bx device supports 4 SIUL2 interrupt vectors aggregating a total of 24 external interrupt sources as shown in Figure 137.

Figure 137. Interrupt to vector mapping at MCU level



16.3.4.3 External interrupt request

The EIRQ input pins on the device are sources for interrupt or DMA requests. The 24 EIRQ pins for the device map to 4 interrupt requests. The mapping of interrupt requests and EIRQ pins is given in *Table 213*.

Table 213. SIUL input trigger connections to the INTC channels

External interrupt number	SIUL IRQ vector
0 to 7	0
8 to 15	1
16 to 19	2
20 to 23	3

16.3.4.4 Interrupt Vector

The 24 EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note: Refer to INTC configuration section in the Chapter Device Configuration for the Interrupt Vector table.

16.3.4.5 DMA requests

Nine out of 16 EIRQ pins on the device map to an independent DMA request channel in the DMA controller.

Note: Refer to the DMA controller configuration section in the Chapter Device Configuration for DMA request mapping table.

17 Crossbar switch (XBAR)

17.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

17.2 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
  - Concurrent accesses from different masters to different slaves
  - Configurable slave arbitration attributes on a slave-by-slave basis
- 64-bit datapath width
- Support for 8-, 16-, and 64-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers including a 4-beat, 64-bit burst for cache line accesses
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

17.3 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require four system bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. Refer to Section 7.3.2: Crossbar switch in Chapter 7: Device configuration for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

Table 214. XBAR memory map

Address offset (hex)	Register name	Location
SLAVE channel *n* (*n* = 0 to 7)

17.3.1 XBAR Priority Registers Slave (XBAR_PRS*n*)

The priority registers (XBAR_PRS*n*) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses.

Once the RO (Read Only) bit has been set in the XBAR Control Register (XBAR_CRSn), the Priority Register Slave (XBAR_PRSn) becomes read-only. Attempts to write on it will have no effect and will result in a bus-error response to the master initiating the write.

Note: Two available master ports cannot be programmed with the same priority level. Attempts to program two or more available masters with the same priority level will result in an error response and the priority will not be updated.

Refer to *Section 7.3.2: Crossbar switch* in *Chapter 7: Device configuration* for XBAR_PRS*n* priority values.

17.4 Functional description

This section provides the functional details of the crossbar switch.

17.4.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes. When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by the XBAR_CRS*n*[PARK]. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using XBAR_CRS*n*[PCTL].

17.4.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

17.4.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

17.4.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the XBAR_PRS*n* (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master’s priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master’s priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer or a locked transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master’s priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

17.4.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Hand-off occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

17.5 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

18 Crossbar Integrity Checker (XBIC)

18.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistence of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core’s decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

18.2 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
  - hready, hresp0, and hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

18.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in *Figure 141* and *Figure 142*.

Figure 141. XBIC system block diagram

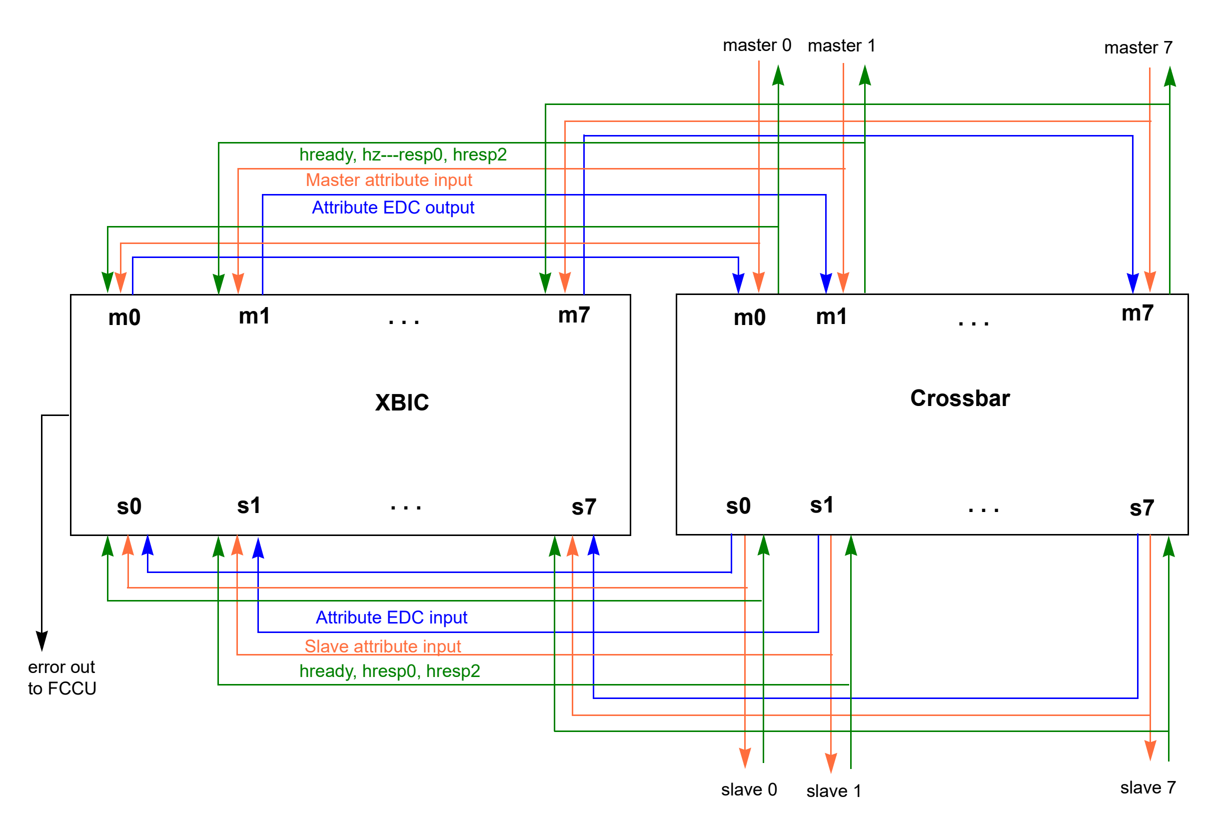

Figure 142. XBIC block diagram

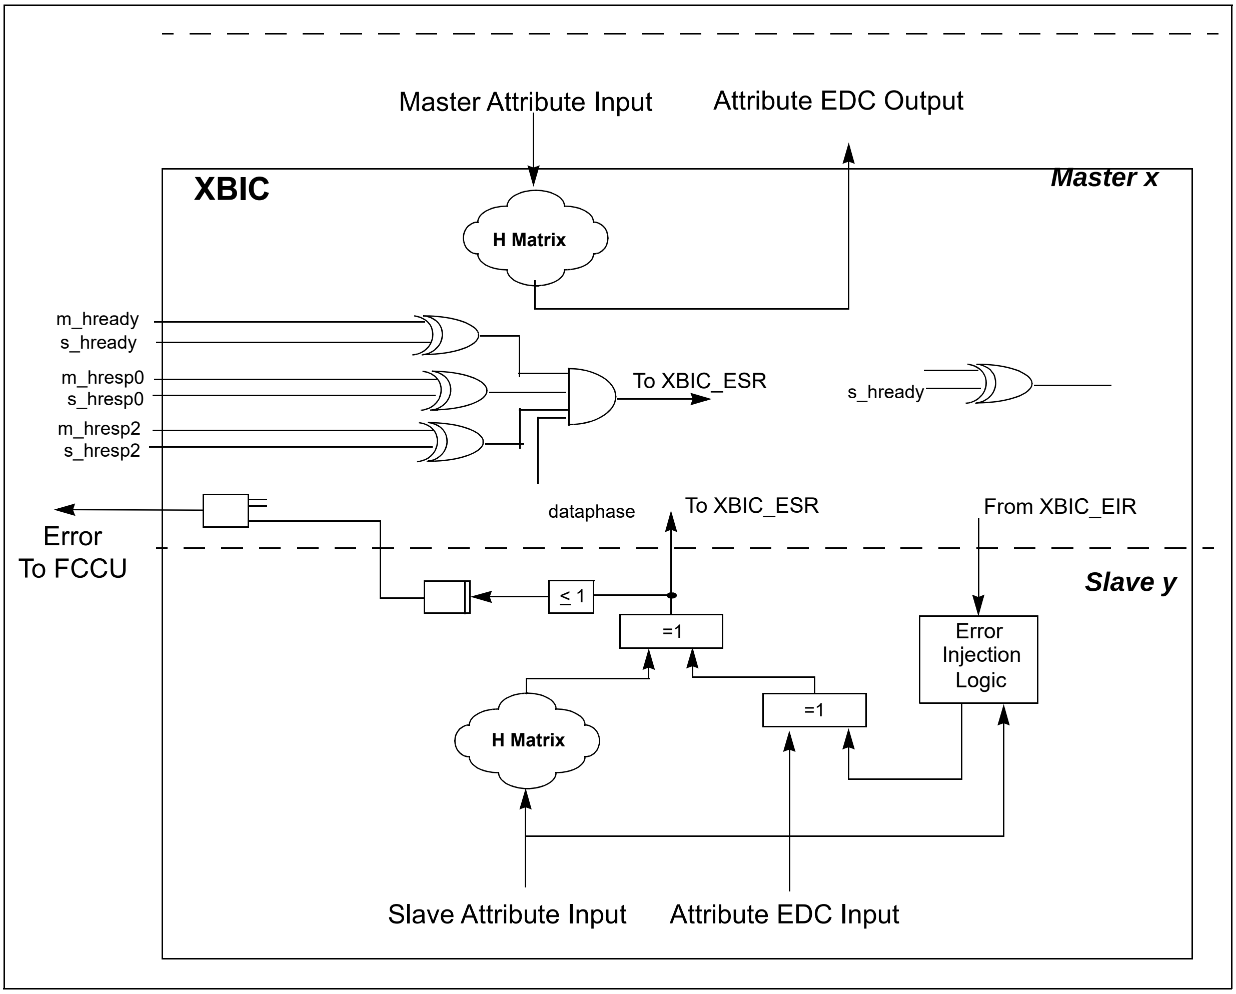

18.4 External signal description

The XBIC has no external interface signals.

18.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

18.5.1 Memory map

The XBIC memory map is shown in *Table 218*.

Table 218. XBIC memory map

Address offset (hex)	Register description	Location

18.5.2.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Offset: 0x0004 Access: Supervisor Read/Write

Table 220. XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable 0 Error injection disabled 1 Error injection enabled
17:19 SLV	Target Slave Port (1) Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20:23 MST	Target Master ID (2) Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24:31 SYN	Syndrome This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

1. For the list of the target slave ports refer to the table “Crossbar switch slave assignments” in section “Crossbar switch” from “Device Configuration” chapter.
2. For the list of the target master IDs refer to the table “AHB Master ID Assignments” in section “Crossbar switch” from “Device Configuration” chapter.

18.5.2.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the *last* transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are captured in the DPSE0*x* and DPME*x* fields.

This register is cleared only on reset.

18.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

Forwarding errors (master to slave) are detected during the AHB address phase. When a forwarding error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in *Table 223*. Any other syndrome indicates a multi-bit error.

XBIC also detects backward signal (slave to master) errors during AHB data phase. For the three slave driven signals (hready, hresp0, and hresp2), XBIC performs the comparison between the input of the slave port and output of the master port during the AHB data phase. When a mismatch occurs, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE*x*, and the current master port will be registered in XBIC_ESR bit field DSME*x*.

19 Peripheral Bridge (PBRIDGE)

19.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space (not all peripheral slots may be used. Refer to Device Configuration chapter or the Memory Map chapter for details on slot assignment).
The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

19.1.1 Features

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality.

19.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map. Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots.
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots.

All other 64-bit accesses result in an error response.

0x1BC	Off-platform Peripheral Access Control Register AF (OPACRAF)	*Section 19.2.4*

1. The following address spaces when programmed, will not terminate in an error. Software should not program these address spaces.
2. Access to this address space will terminate in an error.

19.2.1 Master Privilege Register A (MPRA)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. Refer to Device Configuration chapter for details about the master assignments to these registers.

The MPROT*n* field is defined as shown in *Figure 147*.

19.2.3 Peripheral Access Control Register (PACR*x*)

Each of the on-platform peripherals has a four-bit PACR*n* field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. Refer to Memory Map chapter for the assignments of the device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeros, and writes are ignored.

The PBRIDGE registers themselves are mapped into the PACR0 address space and can only be accessed in supervisor mode by trusted bus masters.

Table 229 shows the top-level structure of the PACRs.

Table 229. PACR memory map

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

19.2.4 Off-Platform Peripheral Access Control Registers (OPACR*x*)

Each of the off-platform peripherals has a four-bit OPACR*n* field which defines the access levels supported by the given module. Eight OPACRs are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignments to each OPACR field are defined by the memory map slot to which the peripherals are assigned. Refer to Memory Map chapter for the assignments of the device. If a peripheral is absent, the corresponding OPACR is not implemented. Reads to the location return zeros and writes are ignored.

Table 232 shows the top-level structure of the OPACR registers.

19.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

19.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

20 System Memory Protection Unit (SMPU)

20.1 Overview

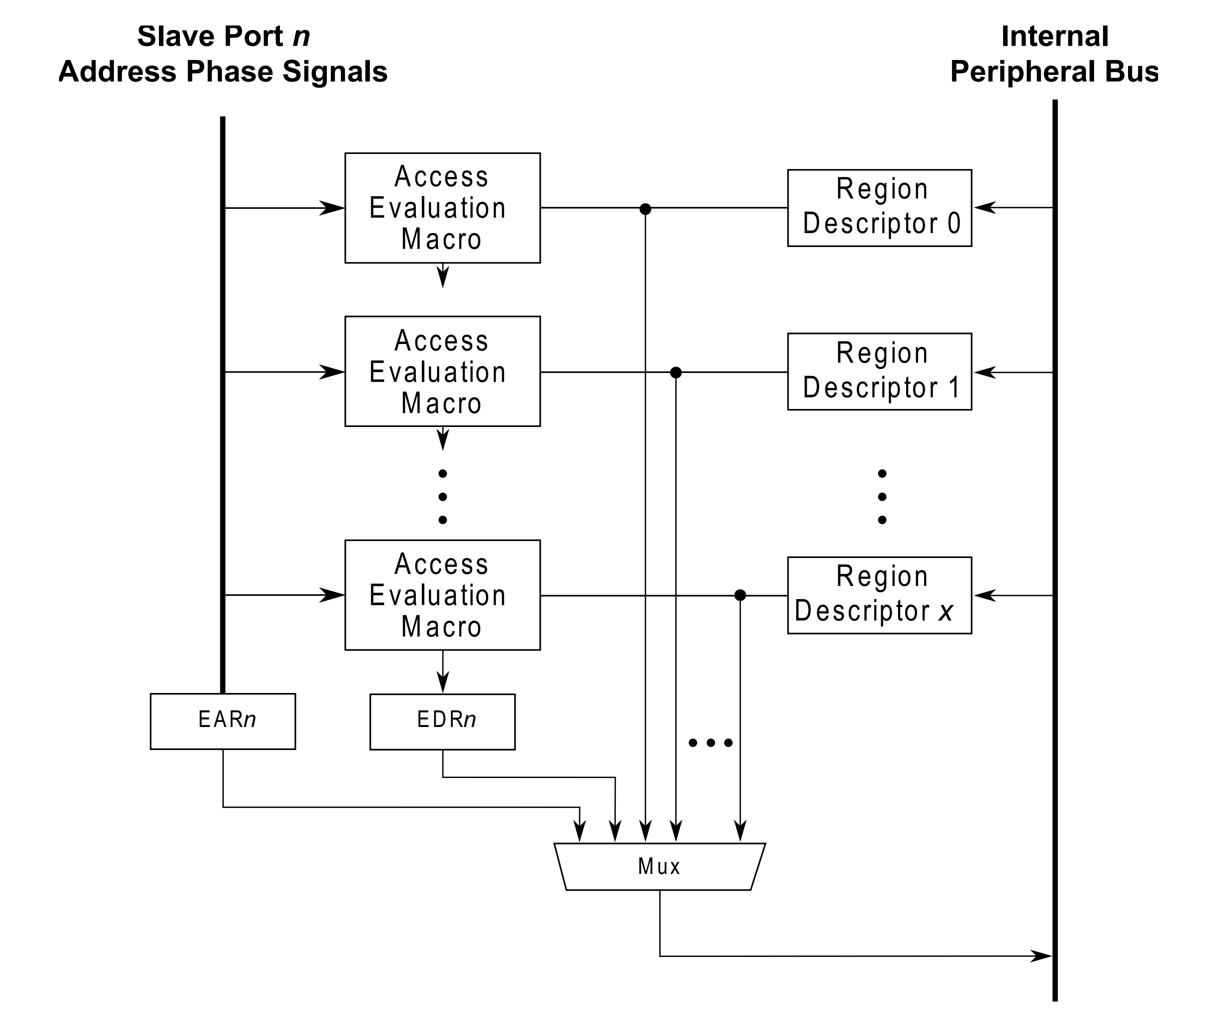
The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

20.2 Block diagram

A simplified block diagram of the SMPU module is shown in *Figure 154*. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, refer to *Section 20.5.1: Access evaluation macro*.

Figure 154. SMPU block diagram



20.3 Features

The SMPU feature set includes:

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24)
  - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
    Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
  - Read/write access control permissions defined in region descriptor
  - Cache-inhibit attribute indicator per region descriptor
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
  - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit

20.4 Memory map and register definition

20.4.1 Memory map

The programming model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

The programming model can be accessed only in supervisor mode.

Note: Refer to the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to 8 region descriptors.

Field	Description
0:15 MERR	Master *n* error, where the bus master number matches the bit number Indicates a captured error in EAR*n* and EDR*n*. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing ‘1’ to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master *n.* 1 An error has occurred for bus master *n.*
16	Reserved This read-only bit is reserved and always has the value ‘1’.
28:30 HRL	Hardware revision level Specifies the SMPU’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

Field	Description
0:15 MEOVR	Master *n* error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master *n* has occurred before the previous error was processed. The details of the first error are recorded in the EAR*n* and EDR*n* registers, and no information on subsequent errors is recorded until the associated CESR0.MERR flag is cleared. 0 No error overrun condition has been detected for bus master *n.* 1 An error overrun condition has been detected for bus master *n.*
16	Reserved This read-only bit is reserved and always has the value ‘1’.
28:31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

20.4.2.3 Error Address Register, Bus Master *n* (EAR*n*)

When the SMPU detects an access error on bus master *n*, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0.MERR is set. Additional information about the faulting access is captured in the corresponding EDR*n* at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Address: 0x0100 + *n**0x8 (*n* = 0 to 15) Access: Supervisor read-only

Field	Description
0:31 EADDR	Error address Indicates the reference address from bus master *n* that generated the access error.

20.4.2.4 Error Detail Register, Bus Master *n* (EDR*n*)

When the SMPU detects an access error associated with bus master *n*, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0.MERR is set. Information on the faulting address is captured in the corresponding EAR*n* register at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1.MEOVR field until the original error is processed.

Table 239. EDRn field descriptions

Field	Description
0:23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDR*n* contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24	Reserved This read-only bit is reserved and always has the value ‘1’.
25:26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28:31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

20.4.2.5 Region Descriptor *n*, Word 0 (RGD*n*_WORD0)

Address: 0x0400 + *n**0x10 (*n* = 0 to 23) Access: Supervisor read/write

Field	Description
0:31 ENDADDR	End address Defines the byte end address of the memory region. **Note:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

20.4.2.7 Region Descriptor *n*, Word 2 Format 0 (RGD*n*_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3.FMT field.

Note: RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: 0x0408 + *n**0x10 (*n* = 0 to 23) Access: Supervisor read/write

Figure 162. Region Descriptor n, Word 3 (RGDn_WORD3)

Table 243. RGD*n*_WORD3 field descriptions

Field	Description
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. **Note:** A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies. 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **Note:** Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect. 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.

Table 243. RGDn_WORD3 field descriptions (continued)

Field	Description
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **Note:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals that the region descriptor is valid. Any write to RGD*n*_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.

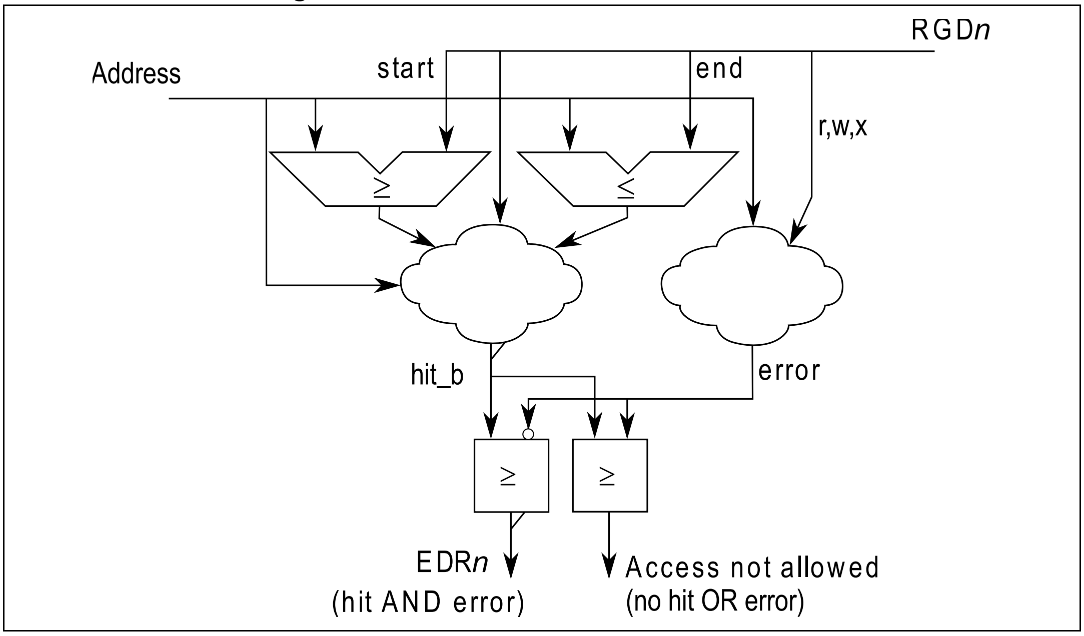
20.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

20.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in *Figure 163*, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD*n*), then performs two major functions: region hit determination and detection of an access protection violation. *Figure 163* shows a functional block diagram.

Figure 163. SMPU access evaluation macro



20.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
      (addr[0:31] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

Where addr is the current reference address, RGDn_Word0.SRTADDR and RGDn_Word1.ENDADDR are the start and end addresses, and RGDn_Word3.VLD is the valid bit.

Note: The SMPU does not verify that ENDADDR ≥ SRTADDR.

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

20.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in *Table 244*.

Table 244. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

20.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, refer to *Section 20.7*.

20.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGD*n*_Word3.VLD. Setting CESR0.GVLD enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0.GVLD = 0). Next, load the appropriate region descriptors (RGD*n*), including the setting of the RGDn_Word3.VLD bits. Finally, set CESR0.GVLD to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

20.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region: Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Modifying a region descriptor: Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor: Clearing RGD*n*_Word3.VLD deletes an existing region descriptor.
- Accessing the SMPU: Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error: The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0.MERR signals. The error registers contain the captured fault data.
- Overlapping region descriptors: Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

21 Intelligent AHB Gasket (IAHBG)

21.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 245 lists the available operation modes.

Table 245. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

21.2 Timing modes

21.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

21.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

21.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master.The 1:4 mode is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write.

22 Interrupt Controller (INTC)

22.1 Introduction

Note: For the chip-specific implementation details of this module's instances, refer to the Section 7.3.5: Interrupt controller (INTC) configuration.

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to the processor (PRC)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

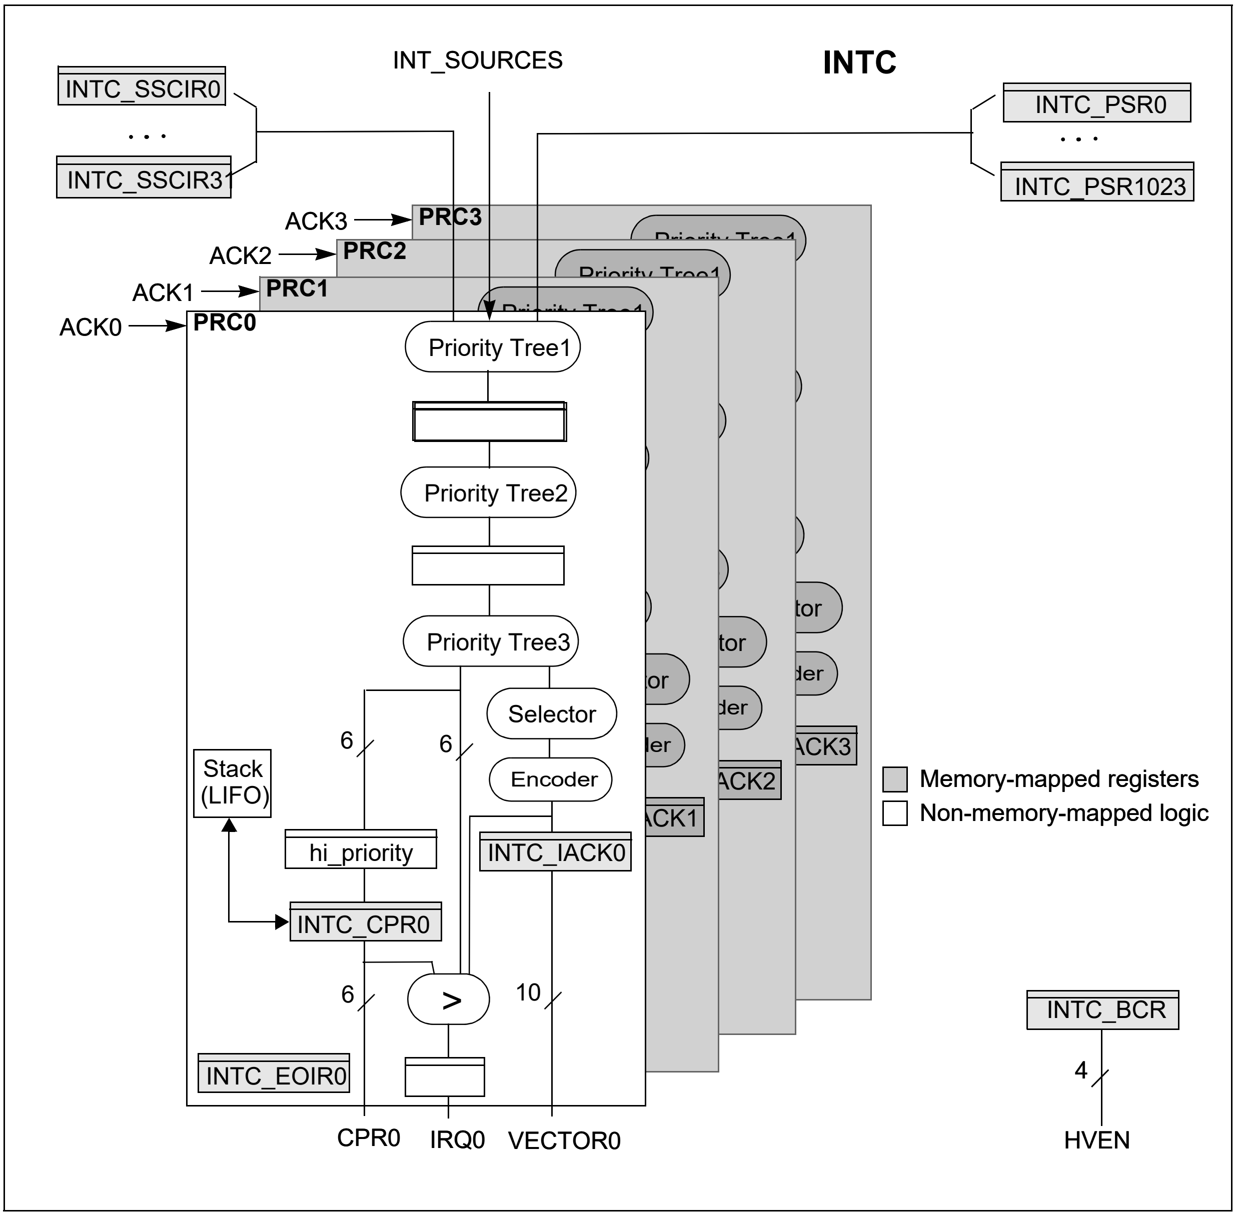
When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

The software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

22.2 Block diagram

The block diagram for the INTC is shown in *Figure 164*.

Figure 164. INTC block diagram



22.3 Features

- Each peripheral interrupt source is software-steerable to processor 2
- 32 software-settable interrupt request sources
- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request

22.4 Modes of operation

The interrupt controller operates with the following handshaking modes: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN2], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ). In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

22.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for the processor when the HVEN2 bit in INTC_BCR (refer to *Section 22.5.2.1*) is negated. The hardware vector enable signal to the processor is driven as negated when the HVEN2 bit is negated. The vector is read from the INTC_IACKR2 register (refer to *Section 22.5.2.3*). Reading the INTC_IACKR2 negates the interrupt request to the processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in INTC_CPR2 (refer to *Section 22.5.2.2*) onto the LIFO, and updates PRI in INTC_CPR2 with the new priority.

22.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for the processor when the HVEN2 bit in INTC_BCR is asserted. The hardware vector enable signal to the processor is driven as asserted.

When the interrupt request to the processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKR2.

The assertion of the interrupt acknowledge signal for the processor pushes the PRI value in the INTC_CPR2 register onto the LIFO and updates the PRI in the INTC_CPR2 register with the new priority. This pushing of the PRI value onto the LIFO and updating PRI in INTC_CPR2 does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs (refer to *Section 22.5.2.5: INTC Software Set/Clear Interrupt Register n (INTC_SSCIRn)*) is written at a time such that the PRI value in the INTC_CPR2 register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in INTC_CPR2 is updated with the new priority, and the LIFO is neither pushed nor popped.

22.5 Memory map and register definition

22.5.1 Memory map

Table 246 is the INTC memory map.

The actual availability and number of registers are chip-specific. For this information, refer to the chapter that describes how modules are configured and connected.

Table 246. INTC memory map

Address offset	Register	Location
0x0000	INTC Block Configuration Register (INTC_BCR)	*Section 22.5.2.1*
0x0004–0x0007	Reserved(1)	
0x0008–0x000F	Reserved	
0x0010-0x0013	Reserved

0x0040–0x005F	INTC Software Set/Clear Interrupt Register 0–31 (INTC_SSCIR0–INTC_SSCIR31)	*Section 22.5.2.5*
0x0060–0x085F	INTC Priority Select Registers 0–1023 (INTC_PSR0–INTC_PSR1023)	*Section 22.5.2.6*
0x0860–0x0FFF	Reserved	

1. Access to this location will not result in transfer error.

Note: A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

22.5.2 Register descriptions

With the exception of the INTC_SSCIR*n* and INTC_PSR*n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8-bit wide, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSIR*n* are 8 bits wide and INTC_PSR*n* are 16-bit wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR2) are the same regardless of the size of the read. In software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR2) does not affect the operation of the write.

22.5.2.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

22.5.2.2 INTC Current Priority Register for Processor 2 (INTC_CPR2)

The INTC_CPR2 masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR2[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR2) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR2) is written, the LIFO is popped into the INTC_CPR2 PRI field. An exception case in hardware vector mode to this behavior is described in *Section 22.4.2*.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. Refer to *Section 22.7.5*.

Note: A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. Refer to Section 22.7.5.2, for example code to ensure coherency.

22.5.2.3 INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)

The Interrupt Acknowledge Register for Processor 2 provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR2 has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKR2 does not have side effects in hardware vector mode.

Table 249. INTC_IACKR2 field descriptions

Field	Description
0:19 VTBA	Vector table base address Must be set with the base address of the vector table prior to enabling interrupts.
20:29 INTVEC	Interrupt vector Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.

22.5.2.4 INTC End of Interrupt Register for Processor 2 (INTC_EOIR2)

Writing to the INTC_EOIR2 signals the end of the servicing of the interrupt request. When the INTC_EOIR2 is written, the priority last pushed on the LIFO is popped into INTC_CPR2. The values and size of data written to the INTC_EOIR2 are ignored. Those values and sizes written to this register neither update the INTC_EOIR2 contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

22.5.2.5 INTC Software Set/Clear Interrupt Register *n* (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Figure 169 shows the structure of the first INTC_SSCIR. The other registers follow the same structure.

7 CLR	Clear flag bit CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

22.5.2.6 INTC Priority Select Register *n* (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSR*n* is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32–1023, and their priorities are configured in INTC_PSR32–1023, respectively.

Figure 170 and *Figure 171* show the structure and numbering scheme of the first and last PSRs, respectively. The other registers follow the same numbering scheme.

Note: Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

Interrupts are not detected while the PSRs are being written.

Figure 171. INTC Priority Select Register *n* (INTC_PSR*n*)

Table 253. INTC_PSR*n* field descriptions

Field	Description
2 PRC_SEL2	Processor 2 select bit If an interrupt source is enabled, PRC_SEL2 selects whether the interrupt request is to be sent to processor 2.
7 SWT	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a ‘1’ to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared.
10:15 PRI	Priority select Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

22.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

22.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI value in INTC_PSR*n* is higher than the PRI value in INTC_CPR2, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in INTC_CPR2 is updated with the corresponding PRI value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

22.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

22.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

The processor will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the processor which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR*n*[PRC_SEL2] bit.

22.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

22.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL2 values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in INTC_CPR2. The results of those comparisons are used to manage the priority of the ISR being executed by the processor. The LIFO also assists in managing that priority.

22.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in *Figure 164* are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for the processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for INTC_IACKR2, and if in hardware vector mode, for the interrupt vector provided to the processor.

22.6.2.1.1 Priority tree

The priority tree for the processor compares all the priorities of all of the asserted interrupt requests assigned to the processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to the processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the selector logic.

22.6.2.1.2 Selector

If only one interrupt request from the priority tree is asserted, then it is passed as asserted to the encoder logic. If multiple interrupt requests from the priority tree are asserted, then only the one with the lowest vector is passed as asserted to the encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

22.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the processor.

22.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the priority arbitrator subblock with PRI in INTC_CPR2. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in INTC_CPR2, or the PRI value in INTC_CPR2 is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in INTC_CPR2 when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI in INTC_PSR*n* are zero will not cause a preemption because their PRI will not be higher than PRI in INTC_CPR2.

Another function of the comparator is to signal an update of INTC_IACKR2 with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of INTC_CPR2 occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

22.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from INTC_CPR2. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in INTC_CPR2 does not need to be loaded from INTC_CPR2 and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored in INTC_CPR2.

The PRI value in INTC_CPR2 is pushed onto the LIFO when INTC_IACKR2 is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode. The priority is popped into PRI in INTC_CPR2 whenever INTC_EOIR2 is written. An exception case in hardware vector mode to this behavior is described in *Section 22.4.2*.

Although the INTC supports up to 64 priorities, an ISR executing with PRI in INTC_CPR2 equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

22.6.3 Handshaking with processor

22.6.3.1 Software vector mode handshaking

22.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to *Figure 172*.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 172*. The INTC examines the peripheral and software-settable interrupt requests.

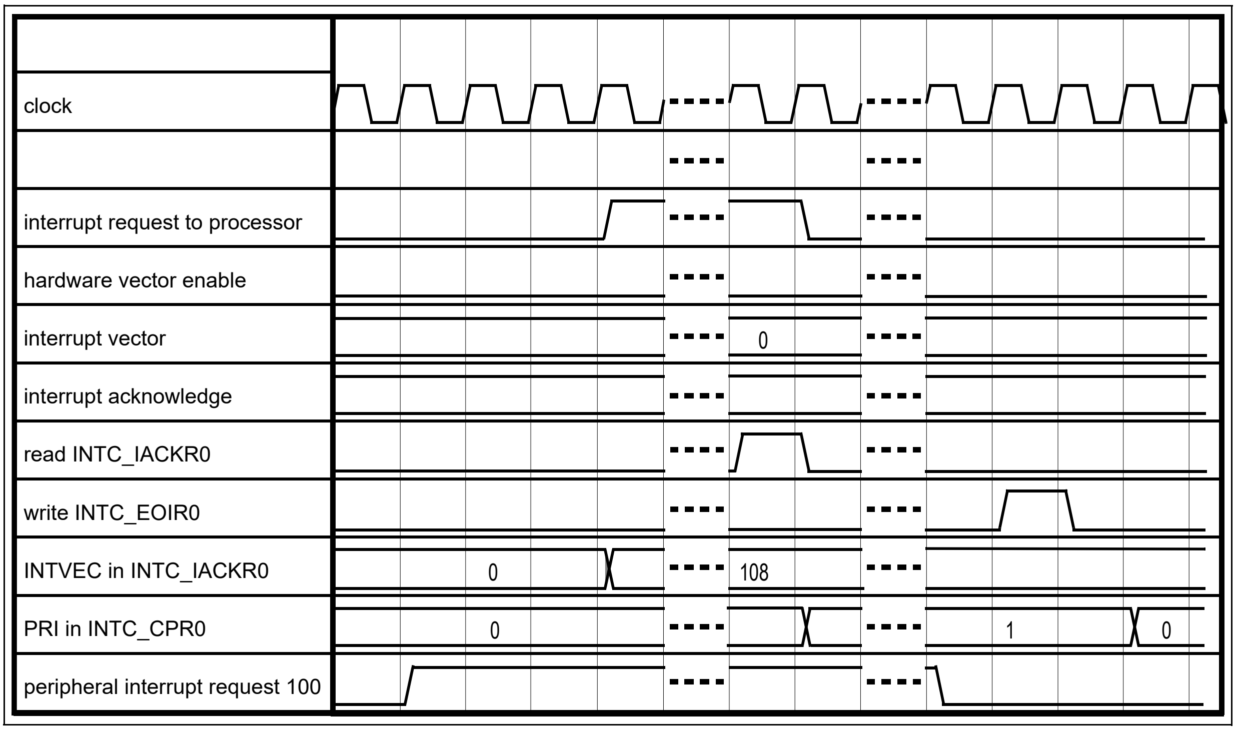
When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in INTC_CPR2, it asserts the interrupt request to the processor. The INTVEC field in INTC_IACKR2 is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in *Section 22.4.1*.

22.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR2 must be written. When it is written, the LIFO is popped so that the preempted priority is restored into PRI of INTC_CPR2. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in INTC_CPR2 is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 172. Timing diagram of software vector mode handshaking

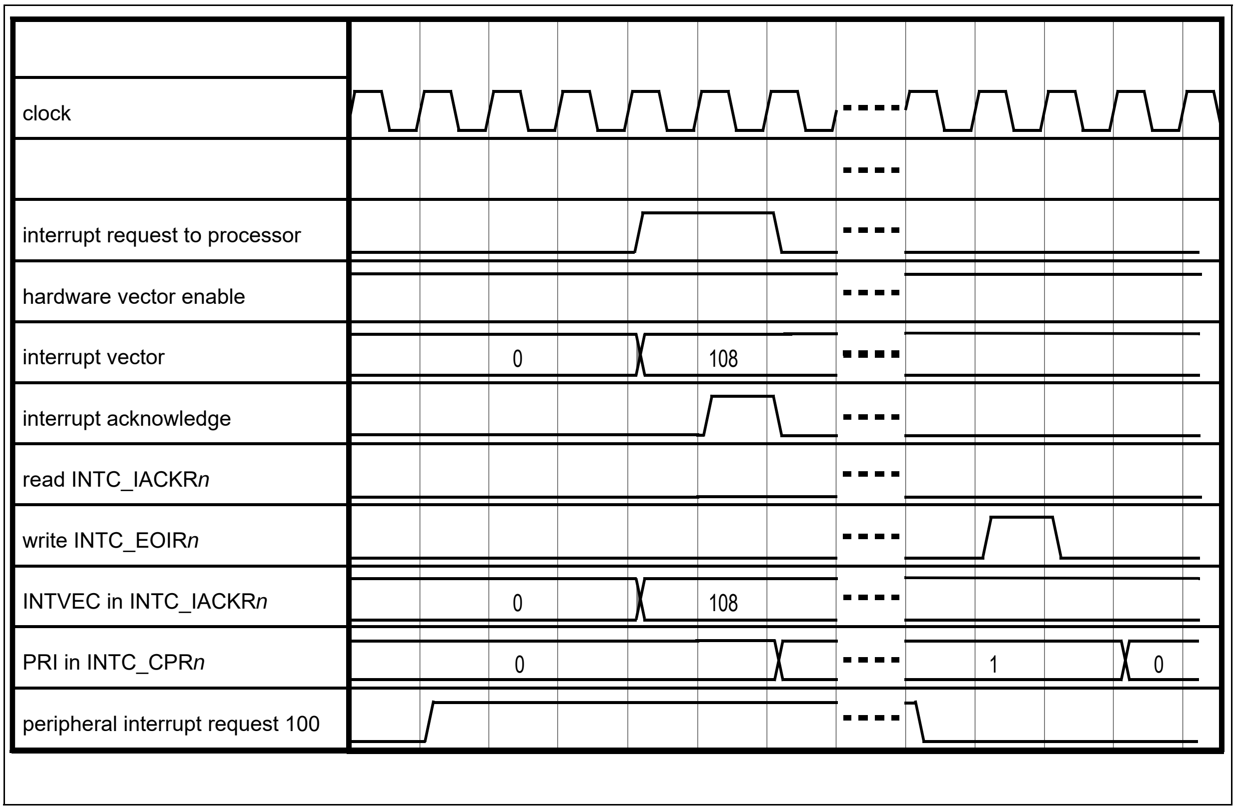


22.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 173*. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in INTC_CPR2, it asserts the interrupt request to the processor. The INTVEC field in INTC_IACKR2 is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. In addition, the value of the interrupt vector to the processor matches the value of the INTVEC field in INTC_IACKR2. The rest of the handshaking is described in *Section 22.4.2*.

The handshaking near the end of the interrupt exception handler, that is the writing to INTC_EOIR2, is the same as in software vector mode. Refer to *Section 22.6.3.1.2: End of interrupt exception handler*.

Figure 173. Timing diagram for hardware vector mode handshaking



22.7 Initialization/application information

22.7.1 Initialization flow

After exiting reset, all of the PRI and PRC_SEL2 fields in INTC_PSR*n* are zero, and PRI in the INTC_CPR2 register is 31. These reset values will prevent the INTC from asserting the interrupt request to the processor. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- Interrupt_request_initialization:
  - Configure HVEN2 in INTC_BCR.
  - Configure VTBA in INTC_IACKR2.
  - Raise the PRI fields and set the PRC_SEL2 fields in INTC_PSR*n*.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC_CPR2 to zero.
  - Enable processor recognition of interrupts.

22.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

22.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

22.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR2 having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR2 priority 0 and outside the control of the RTOS while RTOS executes at INTC_CPR2 priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPR2 priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task’s priority can be elevated in the INTC_CPR2 while the shared resource is being accessed.

An ISR whose PRI in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

22.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in *Table 254* shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 254. Order of ISR execution example

		Code executing at end of step						
Step#	**Step Description**	**RTOS**	**ISR108[1]**	**ISR208**	**ISR308**	**ISR408**	**interrupt exception handler**	**PRI in INTC_CPR at end of step**
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR2.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR2.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3

Table 254. Order of ISR execution example (continued)

		Code executing at end of step						
Step#	Step Description	RTOS	ISR108(1)	ISR208	ISR308	ISR408	interrupt exception handler	PRI in INTC_CPR at end of step
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR2.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR2.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

22.7.5 Priority ceiling protocol

22.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR2) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR2, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR2 to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

22.7.5.2 Ensuring coherency

22.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR2. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR2 can be made by those system services with the code sequence:

Figure 174. OSEK Code Sequence

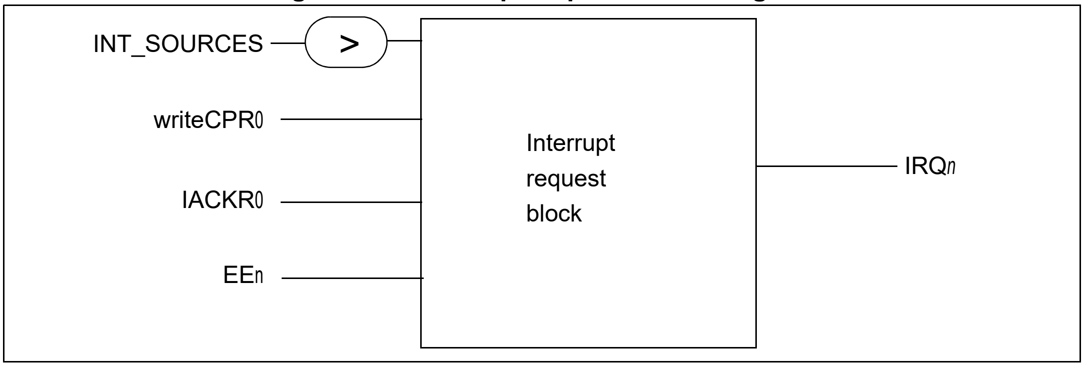
```
GetResource:
   wrteei  0        # disable external interrupts to the Processor
   raise   PRI      # Write to CPR, cache inhibit, guarded
   mbar             # flush out writes from store buffer
   wrteei  1        # enable external interrupts to the Processor
   isync            # re-fetch Processor pipeline

ReleaseResource:
   mbar             # flush out writes from store buffer
   wrteei  0        # disable external interrupts to the Processor
   lower   PRI      # Write to CPR, cache inhibit, guarded
   wrteei  1        # enable external interrupts to the Processor
```

22.7.5.2.1.1 Interrupt request to processor

Referencing *Figure 164*, the interrupt request logic to the processor is shown in *Figure 175*.

Figure 175. Interrupt request block diagram



Assuming that there are no IRQ*n* deasserted (no pending interrupt requests to the processor), if one of the external interrupt sources (INT_SOURCES) has a priority higher than INTC_CPR2, then interrupt request to the processor (IRQ*n*) is asserted. It will stay asserted until one of the following conditions is true:

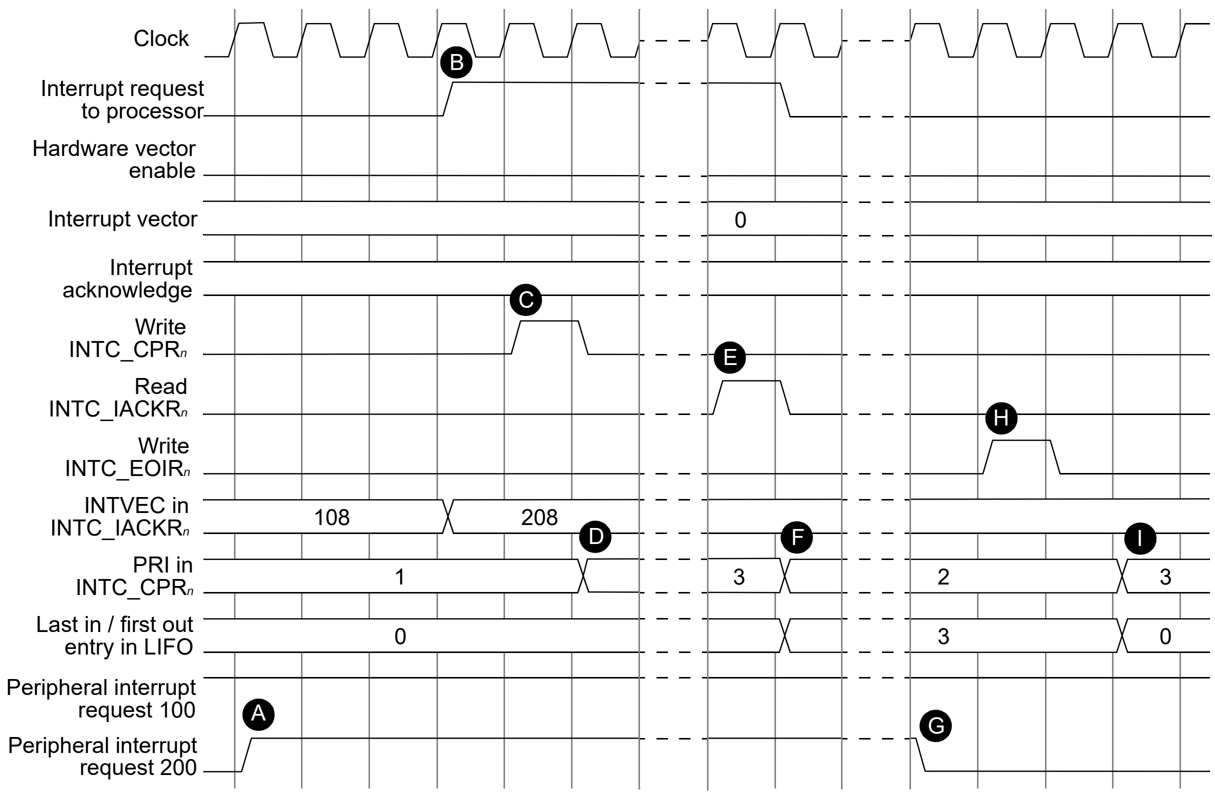
- Interrupt acknowledge (IACKR2) is asserted
- If the EE*n* bit has been cleared by the wrteei instruction (refer to *Figure 174*), IRQ*n* will be re-evaluated when the processor writes to INTC_CPR2 while the processor ignores IRQ*n*

This provides a safe way to guarantee that no interrupts will be recognized by the processor while updating INTC_CPR2.

22.7.5.2.2 Raised priority preserved

Before the instruction and after the GetResource system service executes, all pending transactions are complete. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in INTC_CPR2. The shared coherent data block now can be accessed coherently. *Figure 176* shows the timing diagram for this scenario, and *Table 255* explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 176. Timing diagram of raised priority preserved



Note that n = 2 for above registers

Table 255. Raised priority preserved events

Event	Description
A	Peripheral interrupt request with name equal to 200, asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKR2 updates with vector for that peripheral interrupt request.
C	ISR108 writes to INTC_CPR2 to raise priority to 3 before accessing shared coherent data block.

Table 255. Raised priority preserved events (continued)

Event	Description
D	PRI in INTC_CPR2 now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
E	Interrupt exception handler prolog acknowledges interrupt by reading INTC_IACKR2.
F	PRI of 3 pushed onto LIFO. PRI in INTC_CPR2 updates to 2, the priority of ISR208.
G	ISR208 clears its flag bit, deasserting its peripheral interrupt request.
H	Interrupt exception handler epilog writes to INTC_EOIR2.
I	LIFO pops 3, restoring the raised priority onto PRI in INTC_CPR2. Next value to pop from LIFO is the priority from before peripheral interrupt request with name equal to 100 interrupted. ISR108 now can access data block coherently after interrupt exception handler executes rfi instruction.

22.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor’s ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

22.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR.

22.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR2 with the interrupt acknowledge. The ISR, however, can have a portion of it which need not be executed at this higher priority. Therefore, executing this later portion which need not be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit in INTC_SSCIR*n*. Writing a 1 to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

22.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in *Section 22.7.7.1*) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note: Lowering the PRI value in INTC_CPR2 within an ISR to below the ISR's corresponding PRI value in INTC_PSRn allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

22.7.9 Negating an interrupt request outside of its ISR

22.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

22.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

22.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to *Section 22.6.3.1.2* for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI value in INTC_PSR*n*.

22.7.10 Examining LIFO contents

Normally the user does not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR2). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
pop_lifo:
   store to INTC_EOIR2
   load INTC_CPR2, examine PRI, and store onto stack
   if PRI is not zero or value when interrupts were enabled, branch to
pop_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
   load stacked PRI value and store to INTC_CPR2
   load INTC_IACKR2
   if stacked PRI values are not depleted, branch to push_lifo
```

Note: Reading the INTC_IACKR2 acknowledges the interrupt request to the processor and updates the INTC_CPR2[PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, because the peripheral or software-settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPR2[PRI] is lower than the priorities of those peripheral or software-settable interrupt requests.

22.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, refer to the chapter that describes how modules are configured and connected.

23 Enhanced Direct Memory Access (eDMA)

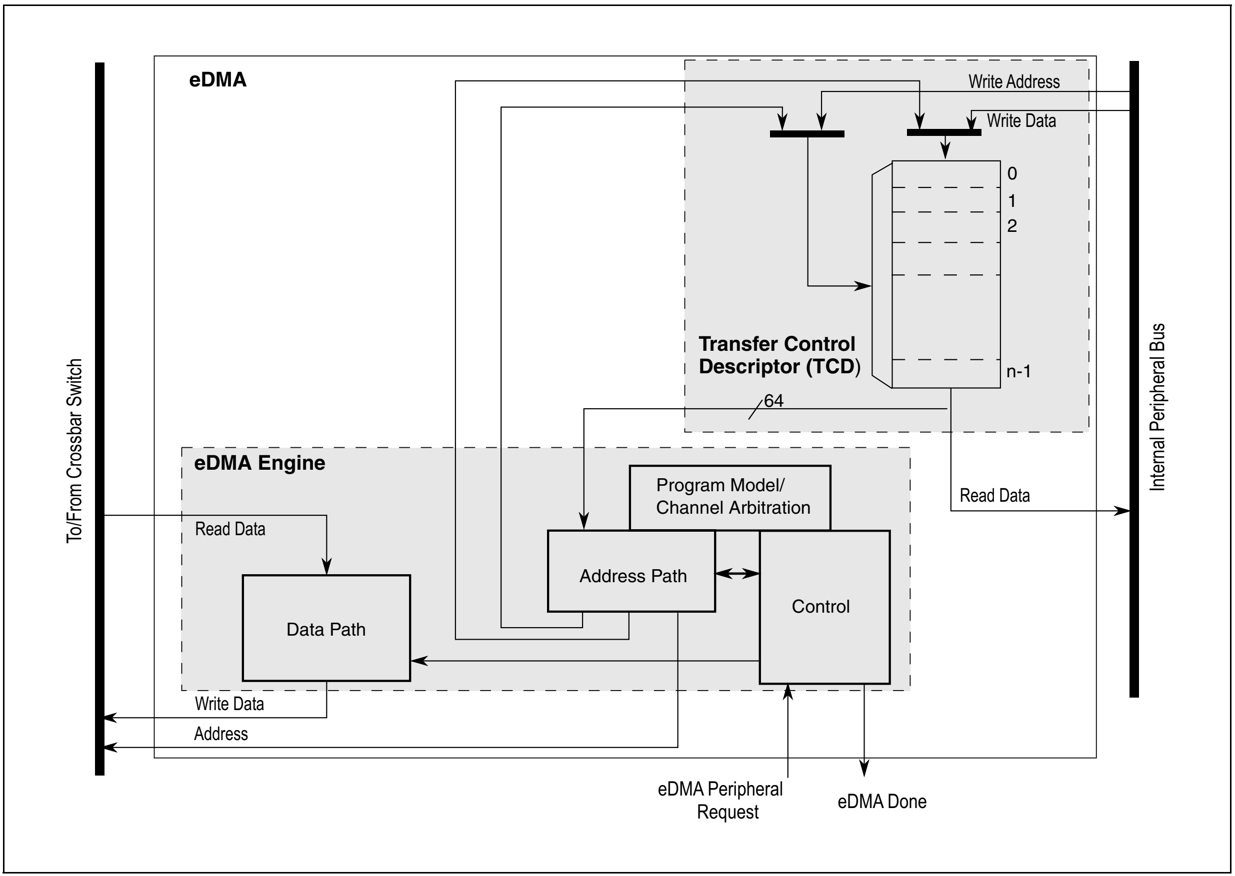
Note: For the chip-specific implementation details of this module's instances, please refer to the device configuration section.

23.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 32 channels.

Figure 177 illustrates the eDMA module.

Figure 177. eDMA block diagram



23.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- Data movements via dual-address transfers: read from source, write to destination:
  - Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes.
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor.
  - Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers.
  - Connections to the crossbar switch for bus mastering the data movements.
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations.
  - 32-byte TCD stored in local memory for each channel.
  - An inner data transfer loop defined by a minor byte transfer count.
  - An outer data transfer loop defined by a major iteration count.
- Channel activation via one of three methods:
  - Explicit software initiation.
  - Initiation via a channel-to-channel linking mechanism for continuous transfers.
  - Peripheral-paced hardware requests (one per channel).
- Fixed-priority and round-robin channel arbitration.
- Channel completion reported via optional interrupt requests.
  - One interrupt per channel, optionally asserted at completion of major iteration count.
  - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller.
- Optional support for scatter/gather DMA processing.
- Support for complex data structures.
- Support to cancel transfers via software.

Throughout this chapter, *n* is used to reference the channel number.

23.2 Modes of operation

The eDMA supports the following modes of operation.

23.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

23.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

23.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

23.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. *Table 256* provides a 32-bit view of the eDMA's memory map.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

23.3.1 Control Register (eDMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in four groups (0, 1, 2, 3) of 16 channels each. Group 3 contains channels 63–48; group 2 contains channels 47–32; group 1 contains channels 31–16; and group 0 contains channels 15–0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (refer to the DCHPRI*n* registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

Note: Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRP*n*PRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

Figure 178. Control Register (eDMA_CR)

Table 257. eDMA_CR field descriptions

Field	Description
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to canceling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt.
20:21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22:23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCD*n*.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCD*n*.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.

Table 257. eDMA_CR field descriptions (continued)

Field	Description
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection within each group. 1 Round-robin arbitration is used for channel selection within each group.
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.

23.3.2 Error Status Register (eDMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

Refer to *Section 23.4.3*, for more details.

Figure 179. Error Status Register (eDMA_ES)

Table 258. eDMA_ES field descriptions

Field	Description
0 VLD	ERRH and ERRL status bits 0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
14 UCE	Uncorrectable ECC error 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error.
15 ECX	Transfer canceled 0 No canceled transfers. 1 The last recorded entry was a zeroed transfer by the error cancel transfer input.
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.

Table 258. eDMA_ES field descriptions (continued)

Field	Description
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18:23 ERRCHN	Error channel number or canceled channel number GPE or last recorded error canceled transfer.
24 SAE	Source address error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCD*n*_SADDR field. TCD*n*_SADDR is inconsistent with TCD*n*_ATTR[SSIZE].
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SOFF field. TCD*n*_SOFF is inconsistent with TCD*n*_ATTR[SSIZE].
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DADDR field. TCD*n*_DADDR is inconsistent with TCD*n*_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DOFF field. TCD*n*_DOFF is inconsistent with TCD*n*_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_NBYTES or TCD*n*_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD*n*_CSR[ESG] is enabled. TCD*n*_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read.
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write.

23.3.3 Enable Request Register Low (eDMA_ERQL)

The ERQL register provides a bit map for the 32 implemented channels to enable the request signal for each channel.

The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQL.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

23.3.4 Enable Error Interrupt Register Low (eDMA_EEIL)

The Enable Error Interrupt Register Low (DMA_EEIL) provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEIL register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

23.3.5 Set Enable Request Register (eDMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQL to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQL to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0x0018 Access: User write-only

1 SAER	Set all enable requests 0 Set only those ERQ bits specified in the SERQ field 1 Set all bits in ERQL
2:7 SERQ	Set enable request Sets the corresponding bit in ERQL

23.3.6 Clear Enable Request Register (eDMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQL to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQL to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 CERQ	Clear enable request Clears the corresponding bit in ERQL

23.3.7 Set Enable Error Interrupt Register (eDMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEIL to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be set. Setting the SAEE bit provides a global set function, forcing the entire EEIL contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 SEEI	Set enable error interrupt Sets the corresponding bit in EEIL

23.3.8 Clear Enable Error Interrupt Register (eDMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEIL to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEIL contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEIL

23.3.9 Clear Interrupt Request Register (eDMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INTL to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INTL to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INTL to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 CAIR	Clear all interrupt requests 0 Clear only those INT bits specified in the CINT field 1 Clear all bits in INTL
2:7 CINT	Clear interrupt request Clears the corresponding bit in INTL

23.3.10 Clear Error Register (eDMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERRL to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERRL to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERRL contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0x001D Access: User write-only

1 CAEI	Clear all error indicators 0 Clear only those ERR bits specified in the CERR field 1 Clear all bits in ERR
2:7 CERR	Clear error indicator Clears the corresponding bit in ERRL

23.3.11 Set START Bit Register (eDMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0x001E Access: User write-only

1 SAST	Set all START bits (activates all channels) 0 Set only those TCD*n*_CSR[START] bits specified in the SSRT field 1 Set all bits in TCD*n*_CSR[START]
2:7 SSRT	Set START bit Sets the corresponding bit in TCD*n*_CSR[START]

23.3.12 Clear DONE Status Bit Register (eDMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2:7 CDNE	Clear DONE bit Clears the corresponding bit in TCD*n*_CSR[DONE]

23.3.13 Interrupt Request Register Low (eDMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INTL.

Field	Description
0:31 INT[31:0]	Interrupt request x 0 The interrupt request for corresponding channel is cleared. 1 The interrupt request for corresponding channel is active.

23.3.14 Error Register Low (eDMA_ERRL)

The ERRL provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

23.3.15 Hardware Request Status Register Low (eDMA_HRSL)

The HRSL provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQL fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQL bits.

Field	Description
0:31 HRS[31:0]	Hardware request status channel x 0 A hardware service request for the corresponding channel is not present. 1 A hardware service request for the corresponding channel is present.

23.3.16 Channel *n* Priority Register (eDMA_DCHPRI*n*)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRI*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRI*n* registers. The group priority is assigned in the DMA control register.

Figure 193. Channel *n* Priority Register (eDMA_DCHPRI*n*)

Table 272. eDMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel *n* cannot be suspended by a higher priority channel's service request. 1 Channel *n* can be temporarily suspended by the service request of a higher priority channel.
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel *n* can suspend a lower priority channel. 1 Channel *n* cannot suspend any channel, regardless of channel priority.
2:3 GRPPRI	Channel *n* current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4:7 CHPRI	Channel *n* arbitration priority Channel priority when fixed-priority arbitration is enabled. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.

23.3.17 Channel *n* Master ID Register (eDMA_DCHMID*n*)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (a core, for example) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID*n* registers.

Address: 0x140 + *n**0x1 (*n* = 0 to 31) Access: User read/write

Figure 196. TCD Transfer Attributes (eDMA_TCD*n*_ATTR)

Table 275. eDMA_TCD*n*_ATTR field descriptions

Field	Description
0:4 SMOD	Source address modulo 0 Source address modulo feature is disabled. Not 0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5:7 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte 110 Reserved 111 Reserved
8:12 DMOD	Destination address modulo See the SMOD definition.
13:15 DSIZE	Destination data transfer size See the SSIZE definition.

23.3.20 TCD Signed Source Address Offset (eDMA_TCD*n*_SOFF)

Refer to *Figure 197* and *Table 276* for details.

Address: 0x1006 + *n**0x20 (*n* = 0 to 31) Access: User read/write

Figure 198. TCD Minor Byte Count (Minor Loop Disabled) (eDMA_TCD*n*_NBYTES_MLNO)

Table 277. eDMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **Note:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

23.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (eDMA_TCD*n*_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

Address: 0x1008 + *n**0x20 (*n* = 0 to 31) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. x = Undefined at reset.

Figure 199. TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (eDMA_TCD*n*_NBYTES_MLOFFNO)

Table 278. eDMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

23.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (eDMA_TCD*n*_NBYTES_MLOFFYES)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset enabled (SMLOE or DMLOE = 1)

Address: 0x1008+ *n**0x20 (*n* = 0 to 31) Access: User read/write

Figure 200. TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (eDMA_TCD*n*_NBYTES_MLOFFYES)

Table 279. eDMA_TCD*n*_NBYTES_MLOFFYES field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2:21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22:31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

23.3.24 TCD Last Source Address Adjustment (eDMA_TCD*n*_SLAST)

Address: 0x100C + *n**0x20 (*n* = 0 to 31) Access: User read/write

Figure 203. TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCD*n*_CITER_ELINKYES)

Table 282. eDMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
1:6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel’s TCD*n*_CSR[START] bit.
7:15 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (for example: final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **Note:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

23.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (eDMA_TCD*n*_CITER_ELINKNO)

See TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) register figure and DMA_TCDn_CITER_ELINKNO field descriptions table as follows.

Figure 206. TCD Last Destination Address Adjustment/Scatter Gather Address (eDMA_TCD*n*_DLASTSGA)

Table 285. eDMA_TCD*n*_DLASTSGA field descriptions

Field	Description
0:31 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCD*n*_CSR[ESG] = 0) then – Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. else – This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, else a configuration error is reported.

23.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCDn_BITER_ELINKYES)

Address: 0x101C + *n**0x20 (*n* = 0 to 31) Access: User read/write

Figure 207. TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (eDMA_TCDn_BITER_ELINKYES)

Table 286. eDMA_TCDn_BITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
1:6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.
7:15 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

1. x = Undefined at reset.

Figure 209. TCD Control and Status (eDMA_TCD*n*_CSR)

Table 288. eDMA_TCD*n*_CSR field descriptions

Field	Description
0:1 BWC	Bandwidth control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBS). **Note:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w
2:7 MAJORLINKCH	Link channel number If (MAJORELINK = 0) then – No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted. else – After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.
8 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **Note:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
9 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.

Table 288. eDMA_TCD*n*_CSR field descriptions (continued)

Field	Description
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. **Note:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **Note:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The current channel’s TCD is normal format. 1 The current channel’s TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable request {H,L} 0 The channel’s ERQ bit is not affected. 1 The channel’s ERQ bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer’s progress. **Note:** If BITER is set to 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
15 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

23.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

23.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
  - Address path:

    This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

    When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n* _{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the TCD*n* _CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
  - Data path:

    This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

    The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
  - Program model/channel arbitration:

    This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
  - Control:

    This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-

bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

- Transfer control descriptor memory
  - Memory controller:

    This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

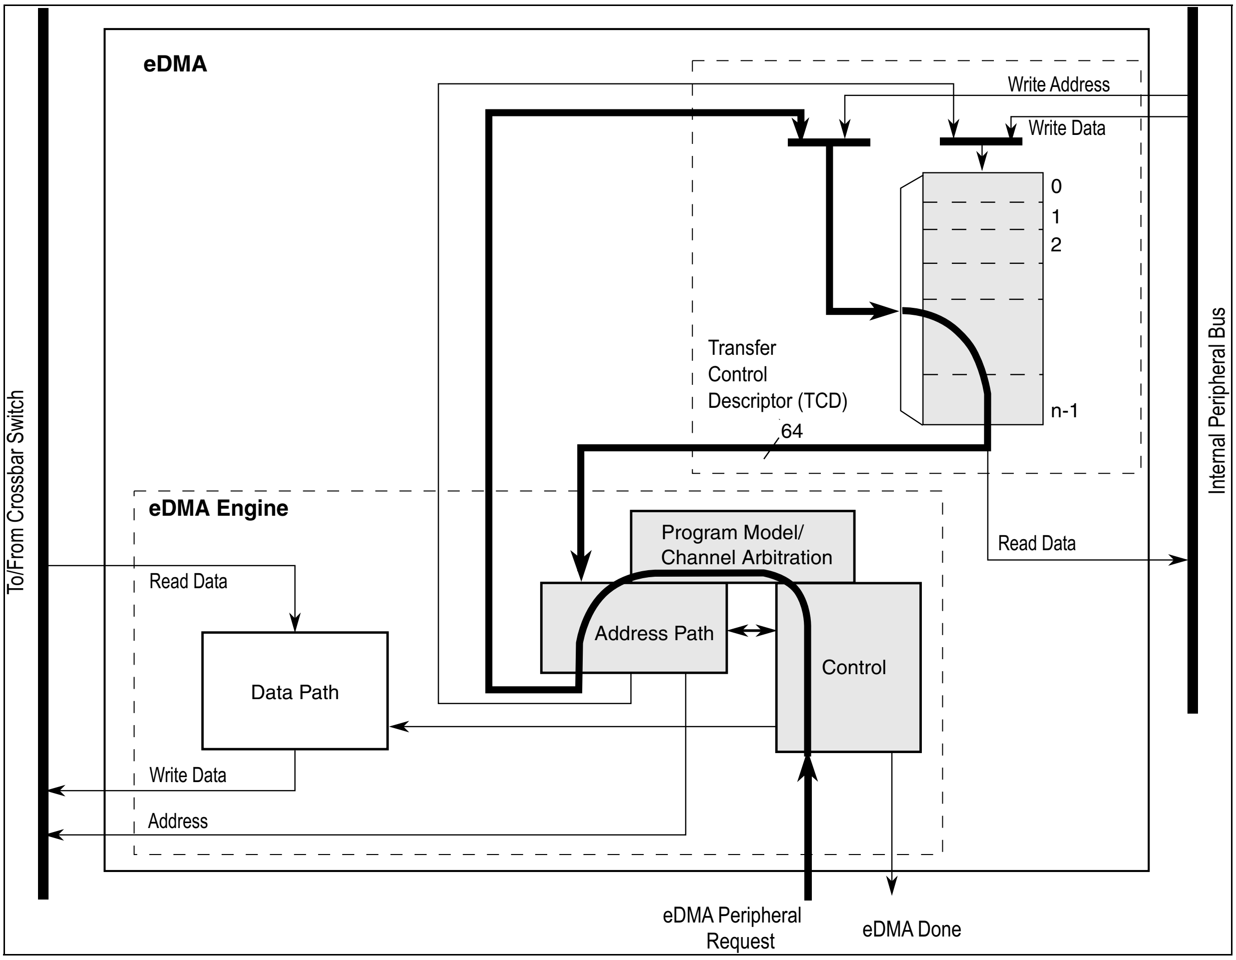
    As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
  - Memory array:

    TCD storage is implemented using a single-port, synchronous RAM array.

23.4.2 eDMA basic data flow

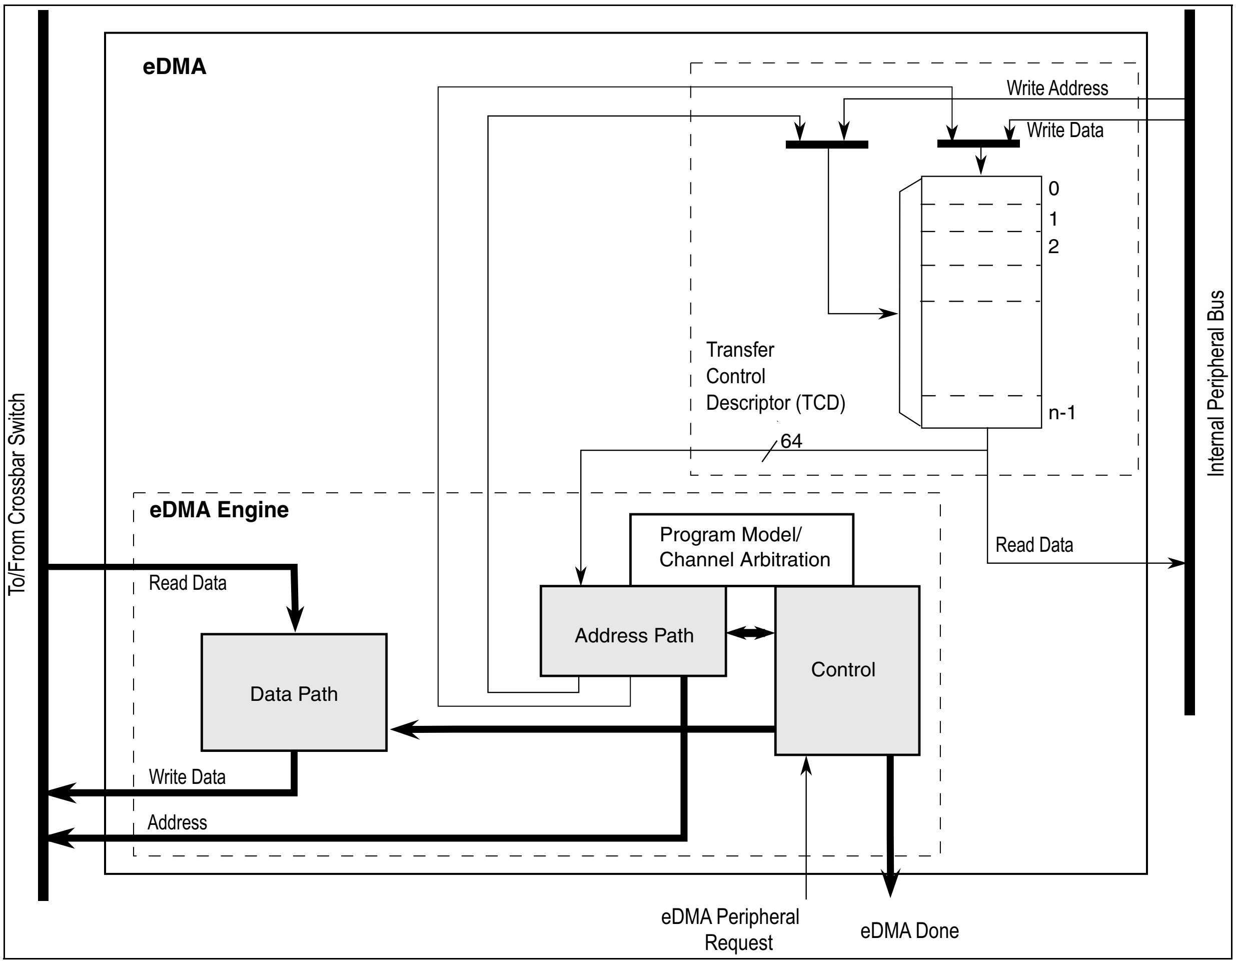
The basic flow of a data transfer can be partitioned into three segments. As shown in *Figure 210*, the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

Figure 210. DMA operation, part 1



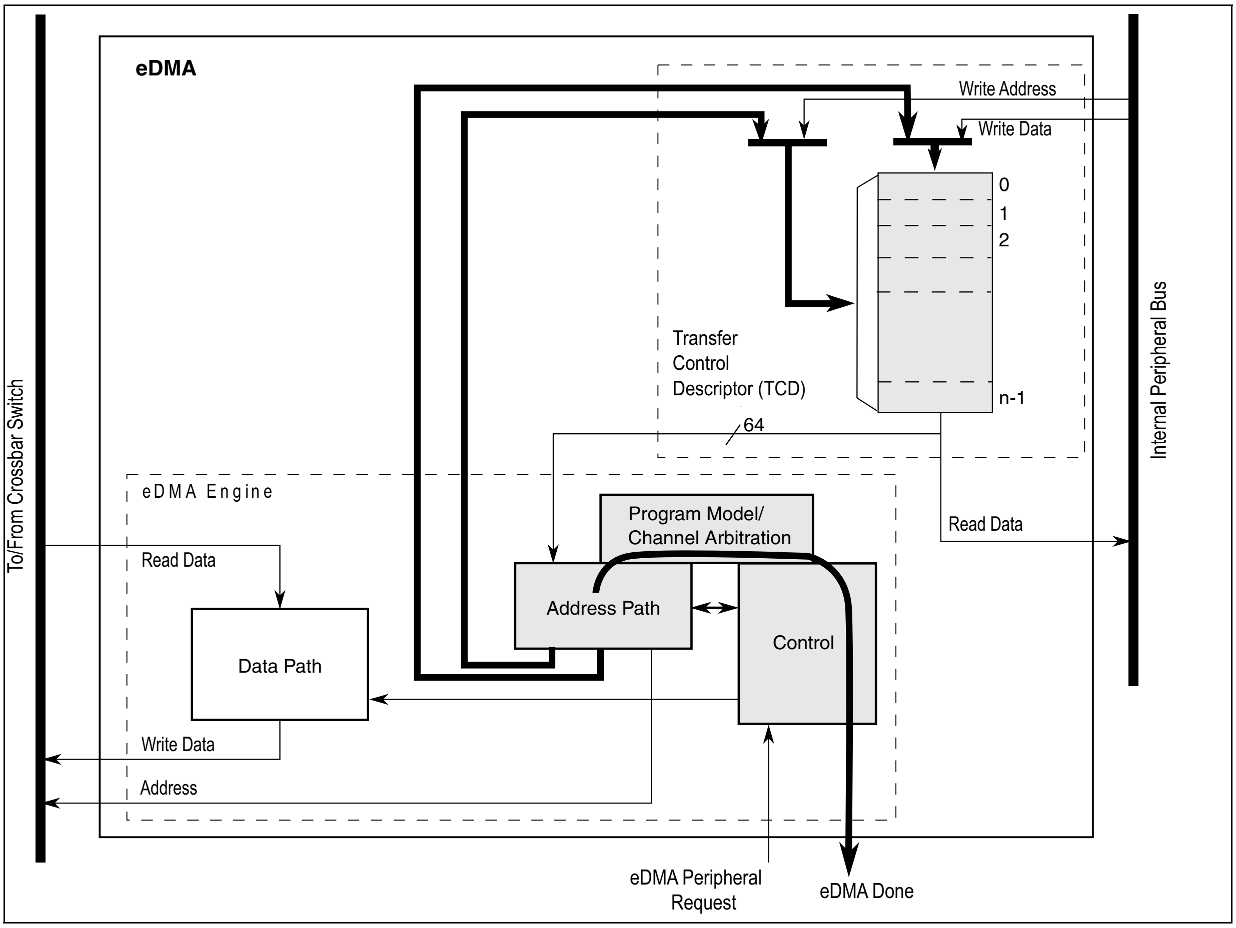
In the second part of the basic data flow as shown in *Figure 211* the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

Figure 211. DMA operation, part 2



After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as a possible fetch of a new TCD from memory does using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in *Figure 212*.

Figure 212. DMA operation, part 3



23.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle.

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes is detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively.
- In Fixed Arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups.

All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when Fixed Arbitration mode is enabled.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD*n*_CITER[E_LINK] bit does not equal the TCD*n*_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be canceled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the canceled channel number and ECX is set. The TCD of a canceled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is canceled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

23.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRI*n*[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRI*n*[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

23.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in *Table 289* and *Table 290*. The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- All internal peripheral bus accesses are 32 bits in size.
- All internal SRAM accesses are 64 bits in size.

Table 289 presents a peak transfer rate comparison, measured in megabytes per second.

Table 289. eDMA peak transfer rates (Mbyte/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD*n* _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* Word 7).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
- Cycles 8 to *x*[g]: The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

  The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles. For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles.
- Cycle *x*[g] + 1: This cycle represents the data phase of the last destination write.
- Cycle *x*[g] + 2: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* Word 7 is read and checked for channel linking or scatter/gather requests.
- Cycle *x*[g] + 3: The appropriate fields in the first part of the TCD*n* are written back into the local memory.
- Cycle *x*[g] + 4: The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle *x*[g] + 5: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles (4 + (3 + 3)/2 + 3). This is the time from Cycle 4 to Cycle *x* + 5. The resulting peak request rate, as a function of the system frequency, is shown in *Table 290*. This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

g. "*x*" represents an undefined cycle value dependent on transfer sizes and response times for the channel's read and write accesses.

Table 290. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

Equation 1 **PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]**

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to internal peripheral bus transfer,

Equation 2 **PEAKreq = 150 MHz / [4 + (1 + 0) + (1 + 1) + 3] cycles = 15.0 Mreq/s**

For an internal peripheral bus-to-SRAM transfer,

Equation 3 **PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 0) + 3] cycles = 15.0 Mreq/s**

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCD*n*_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

23.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

23.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by software (setting the TCD*n*_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in *Table 291*) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD*n*_SADDR) to the destination (as defined by the destination address, TCD*n*_DADDR) continue until the specified number of bytes (TCD*n*_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

Table 291. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

Figure 213 shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of

minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 213. Example of multiple loop iterations

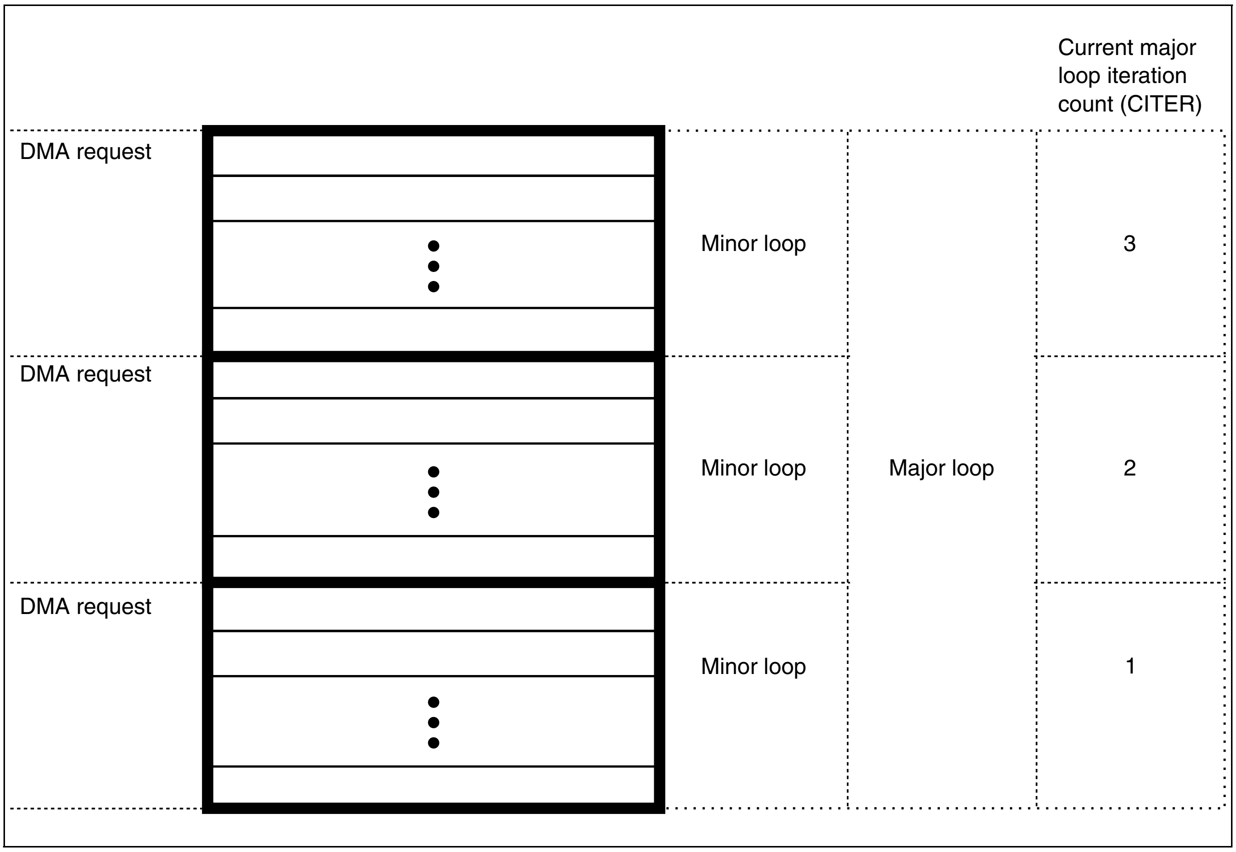


Figure 214 lists the memory array terms and how the TCD settings interrelate.

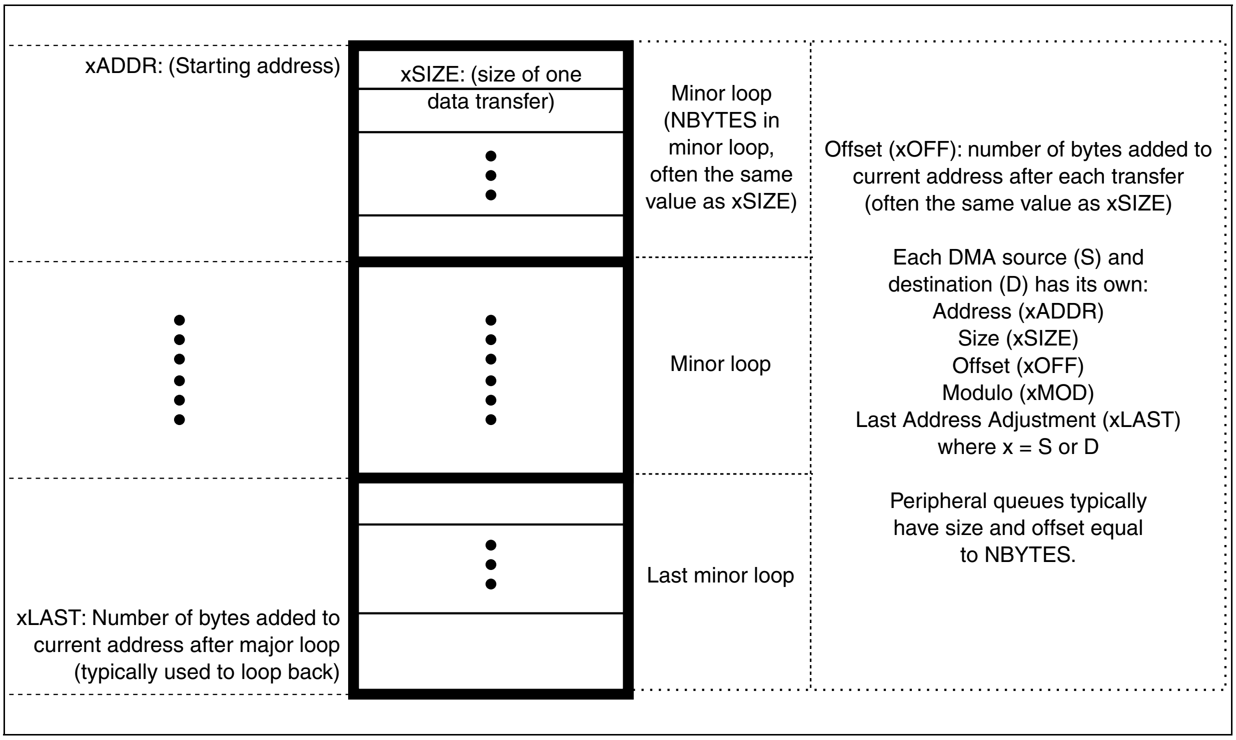
Figure 214. Memory array terms



23.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: the group priority error (ES[GPE]) and the channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes.
2. Group 3 is the highest priority and all channels are unique in that group.
3. Group 2 is the next highest priority and has two channels with the same priority level.
4. If Group 3 has any service requests, those requests will be executed.
5. Once all of Group 3 requests have completed, Group 2 will be the next active group.
6. If Group 2 has a service request, then an undefined channel in Group 2 will be selected and a channel priority error will occur.
7. This repeats until all of the Group 2 requests have been removed or a higher priority Group 3 request comes in.

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

23.5.3 DMA Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

23.5.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller—that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

23.5.3.2 Round-robin group arbitration, fixed-channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with a service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

23.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in *Section 23.5.3.2: Round-robin group arbitration, fixed-channel arbitration*, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

23.5.3.4 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in *Section 23.5.3.1: Fixed-group arbitration, fixed-channel arbitration* but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get much longer as the group priority decreases.

23.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

23.5.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have
 been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h) Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

23.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as the previous one. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.

   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h) Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
   b) Write 32 bits to location 0x2010 → first iteration of the minor loop.
   c) Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
   d) Write 32 bits to location 0x2014 → second iteration of the minor loop.
   e) Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
   f) Write 32 bits to location 0x2018 → third iteration of the minor loop.
   g) Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
   h) Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2(TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

23.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address + offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

Table 292 shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 292. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

23.5.5 eDMA TCD*n* status monitoring

This section discusses how to monitor eDMA status.

23.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute a sequence for a software activated channel as shown in *Table 293*.

Table 293. TCD status sequence – software activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer’s model.

The TCD status bits execute a sequence for a hardware-activated channel as shown in *Table 294*.

Table 294. TCD status sequence – hardware activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit. The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

23.5.5.2 Active channel TCD*n* reads

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

23.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in Fixed-Group, Fixed-Channel Arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and group priorities are treated as equal (constantly rotating) when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

23.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note: The TCDn_CITER[E_LINK] bit and the TCDn_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

Table 295 summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 295. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

23.5.7 Dynamic programming

23.5.7.1 The following sections describe dynamic programming.

23.5.7.2 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode.
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

23.5.7.3 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in *Table 296* is recommended when executing a dynamic channel link request.

Table 296. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: – If TCD.major.e_link = 1b, the dynamic link attempt was successful. – If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

23.5.7.4 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

23.5.7.4.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in *Table 297* may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 297. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to theTCD.d_req bit. *Note: Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.*
3	Write theTCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

23.5.7.4.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in *Table 298* may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 298. Coherency model for method 2

Step	Action
1	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
2	Write theTCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b, read the 32 bit TCD dlast_sga field. – If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

24 DMA channel multiplexer (DMACHMUX)

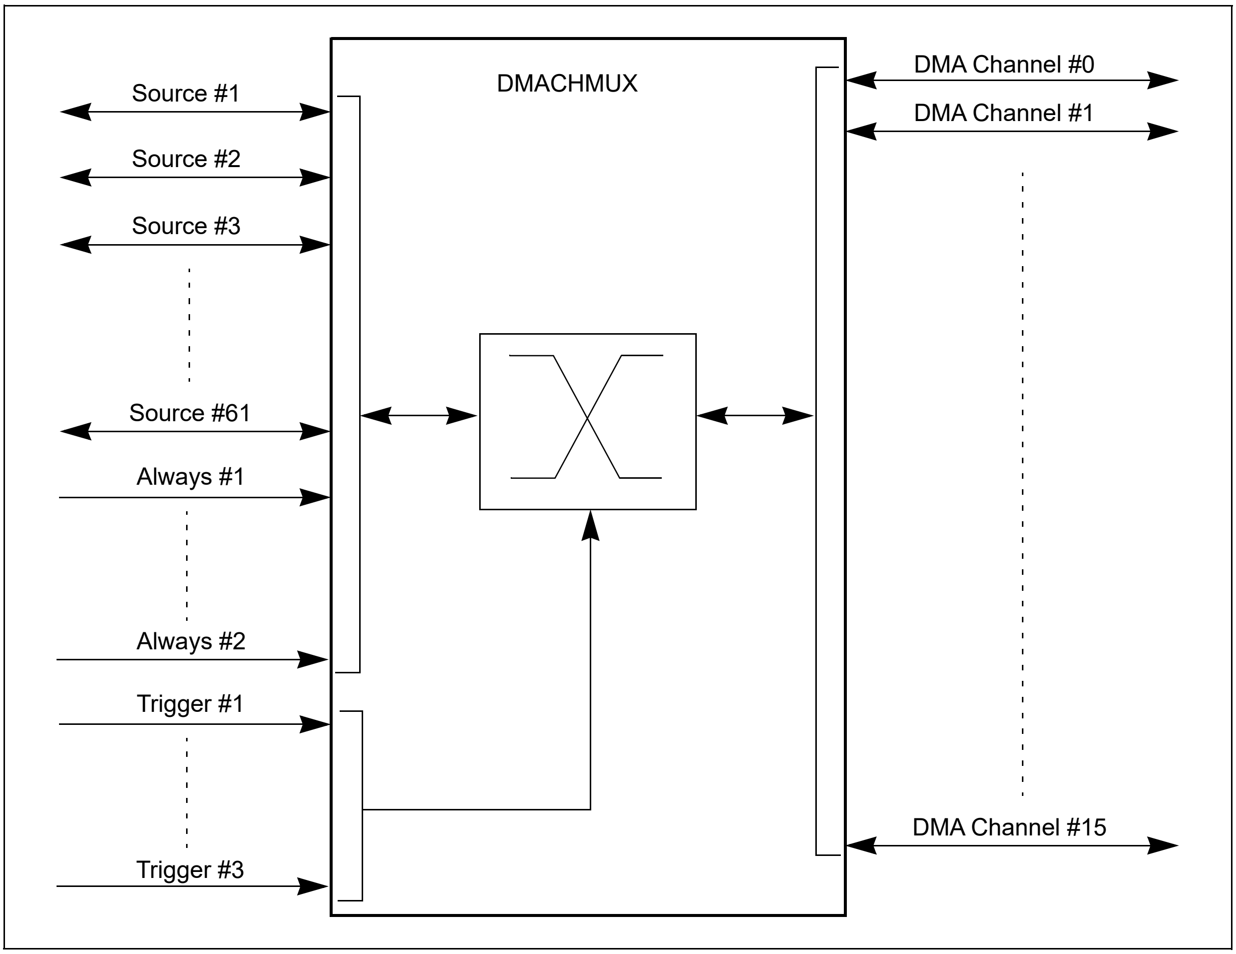
24.1 Introduction

Note: For the chip-specific implementation details of this module's instances, refer to the chip configuration information.

24.1.1 Overview

The DMA channel multiplexer (DMACHMUX) allows to route 61 DMA peripheral sources (called slots) to 16 DMA channels. This is illustrated in *Figure 215*.

Figure 215. DMACHMUX block diagram



24.1.2 Features

The DMACHMUX provides these features.

- 61 peripheral slots + 2 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channels routers.
  - The first 3 channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of 61 possible peripheral DMA slots or to one of the 2 always-on slots.

24.1.3 Modes of operation

The following operation modes are available.

- Disabled Mode
  In this mode, the DMA channel is disabled. Since disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMACHMUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place (for example, changing the period of a DMA trigger).
- Normal Mode
  In this mode, a DMA source (such as DSPI transmit or DSPI receive for example) is routed directly to the specified DMA channel. The operation of the DMACHMUX in this mode is completely transparent to the system.
- Periodic Trigger Mode
  In this mode, a DMA source may only request a DMA transfer (such as when a transmit buffer becomes empty or a receive buffer becomes full) periodically. Configuration of the period is done in the registers of the Periodic Interrupt Timer (PIT). This mode is only available for channels 0–2 of each DMACHMUX instance.

24.2 External signal description

The DMACHMUX has no external pins.

24.3 Memory map and register definition

24.3.1 Memory map

Table 299 lists the DMACHMUX memory-mapped registers. All addresses are offsets; the absolute address can be computed by adding the specified offset to the base address of the DMACHMUX.

Table 299. DMACHMUX memory map

Address offset	Register	Location
eDMA channel registers per channel (*n* = 0 to 15)		
0x0000 + n*0x1	Channel n Configuration registers (CHCFGn)	*Section 24.3.2.1*

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, CHCFG0 through CHCFG3 are accessible by a 32-bit READ/WRITE to address ‘Base + 0x00’, but performing a 32-bit access to address ‘Base + 0x01’ is illegal.

24.3.2 Register descriptions

This section provides a detailed description of the memory-mapped registers in the DMACHMUX.

24.3.2.1 Channel n Configuration registers (CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMACHMUX slots (peripheral slots or always-on slots) in the system.

Address: 0x0000 + n*0x1 (*n* = 0 to 15) Access: User read/write

	0	1	2	3	4	5	6	7
R/W	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

Figure 216. Channel n Configuration registers (CHCFGn)

Table 300. CHCFGn field descriptions

Field	Description
0 ENBL	DMA Channel Enable ENBL enables the DMA Channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMACHMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable (for triggered channels only) TRIG enables the periodic trigger capability for the DMA Channel. 0 Triggering is disabled. If triggering is disabled, and the ENBL bit is set, the DMA Channel will simply route the specified source to the DMA channel 1 Triggering is enabled
2:7 SOURCE	DMA Channel Source (DMACHMUX slot) SOURCE specifies which DMA source, if any, is routed to a particular DMA channel. Please refer to “Device configuration” chapter for further details about the peripherals and their slot numbers

Table 301. Channel and trigger enabling

ENBL	TRIG	Function	Mode
0	X	DMA Channel is disabled	Disabled Mode

Table 301. Channel and trigger enabling (continued)

ENBL	TRIG	Function	Mode
1	0	DMA Channel is enabled with no triggering (transparent)	Normal Mode
1	1	DMA Channel is enabled with triggering	Periodic Trigger Mode

Note: Setting multiple CHCFG registers with the same source value will result in unpredictable behavior.

Before changing the trigger or source settings a DMA channel must be disabled via the CHCFG[n].ENBL bit.

24.4 DMACHMUX functional description

This section provides a functional description of the DMACHMUX. The primary purpose of the DMACHMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMACHMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in *Section 24.5.2: Enabling and configuring sources* is followed, the configuration of the DMACHMUX may be changed during the normal operation of the system.

Functionally, the DMACHMUX channels may be divided into two classes.

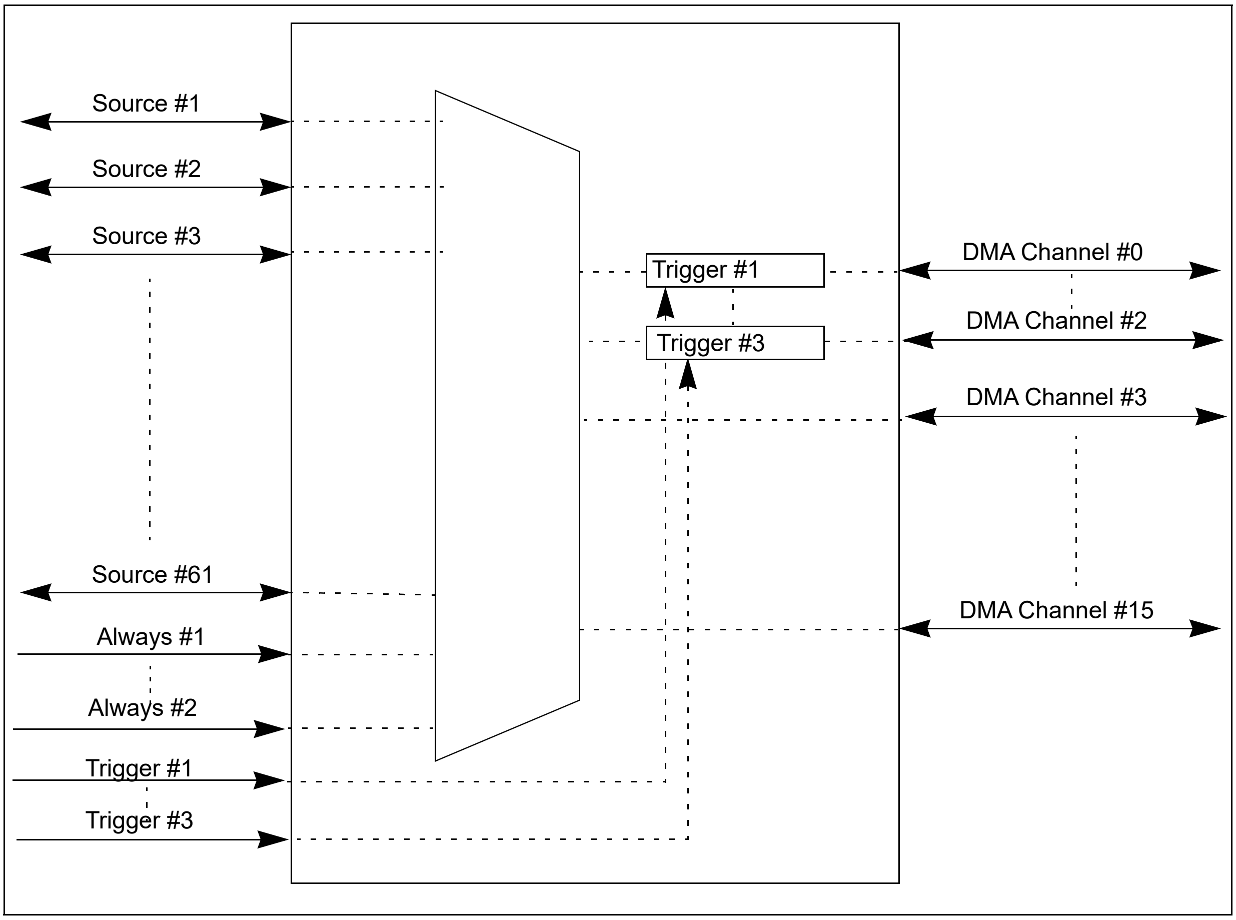
- Channels which implement the normal routing functionality plus periodic triggering capability.
- Channels which implement only the normal routing functionality.

24.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 3 channels of the DMACHMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames or packets at fixed intervals without the need for processor intervention. The trigger is generated by the Periodic Interrupt Timer (PIT): such as the configuration of the periodic triggering interval is done via configuration registers in the PIT. Please refer to the Periodic Interrupt Timer (PIT) chapter for more information on this topic.

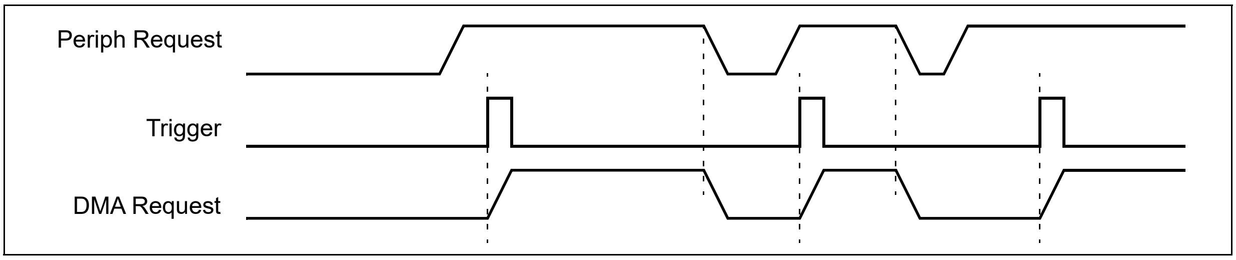
Note: The dynamic nature of the system (such as DMA channel priorities, bus arbitration, interrupt service routine lengths) is such that, the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 217. DMACHMUX triggered channels



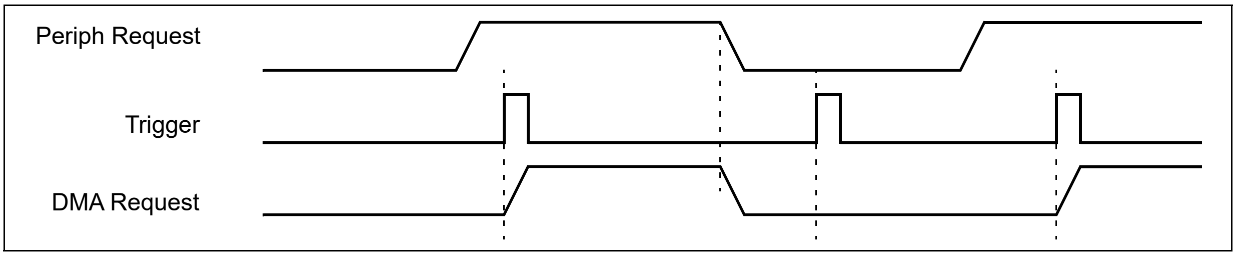
The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the Peripheral to the DMA until a trigger event has been seen. This is illustrated in *Figure 218*.

Figure 218. DMACHMUX channel triggering: normal operation



Once the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral re-asserts its request AND the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, that trigger will be ignored. This situation is illustrated in *Figure 219*.

Figure 219. DMACHMUX channel triggering: ignored trigger



This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations.

- Periodically polling external devices on a particular bus. As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. Once setup, the SPI will request DMA transfers (presumably from memory) as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO Ports to drive or sample waveforms. By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger (such as resolution, range of values) may be found in Periodic Interrupt Timer (PIT) chapter and in the Ethernet chapter.

24.4.2 DMA channels with no triggering capability

The other channels of the DMACHMUX provide the normal routing functionality as described in *Section 24.1.3: Modes of operation*.

24.4.3 “Always Enabled” DMA sources

In addition to the peripherals that can be used as DMA sources, there are 2 additional DMA sources that are “always enabled”. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the *“always enabled”* sources provide no such “throttling” of the data transfers. These sources are most useful in the following cases:

- Doing DMA transfers to/from GPIO: Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Doing DMA transfers from memory to memory: Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Doing DMA transfers from memory to the external bus (or vice-versa): Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation: Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, a *“always enabled”* DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require a new “*start*” event be sent. This can either be a new software activation, or a transfer request from the DMACHMUX. The options for doing this are:

- Transfer all data in a single minor loop. By configuring the DMA to transfer all of the data in a single minor loop (that is major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will incur on the system. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use explicit software reactivation. In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel (by writing to the DMA registers) *after every minor loop*. For this option, the DMA channel should be disabled in the DMACHMUX.
- Use a *“always enabled”* DMA source. In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMACHMUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an *“always enabled”* source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

24.5 Initialization/Application information

24.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (refer to *Section 24.3.2: Register descriptions*). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

24.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 2 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

Note: The following is an example. Refer to the chip configuration details for the number of this device’s DMA channels that have triggering capability.

Example 1 Configure source #5 Transmit for use with DMA Channel 2, with periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #4 above:

In file **registers.h:**

```
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
#include "registers.h"
   :
   :
*CHCFG2 = 0x00;
*CHCFG2 = 0xC5;
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 3 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

Note: The following is an example. Refer to the chip configuration details for the number of this device's DMA channels that have triggering capability.

Example 2 Configure source #5 Transmit for use with DMA Channel 2, with <u>no</u> periodic triggering capability:

1. Write 0x00 to CHCFG2 (Base Address + 0x02).
2. Configure Channel 2 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG2 (Base Address + 0x02).

The following code example illustrates steps #1 and #3 above:

In File **registers.h:**

```
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
```

```
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG2 = 0x00;
  *CHCFG2 = 0x85;
```

Disabling a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module specific configuration may be necessary. Please refer to the appropriate section for more details.

Switching the source of a DMA Channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the ENBL and TRIG bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the ENBL and TRIG bits are set.

Example 3 Switch DMA Channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 does not have triggering capability.
2. Write 0x00 to CHCFG8 (Base Address + 0x08).
3. Write 0x87 to CHCFG8 (Base Address + 0x08). (In this example, setting the TRIG bit would have no effect, due to the assumption that channels 8 does not support the periodic triggering functionality).

The following code example illustrates steps #2 and #3 above.

In File **registers.h:**

```
  #define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
  /* Following example assumes char is 8-bits */
  volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
  volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
  volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
  volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
  volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
```

```
  volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
  volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
  volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
  volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
  volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
  volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
  volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
  volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
  volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
  volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
  volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c:**

```
  #include "registers.h"
     :
     :
  *CHCFG8 = 0x00;
  *CHCFG8 = 0x87;
```

25 Clocking

25.1 Introduction

This chapter describes the architecture of the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive Clock Switching (PCS)

Note: This chapter only covers clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The system clock (SYS_CLK) services the computational shell module (includes the main CPU Main Core_2), that run in the high-speed domain, memories and debug logic. Its independence from the peripheral clocks allows SYS_CLK to be a frequency modulated (FM) clock with reduced electromagnetic emissions while having a precise clock for the peripheral timer and communication functions. It can be reduced during low computational activity periods to lower power consumption while providing a fixed frequency to the communication interfaces and timers.

The internal 16 MHz RC oscillator (IRCOSC) services device boot up and may be enabled via the Mode Entry Module in the event of PLL or external oscillator failure. See the “Mode Entry Module (MC_ME)” chapter for details.

The alternative clock sources are:

- External oscillator/crystal (XOSC)
- Internal 16 MHz RC oscillator (IRCOSC)
- PLL0 (PLL0_PHI)
- PLL1 (PLL1_PHI)

Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM) allow developers to select an independent clock source for each system peripheral. There is an additional System Clock Selector used exclusively for the system clock.

The outputs of the module clock selectors have individual dividers that can divide the clock selector outputs by up to 512 for a given peripheral.

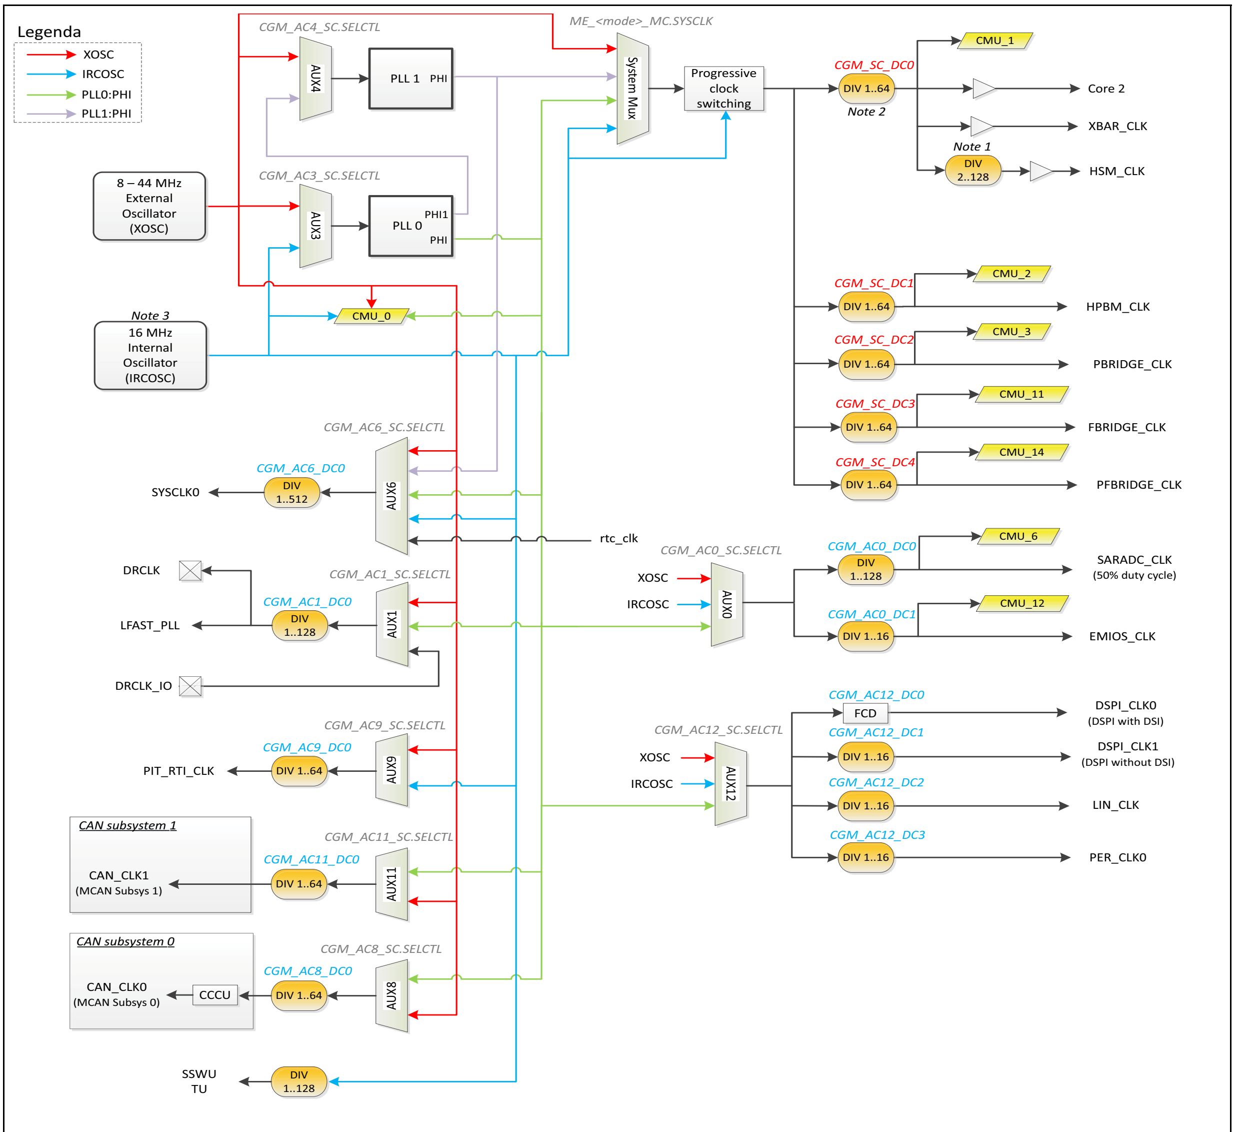
Clock Monitor Units (CMUs) are connected to outputs of clock dividers to verify that clock frequencies stay within operating limits and can be configured to signal an interrupt or initiate a system reset when an issue with a clock is found.

25.2 Clock generation

The top-level clock generation architecture can be seen in *Figure 220*. See *Chapter 28: Clock Generation Module (MC_CGM)*for details on the Fractional Clock Dividers. All clock selectors and dividers are located and programmed in the MC_CGM, with the exception of the Hardware Security Module (HSM) clock divider. All dividers are integer dividers (1, 2, 3, …, *n*) with the ranges shown in the divider blocks in *Figure 220*. All dividers connected to the System Clock Selector must have 50% duty cycle outputs.

Note: Clock Monitoring Units CMU1 to CMU14 in Figure 220 use IRCOSC as their reference clock. The user can select either IRCOSC or XOSC as the reference clock for CMU_0.

Figure 220. Clock generation

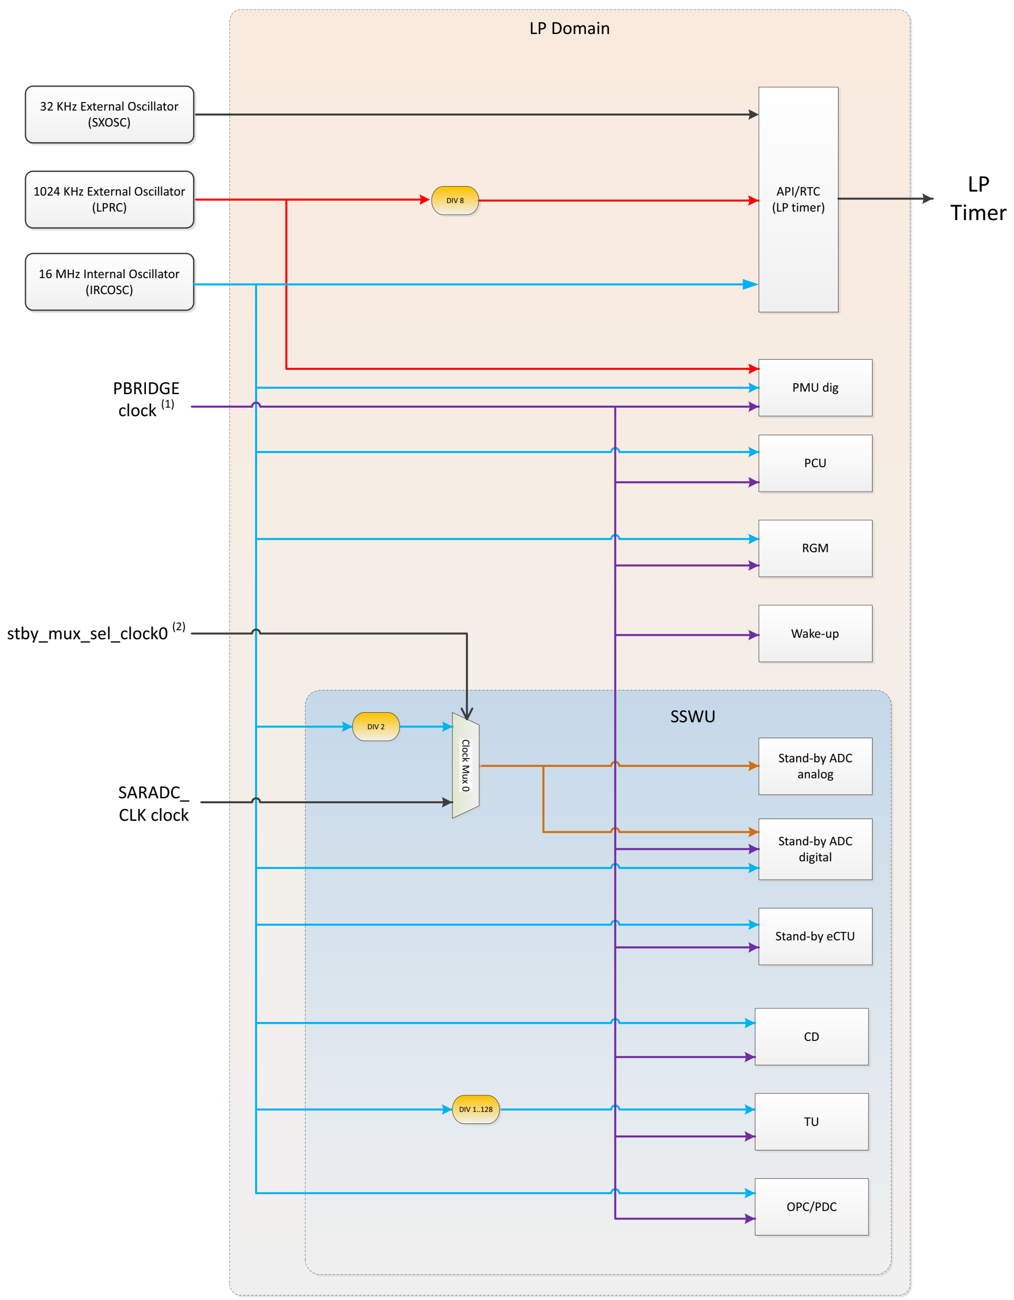


All dividers shown in the diagram are integer dividers with a range of 1, 2, 3,…., n
FCD are fractional clock dividers.
All clock dividers are 50% duty cycle.
Note 1: located within the CSM memory space.It shall be set only to 2 or 4

Note 2: CGM_SC_DC0 divisor can only be set to 1
CGM_SC_DC1 divisor can only be set to 2;
CGM_SC_DC2 divisor can only be set to 4;
Note 3: within the stand-by domain

25.2.1 STAND-BY Domain

Figure 221. Clock distribution in Stand-by Domain



Note 1: IP registers clock, gated for each IP in main domain. not running during stand-by.
Note 2: Default selection on IRC 16MHz. To be set when entering in stand -by.Selection of alternate clock from main domain when stand-by is not used.

ADC 10-bit conversion frequency in smart stand-by: 8MHz (IRCOSC 16 MHz divided by 2). This frequency guarantees the ADC precision required during stand-by.

IRCOSC clock is used to clock all the other IPs used for Smart-stand-by (SSWU). It can be used also to clock PMC during stand-by.

Divider for RCOSC vs ADC and stand-by peripherals can be fixed or programmable (suggested ratios: 1, 2, 4).

IRCOSC can be used without fine calibration during Smart stand-by, if Tmax during stand-by is less than 55°C.

IRCOSC hard macro can be put in power down (see “Smart Stby Gating” in *Figure 221*) when not necessary to clock IPs for Smart-stand-by. This adds a 5 µs delay due to IRCOSC wake up to the smart stand-by execution time, but this delay is acceptable. IRCOSC will be woken up by an RTC/API trigger and will be put in power down by the SSWU Stand-by CTU end of sequence signaling.

Upon entering the stand-by domain, the SW shall switch both the PLL off, because they will not be switched on when the stand-by mode is exited. Rather, the SW shall turn them on again when exiting from the stand-by mode.

25.2.2 MC_CGM registers

Table 302 shows the relationship between the clocks in *Figure 220* and the MC_CGM registers.

Table 302. MC_CGM relationship to clocks

MC_CGM register(s)	Register description	Output clock	CMU(1)
CGM_SC_DC0	System Clock Divider Configuration 0	CORE_CLK (Core_2) XBAR_CLK HSM_CLK	CMU_1_CORE_XBAR
CGM_SC_DC1	System Clock Divider Configuration 1	HPBM_CLK (DMA1, SIPI/1, SWT, STM, INTC)	CMU_2_HPBM
CGM_SC_DC2	System Clock Divider Configuration 2	PBRIDGE_CLK (All peripheral bridges and peripherals not connected to any other system clock divider)	CMU_3_PBRIDGE
CGM_SC_DC3	System Clock Divider Configuration 3	FBRIDGE_CLK	CMU_11_FBRIDGE
CGM_SC_DC4	System Clock Divider Configuration 4	PFBRIDGE_CLK (M_CANx)	CMU_14_PFBRIDGE
CGM_AC0_DC0 CGM_AC0_SC	Aux Clock 0 Divider Configuration 0 Aux Clock 0 Select Control	SARADC_CLK	CMU_6_SARADC
CGM_AC0_DC1 CGM_AC0_SC	Aux Clock 0 Divider Configuration 1 Aux Clock 0 Select Control	EMIOS_CLK	CMU_12_EMIOS

CGM_AC12_DC2 CGM_AC12_SC	Aux Clock 12 Divider Configuration 2 Aux Clock 12 Select Control	LIN_CLK (LIN0/1/2/3/4/5/6/7/8/9/10/11/12/15)	—
CGM_AC12_DC3 CGM_AC12_SC	Aux Clock 12 Divider Configuration 3 Aux Clock 12 Select Control	PER_CLK0	—
Note: See the Clock Generation Module (MC_CGM) for specifics on register implementation.			

1. CMU_0 is not shown in the table since it does not monitor an output clock from the MC_CGM.

25.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in *Table 303*.

Table 303. Maximum system level clock frequencies

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
System clock selector[1]	120	0	CORE_CLK (Core_2), XBAR_CLK	120
System clock selector[1]	120	1	HPBM_CLK	60
System clock selector[1]	120	2	PBRIDGE_CLK	30
System clock selector[1]	120	3	FBRIDGE_CLK	120

Table 303. Maximum system level clock frequencies (continued)

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
System clock selector(1)	120	4	PFBRIDGE_CLK	120
System clock selector(1)	120	—	HSM_CLK (2)	60
Note: The user is responsible to verify that these values are not exceeded. **Note:** Refer to *Figure 220* for clocking architecture overview.				

1. System clock selection is a component of the device run mode switching process. Refer to the Mode Entry Module (MC_ME) chapter for details.
2. Maximum frequency is related to HSM core clock (HSM_CLK). Refer to *Figure 223* for details.

Table 304. Maximum auxiliary level clock frequencies

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
Aux Clock 0 Selector	400	0	SARADC_CLK	16
Aux Clock 0 Selector	400	1	EMIOS_CLK(1)	50
Aux Clock 3 Selector	Refer to the Data Sheet	—	PLL0	—
Aux Clock 4 Selector	Refer to the Data Sheet	—	PLL1	—
Aux Clock 6 Selector	400	0	SYSCLK0	Refer to the Data Sheet, section “I/O output DC characteristics”
Aux Clock 8 Selector	400	0	CAN_CLK0	If CCCU is enabled: 400 If CCCU is bypassed: 80
Aux Clock 9 Selector	40	0	RTI_CLK	40
Aux Clock 11 Selector	400	0	CAN_CLK1	80
Aux Clock 12 Selector	400	0	DSPI_CLK0(2)	100
Aux Clock 12 Selector	400	1	DSPI_CLK1(2)	100
Aux Clock 12 Selector	400	2	LIN_CLK0	100

Table 304. Maximum auxiliary level clock frequencies (continued)

Clock Selector	Nominal programmed max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
Aux Clock 12 Selector	400	3	PER_CLK0	80
Note: The user is responsible to verify that these values are not exceeded. **Note:** Refer to the *Figure 220* for clocking architecture overview.				

1. When BCTU is used to route a trigger event to SARADC, its clock (EMIOS_CLK) must be greater than SARADC_CLK.
2. DSPI_CLK0/1 frequency should always be greater than or equal to 1.25 times of PBRIDGE_CLK.

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

25.3.1 JTAG frequencies

Table 305 shows the maximum frequencies of the JTAG interface.

Table 305. JTAG frequencies

Configuration	e200z4 max. internal JTAG frequency	Max. external JTAG frequency	Notes
Unconfigured clock	—	Refer to electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock on PD (IRC) with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
Clock configured to 120 MHz	60 MHz		JTAG usable at 1/2 CPU frequency

25.4 Default clock configuration

At power up, the 16 MHz IRC is the default system clock for the chip. All clock source and clock control blocks should be reset to their default state.

All auxiliary clock selectors will have a default selection of the first available clock source mapped on the respective clock mux. All clock dividers attached to Auxiliary clock selectors (that is not the System clock selectors) are disabled by default.

At power up, all system clock (SYS_CLK branch) dividers are set to 1 to allow a fast DCF reading operation. From the end of Phase 3, all system clock (SYS_CLK branch) dividers are set to divide by a ratio as described in *Table 306*. The SW shall be able to change them accordingly with the divisor range (keeping in account the clock constraints).

Table 306. SYS_CLK divisor clock ratios at power up

Divisor	Description	Ratio
CGM_SC_DC0	cores, XBAR	1
CGM_SC_DC1	high speed bridge	2
CGM_SC_DC2	slow peripheral bridge	4
CGM_SC_DC3	fast peripheral bridge	1
CGM_SC_DC4	slow-fast peripheral bridge	4

Software must have the option to switch the system clock between the available clocks (PLL, XTAL, RCOSC) and must not cause a glitch.

Under the software responsibility, the value chosen for the divisors CGM_SC_DC0, CGM_SC_DC1 and CGM_SC_DC2 shall respect the ratios shown in *Table 306*.

Synchronous IP blocks need to be clocked during reset for proper initialization. After reset, all clock gates should be disabled except for the clocks required for Core_2 execution. The internal RC oscillator is always kept on and the output clock is considered as safe. This safe clock must be used in the event of PLL or oscillator failure.

25.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (SSCG - Spread Spectrum Clock Generator (FM))
- External oscillator (XOSC)
- External Clock (EXTAL Bypass)
- 16 MHz internal RC oscillator (IRCOSC)

IRCOSC is also the system clock available during the STANDBY and it is placed in STANDBY power domain.

Additionally, there are two low power oscillators in STANDBY domain:

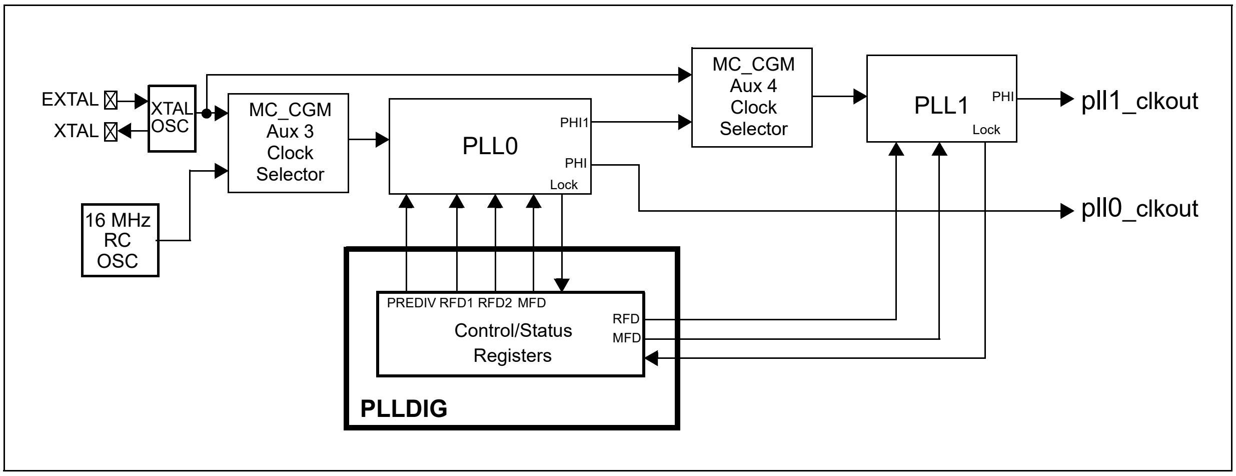
- Low power RC oscillator 1024 KHz (LPRC)
- Slow external crystal oscillator 32 KHz (SXOSC)

These two low power oscillators can be used as clock for counters of API/RTC.

25.5.1 PLL

The Dual PLL provides separate system and peripheral clocks as shown in *Figure 220*. The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in *Figure 222*.

Figure 222. SPC584Bx PLL digital interface block diagram



25.5.1.1 PLL0: base PLL (non-FM)

This primary PLL provides a clock that is not Frequency Modulated to the peripheral IPs and the reference clock to PLL1.

The input clock sources for PLL0 are:

- XOSC
- IRCOSC
- The external reference clock (input on the EXTAL pin)

The output clocks from PLL0 are:

- PHI: drives the peripheral clock and the system clock when PLL1 is not locked or active.
- PHI1: provides the input reference clock for PLL1.

25.5.1.2 PLL1: FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

The input clocks to PLL1 are:

- PHI1 output clock from PLL0
- The external reference clock.

The output clock from PLL1 is:

PHI: drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

25.5.1.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the “Dual PLL Digital Interface” chapter.

25.5.1.4 PLL register write protection

The PLL registers defined in *Table 307* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the PLL register write protection (refer to *Section 7.10.4: Register protection (REG_PROT) configuration* in *Chapter 7: Device configuration* for details).

Table 307. PLL register write protection

Offset	Register
0x00	PLL0 Control Register (PLL0CR)
0x04	PLL0 Status Register (PLL0SR)
0x08	PLL0 Divider Register (PLL0DIVR)
0x20	PLL1 Control Register (PLL1CR)
0x24	PLL1 Status Register (PLL1SR)
0x28	PLL1 Divider Register (PLL1DIVR)
0x2C	PLL1 Frequency Modulation Register (PLL1FMR)
0x30	PLL1 Fractional Divider Register (PLL1FDR)
Note: Refer to Register Protection Configuration chapter for bit field details.	

25.5.1.5 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in *Table 308*. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 308. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset value (hex)
0x0008	PLL0 Divider Register (PLL0DV)	0x0000_0000
0x0028	PLL1 Divider Register (PLL1DV)	0x0000_0000
0x0034	Reserved	—
0x0038	Reserved	—

25.5.1.6 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition.

25.5.1.7 PLLDIG initialization information

Configure PLL0 and related modules.

1. With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.
2. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].
3. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).
4. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

Turn on XOSC and PLL0.

5. Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<mode>_MC[XOSCON] = 1 and MC_ME_<mode>_MC[PLL0ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0(PLL0 PHI output) as the sysclk.
6. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

7. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

   XOSC counter expires (if the new mode configuration changes MC_ME_<mode>_MC[XOSCON] = 1), and

   PLL is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL0ON] = 1)
8. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Configure PLL1 and related modules.

9. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.
10. Program PLL1DV[MFD] and PLL1DV[RFDPHI].
11. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

Turn on PLL1.

12. Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL1 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<mode>_MC[XOSCON] = 1, MC_ME_<mode>_MC[PLL1ON] = 1 and MC_ME_<mode>_MC[PLL1ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.
13. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

14. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

    XOSC counter expires (if the new mode configuration changes XOSCON to 1), and

    PLL1 is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL1ON] = 1).

15. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Note: Refer to the "Mode Entry Module (MC_ME)" chapter in this Reference Manual for more details.

25.5.2 External oscillator (XOSC)

The external oscillator (XOSC):

- Is a reference for the on-chip PLLs.
- Can be used as a clock source for the ADCs, timer, serial interfaces, RTI, LFAST and as a system clock source.
- Is available for observation on either of the SYSCLK0/1 pins.
- Is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators
- Automatic Loop Control (ALC) to remove need for external series resistor
- Gain selection for <= 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues
- Reference clock to PLL0
- Reference clock to CMU0 (IRCOSC trimming)
- Option to drive the CAN protocol clocks directly from the XOSC

The XOSC provides support for 4 MHz - 40 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor

25.5.2.1 XOSC Start-up

Enabling of the oscillator at startup is determined by a bit of Miscellaneous DCF in UTEST Flash memory (refer to *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*). The default value has the XOSC disabled:

UTEST Miscellaneous[24] = 0 (XOSC_EN).

If enabled, the oscillator is started in PHASE 3 of the reset sequence: after negation of the internal POR circuits but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors:

UTEST Miscellaneous[25] = 1 (XOSC_EXT_LOAD).

Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. Refer to the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During PHASE 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module. Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values:

UTEST Miscellaneous[26:30] = 00000b (XOSC_LOAD_CAP_SEL).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value causing an undetectable error in the system.

The XOSC has the ability to be started with 4 MHz - 40 MHz crystal. The default value of this field is for an 35 MHz - 40 MHz:

UTEST Miscellaneous[19:21] = 111b (XOSC_FREQ_SEL).

Refer to the FLASH memory chapter for more information on the UTEST row programming.

25.5.2.2 XOSC register write protection

The XOSC registers defined in *Table 309* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the XOSC register write protection.

Table 309. XOSC register write protection

Offset	Register	Protections
0x00	XOSC Control Register (XOSC_CTL)	Yes
Note: refer to “Register Protection Configuration” chapter for bit field details		

25.5.2.3 XOSC reset value

Table 310 shows the default reset value for the XOSC registers.

Table 310. XOSC register reset values

Offset	Register	Reset value
0x00	XOSC Control Register (XOSC_CTL)	0x8030_8000

25.5.3 16 MHz internal RC oscillator (IRCOSC)

The 16 MHz internal RC oscillator default clock is always enabled on reset and can be the clock source for the PLLs. The register interface is for user trimming of the oscillator and dividing output from 1 to 32.

25.5.3.1 IRCOSC register interface

A dedicated digital interface for the IRCOSC has a user register for fine tuning the IRCOSC frequency. Other read-only registers contain settings and values for the IRCOSC temperature sensor, voltage regulator and capacitor trimming.

25.5.3.2 IRCOSC reset value

Table 311 shows the default reset value for the IRCOSC registers.

Table 311. IRCOSC register reset values

Offset	Register	Reset value
0x04	Native Trimming Register (NT)	0x0000_0000
0x08	Temperature Trimming Register (TT)	0x0000_0000

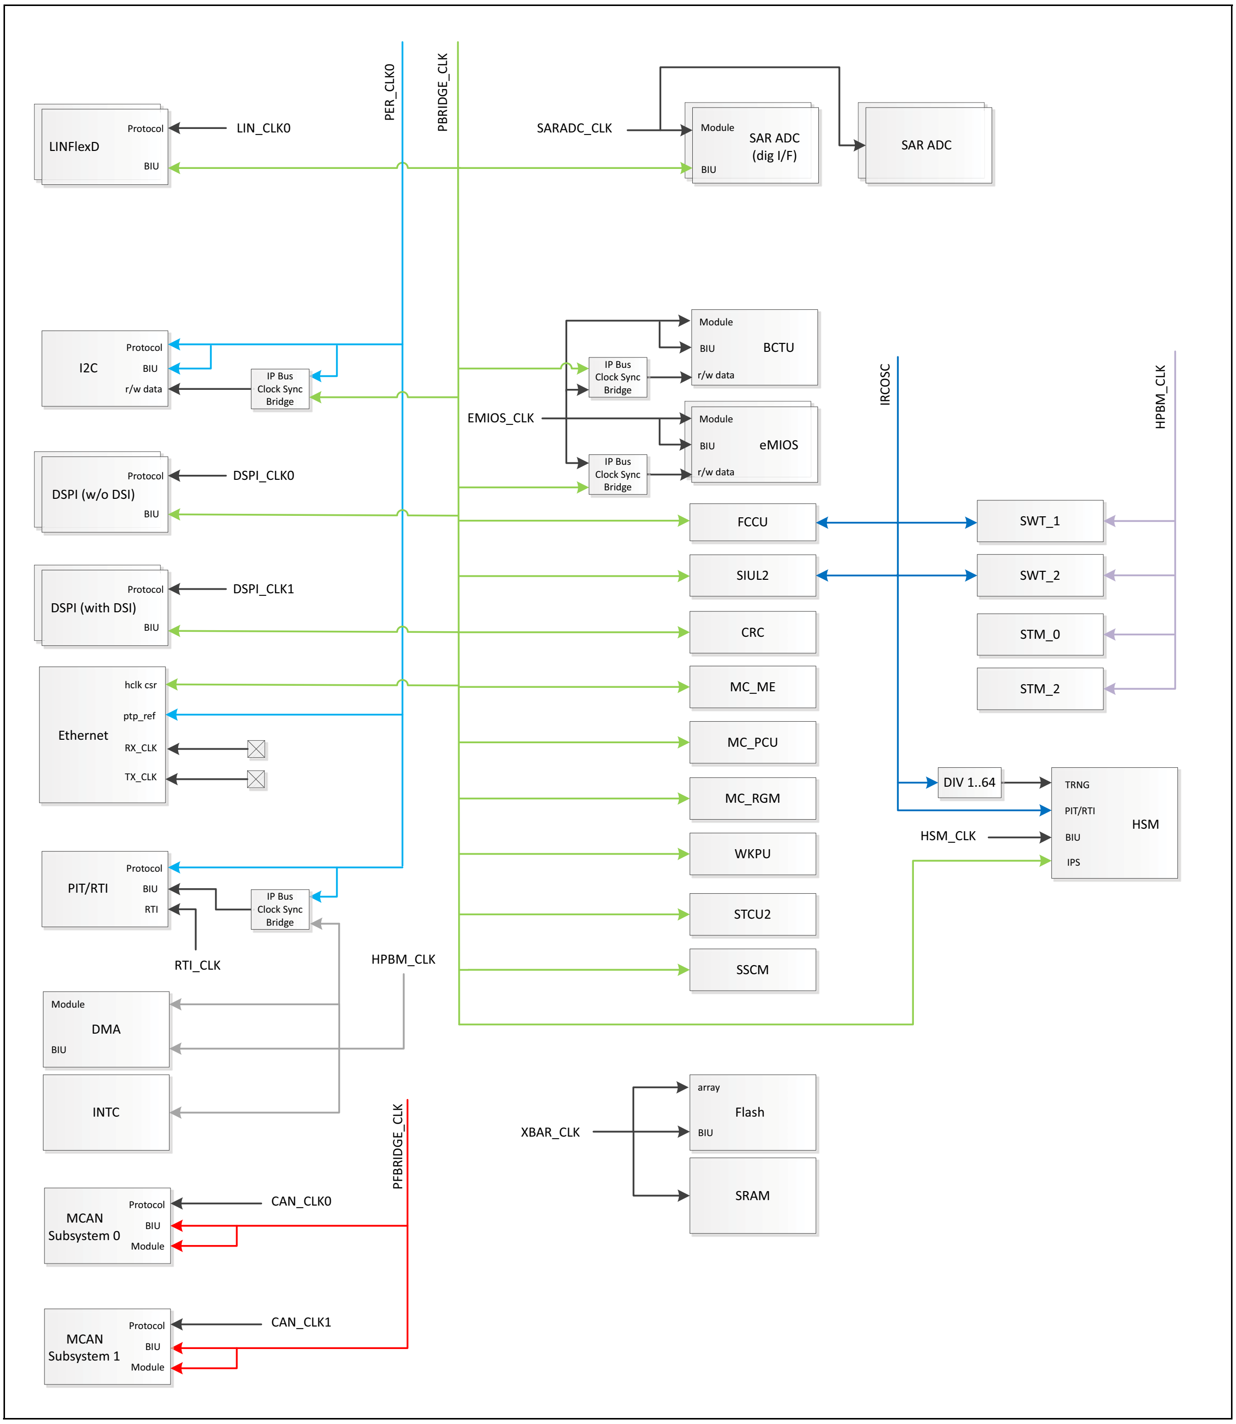
25.5.3.3 IRCOSC register write protection

For IRCOSC register protection, refer to the register protection (REG_PROT) configuration in *Chapter 7: Device configuration*.

25.6 Peripheral clocks

Figure 223 shows the clock distribution to the cores and peripheral modules.

Figure 223. Clock distribution



25.6.1 HSM clock divider

The clock dividers for the HSM core and random number generator (TRNG) are located outside the HSM, but not in the MC_CGM. These dividers are controlled by the HSM. The minimum possible divider after reset is ‘divide by 2’.

The HSM contains an internal PIT/RTI block, which is clocked by the IRCOSC.

The HSM has an internal clock monitor on its input clock, so there is no need for a Clock Monitoring Unit (CMU) for the HSM_CLK in *Figure 220*.

25.6.2 LFAST clocking

The LFAST module is used to support the high speed debug in conjunction with the JTAGM module.

A single LFAST PLL that requires a 10–20 MHz reference supports high speed operation for the LFAST module. For low speed LFAST operation, the reference clock is used directly by the LFAST modules.

The LFAST PLL reference clock source may be selected from multiple sources (AUX Clock selector 1):

- PLL0: PHI output
- external oscillator (XOSC)
- input from the external LFAST device via the DRCLK_IO package pin

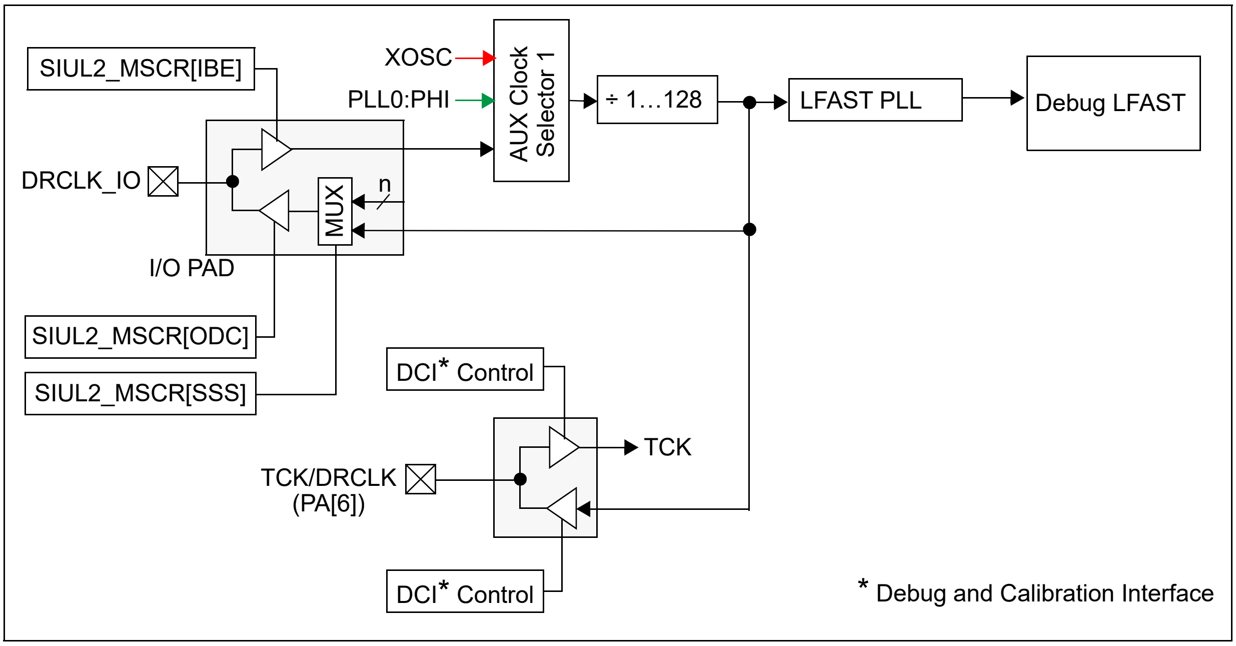
Note that when this reference clock is generated internally, it can be routed as an output onto the DRCLK_IO pin.

In addition, the clock used for the LFAST can also be routed as an output to the JTAG TCK package pin.

The debug LFAST module only supports the operation mode where it outputs the reference clock to a connected LFAST capable tool, as the DRCLK pin only supports output of the DRCLK reference.

Figure 224 shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

Figure 224. Device LFAST clocking

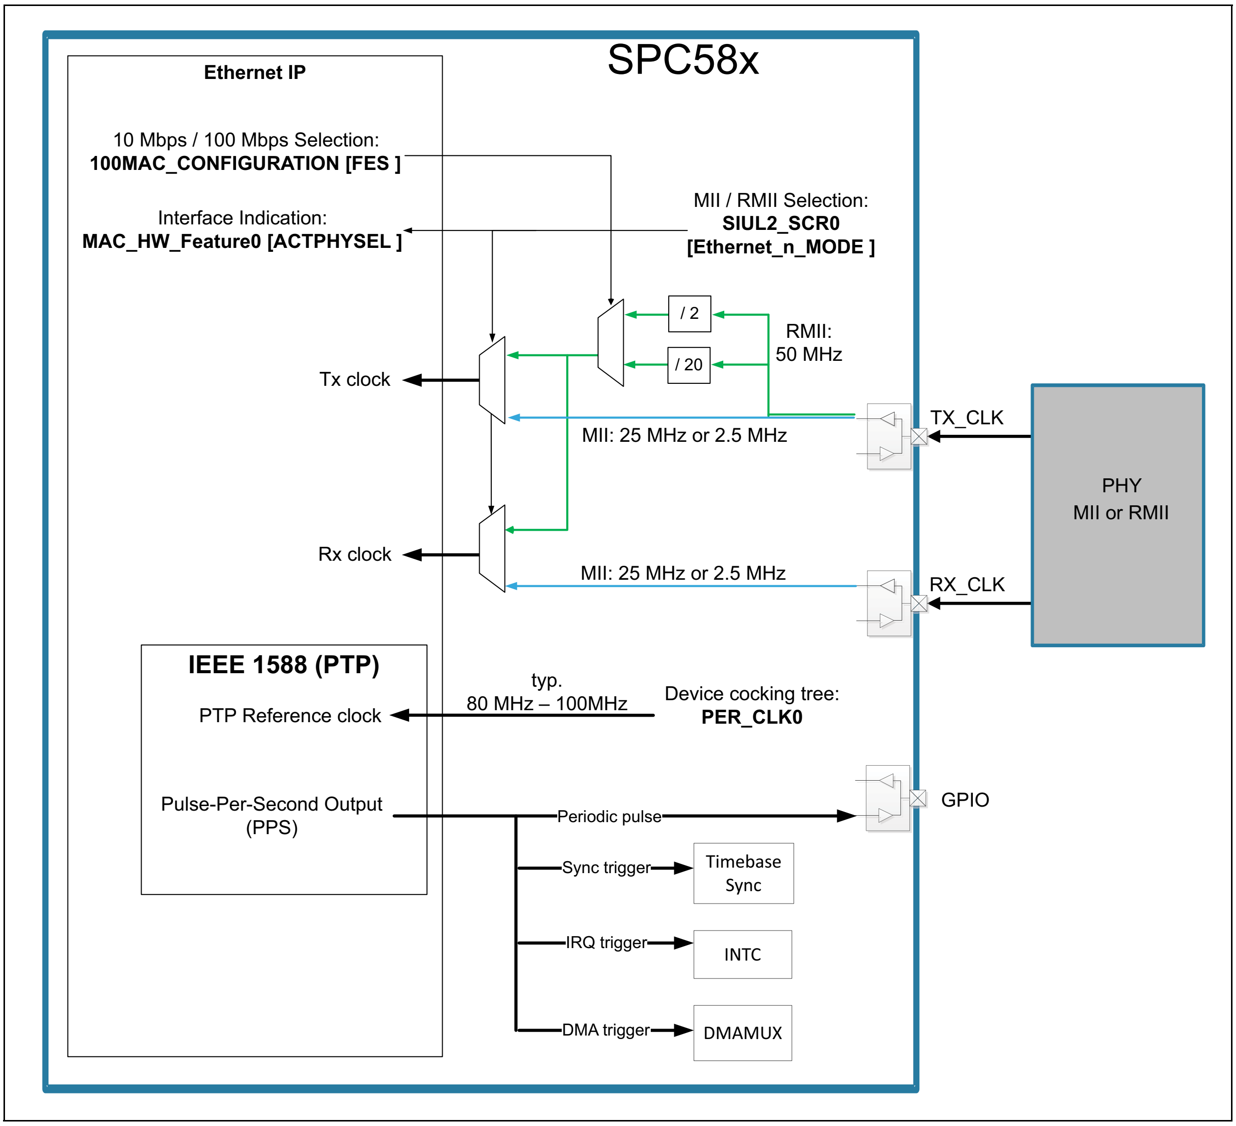


25.6.3 Ethernet clocking

The Ethernet module requires external protocol clock sources for MII and RMII interface modes. The MII clock is 25 MHz in 100 Mbps mode and 2.5 MHz in 10 Mbps mode. The RMII clock is 50 MHz in both modes.

The connections for the Ethernet clocks are as described below.

Figure 225. Ethernet clocking



The RX_CLK pin is an input used in MII mode only and ignored in RMII mode. The TX_CLK pin is an input used in MII mode and RMII mode.

25.6.3.1 Reference Clock for PTP Timestamp Logic

The Ethernet Module supports the Precision Time Protocol (PTP) as defined in IEEE 1588. The PTP Reference clock is the clock at which the PTP system time gets updated. It is connected to PER_CLK0 clock tree provided by the system clock generation module.

Based on the PTP a configurable Pulse-Per-Second signal can be generated as trigger source for several other modules on the device or as periodic pulse as alternate output on a GPIO (refer to *Figure 220*).

25.6.4 M_CAN clocking

25.6.4.1 M_CAN subsystem 0

The CAN_CLK0 is configured in the CGM via the following registers:

- CGM_AC8_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC8_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

The CAN_0 clock passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

25.6.4.2 M_CAN subsystem 1

The CAN_CLK1 is configured in the CGM via the following registers:

- CGM_AC11_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC11_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

The CAN_1 clock passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

25.6.5 System Clock

The system clock SYSCLK0 has an independent source clock selected from:

- PLL0_PHI and PLL1_PHI.
- Internal oscillator (IRCOSC)
- External oscillator (XOSC)
- RTC clock

The register CGM_AC6_SC configures the clocks for SYSCLK0. Refer to *Figure 220*.

25.7 Clock monitoring

For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency.

Each CMU is programmed independently (refer to *Figure 220* for CMU distribution) and uses the IRCOSC or XOSC as the clock monitor reference.

Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

25.7.1 CMU configuration

This section explains the CMU configuration.

Figure 226 shows the block diagram for CMU0 on the SPC584Bx.

Figure 226. CMU0 block diagram

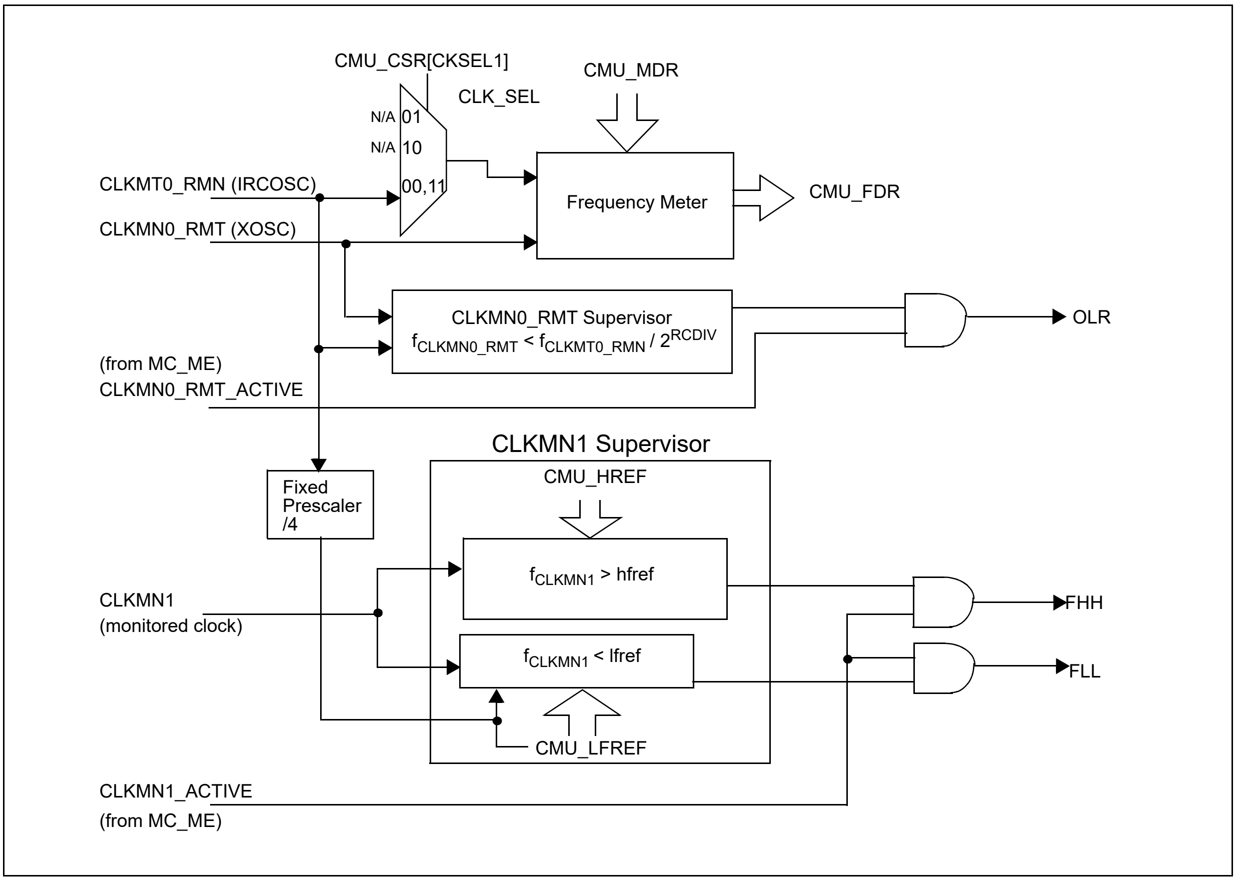


Figure 227 shows the block diagram for the other CMUs on the SPC584Bx.

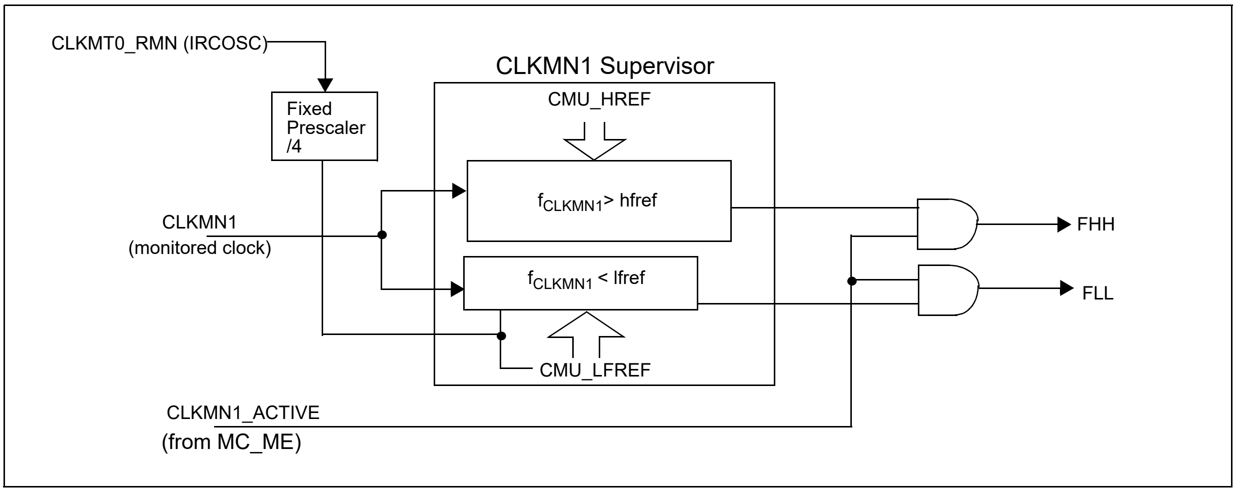
Figure 227. Other CMUs block diagram



25.7.1.1 Clock input sources

Table 312 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 312. Clock input sources

Clock module	Monitored clock	CMU group
CMU_0_PLL0_XOSC_IRCOSC	PLL0:PHI, XOSC, IRCOSC	—
CMU_1_CORE_XBAR	XBAR_CLK	CMU_Platform
CMU_2_HPBM	HPBM_CLK	CMU_Platform
CMU_3_PBRIDGE	PBRIDGE_CLK	CMU_Platform
CMU_6_SARADC	SARADC_CLK	CMU_other
CMU_11_FBRIDGE	FBRIDGE_CLK	CMU_Platform
CMU_12_EMIOS	EMIOS_CLK, BCTU_CLK	CMU_other
CMU_14_PFBRIDGE	PFBRIDGE_CLK	CMU_Platform

25.7.1.2 CMU registers and field availability

Table 313 specifies which registers and fields are available for a given CMU.

Table 313. CMU register availability

Address offset	Register	CMU	Note
0x0000	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CKSEL1] in CMU0 only.
0x0004	CMU_FDR	CMU0	—
0x0008	CMU_HFREFR	All	—
0x000C	CMU_LFREFR	All	—
0x0010	CMU_ISR	All	CMU_ISR[OLRI] in CMU0 only.
0x0014	Reserved	—	—
0x0018	CMU_MDR	CMU0	—

25.7.1.3 CMU register write protection

The CMU registers defined in *Table 314* have write protection with:

- Soft locking: can be unlocked by software after being previously locked.
- Hard locking: can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the CMU register write protection (refer to *Section 7.10.4: Register protection (REG_PROT) configuration* in *Chapter 7: Device configuration* for details).

Table 314. CMU register write protection

Offset	Register[1]
0x0000	CMU Control Status Register (CMU_CSR)
0x0004	CMU Frequency Display Register (CMU_FDR)
0x0008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)
0x000C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)
0x0010	CMU Interrupt Status Register (CMU_ISR)
0x0014	Reserved
0x0018	CMU Measurement Duration Register (CMU_MDR)

1. Refer to Register Protection chapter for bit field details.

25.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

25.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

25.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

25.7.5 System clock monitors

A CMU is assigned to monitor the frequency of the peripheral bridges, peripheral and ADC clocks (refer to *Figure 220*).

25.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. *Figure 228* gives a high-level view of the loss of clock logic.

25.8.1 Loss of PLL/XOSC clock

As shown in *Figure 228*, each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU.

When a clock failure occurs, the FCCU can be programmed to generate:

- A short reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC.
- A long reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC.

There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

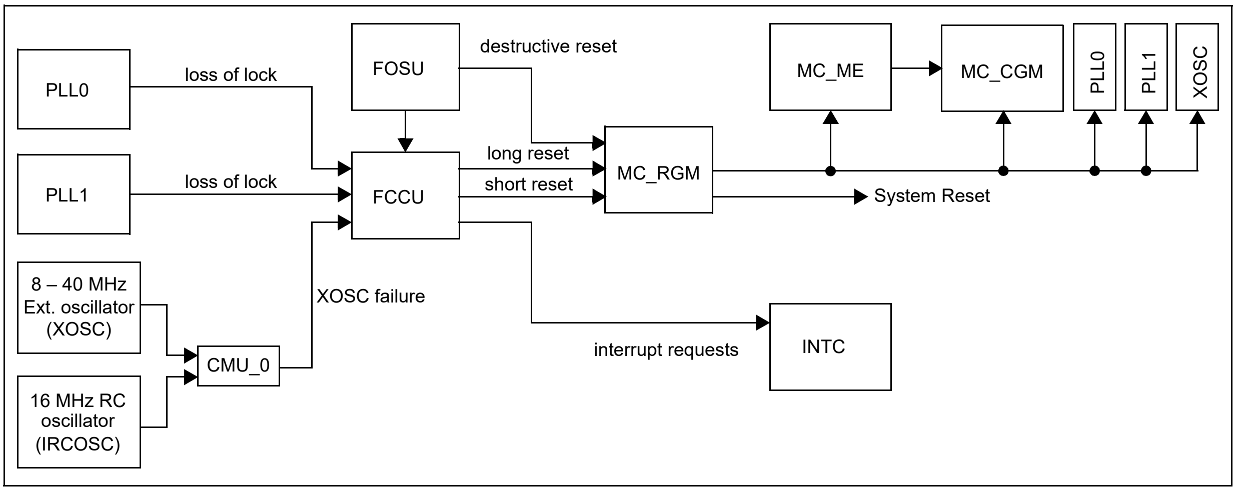
Note: In case of failures related to clocks, device functionality is no more granted till next reset. User should program properly all the safety mechanisms available in oder to reach a device safe-state.

25.8.2 Loss of IRCOSC clock

There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot clock, a failure is a catastrophic failure.

Figure 228. Loss of clock logic



25.9 Progressive clock switching

The Progressive Clock Switching (PCS) blocks are shown in the system-level clock diagram in *Figure 220*. They are used for ramping the system. Refer to *Section 28.4.1.2: Progressive system clock switching* from *Chapter 28: Clock Generation Module (MC_CGM)* for more information on the PCS.

26 Dual PLL digital interface (PLLDIG)

26.1 Introduction

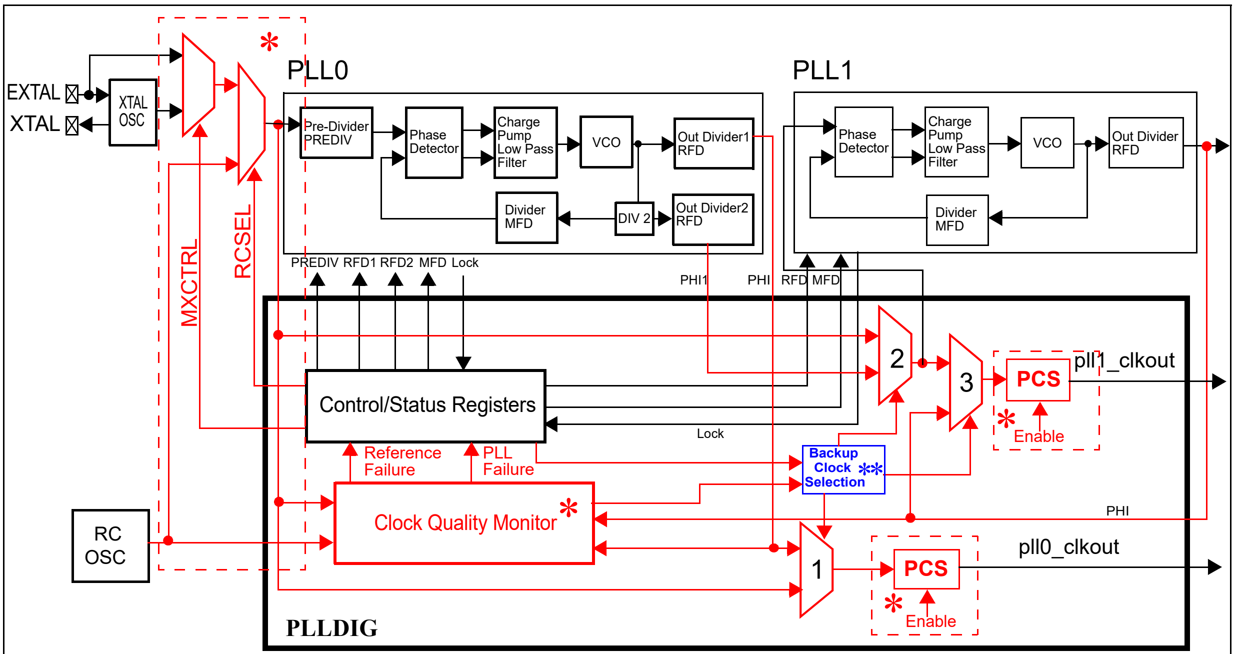
The MCU provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 blocks (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1 as shown in *Chapter 25: Clocking*. The key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1 PHI frequency modulated output.

Note: For chip-specific implementation details, refer to Chapter 25: Clocking.

26.2 Block diagram

Figure 229 shows the block diagram of the PLL Digital Interface.

Figure 229. Dual PLL digital interface block diagram



* Features in red are not included in all configurations (refer to the Clocking chapter).
** “Backup Clock Selection” block in blue is not implemented.

26.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for reducing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- The frequency range after the prescaler is required to be 8-20Mhz.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
  - User-selectable ability to generate an interrupt request upon loss of lock.
  - The loss of lock indication is sent to the FCCU via the system glue logic.

Note: Please refer to the device datasheet for information on the input and output clock frequency range.

26.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The mode of operation for the PLL is defined below:

Normal mode with reference, and either PLL0 or both PLLs enabled.

Note: Mode changes are controlled by configuring the Mode Entry mode configuration registers (<ME_mode>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

When PLL0 is powered down and working in bypass mode, PLL1 should be bypassed and powered down. PLL1 should be configured to work in normal mode only after PLL0 has achieved lock (for example, bypass with PLL0 running or PLL0 in normal mode, PLL*n*SR[LOCK] = 1).

26.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In the normal mode, PLL0 receives an input clock from the reference and the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0_PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, output divider (Reduced Frequency Divider) and whether the PLL1 is modulated or not can be programmed by writing to the PLL1FM register, *Section 26.5.2.7: PLL1 frequency modulation register (PLL1FM)*.

Note: While powering down the PLLs, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Note: Only when the PLL0 achieves lock should PLL1 be configured to work in either mode by programming the appropriate <ME_mode>_MC register (see Section 26.7: Initialization information).

26.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs.

26.5.1 Memory map

Table 315 shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

Table 315. Dual PLL digital interface memory map

Offset (hex)	Register	Section
0x0000	PLL0 Control Register (PLL0CR)	*Section 26.5.2.1*
0x0004	PLL0 Status Register (PLL0SR)	*Section 26.5.2.2*
0x0008	PLL0 Divider Register (PLL0DV)	*Section 26.5.2.3*
0x000C–0x001F	Reserved	
0x0020	PLL1 Control Register (PLL1CR)	*Section 26.5.2.4*
0x0024	PLL1 Status Register (PLL1SR)	*Section 26.5.2.5*
0x0028	PLL1 Divider Register (PLL1DV)	*Section 26.5.2.6*
0x002C	PLL1 Frequency Modulation Register (PLL1FM)	*Section 26.5.2.7*
0x0030	PLL1 Fractional Divide Register (PLL1FD)	*Section 26.5.2.8*
0x0034–0x003F	Reserved	

26.5.2 Register descriptions

Some of the register reset values are specifically configured for each unique device by external configuration signals or parameters.

26.5.2.1 PLL0 control register (PLL0CR)

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be written at any time, but writes are ignored. Reads returns previously written value.
2. Refer to the Clocking chapter for details on loss of lock management.
3. CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate <ME_mode>_MC register.

Figure 230. PLL0 control register (PLL0CR)

Table 316. PLL0CR field descriptions

Field	Description
22:23 CLKCFG	Clock configuration This field indicates the operational state of PLL. 00 PLL off. 01 Reserved 10 Reserved. 11 Normal mode with PLL running When PLLs are externally powered down the CLKCFG field changes to 00b. When external power down is removed, these bits will read 11b. **Note:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1.
24 EXPDIE	External power down cycle complete indication interrupt enable This bit enables generation of an interrupt when the external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion and enable the FCCU failure "Loss of lock flag PLL0"
28 LOLIE	Loss of lock interrupt enable The LOLIE bit enables a loss of lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode. 0 Ignore loss of lock. Interrupt not requested 1 Enable interrupt request upon loss of lock

26.5.2.2 PLL0 status register (PLL0SR)

Offset: 0x0004 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field is reserved, read only.

Figure 231. PLL0 status register (PLL0SR)

Table 317. PLL0SR field descriptions

Field	Description
24 EXTPDF	External power down cycle complete indication interrupt flag This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
28 LOLF	Loss of lock flag This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested 1 Loss of lock detected. Interrupt service requested
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

26.5.2.3 PLL0 divider register (PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider.
The values of PREDIV and MFD should not be changed when the PLL is on and locked (working in Normal mode). If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled.
The reduced frequency divider fields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective after PLL0 is disabled, then re-enabled.

Field	Description
24 EXTPDF	External power down cycle complete indication interrupt flag This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
28 LOLF	Loss of lock flag This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested 1 Loss of lock detected. Interrupt service requested
29 LOCK	Lock status bit Indicates whether PLL has acquired lock. 0 PLL is unlocked 1 PLL is locked

26.5.2.6 PLL1 divider register (PLL1DV)

The PLL1DV register provides the output clock reduced frequency dividers and loop divider values.
The value of MFD should not be changed when the PLL is on and locked (working in Normal mode). If the field is changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled.
The reduced frequency divider field (RFDPHI) can be modified at anytime, but the changes only become effective after PLL1 is disabled, then re-enabled.

26.5.2.7 PLL1 frequency modulation register (PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down).
Changing the values of PLL1FM[MODEN] and PLL1FM[MODSEL] fields once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.
The modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock, however, the output clock from PLL may have an incorrect frequency for a few cycles after either of these updates (as defined in the datasheet).

Table 322. PLL1FM field descriptions

Field	Description
1 MODEN	Modulation enable This bit enables the frequency modulation. 0 Frequency modulation disabled 1 Frequency modulation enabled
2 MODSEL	Modulation selection This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Modulation centered around nominal frequency 1 Modulation spread below nominal frequency
3:15 MODPRD	Modulation period This 13-bit field is the binary equivalent of the modulation period variable derived from the formula: $$MODPRD = round(\frac{f_{ref}}{4 \times f_{mod}})$$ where f_{ref} represents the frequency of the feedback divider and f_{mod} represents the modulation frequency (refer to equation in *Section 26.6.3*).
17:31 INCSTP	Increment step This 15-bit field is the binary equivalent of the INCSTP variable derived from the formula: $$INCSTEP = round(\frac{(2^{15} - 1) \times MD \times PLL1CR[MFD]}{100 \times 5 \times MODPRD})$$ where *md* represents the peak modulation depth in percentage (+/- *MD* for centered modulation, -2**MD* for modulation below nominal frequency), and MFD represents the nominal value of the feedback loop divider (refer to equation in *Section 26.6.3*).

26.5.2.8 PLL1 fractional divider register (PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.
The dither disable and fractional divider fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates .

Figure 237. PLL1 fractional divider register (PLL1FD)

Table 323. PLL1FD field descriptions

Field	Description
1 FDEN	Fractional divide enable This bit enables the fractional divider in the loop divider for PLL1. 0 Fractional divide disabled 1 Fractional divide enabled
14:15 DTHDIS	Dither disable Bit 14 and bit 15 control noise of SSCG and Fractional controller. 00 Increase PLL multiplication factor by 1/2^13 and has maximum noise control of SSCG and Fractional controller. 01 Increase PLL multiplication factor by 1/2^13 and has some noise control of SSCG and Fractional controller. 10 No influence on PLL multiplication factor and has some noise control of SSCG and Fractional controller. 11 No influence on PLL multiplication factor and no noise control of SSCG and Fractional controller.
20:31 FRCDIV	Fractional divide input When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV[MFD]} + (\text{FRCDIV} \div 2^{12}))$ where FRCDIV is the decimal equivalent of the FRCDIV bits (refer to *Section 26.6.2*). **Note:** Depending on DTHDIS value the multiplication factor can change as described in DTHDIS field description.

26.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

26.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for each PLL are discussed in detail in the *SPC584Bx datasheet*.

26.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV and PLL1FD registers, and calculated according to the following equations:

Equation 4

$$f_{pll0\_phi} = f_{pll0\_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]}$$

Equation 5

$$f_{pll0\_phi1} = f_{pll0\_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]}$$

Equation 6

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Note: Depending on DTHDIS value the multiplication factor of *Equation 6* can change as described in PLL1DV[DTHDIS] field description (refer to *Table 323*).

The relationship between the VCO frequency f_{VCO} and the output frequency of the PLLs is determined by the configuration of the PLL0DV, PLL1DV and PLL1FD registers, according to the following equations:

Equation 7

$$f_{pll0\_VCO} = \frac{f_{pll0\_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

Equation 8

$$f_{pll1\_VCO} = f_{pll1\_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} \right)$$

Note: *Depending on DTHDIS value the multiplication factor of Equation 8 can change as described in PLL1DV[DTHDIS] field description (refer to Table 323).*

Note: *f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1.*

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification for PLL0 or PLL1 (refer to the device datasheet). Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of PLL*n*DV are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

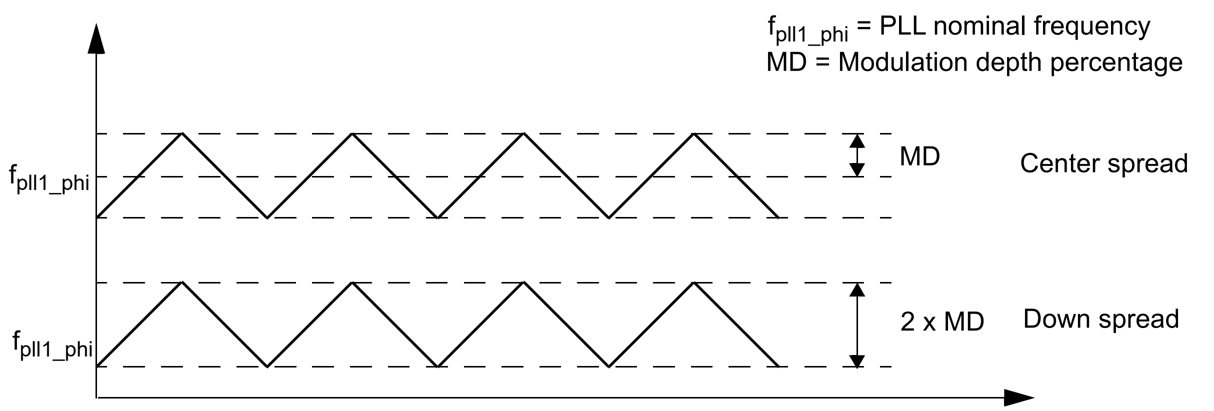
Note: The PLL must be powered down and powered up by configuring <ME_mode>_MC before PLL0CR[PREDIV], PLL0CR[MFD], PLL1CR[MFD] or the input reference clock values are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in *Section 26.7*.

26.6.3 Frequency modulation

Frequency modulation uses a triangular profile as shown in *Figure 238*. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 238. Triangular frequency modulation



Note: The device maximum operating frequency includes the frequency modulation. If center modulation is selected, the fsys must be below fmax by MD percentage such that fmax = fsys(1 + MD%). Refer to the Analog PLL chapter for more details.

The following equations define how to calculate PLL1FM[MODPRD] (*Equation 9*) and PLL1FM[INCSTP] (*Equation 10*) based on the frequency of the feedback divider (f_{pll1_ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD):

Equation 9

$$PLL1FM[MODPRD] = round\left(\frac{f_{pll1\_ref}}{4 \times f_{mod}}\right)$$

Equation 10

$$PLL1FM[INCSTP] = round\left(\frac{(2^{15} - 1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

Equation 11

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is given by the following formula:

Equation 12

$$ModulationDepth = round\left(\frac{PLL1FM[MODPRD] \times PLL1FM[INCSTP] \times 100 \times 5}{(2^{15} - 1) \times PLL1DV[MFD]}\right)$$

As an example, suppose the following configuration:

- Input frequency: 40 MHz
- Loop divider (PLL1DV[MFD]): 20
- Input divider: 1
- Output divider RFD: 5
- VCO frequency: 40 MHz × 20 = 800 MHz
- PLL output frequency: 800 MHz / 2*RFD = 800 MHz / 10 = 80 MHz
- Center spread (PLL1FM[MODSEL] = 0)
- Modulation frequency: 200 kHz
- Modulation depth: ± 1.9% (3.8% peak-to-peak)
- PLL1FM[MODPRD] = Round[(40 × 10^6) / (4 × 200 × 10^3)] = Round[50] = 50
- PLL1FM[INCSTP] = Round[((2^{15} – 1) × 1.9× 20) / (100 × 5 × 50)] = Round[49.8] = 50
- PLL1FM[MODPRD] × PLL1FM[INCSTP] = 50 × 50 = 2500 (which is less than 2^{15})
- MD (quantized) = ((50 × 50 × 100 × 5) / ((2^{15} – 1) × 20) = 1.90740%

In this example, the modulation error is 0.00740%.

The FM parameters do not get reset when PLL0 looses its lock. These parameters get reset on destructive reset. Whenever PLL0 gets relocked FM modulation starts with the previous values. The sequence for reprogramming the FM is:

1. Power down PLL1[h]
2. Program the PLL1FM while PLL1 is powered down
3. Power up the PLL1[i]

h. By writing <ME_mode>_MC[PLL1ON] = 0b.

i. By writing <ME_mode>_MC[PLL1ON] = 1b.

26.7 Initialization information

Coming out of reset the PLLs are disabled per the DRUN mode configuration register (<*ME*>_DRUN_MC). The recommended procedure[j] to program the PLLs and enter normal mode is:

1. Configure PLL0 and related modules.

   Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   a) With PLL0 disabled, program PLL0 clock source in <CGM_ACn>_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write <CGM_ACn>_SC[SELCTL] = 1 to select XOSC as source.

   b) Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

   c) If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the Mode Entry module).

   d) If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

2. Turn on XOSC and PLL0.

   a) Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, <ME>_DRUN_MC) set <ME_mode>_MC[XOSCON] = 1 and <ME_mode>_MC[PLL0ON] = 1. If desired, also set <ME_mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0 PHI output) as the sysclk.

   b) Enter that mode by two writes to <ME>_CTRL register to enter that mode. This is required even if re-entering the same mode.

3. Wait for the mode transition to complete.

   a) Wait for the mode transition to complete by polling <ME>_GS[S_MTRANS] or enabling an interrupt for flag <ME>_IS[I_MTC]. A timer, even if it is the watchdog,

j. The steps from 1 to 6 describe a recommended way to initialize the PLLs. But the mode_transition from DRUN to RUNx with the PLLs ON (with PLL1 as sys_clk and PLL0_PHI1 as source of PLL1 and all other clk sources enabled) can be done with a single mode transition. The only software requirement is to ensure that the reference clocks are also configured ON when the derived clock is configured ON in the target mode.

should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- XOSC counter expires (if the new mode configuration changes <ME_mode>_MC[XOSCON] to 1), and

- PLL is locked (if the new mode configuration changes <ME_mode>_MC[PLL0ON] = 1).

   b) Confirm the desired target mode was entered by checking the status of <ME>_GS[S_CURRENT_MODE].

4. Configure PLL1 and related modules
   a) With PLL1 disabled, program PLL1 clock source in <CGM_ACn>_SC[SELCTL]. Default is <CGM_ACn>_SC[SELCTL] = which selects XOSC.
   b) Program PLL1DV[MFD] and PLL1DV[RFDPHI].
   c) If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.
5. Turn on PLL1
   a) Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL0 on. In a mode configuration register (for example, <ME>_DRUN_MC), initialize <ME_mode>_MC[XOSCON] = 1, <ME_mode>_MC[PLL0ON] = 1 and <ME_mode>_MC[PLL1ON] = 1. If desired, also set <ME_mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.
   b) Enter that mode by two writes to <ME>_CTRL register to enter that mode. This is required even if re-entering the same mode.
6. Wait for the mode transition to complete.
   a) Wait for the mode transition to complete by polling <ME>_GS[S_TRANS] or enabling an interrupt for flag <ME>_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

      XOSC counter expires (if the new mode configuration changes <ME_mode>_MC[XOSCON] = 1), and PLL1 is locked (if the new mode configuration changes <ME_mode>_MC[PLL1ON] = 1).
   b) Confirm the desired target mode was entered by checking the status of <ME>_GS[S_CURRENT_MODE].

Note: Refer to the Mode Entry module chapter for more details.

27 Clock Monitor Unit (CMU)

27.1 Introduction

The Clock Monitor Unit (CMU), also referred to as clock quality checker or clock fault detector, serves three purposes:

- Measures the frequency of clock sources CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and also detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the division factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate events when the CLKMN1 frequency is less than the CLKMT0_RMN frequency divided by four or if CLKMN1 leaves an upper or lower frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of one clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note: Refer to the clocking chapter for the number of instances of the CMU in this device.

27.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as the reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN/n clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN / 4.
- Event generation for various failures detected inside monitoring unit.

27.2 Block diagram

The block diagram of the CMU module(s) is shown in the clocking chapter of this reference manual.

27.3 Signals

Table 324 describes the signals on the boundary of the CMU (in alphabetical order).

Table 324. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference: Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1: Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference: Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

Note: Refer to the clocking chapter for device specific clock sources of each CMU.

27.4 Memory map and register definition

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in Table 325.

Table 325. CMU memory map

Address offset	Register	Location
0x0000	CMU Control Status Register (CMU_CSR)	Section 27.4.1.1
0x0004	CMU Frequency Display Register (CMU_FDR)	Section 27.4.1.2
0x0008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	Section 27.4.1.3
0x000C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	Section 27.4.1.4
0x0010	CMU Interrupt Status Register (CMU_ISR)	Section 27.4.1.5
0x0014–0x0017	Reserved	
0x0018	CMU Measurement Duration Register (CMU_MDR)	Section 27.4.1.6

Note: See Clocking chapter for register and field availability details.

27.4.1 Register descriptions

27.4.1.1 CMU Control Status Register (CMU_CSR)

Offset: 0x0000 Access: User read/write

Figure 239. CMU Control Status Register (CMU_CSR)

1. Not all CMU blocks will utilize this feature. Refer to clocking chapter for device specific CMU implementation details

Table 326. CMU_CSR field descriptions

Field	Description
8 SFM	Start Frequency Measure The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR register. CMU_MDR[MD] must be written before enabling frequency measurement (CMU_CSR[SFM] = 1). Do not write CMU_MDR[MD] while CMU_CSR[SFM] = 1. Software should only read the value of CMU_FDR[FD] bits once the hardware has cleared the CMU_CSR[SFM] bit. 0 Frequency measurement is completed or not yet started. 1 Frequency measurement is not completed.
22:23 CKSEL1	Frequency measure clock selection bit CKSEL1 selects the clock to be measured by the frequency meter. This only effects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected. 01 Reserved 10 Reserved. 11 CLKMT0_RMN is selected.

Table 326. CMU_CSR field descriptions (continued)

Field	Description
29:30 RCDIV	CLKMT0_RMN division factor These bits specify the CLKMT0_RMN division factor. The output clock frequency is f_{CLKMT0_RMN} divided by the factor 2^{RCDIV}. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV] otherwise the operation can lead to a spurious OLR event. The clock division coding is as follows: 00 CLKMT0_RMN divided by 1 (No division). 01 CLKMT0_RMN divided by 2. 10 CLKMT0_RMN divided by 4. 11 CLKMT0_RMN divided by 8.
31 CME	CLKMN1 monitor enable CMU_HFREF and CMU_LFREF registers must be written before enabling the clock monitoring (CMU_CSR[CME] =1) 0 CLKMN1 monitor is disabled. 1 CLKMN1 monitor is enabled.

27.4.1.2 CMU Frequency Display Register (CMU_FDR)

The FDR is used to determine the measured frequency being monitored by the CMU.

Offset: 0x0004 Access: User read-only

Figure 240. CMU Frequency Display Register (CMU_FDR)

Table 327. CMU_FDR field descriptions

Field	Description
12:31 FD	Measured frequency bits This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: f_{sel} = (f_{CLKMN0_RMT} × CMU_MDR[MD]) / CMU_FDR[FD]

27.4.1.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. *Figure 241* and *Table 328* show the CMU_HFREFR register.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 243. CMU Interrupt Status Register (CMU_ISR)

1. Not all CMU blocks will utilize this feature. See Clocking chapter for device specific CMU implementation details.
2. Field is read only.

Table 330. CMU_ISR field descriptions

Field	Description
29 FHHI	CLKMN1 frequency higher than high reference event status This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is ‘ON’ as signaled by the MC_ME. It can be cleared by software by writing ‘1’. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value and CLKMN1 is ‘ON’ as signaled by the MC_ME. It can be cleared by software by writing ‘1’. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than f_{CLKMT0_RMN} / 2^{RCDIV} event status This bit is set by hardware when the f_{CLKMN0_RMT} is less than f_{CLKMT0_RMN} / 2^{RCDIV} frequency and CLKMN0_RMT is ‘ON’ as signaled by the MC_ME. It can be cleared by software by writing ‘1’. 0 No OLR event 1 OLR event occurred

Note: All the flags in CMU_ISR are set asynchronously. This register must be read only after a fault event is triggered by the CMU and mapped on FCCU.

Otherwise, the read access on this register may fetch an incorrect value.

Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

27.4.1.6 CMU Measurement Duration Register (CMU_MDR)

Figure 244. CMU Measurement Duration Register (CMU_MDR)

Table 331. CMU_MDR field descriptions

Field	Description
12:31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

27.5 Functional description

This section describes the functionality of the CMU.

27.5.1 Frequency meter

The purpose of frequency meter is to evaluate the deviation from the nominal metered source (such as, CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the Clocking chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

Equation 13 $\mathbf{f_{sel} = (f_{CLKMN0\_RMT} \times MDR[MD]) / FDR[FD]}$

27.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than frequency of CLKMT0_RMN divided by $2^{CMU\_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

27.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If fCLKMN1 is greater than the reference value determined by field CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

Note: An example of determining the HFREFActual value is as follows. Assume a fCLKMT0_RMN = 16 MHz with an accuracy of +/-5%. In order to monitor *fCLKMN1 = 200 MHz, the ideal HFREFIdeal = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration (HFREFActual = (HFREFIdeal + 2) × 1.05).*

IIf fCLKMN1 is lower than CMU_LFREFR[LFREF] and CLKMN1 is ‘ON’ as signaled by the MC_ME, then

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note: The low reference value must be programmed considering the following factors:

- *Two cycles of f_{CLKMN1} which is the built-in tolerance of the monitor implementation*
- *Frequency variation % of f_{CLKMT0_RMN} across PVT*

For example, assuming f_{CLKMT0_RMN} is 16 MHz with +/-5% variation, in order to monitor the f_{CLKMN1} (200 MHz), the ideal $LFREF_{Ideal}$ is 800. The adjusted value considering the tolerances will be 758 ($LFREF_{Actual}$ = ($LFREF_{Ideal}$ - 2) x 0.95).

The minimum value that can be programmed in CMU_LFREFR[LFREF] is 3. The minimum frequency that can be monitored using the CLKMN1 supervisor must be >= f_{CLKMT0_RMN} / 16.

28 Clock Generation Module (MC_CGM)

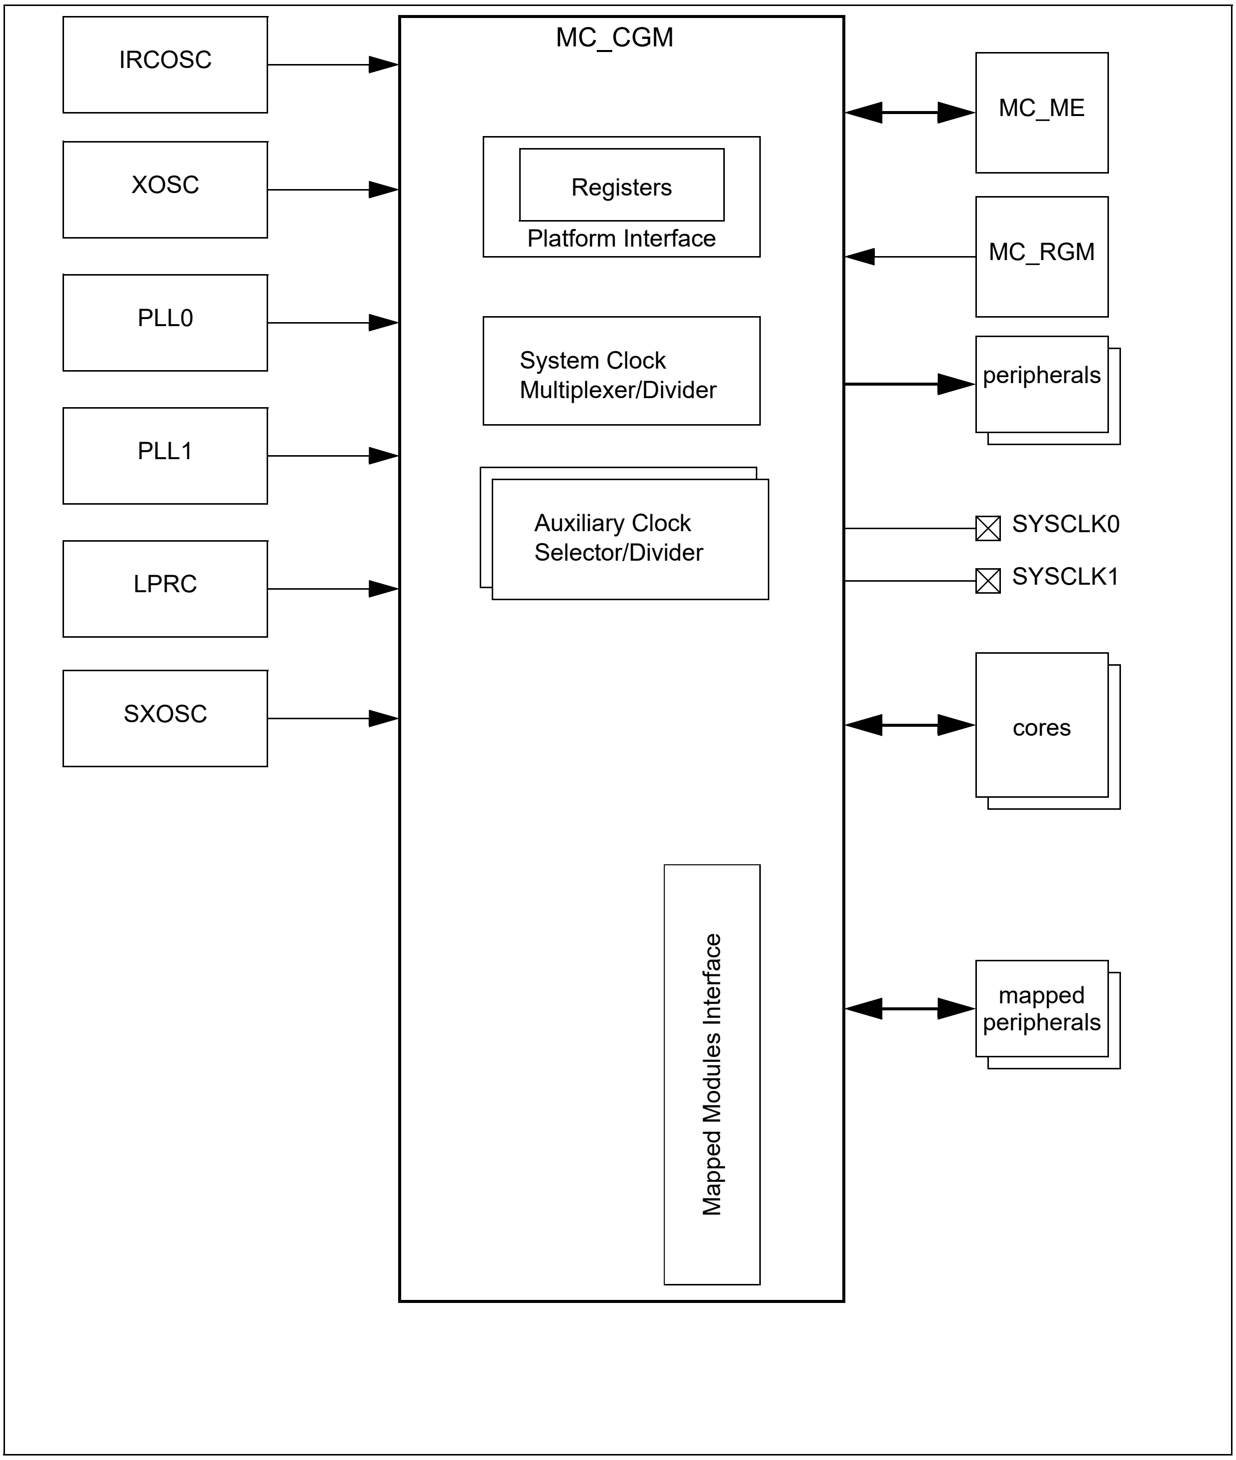
28.1 Introduction

28.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the modules on the chip. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

Figure 245 shows the MC_CGM block diagram.

Figure 245. MC_CGM block diagram



28.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control
- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

28.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use and/or observation.

28.3 Memory map and register definition

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

- *cause a transfer error*

28.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0104, as a half-word at address offset 0x0106, or as a byte at address offset 0x0107.

28.3.1.1 PCS Switch Duration Register (CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See *Section 28.4.1.2: Progressive system clock switching*, for details on how to set this value. This register is reset only on a power-on reset.

Offset: 0x0100 Access: User read/write, Supervisor read/write, Test read/write

Table 333. CGM_PCS_SDUR field descriptions

Field	Description
SDUR	Switch Duration This value defines the duration of one PCS clock switch step in terms of 16 MHz int. RC osc. cycles.

28.3.1.2 PCS Divider Change Register 1 (CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the external crystal osc. on ramp-up and ramp-down, respectively. See *Section 28.4.1.2: Progressive system clock switching*, for details on how to set these values. This register is reset only on a power-on reset.

Note: Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Offset : 0x0104 Access: User read/write, Supervisor read/write, Test read/write

Field	Description
INIT	**Divider Change Initial Value** This is initial change value of the clock divider for the clock ramp-up phase when switching to the external crystal osc..
RATE	**Divider Change Rate** This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the external crystal osc..

28.3.1.3 PCS Divider End Register 1 (CGM_PCS_DIVE1)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the external crystal osc. on ramp-down. See *Section 28.4.1.2: Progressive system clock switching*, for details on how to set this value. This register is reset only on a power-on reset.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

DIVE	Divider End Value This is the clock divider end value for the clock ramp-down phase when switching from the external crystal osc..

28.3.1.4 PCS Divider Start Register 1 (CGM_PCS_DIVS1)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the external crystal osc. on ramp-up. Register *n* corresponds to system clock source *n*. See *Section 28.4.1.2: Progressive system clock switching*, for details on how to set these values. This register is reset only on a power-on reset.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

28.3.1.5 PCS Divider Change Register 2 (CGM_PCS_DIVC2)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL0 PHI on ramp-up and ramp-down, respectively. See *Section 28.4.1.2: Progressive system clock switching*, for details on how to set these values. This register is reset only on a power-on reset.

Note: Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Offset: 0x0110 Access: User read/write, Supervisor read/write, Test read/write

INIT	**Divider Change Initial Value** This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL0 PHI.
RATE	**Divider Change Rate** This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL0 PHI.

28.3.1.6 PCS Divider End Register 2 (CGM_PCS_DIVE2)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the PLL0 PHI on ramp-down. See *Section 28.4.1.2: Progressive system clock switching* for details on how to set this value. This register is reset only on a power-on reset.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Field	Description
DIVS	Divider Start Value This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.

28.3.1.11 System Clock Divider Ratio Change Register (CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations. An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3. The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

Caution: Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

Offset: 0x01D0 Access: User read/write, Supervisor read/write, Test read

28.3.1.12 Divider Update Type Register (CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.

Offset : 0x01D4 Access: User read/write, Supervisor read/write, Test read

Field	Description
SYS_UPD_TYPE	System Clock Divider Update Type 0 The configuration for each system clock divider is updated immediately on writing to the corresponding CGM_SC_DCi register 1 The configuration for each system clock divider is pre-loaded on writing to the corresponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register

28.3.1.13 Divider Update Trigger Register (CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to '1' in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

Offset: 0x01D8 Access: User read/write, Supervisor read/write, Test read

Field	Description
DIV_UPD_TRIGGER	Writing any value to this register causes all dividers that have corresponding bits set to '1' in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register always returns all zeroes.

28.3.1.14 Divider Update Status Register (CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the CGM_DIV_UPD_TYPE[i] is '0', CGM_DIV_UPD_STAT[i] is set to '1' immediately on writing to one of the corresponding divider configuration registers. Otherwise, CGM_DIV_UPD_STAT[i] is set to '1' immediately on writing to the CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. CGM_DIV_UPD_STAT[i] is cleared to '0' as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

Figure 265. System Clock Divider 4 Configuration Register (CGM_SC_DC4)

Table 352. CGM_SC_DC4 field descriptions

Field	Description
DE	Divider 4 Enable This divider is always enabled. Therefore, this bit is read-only and always returns a value of ‘1’.
DIV	Divider 4 Division Value The resultant PFBRIDGE_CLK will have a period ‘DIV + 1’ times that of the system clock.

28.3.1.21 Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 0 divider 0: SARADC_CLK
- divided by auxiliary clock 0 divider 1: EMIOS_CLK

Offset: 0x0200 Access: User read/write, Supervisor read/write, Test read/write

28.4 Functional description

28.4.1 System clock generation

Figure 220: Clock generation shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz int. RC osc. as the system clock and to ignore the system clock select.

28.4.1.1 System clock source selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

28.4.1.2 Progressive system clock switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up based on the power level values of the current and target modes.

During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVC*n*, and CGM_PCS_DIVE*n* registers, where *n* corresponds to the current system clock source selection.

During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVC*n*, and CGM_PCS_DIVS*n* registers, where n corresponds to the target system clock source selection.

28.4.1.2.1 Generic clock change requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in *Equation 14:* .

Equation 14

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

28.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of 16 MHz int. RC osc.. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

28.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the PCS_DIVC*n*[RATE] register is given in *Table 382*.

Table 382. MC_CGM CGM_PCS_DIVC*n*[RATE] values

a_{max}	d	CGM_PCS_DIVCn[RATE]
0.05	0.012	12
0.10	0.048	48
0.15	0.112	112
0.20	0.184	184

28.4.1.2.4 Generic clock change properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in *Equation 15:* .

Equation 15

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

28.4.1.2.5 Clock ramp-down

The clock ramp-down starts with the divider value 1 and with the given divider increment value PCD_DIVCn[RATE] and ends with the given divider value PCS_DIVEn[DIVE].

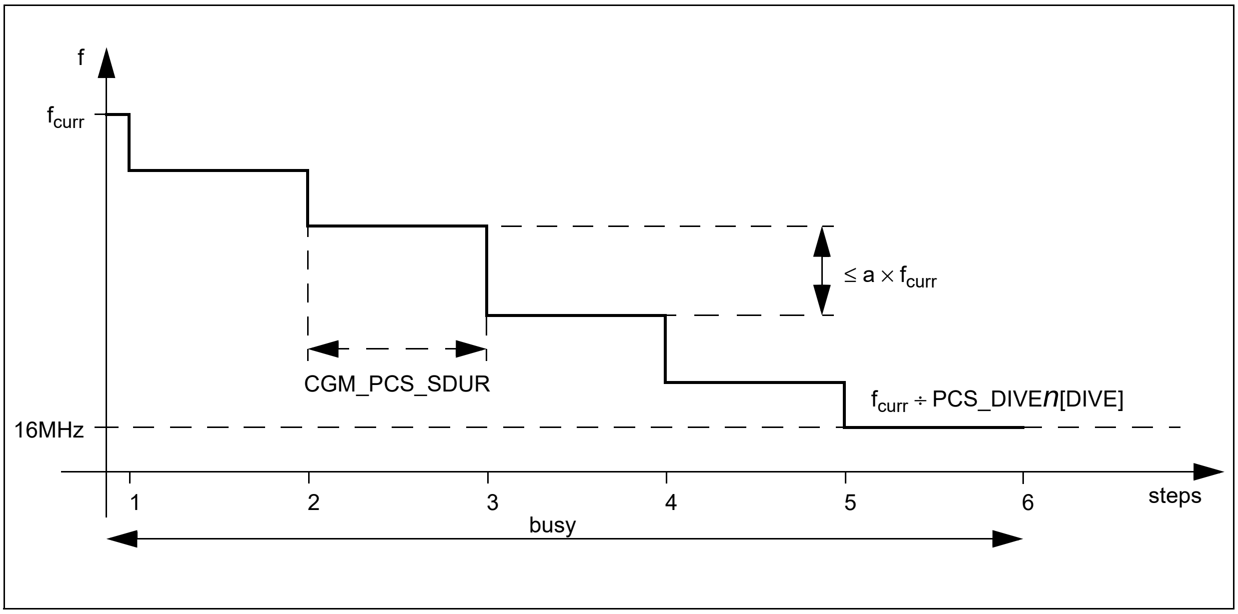
The divider end value for clock ramp-down is given in *Equation 16:* .

Equation 16

$$\mathbf{PCS\_DIVEn[DIVE]} = \frac{f_{src}}{16MHz} \times 1000 - 1$$

Where f_{curr} is the frequency of the currently selected system clock source.

Figure 295. MC_CGM System Clock Ramp-Down Timing (k = 6 example)



28.4.1.2.6 Clock ramp-up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in *Equation 17:* .

Equation 17

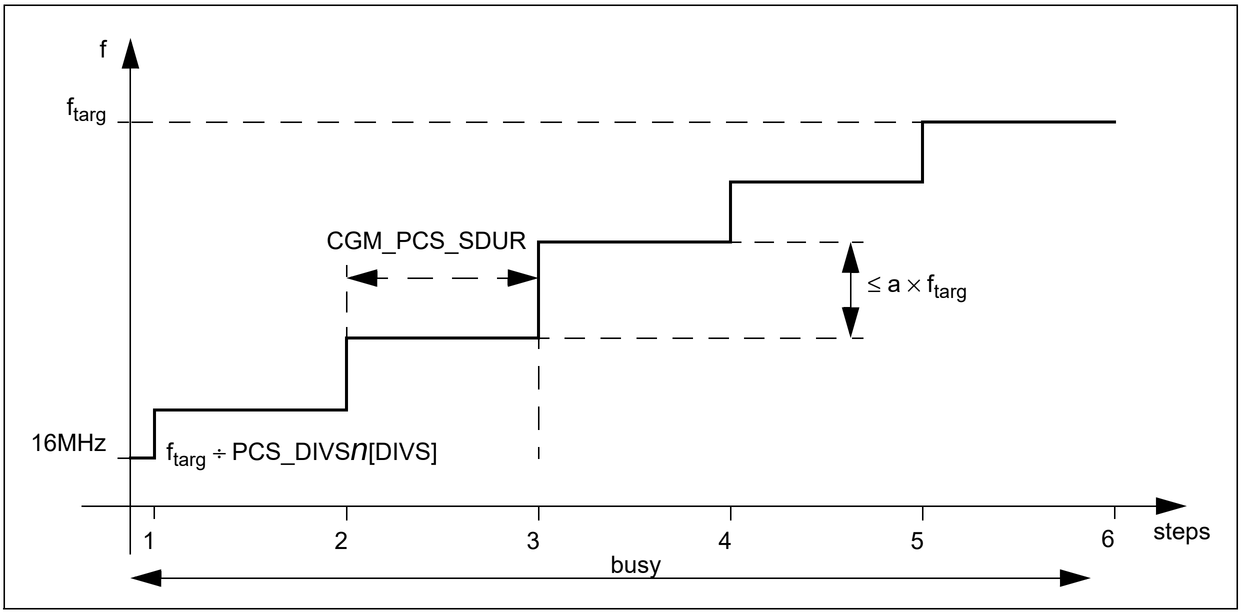
$$\mathbf{PCS\_DIVCn[INIT]} = d \times k \times 1000 - 1$$

Where k is calculated from *Equation 15:* using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in *Equation 18:* .

Equation 18

$$\textbf{PCS\_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Figure 296. MC_CGM System Clock Ramp-Up Timing (k = 6 example)



28.4.1.3 System clock disable

During the TEST mode, the system clock can be disabled by the MC_ME.

28.4.1.4 System clock dividers

The MC_CGM generates the following derived clocks from the system clock:

- CORE_CLK (Core_2), HSM_CLK, XBAR_CLK - controlled by the CGM_SC_DC0 register
- HPBM_CLK - controlled by the CGM_SC_DC1 register
- PBRIDGE_CLK - controlled by the CGM_SC_DC2 register
- FBRIDGE_CLK - controlled by the CGM_SC_DC3 register
- PFBRIDGE_CLK - controlled by the CGM_SC_DC4 register

28.4.1.4.1 System clock divider synchronization

The system clock dividers are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

The allowed combinations of division factors is given in *Table 306: SYS_CLK divisor clock ratios at power up*.

28.4.1.4.2 System clock divider update triggering

As opposed to the auxiliary clock dividers, which update immediately on a configuration change, the system clock dividers are updated only with the next software triggered mode change. This is to ensure that the system clock dividers are updated simultaneously and that no intermediate inconsistent configurations can occur. It also ensures that the divider configurations are aligned with the target mode’s system clock selection.

The system clock divider configuration update sequence is as follows:

1. Configure the target mode in the MC_ME to select the desired system clock source.
2. Configure the CGM_SC_DC0-4 registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in *Section 28.4.1.4.1: System clock divider synchronization*.
3. Request a mode change in the MC_ME to the desired target mode.
4. When mode change has completed and the system clock switching has been successful, the new system clock divider configuration will be in effect.

See *Chapter 56: Mode Entry Module (MC_ME)*, for details on how to configure modes and make mode change requests.

28.4.2 Auxiliary clock generation

Figure 220: Clock generation shows the block diagrams of the generation logic for the various auxiliary clocks.

See the following sections for auxiliary clock selection control:

- *Section 28.3.1.21: Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)*
- *Section 28.3.1.25: Auxiliary Clock 1 Select Control Register (CGM_AC1_SC)*
- *Section 28.3.1.28: Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)*
- *Section 28.3.1.30: Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)*
- *Section 28.3.1.32: Auxiliary Clock 6 Select Control Register (CGM_AC6_SC)*
- *Section 28.3.1.35: Auxiliary Clock 8 Select Control Register (CGM_AC8_SC)*
- *Section 28.3.1.38: Auxiliary Clock 9 Select Control Register (CGM_AC9_SC)*

- *Section 28.3.1.44: Auxiliary Clock 12 Select Control Register (CGM_AC12_SC)*

28.4.2.1 Auxiliary clock dividers

The MC_CGM generates the following derived clocks:

- SARADC_CLK - controlled by the CGM_AC0_DC0 register
- EMIOS_CLK - controlled by the CGM_AC0_DC1 register
- LFAST_PLL - controlled by the CGM_AC1_DC0 register
- SYSCLK0 pin clock - controlled by the CGM_AC6_DC0 register
- CAN0 clock - controlled by the CGM_AC8_DC0 register
- RTI_CLK - controlled by the CGM_AC9_DC0 register
- CAN1 clock - controlled by the CGM_AC11_DC0 register
- DSPI_CLK0 - controlled by the CGM_AC12_DC0 register
- DSPI_CLK1 - controlled by the CGM_AC12_DC1 register
- LIN_CLK - controlled by the CGM_AC12_DC2 register
- PER_CLK0 - controlled by the CGM_AC12_DC3 register

28.4.3 Dividers functional description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System clock divider configuration registers
  - *Section 28.3.1.16: System Clock Divider 0 Configuration Register (CGM_SC_DC0)*
  - *Section 28.3.1.17: System Clock Divider 1 Configuration Register (CGM_SC_DC1)*
  - *Section 28.3.1.18: System Clock Divider 2 Configuration Register (CGM_SC_DC2)*
  - *Section 28.3.1.19: System Clock Divider 3 Configuration Register (CGM_SC_DC3)*
  - *Section 28.3.1.20: System Clock Divider 4 Configuration Register (CGM_SC_DC4)*
- Auxiliary clock divider configuration registers
  - *Section 28.3.1.23: Auxiliary Clock 0 Divider 0 Configuration Register (CGM_AC0_DC0)*
  - *Section 28.3.1.24: Auxiliary Clock 0 Divider 1 Configuration Register (CGM_AC0_DC1)*
  - *Section 28.3.1.27: Auxiliary Clock 1 Divider 0 Configuration Register (CGM_AC1_DC0)*
  - *Section 28.3.1.34: Auxiliary Clock 6 Divider 0 Configuration Register (CGM_AC6_DC0)*
  - *Section 28.3.1.37: Auxiliary Clock 8 Divider 0 Configuration Register (CGM_AC8_DC0)*
  - *Section 28.3.1.40: Auxiliary Clock 9 Divider 0 Configuration Register (CGM_AC9_DC0)*
  - *Section 28.3.1.43: Auxiliary Clock 11 Divider 0 Configuration Register (CGM_AC11_DC0)*
  - *Section 28.3.1.46: Auxiliary Clock 12 Divider 0 Configuration Register (CGM_AC12_DC0)*
  - *Section 28.3.1.47: Auxiliary Clock 12 Divider 1 Configuration Register (CGM_AC12_DC1)*
  - *Section 28.3.1.48: Auxiliary Clock 12 Divider 2 Configuration Register (CGM_AC12_DC2)*
  - *Section 28.3.1.49: Auxiliary Clock 12 Divider 3 Configuration Register (CGM_AC12_DC3)*

The reset value of all counters is ‘1’. If a divider has its DE bit in the respective configuration register set to ‘0’ (the divider is disabled), any value in its DIV field is ignored.

28.4.3.1 Fractional divider details

The clock divider divides the selected clock source frequency by a fractional value given by the DIV and DIV_FMT fields of the CGM_AC register.

Equation 19

$$F_{\text{divided clock}} = F_{\text{source clock}} \div ((\mathbf{DIV} + 1) \div 10^{\mathbf{DIV\_FMT}})$$

The divided clock frequency is actually an average frequency, since the divider uses only the available rising and falling edges of the source clock. Therefore, the actual frequency switches between two frequencies which are the two frequencies closest to the desired frequency (above and below) which can be extracted by a division factor *n*/2, where *n* is an integer greater than 1. The switching between the two frequencies is such that the resultant clock's rising edge never deviates from the ideal clock's rising edge by more than 25% of the source clock period and that the resultant average frequency over DIV + 1 source clock periods (= 10^{DIV_FMT} divided clock periods) is the desired frequency.

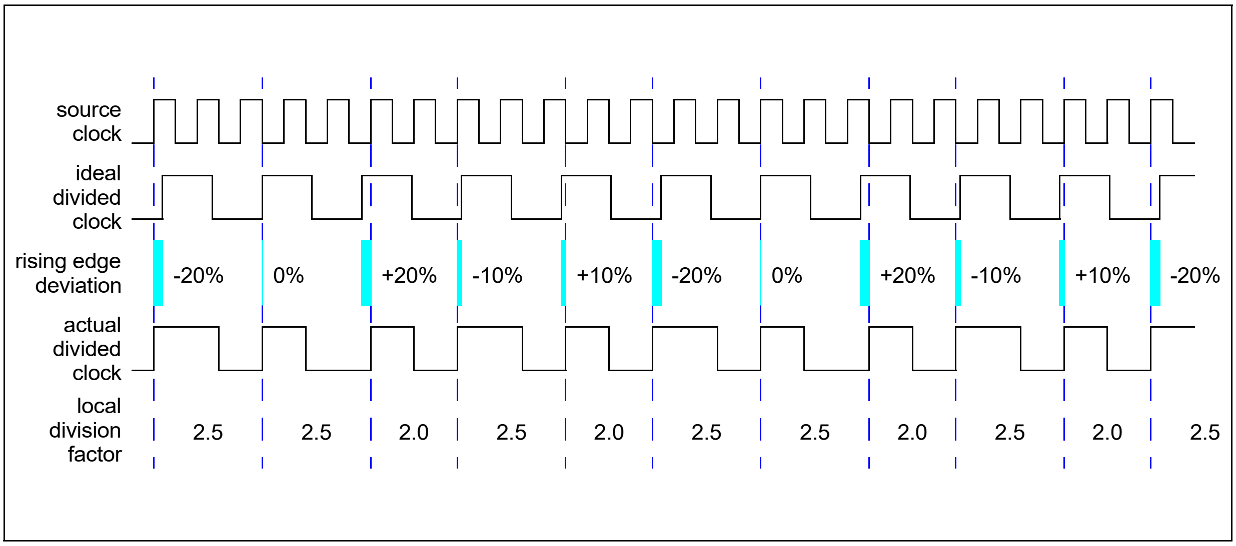
Example 1 Example: Fractional clock division

Desired division factor = 2.3

DIV = 22

DIV_FMT = 1

Figure 297. MC_CGM fractional division example waveform (divide by 2.3)



Equation 20

$$F_{\text{divided clock}}\big|_{\text{max}} = F_{\text{source clock}} \div 2.0$$

Equation 21

$$F_{\text{divided clock}}\big|_{min} = F_{\text{source clock}} \div 2.5$$

Equation 22

$$F_{\text{divided clock}}\big|_{ave} = F_{\text{source clock}} \div \frac{((2.5 \times 6) + (2.0 \times 4))}{10}$$

Therefore,

Equation 23

$$F_{\text{divided clock}}\big|_{ave} = F_{\text{source clock}} \div 2.3$$

28.4.3.2 Divider Update Triggering

There are two methods to update the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the CGM_DIV_UPD_TYPE register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the CGM_UPD_STAT register is set. This bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

28.4.3.2.1 Immediate Divider Update

If a divider group has been configured to be updated immediately (such as the corresponding CGM_DIV_UPD_TYPE register bit = ‘0’), the configuration of a divider in that group will be applied immediately on the write to that divider’s configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

28.4.3.2.2 Software-triggered divider update

If a divider group has been configured to be updated via a software trigger (such as the corresponding CGM_DIV_UPD_TYPE register bit = ‘1’), the configuration of a divider in that group will not be applied immediately on the write to that divider’s configuration register. Instead, the configuration in the corresponding configuration register will be applied only when software writes any value to the CGM_DIV_UPD_TRIG register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

In the case of the system clock dividers, if the SYS_DIV_RATIO_CHNG bit in the CGM_SC_DIV_RC register = ‘1’, the crossbar switch is requested to halt its ongoing transactions, and only after the crossbar switch has acknowledged the request does the update of the system clock dividers take place. Once these updates have completed, the halt request to the crossbar is deasserted.

Note: If halting the crossbar can cause a bus master to starve and thus lead to lost data or other problems, it is recommended to vary the system clock divider configurations without changing the ratios and to set CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] to ‘0’.

In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (such as all relevant bits in the CGM_DIV_UPD_STAT register are ‘0’) before triggering a new update via the CGM_DIV_UPD_TRIG register.

29 OSC digital interface (XOSC)

29.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provides the register interface for the programmable features. Selection of the XOSC as a source clock is controlled by the Clock Generation module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

29.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that can used as an input to PLL(s) and can be selected as the reference clock for many of the peripherals on the device.

Table 383 shows the possible configurations of the XOSC.

Table 383. XOSC configurations

OSC EN	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC output	XOSC mode
0	0	No crystal, high-impedance	No crystal, high-impedance	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

29.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<*mode*>_MC[XOSCON] controls the power-down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

29.2.2 Oscillator startup delay

A bit in the UTEST Flash memory determines whether the oscillator is enabled at power-up of the device (if the DCF client miscellaneous has been programmed, otherwise the valid configuration is the value present in *Chapter 9: Device Configuration Format (DCF) Records*, *Table 107: DCF client list*). If enabled, the oscillator is started after Phase3 of the device reset sequence. In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL(s)).

The default value for this field after reset depends on implementation and can be found in the XOSC section of the Device Configuration chapter. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note: It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

29.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

29.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software, and is only cleared by a system reset. In bypass mode, the oscillator is disabled, and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

Note: The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

29.2.4.1 Automatic Level Control (ALC)

The function of the ALC block is to provide high drive current during oscillator start up, and reduce current after oscillation in order to reduce power, distortion, RFI; and to avoid overdriving the crystal. ALC block can be controlled via DCF by configuring the UTEST miscellaneous bit 17 [XOSC_ALC_DIS]. Comparing the configurations with ALC disabled respect the case with ALC enabled, there are the following attributes:

- Higher oscillation amplitudes at crystal
- Distorted oscillation with several harmonics
- Increased EMI
- Higher crystal drive level
- Less susceptible to noise

The ALC enable configuration is suitable for most applications. The amplitude of oscillations is lower, hence less distortion in oscillations, less EMI, and also less crystal drive level. Feedback resistor is integrated thus, it does not require external resistors by offering a lower cost solution and simpler PCB design.

Note: It is recommended to make ALC feature enabled (that is, XOSC_ALC_DIS = 0) for low dissipation in crystal (crystal drive level).

Consult with crystal supplier for determining the need of extra resistance in XTAL to avoid crystal overdrive.

29.3 Memory map and register definition

Table 384 shows the memory map of the XOSC registers.

Table 384. XOSC memory map

Figure 298. XOSC Control register (XOSC_CTL)

Table 385. XOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
8:15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.

Table 385. XOSC_CTL field descriptions (continued)

Field	Description
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
24 I_OSC	Crystal oscillator clock interrupt This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV $\times$ 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.

30 IRCOSC digital interface

30.1 Introduction

The Internal RC Oscillator digital interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC)

It provides access to trimming information used for safety implementations.

30.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see Data Sheet for timing information) which is required for stabilization. The IRCOSC status indication is found in the MC_ME_GS[S_IRC] field (see the “Mode Entry Module MC_ME” chapter).

During a power on reset sequence the following are initialized from TEST Flash memory:

- Native trimming bits
- Fine trimming bits

For safety reasons, these bits can be accessed through the IRCOSC Native Trimming register (NT). The main IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[5:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

30.3 Memory map and register definition

Table 386 shows the memory map of the IRCOSC registers.

31 LPRC digital interface

31.1 Introduction

The LPRC digital interface controls the internal Low Power RC oscillator (LPRC). It holds control and status registers accessible for application.

31.2 Low Power RC oscillator

The Low Power RC oscillator provides a low frequency clock of 1.024 MHz with a good stability with respect to supply and temperature variation.

Low Power RC oscillator is enabled during power on reset sequence and it is not expected that application switches off the LPRC oscillator (note that the software shall keep to 0 the MISC_CTRL_REG[LPRCREG_ENB] bit). In all modes the Low Power RC oscillator is always enabled. After switch on, the output clock is available only after 8.5 us which is required for stabilization. The clock source status is updated in the S_LPRC bit of LPRC_CTL register.

The LPRC clock can be further divided by a configurable division factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by the LPRCDIV[4:0] bits of LPRC_CTL register.

31.3 Memory map and register definition

The LPRC registers are listed in *Table 389*.

32 OSC32K digital interface (OSC32K)

32.1 Introduction

The OSC32K digital interface controls the operation of the 32 KHz slow external crystal oscillator. It holds control and status registers accessible for application.

The programmable features of the OSC32K digital interface are as follows:

- Oscillator power-down control and status
- Oscillator clock available interrupt
- Oscillator bypass mode control
- Output clock division factors ranging from 1 to 32

32.2 Memory map and register definition

Table 391 shows the memory map of the OSC32K registers.

Table 391. XOSC32K memory map

1. You can read this field, and you can write a value of “1” to it. Writing a “0” has no effect. A reset will also clear this bit.
2. You can write a value of "0" or "1" to this field. However, writing a "1" will clear this field, and writing "0" will have no effect on the field value.

Figure 302. OSC32K Control register (SXOSC_CTL)

Table 392. SXOSC_CTL register field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock 1 EXTAL is used as root clock
8:15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked 1 Crystal oscillator clock interrupt is enabled
19:23 OSCDIV	Crystal oscillator clock division factor These bits specify the crystal oscillator output clock division factor. The output clock is divided by the factor OSCDIV+1.

Table 392. SXOSC_CTL register field descriptions (continued)

Field	Description
24 I_OSC	Crystal oscillator clock interrupt This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV $\times$ 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred 1 Oscillator clock interrupt pending
30 S_OSC	Crystal oscillator status 0 Crystal oscillator output clock is not stable 1 Crystal oscillator is providing a stable clock
31 OSCON	Crystal oscillator power-down control 0 Crystal oscillator is switched off 1 Crystal oscillator is switched on

32.3 Functional description

The OSC32K circuit includes an internal oscillator driver and an external crystal circuitry. It can be used as a reference clock to specific modules depending on system needs.

The OSC32K can be controlled via the SXOSC_CTL register. The OSCON bit controls the power-down while bit S_OSC provides the oscillator clock available status.

After system reset, the oscillator is put to power-down state and software has to switch on when required. Whenever the OSC32K is switched on from off state, the OSCCNT counter starts and when it reaches the value EOCV[7:0] × 512, the oscillator clock is made available to the system. Also, an interrupt pending SXOSC_CTL[I_OSC] bit is set. An interrupt will be generated if the interrupt mask bit M_OSC is set.

The oscillator circuit can be bypassed by writing SXOSC_CTL[OSCBYP] bit to ‘1’. This bit can only be set by software. A system reset is needed to reset this bit. In this bypass mode, the output clock has the same polarity as the external clock applied on the OSC32K_EXTAL pin and the oscillator status is forced to ‘1’. The bypass configuration is independent of the power-down mode of the oscillator.

Table 393 shows the truth table of different configurations of the oscillator.

Table 393. OSC32K configurations

SXOSC_CTL fields		OSC32K_XTAL	OSC32K_EXTAL	OSC32K	Oscillator mode
OSCON	OSCBYP				
0	0	No crystal, high Z	No crystal, high Z	0	Power-down, IDDQ
x	1	x	External clock	OSC32K_EXTAL	Bypass, OSC Disabled
1	0	Crystal	crystal	OSC32K_EXTAL	Normal, OSC Enabled
		Ground	External clock	OSC32K_EXTAL	Normal, OSC Enabled

The OSC32K clock can be further divided by a configurable factor in the range 1 to 32 to generate the divided clock to match system requirements. This division factor is specified by SXOSC_CTL[OSCDIV] field.

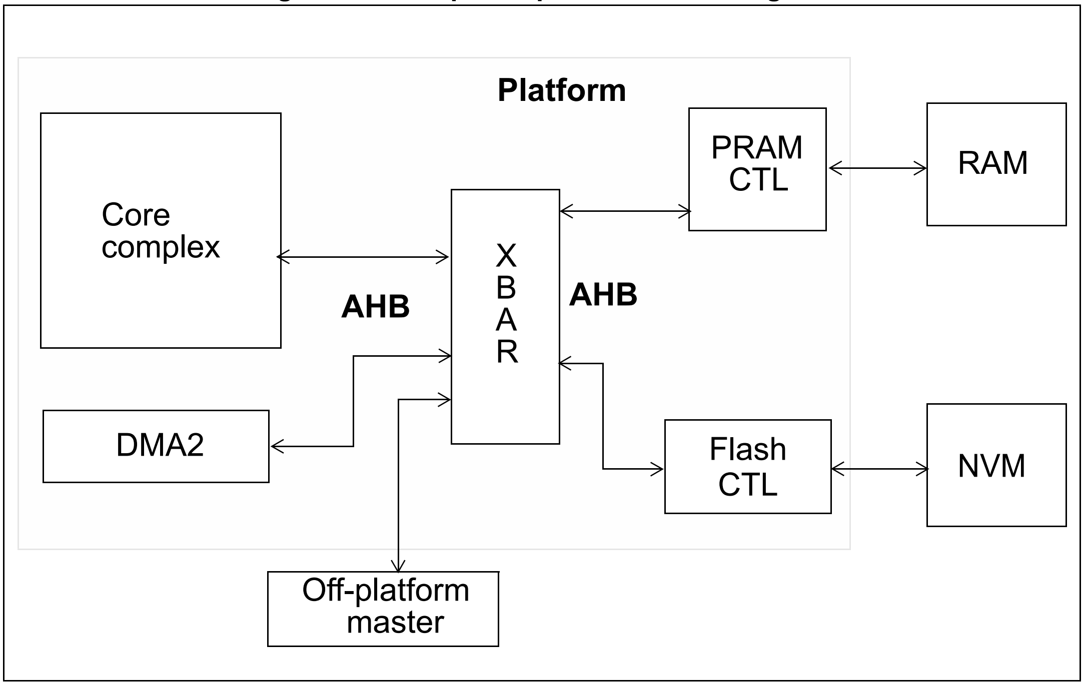
33 Platform RAM controller AHB (PRAMC_AHB)

33.1 Introduction

This section provides an overview of the Platform RAM Controller. The PRAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The PRAM controller supports two 64-bit AHB and one 64-bit RAM array interfaces. The first AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The second AHB port provides a connection from the flash controller to facilitate calibration overlay access. *Figure 303* is a simplified block diagram depicting the position of the PRAM controller within a typical platform architecture:

Figure 303. Simplified platform block diagram



The following list summarizes the key features of the PRAM controller:

- System bus supports 64-bit data and 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data and 8-bit ECC interface
- Late-write support via 64-bit data and 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than 64-bit data

The address path of the PRAM controller contains a multiplexer that chooses among the addresses presented on the system bus during read/write requests to RAM. These addresses are transferred to RAM array either immediately, for read accesses, or, for write accesses, through a temporary write address buffer or through a late-write address buffer.

The temporary write address buffer contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to simultaneously present the address and associated write data, because the write data is not valid until the AHB data phase. The late-write buffer holds write requests which are delayed to facilitate single-cycle responses on the system bus.

The read data is the result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire data path of the PRAM controller, including the late-write buffer, to support end-to-end ECC (e2eECC) coverage.

The write data path contains the multiplexer that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and stored directly in the RAM.

33.2 SRAM controller memory map and register definitions

The PRAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses will generate an IPS error.

Table 394. PRAMC_AHB memory map

Figure 304. Platform RAM configuration register 1 (PRCR1)

Table 395. PRCR1 field descriptions

Field	Description
22 PRI1	Not used, since port 1 is not used. This bit can be written by software.
23 PRI0	Not used, since port 1 is not used. This bit can be written by software.
24 P1_BO_DIS	Not used, since port 1 is not used. This bit can be written by software.
25 P0_BO_DIS	Port p0 read burst optimization disable 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response(1) when PRCR[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response(1) when PRCR[FT_DIS]=1
31 FT_DIS	Flow through disabled This field defines the AHB read response of the PRAM controller . The state of this field has no impact on the write response latency. This bit is cleared by hardware reset. **Note:** Do not change the FT_DIS bit value while accessing system RAM. Realocate code programming the FT_DIS bit to another area (for example, local core memory). 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

1. The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM Controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM Controller clock frequency.

33.3 Functional description

33.3.1 Read/Write introduction

The PRAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The PRAM controller captures read data from the RAM array and drives it onto the AHB along with the associated dataphase termination signals. To facilitate operating at higher frequencies, the PRAM controller can optionally incur a single wait state on the AHB response.

33.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

33.3.1.2 Optional read wait-state

The PRAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCR1[FT_DIS] = 0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCR1[FT_DIS] = 1, and a WRAP4 burst will have an access time of 3-2-2-2.

33.3.2 Writes

33.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Instead, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

33.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme’s 64-bit granularity. In the case of a read-modify-write action, the PRAM controller performs single-error correction, double-error detection on the read data. The write data is merged into the appropriate byte lanes along with the potentially-corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. For details on the ECC coding scheme, refer to *Section 33.5: Safety considerations*.

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of less than 64 bits require the insertion of one wait state before the data phase can be completed.

33.3.2.3 Unaligned writes

The PRAM controller is compliant with the AMBA-AHB2.v6 extensions specification concerning byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

Note: Unaligned writes always generate read-modify-write operations in the PRAM controller in order to preserve the validity of the ECC codeword.

33.4 Initialization/application information

Prior to reading, the ECC must be initialized by writing a known 64-bit value to each memory address. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Reading from an uninitialized address is likely to generate an uncorrectable ECC event.

The PRAM memory space can be initialized by storing a 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

33.5 Safety considerations

33.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named after M.Y. Hsiao, an IBM researcher who published a paper in the early 1970s about SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns
2. Every column is distinct
3. Every column contains an odd number of ones, and hence is “odd weight”

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in *Table 396*. A ‘*’ in *Table 396* indicates the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses the AHB bit numbering convention where bit[0] is the least significant bit.

Table 396. PRAM controller basic H-matrix definition

Checkbits [7:0]	Data Bit[(1)]																															
	Byte 7								Byte 6								Byte 5								Byte 4

0	*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*			

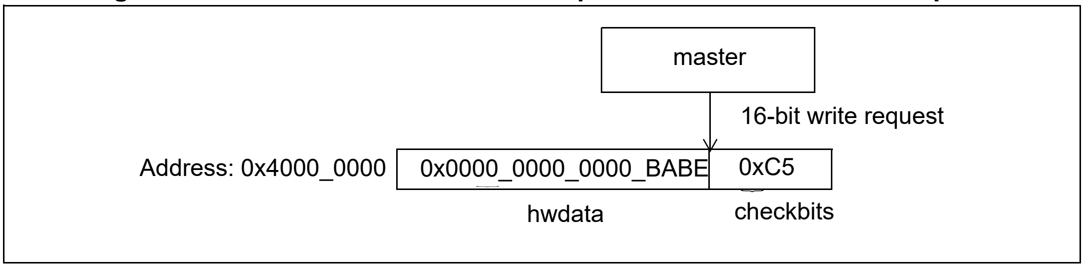
1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

33.5.1.1 E2EECC considerations on less-than-64-bit write transactions

Writes of less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the PRAM controller performs SEC/DED on the read data. The PRAM controller uses the following checkbit manipulation technique to ensure that any faults in the PRAM control logic, associated with performing the read-modify-write action, will ultimately be detectable by e2eECC:

- On an 8-bit, 16-bit or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non pertinent byte lanes zeroed out, and the associated checkbit is based on this “zero-padded” write data.
  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

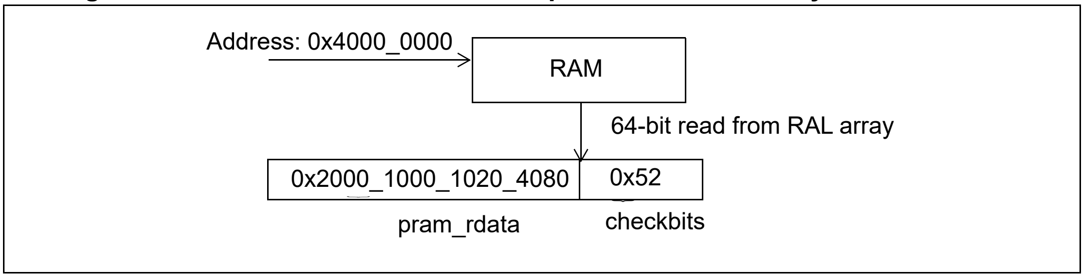
Figure 305. E2EECC consideration for partial write - 16-bit write request



- The PRAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

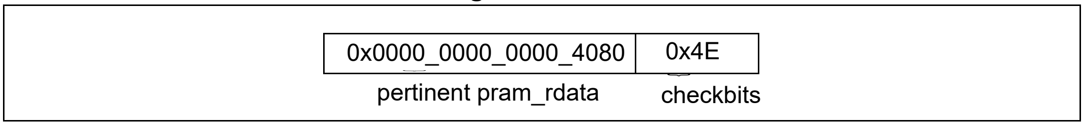
  If a non correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

Figure 306. E2EECC consideration for partial write - memory read from RAM



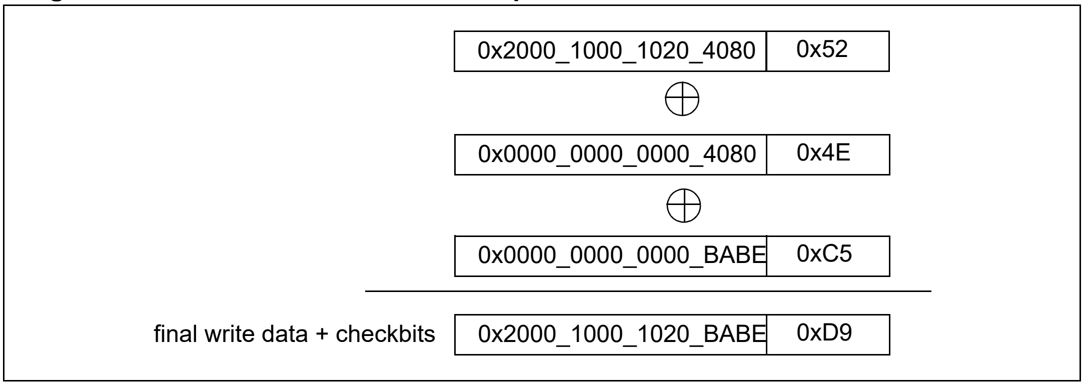
- The PRAM controller isolates the pertinent byte lanes of the read data by zero-padding the non pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

Figure 307. E2EECC consideration for partial write - Separation of check-bits of targeted bit-lines



- The PRAM controller merges the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

Figure 308. E2EECC consideration for partial write - calculation of final check-bits



This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and PRAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The PRAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

33.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by an e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the PRAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions

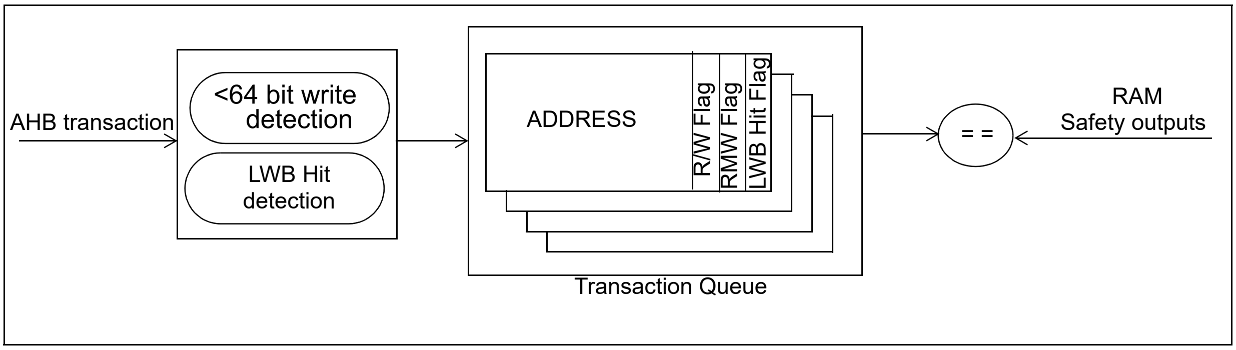
- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, the safety feature compare outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

Figure 309. RAM controller transaction monitor block diagram



34 Flash memory controller

34.1 Introduction

The Flash memory controller act as an interface between the system bus (AHB-Lite 2.v6) and the Flash memory arrays.

The Flash memory controllers support two 64-bit AHB buses and a 256-bit read data interface from each Flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the Flash arrays into the mini-cache. This buffer mechanism serves to deliver Flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed Flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the Flash array page size and providing 256 bytes of total buffered storage.

Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the Flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

34.2 Features

The following list summarizes the key features of the Flash memory controller:

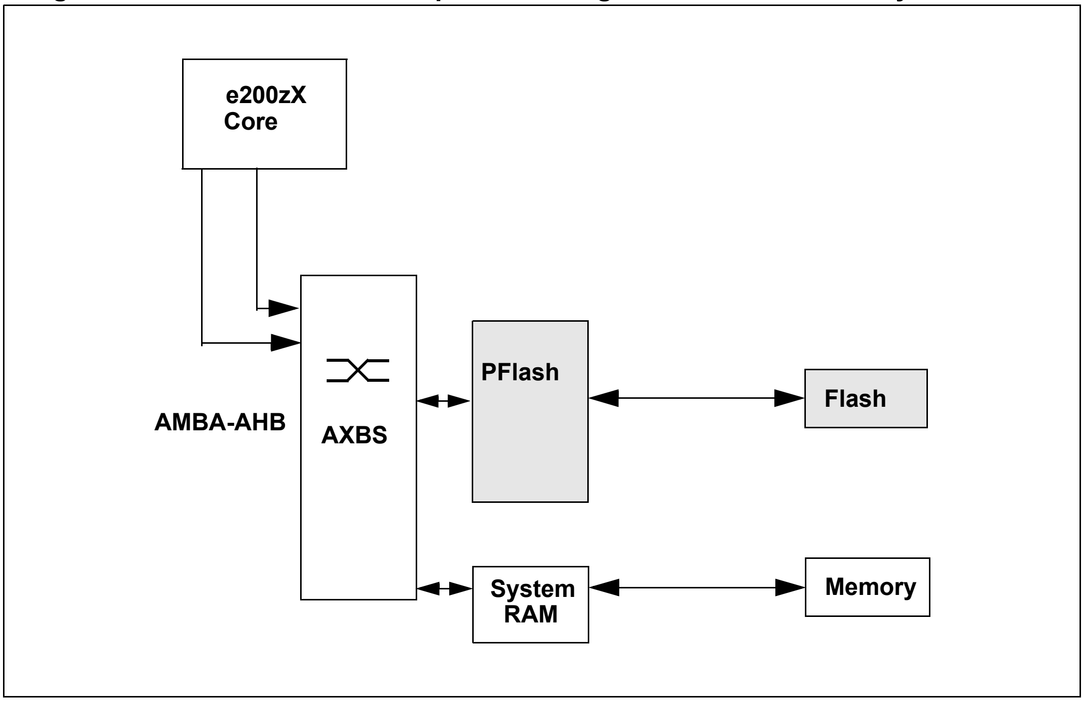
- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle “buffer hit” read response
- Configurable access control based on read/write and AHB master ID attributes
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets
- Optional address pipelining capability to maximize throughput
- Support for reporting of single-, double- and multi-bit Flash ECC events on a 64-bit doubleword boundary

34.3 Block diagrams

Figure 310 provides a block diagram showing the Flash memory controller and the attached Flash array.

Note: This module is also known as the Platform Flash controller, that is, PFlash.

Figure 310. Platform-centric simple block diagram with Flash memory controllers



34.4 Flash memory controller memory map

34.4.1 Overview

The Flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of Flash memory access configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The Flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the Flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario.

There is no idle indicator for the Flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the Flash, code execution must be temporarily moved to system RAM.

Table 397. Flash memory controller memory map

3 P0_M12PFE	Port0 Master 12 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 12. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P0_M11PFE	Port0 Master 11 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 11. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P0_M10PFE	Port0 Master 10 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 10. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P0_M9PFE	Port0 Master 9 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 9. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P0_M8PFE	Port0 Master 8 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 8. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
8 P0_M7PFE	Port0 Master 7 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 7. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P0_M6PFE	Port0 Master 6 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table 398. PFCR1 field descriptions (continued)

Field	Description
11 P0_M4PFE	Port0 Master 4 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16:18 APC	Address Pipeline Control This field controls the number of cycles that a subsequent Flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. 000 Pipelined access to the Flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 Reserved 011 Reserved 1xx Pipelined access to the Flash is disabled and one wait state is inserted before a subsequent access can be initiated

Table 398. PFCR1 field descriptions (continued)

Field	Description
19:23 RWSC	Read Wait State Control This field controls the number of wait-states to be added to the best-case Flash array access time for reads. The best-case Flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the Flash memory controller and the actual read access time of the Flash memory controller. The required settings are documented in the device data sheet. Higher operating frequencies require non-zero settings for this field for proper Flash operation. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added **Note:** Refer to the device data sheet for wait state configuration
25 P0_DPFEN	Port0 Data Prefetch Enable This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P0_IPFEN	Port0 Instruction Prefetch Enable This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
29:30 P0_PFLIM	Port0 PFlash Prefetch Limit This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 1x The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

34.4.1.2 Platform Flash configuration register 2 (PFCR2)

The PFlash configuration register 2 (PFCR2) specifies operation Port1 of the Flash memory controller.

Table 400. PFCR3 field descriptions

Name	Description
0:1 P0_WCFG	Port0 Way Configuration This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the Flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the Flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any Flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved.
2:3 P1_WCFG	Port1 Line Buffer Configuration This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the Flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the Flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any Flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffer 0 allocated for instruction fetches and buffer 1 for data accesses. 11 Reserved

Table 400. PFCR3 field descriptions (continued)

Name	Description
15 BAF_DIS	BAF Disable This field controls executable access to the BAF (Boot Assist Flash) region of the Flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF Flash region is allowed. 1 Executable access to the BAF Flash region is prohibited.
16:17 ARBM	Arbitration Mode This 2-bit field controls the arbitration of concurrent Flash access requests from the two AHB ports of the Flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 1x Round-robin arbitration

34.4.1.4 Platform Flash access protection register (PFAPR)

The PFlash access protection register (PFAPR) is used to control read and write accesses to the Flash array.

34.5 Functional description

As shown in *Figure 310* the Flash memory controllers interface between:

- The AHB system bus ports
- Flash memory array

For accesses targeting the Flash array, the Flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the Flash array. The Flash memory controller captures read data from the Flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the Flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

34.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

34.5.2 Access protections

34.5.2.1 PFAPR - Platform Flash access protection register (PFAPR)

The Flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash access protection register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in *Section 34.4.1.4*. Detection of a protection violation results in an error response from the Flash memory controller on the AHB transfer.

34.5.2.2 BAF execution disable

The Flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash configuration register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on either Port0 or Port1 are evaluated. If the Flash memory controller detects an attempted instruction fetch access to the BAF region of the Flash, the Flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

34.5.3 Read cycles – buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. In the event of a buffer miss, a Flash access is initiated.

If the Flash access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as most-recently-used. If the Flash access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

34.5.4 Read cycles – buffer hit

Single cycle read responses to the AHB are possible with the Flash memory controller when the requested read access was previously loaded into one of the page buffers. In these “buffer hit” cases, read data is returned on the system bus with a zero wait-state response.

34.5.5 Error termination

The Flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read access Control or Write access Control settings do not allow the access, thus causing a protection violation. See *Section 34.4.1.4* for more detail. In this case the Flash memory controller does not initiate a Flash array access.
- Attempted instruction fetch by an AHB master to the BAF Flash region when the PFCR3[BAF_DISABLE] field in Platform Flash configuration register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See *Section 34.4.1.3* for more detail. In this case, the Flash memory controller does not initiate a Flash array access.
- The Flash returns an error response on an attempted access (see *Section 34.5.6*).
- Attempted access by an AHB master to a reserved region in the Flash memory map.

34.5.6 Flash error response operation

The Flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations, or improper sequencing during array integrity testing. When an error response is received, the Flash memory controller does not update or validate a page read buffer. An error response may be signaled on read or interlock write operation. For more information on the specifics related to signaling of Flash errors, including Flash ECC events, array integrity testing and read-while-write events, refer to the Flash memory chapter.

34.5.7 Security module exclusive control

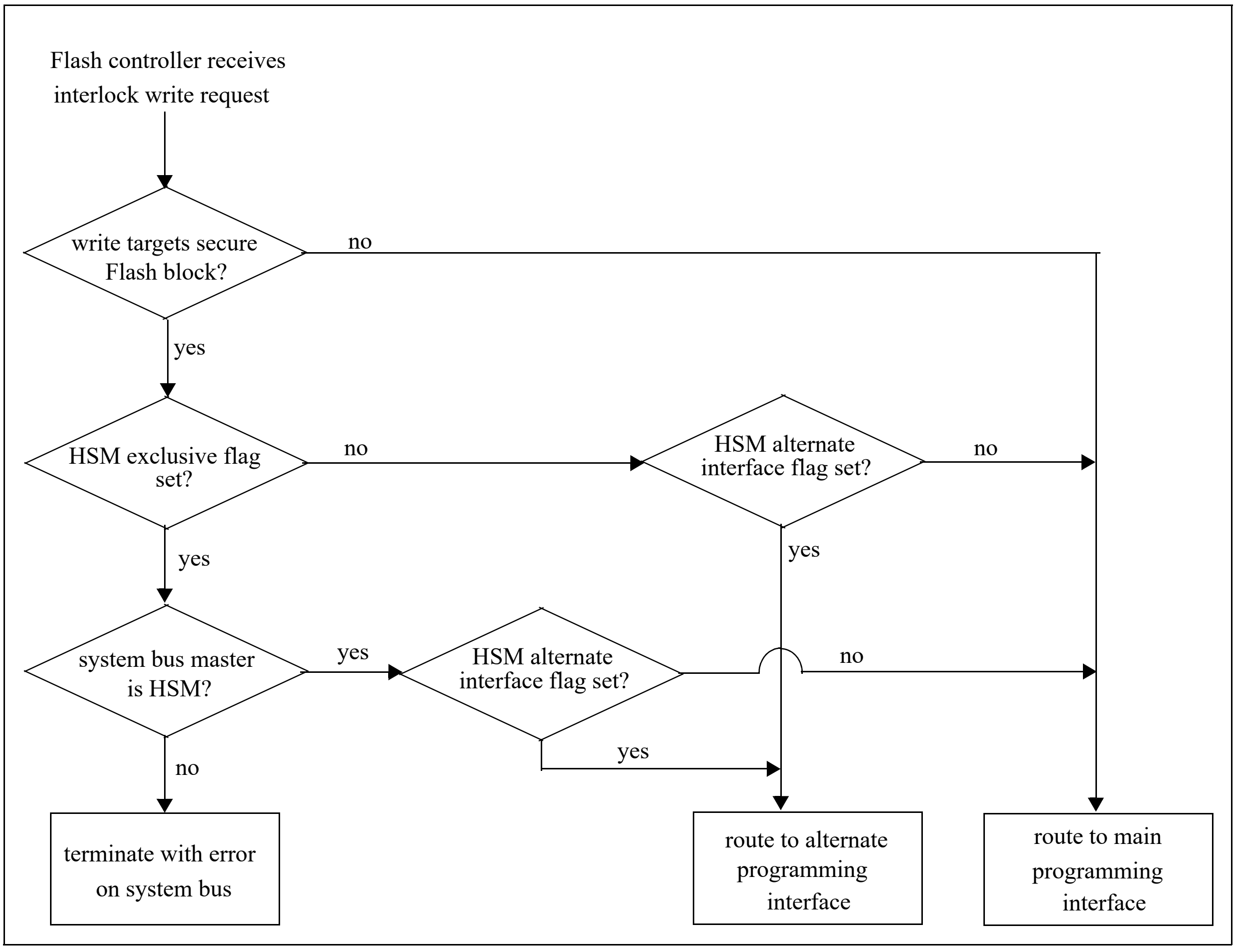
During “Production at OEM” lifecycle state and beyond, the HSM can establish the secure Flash blocks to be exclusive to the HSM and route program or erasing of secure Flash blocks to the alternate programming interface.

The secure Flash space is independently controlled for each of the following regions:

- 16 KB secure code Flash block at address range 0x0060_C0000 - 0x0060_FFFF
- 128 KB secure code Flash block at address range 0x0061_0000 - 0x0062_FFFF
- Two 16 KB secure data Flash blocks at address range 0x0068_0000 - 0x0068_7FFF

The HSM provides flags to individually control the HSM-exclusivity for each of the four secure Flash regions. When a given secure Flash block is marked as exclusive to the HSM, the HSM is the only system bus master granted access to that block and access attempts by non-HSM masters are terminated with error. Once HSM-exclusivity is established for a given secure Flash block, the HSM is guaranteed access to that block, regardless of the state of the censorship controls. Secure Flash exclusivity applies to read and write accesses.

Figure 315. Interlock Write Alternate Programming Interface Routing Flowchart



34.5.8 Access pipelining

Accesses to the Flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the Flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the Flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal Flash access.

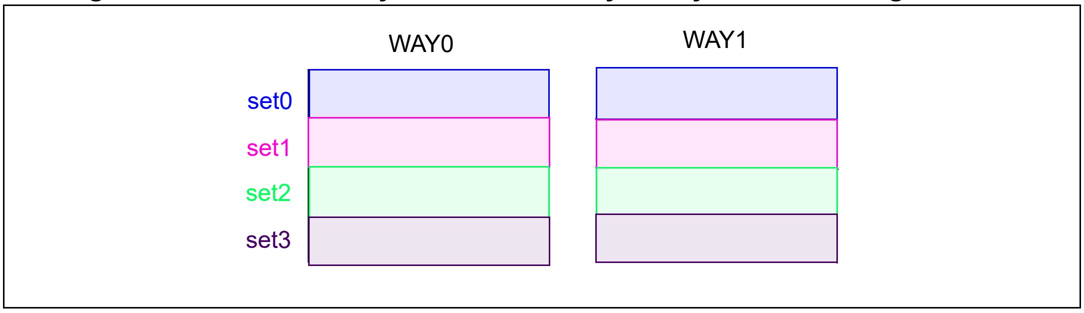
Note: Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

34.5.9 Line read buffers and prefetch operation

The AHB ports of the Flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the Flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Section 34.4.1.1). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the Flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32 bytes, and a subsequent Flash access is initiated. A Flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 316. Flash memory controller 4-entry, 2-way mini-cache organization



Once the candidate line buffer has been selected, the Flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of Flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted Flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Section 34.4.1.1. More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to ‘1’,
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted

Refer to Section 34.4.1.1 for a description of these controls.

34.5.10 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Section 34.4.1.1 for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to

Section 34.4.1.2 for a description of these controls. Prefetches are never triggered by write cycles.

34.5.11 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Section 34.4.1.1 for a description of these controls.

34.5.12 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to Section 34.4.1.3. The buffers can be organized as a “pool” of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

34.5.13 Safety considerations

34.5.13.1 e2eECC (End-to-End ECC)

34.5.13.1.1 e2eECC and Flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with Flash memory. The basic issues involve: the default state of a Flash block that is erased (all ones) and the fact that programming an erased Flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the Flash memory in three ways.

First, the all ones codeword, since it reflects the state of an erased Flash location, is treated as a valid, error free encoding; in particular, it is required that the checkbits associated with the all ones data value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased Flash block generates an all ones data for all locations, the address field cannot be included in the ECC code used by the Flash. The Flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the Flash memory and its support for EEPROM emulation.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the Flash memory in multiple ways. The required ECC adjustments are handled by the platform Flash controller before data is written to the Flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a Flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all ones erased state.

On a Flash read operation, a similar but “reversed” set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the Flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following Flash ECC example. Let the Flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The Flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

```
addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)
```

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

```
addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3
```

Before performing the interlock write to the Flash array, the Flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the Flash array is:

```
fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8
```

3. Read address 0x00345678. The Flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The Flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

```
addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3
```

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The Flash memory controller performs EDC after ECC check on all Flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

34.5.13.2 Flash address generation check

Functional safety coverage of the address and data are handled by ECC performed within the Flash and e2eECC performed at the master. Functional safety coverage of the address path and control within the Flash memory controller rely on a feedback path between the Flash controller and Flash. Recall on a requested access to Flash, the Flash memory controller must decode the system AHB bus signals to generate the corresponding Flash interface signals to invoke a Flash lookup. In addition to providing the requested read data, the Flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.In the event of EDC after ECC errors detected on accesses to data and secure data flash, the event is not reported.

This sideband information is used by the Flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the Flash memory controller or the transmission path between the Flash memory controller and Flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

34.5.14 e2eECC on data Flash accesses

ECC events detected on accesses to the EEPROM Flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit or double-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU. In the event of EDC after ECC errors detected on accesses to data and secure data flash, generation of the fault is suppressed. The related bit in MCR is not set and the event is not forwarded to the FCCU.

34.5.15 Array integrity considerations

During an array integrity sequence, the Flash memory array ignores any incoming read requests. When a Flash array integrity check is in progress, the Flash memory controller terminates all Flash access requests with an error.

35 Embedded Flash Memory

35.1 Introduction

The Flash Memory module serves as electrically programmable and erasable nonvolatile memory, for instructions and data storage.

The Flash Memory module is a nonvolatile, solid-state silicon memory device consisting of blocks of single transistor storage elements, an electrical means for selectively adding (programming) and removing (erasing) charge from these elements, and a means of selectively sensing (reading) the charge stored in these elements.

The Flash Memory module has two functional units:

- The Flash core: it is composed of a common high voltage HV block and a Flash array which can contain one or more Flash partitions. Each Flash partition is composed of arrayed nonvolatile storage elements, sense amplifiers, row decoders and column decoders. The arrayed storage elements in the Flash partitions are subdivided into physically separate units referred to as blocks.
- The Memory interface: it contains the registers and logic which control the operation of the Flash core and contains two main ports: the Array Interface and the Registers Interface. The memory interface is also the interface between the Flash Memory module and a Bus Interface Unit (BIU) and contains the ECC and redundancy logic.

35.1.1 Overview

The 2320 KB Flash Memory module contains two array partitions. Read-While-Write operations are only possible for separate partitions, meaning fetching/reading from one (or more) partition(s) while a program/erase operation is active on another partition. Each module counts as an RWW partition.

EEPROM emulation is managed as 4 × 16 KB blocks in one partitions, referred to as Data Flash.

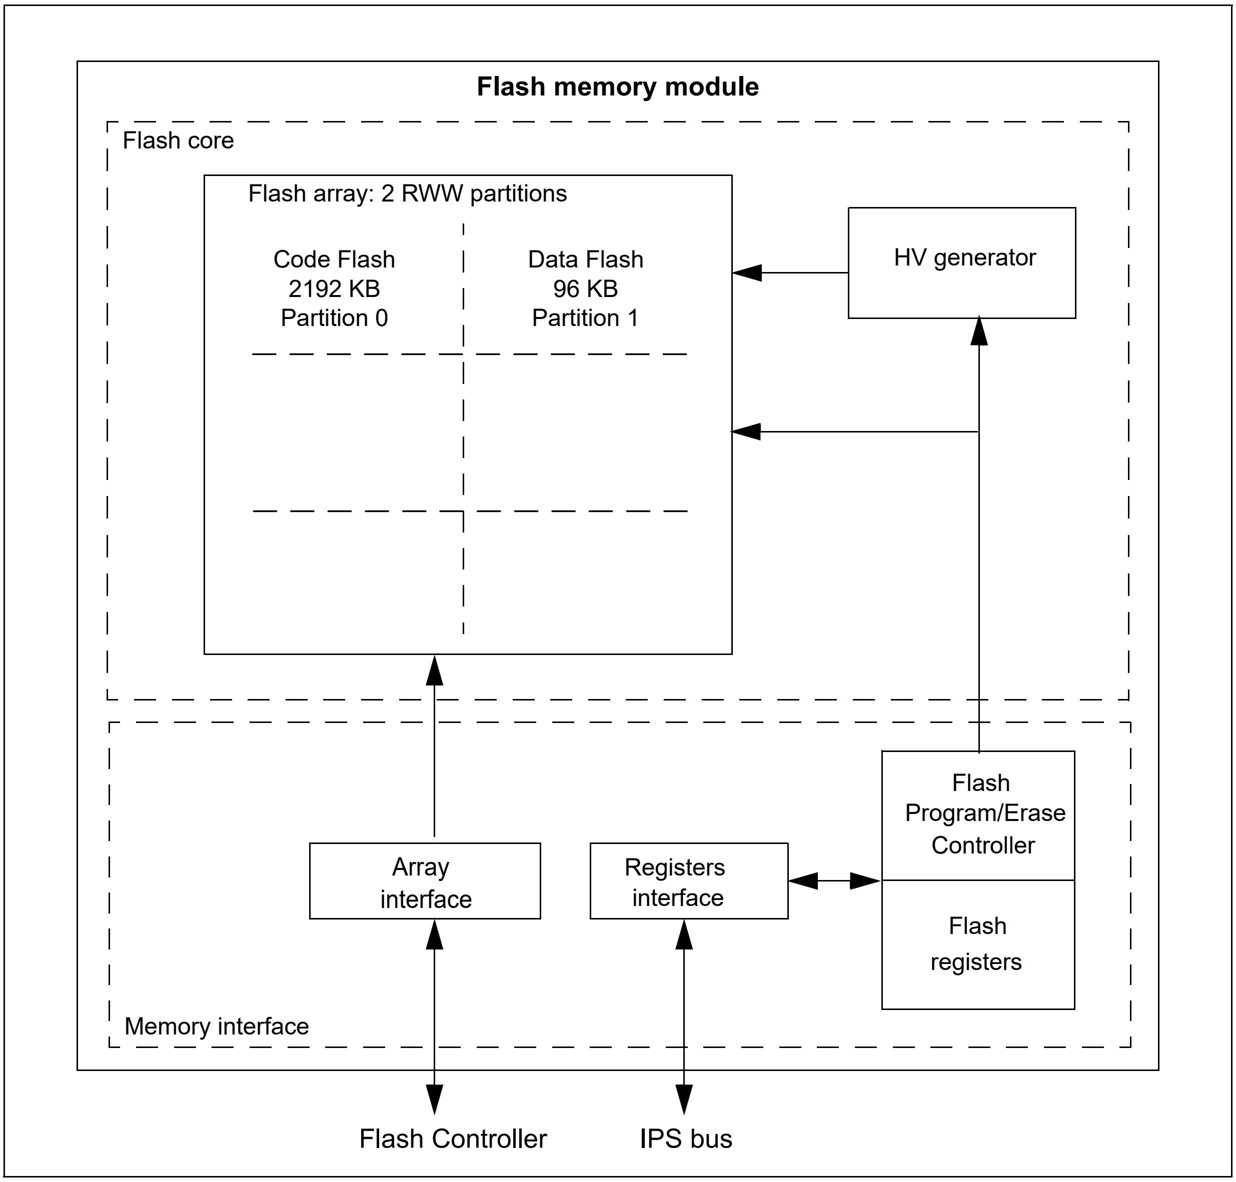
HSM EEPROM emulation is managed as 2 × 16 KB blocks in one partition, referred to as HSM Data Flash.

The Modify operations are managed by an embedded Flash Program/Erase Controller (FPEC). Commands to the FPEC are delivered through a User Registers interface.

The Read Data bus is 256-wide, while the Flash registers are on a separate, 32-bit bus.

The high voltages needed for Program and Erase operations are internally generated and are common for the two partitions.

Figure 317. Flash memory module structure



The Flash Memory module is designed for use in embedded applications which require high density non-volatile memories with high-speed Read access.

The Flash array is addressable:

- For programs in data partition: by word (32 bits) or doubleword (64 bits). ECC granularity is 64 bits.
- For programs in code partition: by word (32 bits) or doubleword (64 bits). ECC granularity is 128 bits.
- For reading code partitions – by page (256 bits).
- For reading data partitions – by half-page (128 bits).

Multiple-word or doubleword writes to the Flash memory may be performed to fill the program page buffer (256 bits), enabling page programming (256 bits – requiring 4 doubleword writes) and quad-page programming (1024 bits – requiring 16 doubleword writes). Code Flash memory reads always return 256, although Read buffering may be performed by the Bus Interface Unit (BIU). The address for each word retrieved within a page differs from the other addresses in the page by address bits (4:2).

Data Flash memory reads always return 128 bits, or two consecutive doublewords of information. The address for each word retrieved within a doubleword differs from the other addresses by address bits (3:2).

The Flash Memory module supports fault tolerance through Error Correction Code (ECC) and error detection. The ECC implemented within the Data Flash Memory module corrects up to double bit failures and detects triple bit failures (as uncorrectable).The ECC implemented within the Code Flash Memory module corrects double bit failures and detects triple bit failures (as uncorrectable).

The Flash Memory module uses an embedded hardware algorithm implemented in the Flash Program/Erase Controller to program and erase the Flash partitions.

Control logic that works with the software block-enables and software lock mechanisms are included in the embedded hardware algorithm to guard against accidental program/erase. The hardware algorithm performs the necessary steps to ensure that the storage elements are programmed and erased with sufficient margin to guarantee data integrity and reliability.

A programmed bit in the Flash array reads as logic level ‘0’ (or low). An erased bit in the Flash array reads as logic level ‘1’ (or high).

Programming and Erasing of the Flash array requires multiple system clock cycles to complete.

The Program and Erase sequences may be suspended or aborted.

35.1.2 Features

- 30 ns code/data array access time
- Code Partition High Read parallelism: 256 bits
- Data Partition Read parallelism: 128 bits
- Error Correction Code (Double Error Correction-Triple Error Detection) to enhance data integrity
- Data Partition Doubleword program granularity: 64 bits
- Erase with fast erase time at factory
- Blocks one time programmable (OTP) marking
- Read-While-Modify capability when the accesses are to different partitions
- Erase/Program Suspend
- Programming during Erase-Suspend
- Software programmable program/erase protection to avoid unwanted writings
- Temperature range (-40 °C to 150 junction)
- UTEST mode (user-accessible Test modes)
- Alternate interface provided for program and erase operations to dedicated master as private access to blocks
- Critical flops, which may affect Flash content, are triple-voted for safety application.

35.1.3 Modes of operation

The Flash Memory module supports the following modes of operation:

- Reset: the Flash Memory module initializes when the reset is deasserted.
- Power-down (Disable mode): the Flash Memory module removes all static consumption. The embedded Flash memory (array and registers) is not accessible to Read, Program or Erase once disabled. The wake-up time from Disable mode is longer than the wake-up time from Sleep mode.
- Low-power mode (Sleep mode): the Flash Memory module removes most of the static consumption. It is not accessible to Read, Program or Erase once disabled, however it does maintain a faster exit to Read mode with respect to Power-Down.
- Read mode: the Flash Memory module accepts Read accesses to the array.
- Modify mode: it is possible to read and write registers, Interlock Write the memory array, program the memory array, and erase the memory array. Program and Erase operations are initiated by performing array and register writes, and controlled by an internal state machine. Program/Erase operations or User Test modes (Margin Read or Array Integrity Check) are considered Main Modify modes.
- Read-While-Write: The Flash Memory module accepts Read accesses to array partitions that are not in Modify mode.
- Alternate Modify mode: blocks in LOW and MID space could be assigned to Alternate interface, though which it is possible to read and write registers, Interlock Write the assigned memory array, program the assigned memory array, and erase the assigned memory array. Program and Erase operations are initiated by performing array and alternate register writes, and are controlled by the same internal state machine as in Main. Alternate Program/Erase operations are considered Alternate Modify modes. Alternate Modify modes operates concurrently to Main ones and, although functionally independent, timing can be mutually influenced.

Such modes of operation are described in detail in *Section 35.4: Functional description*.

35.2 Flash memory map and description

The Flash Memory module block subdivision also facilitates independent Erase and Program protection. A software mechanism is provided to independently lock and unlock each block in Low, Mid, High and Data address spaces against program and erase.

35.2.1 Flash array memory map

35.2.1.1 Code Flash

Partition 0 accounts for 2192 KB of the total Flash Memory and is divided in 14 user blocks for code storage.

The sectorization of partition 0 of the Flash Memory is shown in *Table 402*.

Table 402. Flash memory partition 0 memory map

Block	Addresses	Size	Address space	LOCK	SEL
B0F0	0x00FC_0000 to 0x00FC_3FFF	16 KB	Low	LOWLOCK[1]	LOWSEL[1]
B0F1	0x00FC_4000 to 0x00FC_7FFF	16 KB	Low	LOWLOCK[2]	LOWSEL[2]
B0F2	0x00FC_8000 to 0x00FC_FFFF	32 KB	Low	LOWLOCK[4]	LOWSEL[4]
B0F3	0x00FD_0000 to 0x00FD_7FFF	32 KB	Low	LOWLOCK[5]	LOWSEL[5]
B0F4	0x00FD_8000 to 0x00FD_FFFF	32 KB	Low	LOWLOCK[6]	LOWSEL[6]
B0F5	0x00FE_0000 to 0x00FF_FFFF	128 KB	256K	A256KLOCK[0]	A256KSEL[0]
B0F6	0x0100_0000 to 0x0103_FFFF	256 KB	256K	A256KLOCK[1]	A256KSEL[1]
B0F7	0x0104_0000 to 0x0107_FFFF	256 KB	256K	A256KLOCK[2]	A256KSEL[2]
B0F8	0x0108_0000 to 0x010B_FFFF	256 KB	256K	A256KLOCK[3]	A256KSEL[3]
B0F9	0x010C_0000 to 0x010F_FFFF	256 KB	256K	A256KLOCK[4]	A256KSEL[4]
B0F10	0x0110_0000 to 0x0113_FFFF	256 KB	256K	A256KLOCK[5]	A256KSEL[5]
B0F11	0x0114_0000 to 0x0117_FFFF	256 KB	256K	A256KLOCK[6]	A256KSEL[6]
B0F12	0x0118_0000 to 0x011B_FFFF	256 KB	256K	A256KLOCK[7]	A256KSEL[7]
B0F13	0x0060_C000 to 0x0060_FFFF	16 KB	Low	LOWLOCK[3]	LOWSEL[3]
B0F14	0x0040_0000 to 0x0040_3FFF	128 KB	Low	LOWLOCK[7]	LOWSEL[7]
B0UT	0x0040_0000 to 0x0040_3FFF	16 KB	Low	TSLOCK	—
B0BF	0x0040_4000 to 0x0040_7FFF	16 KB	Low	LOWLOCK[0]	—

35.2.1.2 Data Flash

Data Flash is allocated in partition 1 of the Flash Memory as 4 × 16 KB blocks destined for data storage.

The Data Flash sectorization of the Flash Memory module is listed below.

Table 403. Flash Memory EEPROM DATA Partition 1 memory map

Block	Addresses	Size	Address Space	LOCK	SEL
D0_00	0x0080_0000 to 0x0080_3FFF	16 KB	High	HIGHLOCK[0]	HIGHSEL[0]
D0_01	0x0080_4000 to 0x0080_7FFF	16 KB	High	HIGHLOCK[1]	HIGHSEL[1]
D0_02	0x0080_8000 to 0x0080_BFFF	16 KB	High	HIGHLOCK[2]	HIGHSEL[2]
D0_03	0x0080_C000 to 0x0080_FFFF	16 KB	High	HIGHLOCK[3]	HIGHSEL[3]

HSM Data Flash is allocated in partition 1 and is composed by 2 x 16 KB blocks. The HSM Data Flash sectorization is listed below.

Table 404. Flash Memory HSM EEPROM Data Partition 1 memory map

Block	Addresses	Size	Address Space	LOCK	SEL
H0_00	0x0068_0000 to 0x0068_3FFF	16 KB	Mid	MIDLOCK[0]	MIDSEL[0]
H0_01	0x0068_4000 to 0x0068_7FFF	16 KB	Mid	MIDLOCK[1]	MIDSEL[1]

35.2.1.3 UTEST block memory map

The UTEST block is programmed and read independently of the other blocks. UTEST is included to support systems which require nonvolatile memory for security and to store system initialization information.

The usage of reserved UTEST block is detailed in *Table 405*.

Table 405. UTEST block memory map

Address Offset	Description	Size	Access
UTEST (Base Address 0x0040_0000 to 0x0040_3FFF)			
0x0000	Reserved	32 bytes	R
0x0020	Factory Erase Diary Location	16 bytes	R/P
0x0030	Test Mode Disable Override Passcode	16 bytes	R/P
0x0040	Test Mode Disable Seal	16 bytes	R/P
0x0050	Test Mode Disable Group A	16 bytes	R/P
0x0060	Test Mode Disable Group B	16 bytes	R/P
0x00A0	UID	32 bytes	R
0x00C0	SW-DCF Start address	16 bytes	R
0x00D0	Reserved	48 bytes	R
0x0100	Password to enable the Flash Test Mode when in FA	32 bytes	R
0x0120	JTAG Password	32 bytes	R/P
0x0140(1)	PASS password - Group 0	32 bytes	R/P
0x0160	PASS password - Group 1	32 bytes	R/P
0x0180	PASS password - Group 2	32 bytes	R/P
0x01A0	PASS password - Group 3	32 bytes	R/P
0x01C0	Reserved	32 bytes	R/P
0x01E0	Life Cycle slot 0 - ST Production	32 bytes	R/P
0x0200	Life Cycle slot 1 - Customer Delivery	32 bytes	R/P
0x0220	Life Cycle slot 2 - OEM Production	32 bytes	R/P
0x0240	Life Cycle slot 3 - In Field	32 bytes	R/P
0x0260	Life Cycle slot 4 - Failure Analysis	32 bytes	R/P
0x0280	Customer Single Bit Correction area	32 bytes	R
0x02A0	Customer Double Bit Correction area	32 bytes	R

Table 405. UTEST block memory map (continued)

Address Offset	Description	Size	Access
0x02C0	Customer Triple Bit Detection area	32 bytes	R
0x02E0	Customer Programmable Detection Area	32 bytes	R
0x0300	DCF Records	3328 bytes	R/P
0x1000	Customer OTP data	12288 bytes	R/P

1. The offset 0x140 contains the least significant 32-bit of the PASS password - Group 0. The offset 0x15C contains the most significant 32-bit of the PASS password - Group 0. The same endianess also applies to the other groups of the PASS password.

UTEST block supports RWW, and is grouped with the Code Flash in partition 0.

Programming of any section of the UTEST block is subject to similar restrictions as the array in terms of how ECC is calculated. Only one program is allowed per 128-bit ECC segment.

The UTEST Nonvolatile Memory section is OTP and erase is not allowed. User mode programming of the UTEST section is enabled only when MCR.PEAS is high. The UTEST section is divided into a *Flexible* area where content is managed at System level, and a *Reserved* area where addresses are pre-allocated for storing certain content. The UTEST section may be locked and unlocked against programming via LOCK0.TSLOCK in conjunction with the relative sideband (System specific). For locking purposes, UTEST is treated as a stand-alone block. UTEST access (both Read and Modify) is disabled in Test mode once the Test Mode Disable Seal password is written. Test Flash logical block gets also protected by the Test Mode Disable Seal.

The UTEST section is also set as OPP once the Test Mode Disable Seal password is written, thus programming is only allowed on virgin 128-bit locations.

35.3 Register memory maps and descriptions

In this section some nonvolatile registers are described as well as the usual volatile registers. Note that such entities are not Flip-Flops, but Test Flash block locations with a specific purpose.

During the Flash Initialization phase, the FPEC reads these nonvolatile registers and updates their corresponding volatile registers. When the FPEC detects ECC uncorrectable errors in these special locations, it behaves in the following way:

- In the case of failing system locations (configurations, redundancy, EmbAlgo firmware), the initialization phase is interrupted and a Fatal Error is flagged.
- In the case of failing coherency checks, the volatile registers are filled with ‘1’s and the Flash Initialization ends setting MCR.RE.

35.3.1 Register memory maps

This section presents the memory mapping of all the Flash memory registers.

35.3.1.1 User register memory maps

The Flash User registers represent the communication interface between the host CPU and the FPEC.

Some register bits (command bits) are Read/Write for the CPU and read only for the FPEC. Other register bits (status bits) are Read/Write for the FPEC and read only for the CPU.

The Flash User Registers mapping is shown in *Table 406*.

Table 406. Flash user registers memory map

Address offset	Description	Location
0x0000	Module Configuration Register (MCR)	*Section 35.3.2.1*
0x0004	Alternate Module Configuration Register (MCRA)	*Section 35.3.2.2*
0x0008	Extended Module Configuration Register (MCRE)	*Section 35.3.2.3*
0x000C–0x000F	Reserved

35.3.2 User register descriptions

This section consists of user register descriptions in address order.

35.3.2.1 Module Configuration Register (MCR)

The Module Configuration Register is used to enable and monitor all the Modify operations of the Flash Memory module and to monitor the Read operations.

Address: 0x0000 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 318. Module Configuration Register (MCR)

Table 407. MCR field descriptions

Field	Description
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the analog Read references. If the current and voltage Read references are out of range, this bit is set to signify that previous reads requested may have been corrupted. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A Read Reference Error occurred during a previous Read.
2 AEE	Address Encode Error On every Read request to the Flash, the incoming address is compared to an encoded address (row, column, and block) from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error is recorded. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An Address Encode Error occurred during a previous Read.
3 EEE	EDC after ECC Error EEE provides information on previous reads monitoring the EDC after ECC feature. On every Read request to the Flash, ECC parity is recomputed (encoding) just after ECC decoding, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error is reported. The EEE flag indicates this event when data is legal or containing up to 3 bit errors. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A previous Read may have been decoded by an ECC logic corrupted.
4:7 DWEE	Double Word Uncorrectable ECC Error DWEE identifies which Double Word is involved in ECC Uncorrectable Error Event. In Code Flash 4 Double Words are read in parallel and ECC is evaluated on a couple of Double Words basis. Therefore DWEE value could be: 1111 if an ECC Uncorrectable Error is found in both couples of Double Words 1100 if an ECC Uncorrectable Error is found in the couple of Double Words at high address 0011 if an ECC Uncorrectable Error is found in the couple of Double Words at low address 0000 if no ECC Uncorrectable Error is found In Data Flash 2 Double Words are read in parallel and ECC is evaluated on a single Double Word basis. Therefore DWEE value could be: 1111 if an ECC Uncorrectable Error is found in both Double Words 1010 if an ECC Uncorrectable Error is found in Double Word at high address 0101 if an ECC Uncorrectable Error is found in Double Word at low address 0000 if no ECC Uncorrectable Error is found DWEE is a read only. Flags bits get cleared when EER is cleared.

Table 407. MCR field descriptions (continued)

Field	Description
11 SBC1	Single Bit Correction 1 SBC1 provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection or ECC Double Error correction, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE1). 0 Reads are occurring normally. 1 An ECC Single Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.
12 SAK	Suspend Acknowledge SAK provides information about the Acknowledge of a suspend request at the setting of DONE: SAK qualifies if the suspend has been accepted (initiated by PSUS or ESUS setting) or if the running command has been completed, since very close to natural end. The aim of this bit is for monitor. The sequence to resume normal functionality (PSUS or ESUS clearing) is the same both is suspend has been acknowledged or not. SAK is read Only 0 Operation has been completed prior that Suspend got processed 1 Suspend Acknowledged
13 LSW	Lock-Sel Write Error LSW provides information about Lock and Sel write denied during the program and erase sequence. If LSW is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Lock and Sel write successful 1 Lock and Sel write not succeeded
14 PEP	Program and Erase Protection Error PEP provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a Locked block, or if an erase is selected to a locked block. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations will not be attempted for this request. If PEP is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program and Erase protection errors do not exist 1 Previous program or erase protection error encountered

Table 407. MCR field descriptions (continued)

Field	Description
15 PES	Program Erase Sequence Error PES provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an out-of-order event is detected, PES will assert, and the remainder of the sequence will not be accepted. Sequence errors are checked from the time the PGM or ERS are set (or remains set from previous operation) until EHV is set. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program or Erase phase accepted 1 Program or Erase command encountered an error
16 EER	ECC uncorrectable Event Error EER provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. EER may not be set to ‘1’ by the user. EER is not set for a ECC correctable Error detection and related correction event. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An ECC uncorrectable Error occurred during a previous Read. In Code Flash, with 128b ECC coding, ECC error is evaluated on couple of Double word basis. In Data Flash for EEE, ECC error is evaluated on each Double word.
17 RWE	Read-while-Write event Error RWE provides information on previous Reads during a Modify operation. Read-While-Write Error means that a Read access to the Flash Array partition has occurred while the FPEC was performing a Program or Erase operation or an Array Integrity Check on the same partition. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A RWW Error occurred during a previous Read.
18 SBC	double Bit Correction SBC provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of an ECC Triple Error detection, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0.SBCE). 0 Reads are occurring normally. 1 An ECC Double Error occurred and was corrected during a previous Read. In Code Flash, with 128b ECC coding, ECC correction is evaluated on couple of Double word basis. In Data Flash for EEE, ECC correction is evaluated on each Double word.

Table 407. MCR field descriptions (continued)

Field	Description
19 RE	Reset Error This bit provides information on previous resets. Checks are done within the Flash, and if a coherency issue or ECC error is detected during the reset reads used for trimming on the Flash, this status flag will assert. This bit is status only, and is not writable. 0 Flash Boot phase has occurred normally. 1 A reset error has been encountered.
20 PEAS	Program/Erase Access Space PEAS is used to indicate which space is valid for Program and Erase operations: main array space or UTEST section within Test Flash block. – PEAS is captured and held with the first Interlock Write done for Modify operations. – PEAS is retained between sampling events (that is subsequent to first interlock writes). – PEAS is changed during erase-suspended program (when program is in UTEST) and reverts back to its original state (related to erase suspended operation) once the erase-suspended program is completed (at MCR.PGM 1-0 transition). 0 UTEST address space is disabled for program and main address space enabled. 1 UTEST address space is enabled for program and main address space disabled.
21 DONE	Modify operation DONE DONE indicates if the Flash Memory module is performing a high voltage operation. DONE is set to ‘1’: – On termination of the Flash Memory module reset. – At the end of program and Erase High Voltage sequences. – After “1-0” transition of EHV, which aborts a high voltage Erase/Program operation (within a time equal or below to t_{ESUS}/t_{PSUS} that are Erase/Program Suspend Latency). – After “0-1” transition of ESUS/PSUS which suspends an Erase/Program operation (within t_{ESUS}/t_{PSUS} time equal to the Erase/Program Suspend Latency). DONE is cleared to ‘0’: – just after “0-1” transition of EHV, which initiates a high voltage operation, or after resuming a suspended operation. 0 Flash is executing a high voltage operation. 1 Flash is not executing a high voltage operation.

Table 407. MCR field descriptions (continued)

Field	Description
22 PEG	Program/Erase Good PEG is automatically updated to show the completion status of the last Flash Program or Erase sequence involving high voltage operations. PEG is evaluated on the completion status of only the interlocked doubleword during page program or quad-page programming where some doubleword addresses are not interlocked (already programmed or intended to remain virgin). PEG is set to ‘0’ after Aborting a Program/Erase high voltage operation, indicating sequence failure. PEG is set to ‘1’ when the Flash Memory module is reset, unless a Flash Initialization error has been detected. **Note:** PEG is valid only when PGM=1 or ERS=1, or both, and after DONE 0-1 transitions due to an Abort or the completion of a Program/Erase operation. PEG remains valid until PGM/ERS 1-0 transitions or EHV 0-1 transitions. PEG is not valid after DONE 0-1 transitions when ESUS/PSUS is set to logic ‘1’. If Program or Erase is attempted on blocks that are locked, PEG=1 indicating that the content of the block were properly protected from the Program or Erase operation. Blocks can be locked through LOCK0/1/2/3 registers OR with flh_plock0/1/2/3 sideband signals. If a Program operation tries to write ‘1’ to bits that are ‘0’, the program operation is correctly executed on the new bits to be programmed at ‘0’, but PEG is cleared indicating that the requested operation has failed. If Programming during an Erase-Suspend a location that was under suspended erase, program is not executed and PEG is set to ‘0’. With end2end ECC scheme, during an Interlock Write also ECC parity bits are input. After setting EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, in the page program or in the quad-page program, contains an inconsistency between data and parity, the whole operation is rejected and a PEG=0 is set. PEG behavior with blocks marked as OPP (though flh_otpen0/1/2/3 sideband signals) is the following: PEG=0 if the location to be programmed is not virgin, and thus would not be over programmed. In Array Integrity Check or Margin Read PEG is not altered when the operation is completed, regardless of the occurrence of any error, abort, break point or suspend. The presence of errors can only be detected by comparing the checksum value stored in UM0-9 and by checking the MCR flags. 0 Program, Erase operation failed or Program, Erase aborted. 1 Program or Erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag. 0 An interrupt request is not generated when the DONE flag is set. 1 An interrupt request is generated when the DONE flag is set.

Table 407. MCR field descriptions (continued)

Field	Description
24 FERS	Factory Mode FERS is used for Erase and Program operations to enable a faster operation. Factory Mode must adhere to *Initial maximum (All Temperatures)* conditions, with respect to voltage conditions and Write/Erase cycling. The temperature can range from -40 °C to 150 °C. Factory Mode does not support Read and RWW operations. – FERS may be set to enable a Factory Erase or Program after setting ERS or PGM but prior to setting EHV. – FERS can be cleared only when EHV is low and DONE is high. – FERS is cleared on reset **Note:** Factory Mode may be permanently disabled by writing a location in the UTEST Nonvolatile Memory space. Offset 0x0020 in the UTEST Nonvolatile Memory space is checked at reset, and if programmed with data that contains at least one zero, a Factory Mode is not allowed, and FERS is locked. Writes attempted that violate the above cases result in FERS remaining cleared. 0 Factory Mode is disabled. 1 Factory Mode is enabled.
27 PGM	Program PGM is used to setup the Flash Memory module for a Program operation. – “0-1” transition of PGM initiates a program sequence. – “1-0” transition of PGM ends the program sequence. PGM can only be set in the following conditions: – User Mode Read (ERS is low and UT0.UTE is low); – Erase Suspend (ERS and ESUS high) with EHV low. PGM can only be cleared by the user when PSUS and EHV are low and DONE is high. PGM is cleared on reset. **Note:** In an erase-suspended program, programming Flash memory locations in blocks which were being operated on in the Erase is forbidden. Command is not accepted and PEG is set to ‘0’ 0 Flash is not executing a program sequence. 1 Flash is executing a program sequence.

Table 407. MCR field descriptions (continued)

Field	Description
28 PSUS	Program Suspend PSUS is used to indicate that the Flash Memory module is in Program Suspend or in the process of entering a Suspend state. The Flash Memory module is in Program Suspend when PSUS=1 and DONE=1. – PSUS can be set high only when PGM and EHV are high. – "0-1" transition of PSUS starts the sequence which sets DONE and places the Flash in Program Suspend. The Flash Memory module enters Suspend within t_{PSUS} of this transition. – PSUS can be cleared only when DONE and EHV are high. – "1-0" transition of PSUS with EHV=1 starts the sequence which clears DONE and returns the module to Program. The Flash Memory module cannot exit Program Suspend and clear DONE while EHV is low. In the case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), PSUS has to be cleared first in order to resume currently higher level suspended operation that is program. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERS	Erase ERS is used to setup the Flash Memory module for an Erase operation. – "0-1" transition of ERS initiates an Erase sequence. – "1-0" transition of ERS ends the Erase sequence. ERS can be set only under User Mode Read (PGM is low and UT0.UTE is low). ERS can be cleared by the user only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash is not executing an Erase sequence. 1 Flash is executing an Erase sequence.

Table 407. MCR field descriptions (continued)

Field	Description
30 ESUS	Erase Suspend ESUS is used to indicate that the Flash Memory module is in Erase Suspend or in the process of entering a Suspend state. The Flash Memory module is in Erase Suspend when ESUS = 1 and DONE=1. – ESUS can be set high only when ERS and EHV are high and PGM is low. – “0-1” transition of ESUS starts the sequence which sets DONE and places the Flash in Erase Suspend. The Flash Memory module enters Suspend within t_{ESUS} of this transition. – ESUS can be cleared only when DONE and EHV are high and PGM is low. – “1-0” transition of ESUS with EHV=1 starts the sequence which clears DONE and returns the module to Erase. The Flash Memory module cannot exit Erase Suspend and clear DONE while EHV is low. In case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), ESUS cannot be cleared first. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.

Table 407. MCR field descriptions (continued)

Field	Description
31 EHV	Enable High Voltage The EHV bit enables the Flash Memory module for a high voltage Program/Erase operation. EHV is cleared on reset. EHV must be set after an Interlock Write to start a Program/Erase sequence. EHV may be set under one of the following conditions: – Erase (ERS=1, ESUS=0, UT0.AIE=0) – Program (ERS=0, ESUS=0, PGM=1, UT0.AIE=0) – Erase-suspended program (ERS=1, ESUS=1, PGM=1, PSUS=0, UT0.AIE=0). For a program operation to initiate while an Erase is suspended, EHV must be cleared while in Erase-Suspend (after DONE transitions to 1) before setting PGM. In normal operation, a “1-0” transition of EHV with DONE high, PSUS low and ESUS low terminates the current Program/Erase high voltage operation. In an erase-suspended program operation, a “1-0” transition of EHV with DONE, ESUS, PGM and ERS high and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a “1-0” transition of EHV with DONE low and the eventual Suspend bit for the current program/erase operation low. An Abort causes the value of PEG to be cleared, indicating failed Program/Erase. Address locations being operated on by the aborted operation contain indeterminate data after an Abort. EHV cannot be set to ‘1’ after an Abort request (EHV being cleared) until the Abort sequence is completed (DONE transitions to 1). Once the Abort sequence is completed (DONE=1) a new operation of the kind aborted can start provided that a new interlock is given and then EHV is set to ‘1’ again. A suspended operation cannot be aborted. Aborting a high voltage operation leaves the Flash Memory module addresses in an indeterminate data state. This may be recovered by executing an Erase on the affected blocks. EHV may be written during Suspend. EHV must be high to exit Suspend, resuming previously suspended command. EHV cannot not be written during transition into Suspend state (after Suspend bit (ESUS or PSUS) is set high) until DONE transitions to ‘1’. EHV may not be written after ESUS is set and before DONE transitions high. EHV may not be cleared after ESUS is cleared and before DONE transitions low. 0 Flash is not enabled to perform a high voltage operation. 1 Flash is enabled to perform a high voltage operation.

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

The Flash Memory module does not allow the user to write bits simultaneously (which puts the device into an illegal state). This is implemented through a priority mechanism among the bits shown in *Table 408*.

Table 408. MCR Bits Set/Clear Priority Levels

Priority level	MCR bits
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If the user attempts to write two or more MCR bits simultaneously then only the bit with the lowest priority level is written.

35.3.2.2 Alternate Module Configuration Register (MCRA)

The Alternate Module Configuration Register is used to enable and monitor all the Modify operations of the Flash Memory module managed through Alternate interface.

Address: 0x0004 Access: User Read/Write

Reset	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0

Figure 319. Alternate Module Configuration Register (MCRA)

Table 409. MCRA field descriptions

Field	Description
12 SAKA	Alternate Suspend Acknowledge SAKA provides information about the Acknowledge of a suspend request at the setting of DONEa: SAKA qualifies if the suspend has been accepted (initiated by PSUSa or ESUSa setting) or if the running command has been completed, since very close to natural end. The aim of this bit is for monitor. The sequence to resume normal functionality (PSUSa or ESUSa clearing) is the same both is suspend has been acknowledged or not. SAKA is read Only 0 Operation has been completed prior that Suspend got processed. 1 Suspend Acknowledged
13 LSWA	Alternate Lock Write Error LSWA provides information about Lock write denied during the program and erase sequence. If LSWA is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Lock and Sel write successful. 1 Lock and Sel write not succeeded.
14 PEPA	Alternate Program and Erase Protection Error PEPA provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a Locked block, or if an erase is selected to a locked block. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations will not be attempted for this request. If PEPA is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program and Erase protection errors do not exist. 1 Previous program or erase protection error encountered.
15 PESA	Alternate Program Erase Sequence Error PESA provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an out-of-order event is detected, PESA will assert, and the remainder of the sequence will not be accepted. Sequence errors are checked from the time the PGMA or ERSA are set (or remains set from previous operation) until EHVA is set. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Program or Erase phase accepted 1 Program or Erase command encountered an error
20 PEASA	Program/Erase Access Space PEASA is used to indicate which space is valid for Program and Erase operations: main array space or UTEST block. It should be noted that erase is not allowed to the UTest NVM space, therefore If an interlock write is done to the UTest NVM space with ERSA set, PEASA will remain 0. See PEAS definition in the MCR register for more information(*Table 407*).
21 DONEA	Modify operation DONE DONEA indicates if the embedded Flash memory is performing a high-voltage operation for the Alternate program and erase interface. See DONE definition in the MCR register for more information (*Table 407*).

Table 409. MCRA field descriptions (continued)

Field	Description
22 PEGA	Program/Erase Good The PEGA bit indicates the completion status of the last Flash memory program or erase sequence for which high-voltage operations were initiated for the Alternate program and erase interface. See PEG definition in the MCR register for more information (*Table 407*). It should be noted that in the event of a error on the alternate interface PEGA will clear, but the ADR register will not be updated with the failing location. The ADR register is only valid for main interface program or erase fails, and other fails noted in the ADR register.
27 PGMA	Program PGMA is used to set up embedded Flash memory for a program operation for the Alternate program and erase interface. See PGM definition in the MCR register for more information (*Table 407*).
28 PSUSA	Program Suspend PSUSA is used to indicate the embedded Flash memory is in program suspend or in the process of entering a suspend state for the Alternate program and erase interface. See PSUS definition in the MCR register for more information (*Table 407*).
29 ERSA	Erase ERSA is used to set up embedded Flash memory for an erase operation for the Alternate program and erase interface. See ERS definition in the MCR register for more information (*Table 407*).
30 ESUSA	Erase Suspend ESUSA is used to indicate that the embedded Flash memory is in erase suspend or in the process of entering a suspend state for the Alternate program and erase interface. See ESUS definition in the MCR register for more information (*Table 407*).
31 EHVA	Enable High Voltage The EHVA bit enables the embedded Flash memory for a high-voltage program/erase operation for the Alternate program and erase interface. See EHV definition in the MCR register for more information (*Table 407*).

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

35.3.2.3 Extended Module Configuration Register (MCRE)

The Extended Module Configuration Register value is based on the size, blocks and address space configuration of the Flash Memory module.

Field	Description
24:26 N64KL	Number of 64 KB blocks in low space N64KL is read only. 000 Zero 64 KB block. 001 Two 64 KB blocks. 010 Four 64 KB blocks. 011 Six 64 KB blocks. 100 Eight 64 KB blocks. 101 Three 64 KB blocks + One 96KB block. 110 Reserved. 111 Reserved.
27:28 N32KL	Number of 32 KB blocks in low space N32KL is read only. 00 Zero 32 KB block. 01 Two 32 KB blocks. 10 One 32 KB block. 11 Three 32 KB blocks.
29:31 N16KL	Number of 16 KB blocks in low space N16KL is read only. 000 Zero 16 KB block. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Eight 16 KB blocks. 101 Three 16 KB blocks. 110 Five 16 KB blocks. 111 Reserved.

35.3.2.4 Lock 0 register (LOCK0)

The LOCK0 (Low/Mid Address Space Block Locking) register provides a means of protecting blocks from being modified. LOWLOCK and MIDLOCK bits corresponding to non existent blocks are read as ‘1’.

To determine the effective status of the Low/Mid Address Space, combine (Or) LOCK0 with sidebands:

- flh_plock0 – in order to evaluate protection against programming.
- flh_elock0 – in order to evaluate protection against erase.

The effect of programming or erasing a block protected with LOCK0 is that no modification occurs and PEG is set to ‘1’.

Address: 0x0010 Access: User Read/Write

Figure 321. Lock 0 register (LOCK0)

Table 411. LOCK0 field descriptions

Field	Description
0 TSLOCK	UTEST NVM block lock This bit is used to lock the UTEST NVM from programming (UTEST NVM is not erasable). The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0.TSLOCK with sidebands *flh_plock0.31* in order to evaluate protection against program. 0 Test Address Space Block is unlocked and can be modified. 1 Test Address Space Block is locked and cannot be modified.

Table 411. LOCK0 field descriptions (continued)

Field	Description
2:15 LOWLOCK	Low address space block lock These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the LOWLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the LOWLOCK bits default to locked and are not writable. The reset value is always '1' and register writes have no effect. 0 Low Address Space Block is unlocked and can be modified. 1 Low Address Space Block is locked and cannot be modified.
16:31 MIDLOCK	Mid address space block lock These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the MIDLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the MIDLOCK bits default to locked, and are not writable. The reset value is always '1' and register writes have no effect. 0 Mid Address Space Block is unlocked and can be modified. 1 Mid Address Space Block is locked and cannot be modified.

35.3.2.5 Lock 1 register (LOCK1)

The LOCK1 (High/Data Address Space Block Locking) register provides a means of protecting blocks from being modified. HIGHLOCK bits corresponding to nonexistent blocks on are read as ‘1’.

- To determine the effective status of the High Address Space, combine (Or) LOCK1 with sidebandsflh_plock1 – in order to evaluate protection against program
- flh_elock1 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK1 is that no modification occurs and PEG is set to ‘1’.

Table 412. LOCK1 field descriptions

Field	Description
16:31 HIGHLOCK	High address space block lock These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR.DONE is set and MCR.EHV gets cleared. – If a high voltage operation is suspended. The default value of the HIGHLOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

35.3.2.6 Lock 2 Register (LOCK2)

The LOCK2 (256K Address Space Block Locking) register provides a means of protecting blocks from being modified. The A256KLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the A256KLOCK Address Space, combine (Or) LOCK2 with sidebands:

- flh_plock2 – in order to evaluate protection against program
- flh_elock2 – in order to evaluate protection against erase

The effect of programming/erasing a block protected with LOCK2 is that no modification occurs and PEG is set to ‘1’.

The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0A.TSLOCKA with sidebands *flh_aplock_utest* in order to evaluate protection against program. 0 The UTEST Block is unlocked and can be modified on the alternate interface. 1 The UTEST Block is locked and cannot be modified on the alternate interface.

Table 415. LOCK0A field descriptions (continued)

Field	Description
2:15 LOWLOCKA	Alternate Low address space block lock These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the LOWLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the LOWLOCKA bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Alternate Low Address Space Block is unlocked and can be modified. 1 Alternate Low Address Space Block is locked and cannot be modified.
16:31 MIDLOCKA	Alternate Mid address space block lock These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the MIDLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). In the event that blocks are not present (due to configuration or total memory size), the MIDLOCKA bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Alternate Mid Address Space Block is unlocked and can be modified. 1 Alternate Mid Address Space Block is locked and cannot be modified.

35.3.2.9 Alternate Lock 1 register (LOCK1A)

The Alternate LOCK1A (Alternate High Address Space Block Locking) register provides a means of protecting blocks from being modified on the alternate program and erase interface. HIGHLOCK bits corresponding to nonexistent blocks on are read as ‘1’.

The effect of programming/erasing a block protected with LOCK1a is that no modification occurs and PEGa is set to ‘1’.

Field	Description
16:31 HIGHLOCKA	Alternate High address space block lock These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCKA[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until DONEA is set and MCR.EHVA gets cleared. – If a high voltage operation is suspended. The default value of the HIGHLOCKA bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writable. This enables blocks to be present in only one program and erase space (main or alternate). When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

35.3.2.10 Select 0 register (SEL0)

The SEL0 (Low/Mid Address Space Block Select 0) register provides a means to select blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL0 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 35.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL0 at the start of the Erase operation) while writing has no effect.

This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared. – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size) the corresponding HIGHSEL bits default to unselected and are not writable. The reset value is always '0' and register writes have no effect. 0 High Address Space Block is unselected for Erase. 1 High Address Space Block is selected for Erase.

35.3.2.12 Select 2 register (SEL2)

The SEL2 (256K Address Space Block Select 2) register provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL2 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 35.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL2 at the start of the Erase operation) while writing has no effect.

Address: 0x0040 Access: User Read/Write

Figure 329. Select 2 register (SEL2)

Table 419. SEL2 field descriptions

Field	Description
0:31 A256KSEL	256K address space block select A256KSEL[31:0] The block numbering for the 256 KB blocks starts with A256KSEL[0] and continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size) the corresponding A256KSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 A256K Address Space Block is unselected for Erase. 1 A256K Address Space Block is selected for Erase.

35.3.2.13 Select 3 register (SEL3)

The SEL3 (256K Address Space Block Select 3) register provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL3 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR.ERS (see step 4 in *Section 35.4.5.2: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR.EHV with MCR.ERS=1 and with MCR.ESUS=0). Reading returns latched data (image of the SEL3 at the start of the Erase operation) while writing has no effect.

0:31 A256KSEL	256K address space block select A256KSEL[63:32] The block numbering for the 256 KB blocks starts with A256KSEL[32] and continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared – a high voltage operation is suspended. – when UT0.AIE is high. When blocks are not present (due to configuration or total memory size) the corresponding A256KSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 A256K Address Space Block is unselected for Erase. 1 A256K Address Space Block is selected for Erase.

35.3.2.14 Program Address register (PAR)

The Program Address register provides the last successful address programmed. A successful program is defined as a program operation of data that is not all 1s, to an unlocked block and the operation results in MCR.PEG returning a ‘1’. This value is held until the next successful address program event.

Figure 331. Program Address register (PAR)

Table 421. PAR field descriptions

Field	Description
8:28 PAR	Address The Address Register provides the last successful address programmed through the Main Interface. Address given is in Flash format and has to be intended as in the Flash memory Map: offset respect to absolute address. Mapping can be found in *Section 35.3.2.15: Address register (ADR)*

35.3.2.15 Address register (ADR)

The Address register provides the first failing address in the event of module failures (ECC, RWW or FPEC). ADR captures the first failing address for the modes listed in *Table 423* according to the priority rules in *Table 424*.

In case of Array Integrity Check or Margin Read with Break Point enabled (UT0.AIBPE=1), the ADR value matches the address where the Break Point was triggered only when the current run (first start or re-start after a breakpoint (NAIBP cleared)) starts with MCR.ERR and MCR.SBC flags cleared, otherwise the ADR priority rule overrides Break Point.

Figure 332. Address register (ADR)

Table 422. ADR field descriptions

Field	Description
0 SAD	Test Address When this bit is high, the address indicated by ADDR[23:3] belongs to the Test Block.
8:28 ADDR	Address The Address Register provides the first failing address in the event of ECC Uncorrectable error (MCR.EER set) or the first failing address in the event of RWW error (MCR.RWE set), or the address of a failure that may have occurred in a FPEC operation (MCR.PEG cleared). The Address Register also provides the first address at which a ECC correction occurs (MCR.SBC or MCR.SBC1, or both are set) if the SoC is configured to show this feature through UT0.SBCE or UT0.SBCE1, or both. The ECC uncorrectable error detection takes the highest priority, followed by the RWW error, the FPEC error and the ECC error corrections. When accessed, ADR provides the address related to the first event occurred with the highest priority. In case of a simultaneous ECC Events Detection, bits ADDR[4] and ADDR[3] output ‘0’. In User mode the Address Register is read only. Address given is in Flash format and has to be intended as in the Flash memory Map.

Table 423. ADR update mode list

Mode	Update on error	Note
Read	ECC Uncorrectable Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	—
Modify	FPEC error	—
RWW	Read-While-Write error	In RWW all Read and Modify cause of update on error may also occur
User Test	ECC Uncorrectable Error Detection, ECC Double Error Correction (if UT0.SBCE=1) ECC Single Error Correction (if UT0.SBCE1=1)	With Break Point enabled (UT0.AIBPE=1), ADR requires MCR.ERR and MCR.SBC to be cleared

Table 424. ADR content: priority list

Priority level	Error flag	ADR content
1	MCR.EER = 1	Address of first ECC Uncorrectable Error
2	MCR.RWE = 1	Address of first RWW Error
3	MCR.PEG = 0	Address of first FPEC Error
4	MCR.SBC = 1	Address of first ECC Double Error Correction
5	MCR.SBC1 = 1	Address of first ECC Single Error Correction

35.3.2.16 User Test 0 register (UT0)

The User Test 0 register feature gives the user of the Flash Memory module the ability to perform test features on the Flash.

The User Test 0 register allows control of the way the Flash content check is performed. Bits MRE, MRV and AIS of the User Test 0 register are not accessible when MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

Address: 0x0054 Access: User Read/Write

Figure 333. User Test 0 register (UT0)

Table 428. UT0 field descriptions

Field	Description
0 UTE	User Test Enable This status bit gives indication when User Test is enabled. All bits in UT0 and UM0–UM9 are locked when this bit is ‘0’. This bit is not writable to a ‘1’, but may be cleared. The reset value is ‘0’. To set UTE, write the password 0xF9F99999 to the UT0 register. The UTE password is only accepted if PGM=0 and ERS=0 (Program and Erase are not being requested). UTE can only be cleared if AID=1, MRE=0 and AIE=0. While clearing UTE, writes to set AIE or MRE are ignored.
1 SBCE	Double Bit Correction Enable This bit, when high, enables to flag the information about any eventual ECC Double Bit Correction in the Flash array (MCR.SBC and ADR). This is true in read mode and in Array Integrity Check. SBCE is also used as an Enable for interrupt signals created by the embedded Flash memory. ECC corrections that occur when SBCE is cleared are not logged.
8 SBCE1	Single Bit Correction Enable This bit, when high, enables to flag the information about any eventual ECC Single Bit Correction in the Flash array (MCR.SBC1 and ADR). This is true in read mode and in Array Integrity Check. SBCE1 is also used as an Enable for interrupt signals created by the embedded Flash memory. ECC corrections that occur when SBCE1 is cleared are not logged.
13 CPR	Customer Programmable Read Voltage and Reference Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set and the Customer Programmable Detection location in UTEST is read, a Read Voltage and Reference Error detection is set. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled.
14 CPA	Customer Programmable Address Encode Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read an Address Encode Error detection is set. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read a EDC after ECC Error detection is set. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled

Table 428. UT0 field descriptions (continued)

Field	Description
19 VTD	Vth Distribution To enable Vth Distribution, VTD may be set. Effective setting of this bit is allowed when SoC has been brought into Failure Analysis Mode. When Vth Distribution is enabled, multiple run are needed to assess the Vth status of the cells belonging to selected blocks. At the end of each run NAIPB has to be checked and if equals to '1' it has to be cleared to start an increased voltage step run. See NAIBP description for more information. 0 Vth Distribution is not enabled. 1 Vth Distribution is enabled.
22 NAIBP	Next Array Integrity Break Point If AIBPE is set, NAIBP is set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to '1' but may be cleared to '0'. Clearing NAIBP to '0' enables the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID is set with NAIBP remaining '0'. If VTD is set, NAIBP is set once a voltage step run has been completed during the voltage sweep in Vth Distribution. NAIBP is not writable to '1' but may be cleared to '0'. Clearing NAIBP to '0' enables the Vth Distribution run yo be re-started with an increased voltage step. If the Vth Distribution completes the last voltage step run, AID is set with NAIBP remaining '0'. 0 Array Integrity-Vth Distribution is not currently at a break point. 1 Array Integrity-Vth Distribution is at a break point.
23 AIBPE	Array Integrity Break Point Enable To enable breakpoints during an Array Integrity test, AIBPE may be set. When breakpoints are enabled, if the run has been started with MCR.ERR (and MCR.SBC when UT0.SBCE=1) flag cleared, on the eventual occurrence of a breakpoint condition, MCR flags and ADR value may be updated. See NAIBP description for more information about Array Integrity breakpoints. 0 Array Integrity breakpoints are not enabled. 1 Array Integrity breakpoints are enabled during Array Integrity Checks.
25 AISUS	Array Integrity Suspend AISUS toggles Suspend of an Array Integrity - Margin Read Operation. AISUS can be written to '1' only when AID is low AISUS can be written to '0' only when AID is high. Attempting to Write AISUS and AIE on the same clock cycle results in only AIE being written. 0 Array Integrity sequence not suspended. 1 Array Integrity sequence is suspended.
26 MRE	Margin Read Enable MRE enables margin reads to be done. MRE combined with MRV enables User Margin mode reads to be done. Margin reads run on a block-by-block basis in linear address sequence selected by SEL0, SEL1 and SEL2. This bit is not accessible when MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Margin Read is not enabled. 1 Margin Read is enabled.

Table 428. UT0 field descriptions (continued)

Field	Description
27 MRV	Margin Read Value If MRE is high, MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). This bit is not accessible whenever MCR.DONE or UT0.AID are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Zero's (programmed) margin reads are requested (if MRE=1). 1 One's (erased) margin reads are requested (if MRE=1).
29 AIS	Array Integrity Sequence AIS determines the address sequence to be used during Array Integrity checks. The default AIS=0 checks the read propagation paths along proprietary sequences followed by user code. The sequential run sequence time is significantly shorter than the proprietary sequence. AIS is not writable if AIE is high. This bit is not accessible whenever MCR.DONE or UT0.AID are low: reading returns indeterminate data while writing has no effect. 0 Array Integrity sequence is proprietary sequence. 1 Array Integrity sequence is sequential.
30 AIE	Array Integrity Enable Setting AIE to '1' starts the Array Integrity Check and the Margin Read on all selected blocks. The sequence is selected by AIS and the MISR (UM0–UM9) is checked on completion to determine if a correct signature is obtained. AIE can be set only if MCR.ERS, MCR.PGM and MCR.EHV are all low. AIE is not simultaneously writable to '1' while UTE is being cleared to '0'. Clearing AIE terminates the check when an Array Integrity operation finishes (AID=1) and aborts the check when and Array Integrity operation is ongoing (AID=0). AIE remains '1' when the Array Integrity Check - Margin read are suspended or are in breakpoint and cannot be cleared. (AIE can be cleared if NAIBP=0 and AISU=0) 0 Array Integrity Check and Margin Read and are not enabled. 1 Array Integrity Check and Margin Read are enabled.
31 AID	Array Integrity Done AID is set to indicate that the Array Integrity Check - Margin Read is complete and the MISR (UM0–9) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set) and the breakpoint condition is met. AID may also assert if Suspend is set (AISUS 0–1). AID can not be written, and is status only. 0 Array Integrity Check is on-going. 1 Array Integrity Check is done.

35.3.2.17 User Multiple Input Signature registers

The Multiple Input Signature registers allow evaluation of the Array Integrity or Margin Read run on a block-by-block basis by accumulating signatures from data bit fields.

These registers are not accessible whenever MCR.DONE or UT0.AID are low. Reading returns indeterminate data while writing has no effect.

The registers can be written in order to seed signatures before starting an AIC or MR operation.

Note: Do not write to the MISR registers during an Array Integrity operation (including Suspend or Breakpoint) as it may alter the final signature in an unpredictable way.

If reads extend into an invalid address location during address sequencing (that is greater than the maximum address for a given array size), reads are still executed to the array but the results are not deterministic: MISR registers are not recalculated and the previous value is retained.

35.3.2.17.1 User Multiple Input Signature 0 register (UM0)

UM0 represents bits 31–0 of the whole 288-bit word (4 doublewords including ECC).

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 348. Test Mode Disable Password Check register (TMD)

Table 443. TMD field descriptions

Field	Description
0:31 PWD	The Test Mode Disable Check register is used as a location to provide a password challenge to unlock blocks selected to be sealed as part of the Test Mode Disable seal mechanism. Please see *Section 35.4.8.2: Test Mode Disable* for more information. Writes to the register have no effect except for a password challenge. Reads to this register will always return 0. The register's reset value is 0. **Note:** PWD bit field is byte-reversed compared to UTEST TMD password: for instance, if UTEST TMD password is written 0x01020304, the PWD bit field must be written 0x04030201

35.3.2.20 HSM Alternate selector registers

HSM Alternate selectors assign blocks from default to ALTERNATE Program & Erase interface. These registers show the HSM Alternate assignment status. See *Section 35.4.6: Alternate program and erase interface*.

35.3.2.20.1 HSM ALT-SEL register 0 (ALTSEL0)

The Low/Mid Address Space is assigned between MAIN and ALT Interface. Through the HSM ALT-SEL register it is possible to read the actual status of the assignment.

Address: 0x0094 Access: User Read

For the address mapping, refer to *Section 35.3.2.15: Address register (ADR)* description.

35.4 Functional description

This chapter describes the details of all the modes of operation available to the Flash Memory module.

35.4.1 Reset

A reset is the highest priority operation for the Flash Memory module and terminates all other operations.

The Flash Memory module uses reset to initialize register and status bits to their default reset values. If the Flash Memory module is executing a Program or Erase operation (MCR.PGM=1 or MCR.ERS=1) and a reset is issued, the operation is immediately terminated and the module disables the high voltage circuits.Reset terminates all operations and forces the Flash Memory module into Read mode ready to receive Read/Write accesses.

Warning: Reset and Power-Off must not be used as a systematic way to terminate a Program or Erase operation.

After reset is negated Read register access may be performed, although registers that require updating from shadow information or other inputs may not read updated values until MCR.DONE transforms. MCR.DONE may be polled to determine if the Flash Memory module has transitioned out of reset. Note that the registers cannot be written until MCR.DONE is high.

35.4.2 Power-down mode (Disable mode)

The Power-down (or Disable) mode allows the turning-off of all Flash DC current sources. All power dissipation in this mode is due solely to leakage.

In Power-down mode no Read from or Write to the Flash array is possible. Every Flash array Read access executed when the Power-down mode is active outputs invalid data,.

The user may not read some registers (UM0–UM9 and part of UT0) until the Power-down mode is exited.On the contrary, Write access is locked on all the registers in Power-Down mode.

When enabled the Flash Memory module returns to its predisable state in all cases unless in the process of executing an Erase or a Program High Voltage operation at the time of disable. If the Flash Memory module is disabled during an Erase operation, the operation is suspended and MCR.ESUS bits are set to ‘1’. The user may resume the Erase operation at the time the module is enabled by clearing MCR.ESUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is disabled during a program operation, the operation is suspended and MCR.PSUS bit is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR.PSUS bit. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is disabled during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled PSUS must be cleared first to resume the program. Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

If the Flash Memory module is put in Power-down mode and the Vector Table remains mapped in the Flash Address space, the user must be mindful that the Flash Memory module significantly increases the interrupt response time by adding several Wait States.

Note: Do not enter Low-power mode when the Power-down mode is active.

35.4.3 Low-power mode (Sleep mode)

The Low-power (or Sleep) mode turns-off most of the DC current sources within the Flash Memory module. Wake-up time from Low-power mode is faster than wake-up time from Power-down mode.

In Low-power mode no Read from or Write to the Flash array is possible. Every Read access executed when the Low-power mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the Low-power mode is exited. Write access is locked on all the registers in Low-power mode.

When exiting from Low-power mode the Flash Memory module returns to its presleep state in all cases unless in the process of executing an Erase High Voltage operation at the time of entering sleep mode. If the Flash Memory module is put in sleep mode during an Erase operation, MCR.ESUS is set to ‘1’. The user may resume the Erase operation at the time the module exits from sleep by clearing MCR.ESUS. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during a program operation, the operation is suspended and MCR.PSUS is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR.PSUS. MCR.EHV must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled, PSUS must first be cleared for the program to resume. The Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

Note: Do not enter Power-down mode when the Low-power mode is active.

35.4.4 Read mode

Read mode is the active mode of operation of the Flash Memory module in which the Flash array can be read or ‘written’ (the so-called Interlock Write), or the Flash registers can be read or written.

The Flash Memory module enters Read mode when exiting from reset. The default state of the Flash Memory module is Read mode.

The main spaces (Low, Mid, High, and 256K) and UTEST address space of Flash array can only be read in Read mode.

Flash registers can even be read when the module is in Power-down or Low-power mode (except a few documented registers) as well as in Read mode. However, Flash registers can only be written while in Read mode.

Flash memory module is in Read mode, granting the same access time, under the following conditions:

- The Read state is active when the module is enabled (User Mode Read)
- The Read state is active when MCR.ERS and MCR.ESUS are high and MCR.PGM is low (Erase Suspend)
- The Read state is active when MCR.PGM and MCR.PSUS are high (Program Suspend)
- The Read state is active when MCR.PGM or MCR.ERS are high and High Voltage operation is ongoing on one partition, thus MCR.EHV is high (condition referred as Read-While-Write). In this case reads done on the other partitions are allowed, while reads done to the partition being operated on (either Erase or Program) result in an

error with MCR.RWE set and the data read back possibly being random including the possibility of ECC errors.

- The Read state is active when MCRA.ERSA and MCRA.ESUSA are high and MCRA.PGMA is low (Alternate Erase Suspend)
- The Read state is active when MCRA.PGMA and MCRA.PSUSA are high (Alternate Program Suspend)
- The Read state is active when MCRA.PGMA or MCRA.ERSA are high and High Voltage operation is ongoing on one partition, thus MCRA.EHVa is high (condition referred as Alternate Read-While-Write). In this case reads done on the other partitions are allowed, while reads done to the partition being operated on (either Alternate Erase or Alternate Program) result in an error with MCRA.RWEA set and the data read back possibly being random including the possibility of ECC errors.

Code Flash partitions reads return 256 bits (1 page = 4 doublewords). Data Flash partition reads return 128 bits. Register reads return 32 bits (1 word).

Flash array reads are performed through the Bus Interface Unit. In many cases the BIU applies “Read Page Buffering” to allow sequential reads to be executed with higher performance. This can provide data coherency issues that must be handled by software. Data coherency may be an issue after a program or an Erase operation, as well as Test block operations.

Flash array reads to invalid locations result in indeterminate data. Invalid locations occur when addressing points to blocks that are not included in the Flash memory Map of any partition. Interlock writes to invalid locations result in an interlock occurring, but attempts to program these blocks do not eventuate since they are forced into a locked state. Erase occurs to selected and unlocked blocks even if the Interlock Write is to an invalid location.

Register reads to unmapped register address spaces return all 0’s. Registers writes to unmapped register address spaces have no effect.

Simultaneous Read cycles on the Flash array and Read/Write cycles on the registers are possible, but not simultaneous register Read/Write accesses with Flash Array Interlock Writes are forbidden.

35.4.4.1 Error correction code

The Flash Memory module implements a strategy for improving the reliability of the data stored in Flash via the use of Error Correction Code.
In Code Memory the ECC size is 128 bits with 17 ECC bits associated. In Data Memory the ECC size is 64 bits with 15 ECC bits associated.
ECC function is implemented in such a way to guarantee Double Error Correction and Triple Error Detection (DEC-TED) in Data Memory.
ECC function is implemented in such a way to guarantee Double Error Correction and Triple Error Detection (DEC-TED) in Code Memory.
ECC coding has all 0’s (intended as data and parity) as an invalid word and all 1’s as a valid word.

In addition to providing the requested Read data, the Flash also provides output sidebands reflecting the status of the single and double error corrections and triple error detections performed at the end of each Read.

For functional safety coverage, Flash performs an EDC post ECC operation at every Read to detect mismatches in the ECC logic detection and correction. The result is output as sideband. Also active is a monitor circuit that checks the reference current in the sense amplifiers, including control of the internally regulated Read voltage, to prevent anomalous Read operation.

ECC circuitry provides single-bit fault correction used to achieve automotive reliability targets. Some units experience single-bit corrections throughout the life of the product with no impact on product reliability.

35.4.4.1.1 Multi-bits error management (more errors than uncorrectable detection capability)

In this case, behavior cannot be predicted without knowing the original data and the position of the bit flips. The hardware can react in multiple ways:

1. do nothing (that is, not signaling of any flag)
2. assert either SBC, SBC1, or EER without EEE
3. assert either SBC, SBC1, or EER with EEE
4. assert EEE only.

Note: SBC and SBC1 reporting have to be activated in UT0.

It is worth highlighting that by design the purpose of the ECC logic is not to detect multi-bit errors but cope with errors in the data and parity containing maximum number of bit flip till uncorrectable detection capability. In this condition, the EDC after ECC monitors the integrity of the ECC logic.

Other mechanisms must detect multi-bit errors or avoid their occurrence.

For example running the Array Integrity Check once after the boot before the safety application starts to protect the Data with an application level checksum.

An example of a mechanism that decreases the possibility of multi-bit errors in the array is the multiplexing. The bits of the same word are not one next to each other, but they are spaced of a fixed number of bits.

35.4.4.1.2 EEPROM emulation

The chosen ECC allows some bit manipulation so that a doubleword can be re-written several times without needing an erase of the block. This allows the use of a doubleword to store flags useful for the EEPROM emulation.

The sequence provided in *Table 454: Bits Manipulation: doublewords preserving ECC integrity* is related to Data Memory (therefore would not apply on Code Memory). The ECC coding allows, starting from an all 1's doubleword value, to rewrite subsequent predefined code values changing only 0s into 1s and preserving the ECC integrity.

Caution: Predefined code values have to be applied following the exact Byte order, as reported in the table.

Table 454. Bits Manipulation: doublewords preserving ECC integrity

Doubleword	ECC parity bits	Sequence
B7-B6-B5-B4-B3-B2_B1-B0		
0xFFFF_FFFF_FFFF_FFFF	0x7FFF	erase
0xFFFF_FFFF_FFFF_FFFE	0x3C88	write1
0xFFFF_FFFF_FEFE_FC80	0x3C88	write2

Table 454. Bits Manipulation: doublewords preserving ECC integrity (continued)

Doubleword	ECC parity bits	Sequence
B7-B6-B5-B4-B3-B2_B1-B0		
0xFFFF_FFFC_FEFC_FC80	0x1880	write3
0xFCFC_FFFC_FCFC_F880	0x1880	write4
0xFCF8_F8F0_FCE0_E080	0x1800	write5
0xF8F8_E080_F0E0_E000	0x1000	write6
0xE0E0_E080_E0E0_C000	0x1000	write7
0xE000_8000_00C0_0000	0x1000	write8

35.4.4.2 Flash address generation check

For functional safety coverage, Flash provides output sidebands reflecting the re-encoded address used to perform the actual Read operation. In the re-encoding process both word line and column within the selected block are evaluated. For the completion of the re-encoding operation, the addresses related to block selections are also computed. Re-encoding circuitry is able to detect both no-selection as well as multi-selection. Flash provides a self-check of address consistency comparing at each Read the sampling of the current Read address with the re-encoded one, and in case of mismatch an error sideband is set.

35.4.5 Modify mode

All the Modify operations of the Flash Memory module are managed through the Flash User Registers interface. This interface is referred as MAIN.

When a Modify operation is active on some blocks, no Read access is possible on any other block of the same Flash Partition. The Read-While-Modify is supported only among different Flash partitions.

During a Flash Modify operation any attempt to read any Flash location in the same Flash partition outputs invalid data and MCR.RWE is automatically set.

If a reset occurs during a Modify operation, the operation is immediately terminated and the module is reset to Read mode. The data integrity of the Flash section where the Modify operation was terminated is not guaranteed: the interrupted Flash Modify operation must be repeated.

In general each Modify operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in MCR.PGM or MCR.ERS or UT0.MRE.
2. The second step is the definition of the operands: the address and the data for Programming, or the blocks for Array Integrity Check or Margin Read.
3. The third instruction is used to start the Modify operation by setting MCR.EHV or UT0.AIE.

Once selected, but not yet initiated, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Modify operations are shown in *Table 455*.

Table 455. Flash Modify operations

Operation	Select bit	Operands	Start bit
Doubleword Program	MCR.PGM	Address and Data by Interlock Writes	MCR.EHV
Block Erase	MCR.ERS	SEL0, SEL1, SEL2 and SEL3	MCR.EHV
Array Integrity Check	None	SEL0, SEL1, SEL2 and SEL3	UT0.AIE
Margin Read	UT0.MRE	UT0.MRV + SEL0, SEL1, SEL2 and SEL3	UT0.AIE

Once MCR.EHV (or UT0.AIE) is set, all the operands can no longer be modified until MCR.DONE (or UT0.AID) is high.

In general each Modify operation is completed through a sequence of 4 steps:

1. Wait for operation completion: wait for MCR.DONE (or UT0.AID) to go high.
2. Check operation result: check bit MCR.PEG (or compare UM0–UM9 with expected value).
3. Switch-Off FPEC by resetting MCR.EHV (or UT0.AIE).
4. Deselect current operation by clearing MCR.PGM/ERS (or UT0.MRE).

Note: Do not initiate a Modify operation on a Flash Memory module while another Modify operation is in progress on a separate module.

In the following sections, all the possible Modify operations are described with accompanying examples of the sequences needed to activate them.

35.4.5.1 Program

A Flash Program sequence operates on any doubleword within the Flash core. Up to two words within the doubleword may be altered in a single doubleword program operation. A single program operation can also alter one page (4 doublewords, 32 bytes), or 4 pages max (128 bytes in total). It is possible to program only certain doublewords in the page or the quad-page, leaving the others with their original content. Whenever the array is programmed, the ECC bits are also programmed.

ECC is handled on a 64-bit boundary in Data Flash and 128b boundary in Code Flash. Whenever you program, ECC bits are also programmed. Thus, if only one word in any given ECC segment is programmed, the adjoining word/s (in that segment) should not be programmed later on, since ECC calculation has already completed for that segment. Attempts to program the adjoining word will probably result in an operation failure. All programming operations should be from 64 bits to 1024 bits, should be 64-bit aligned for Data Flash and 128-bit aligned for Code Flash. The programming operation should completely fill selected ECC segments.

Due to the fact that Flash functions in a System with an end2end ECC scheme, ECC parity bit are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, the page program or the quad-page program contains an inconsistency between data and parity, the whole operation is rejected and a MCR.PEG=0 is set. The doublewords without data and with parity inconsistency are thus not programmed.

Programming changes the value stored in an array bit from logic ‘1’ to logic ‘0’ only. Programming cannot change a stored logic ‘0’ to a logic ‘1’. If a logic ‘0’ is attempted to be over programmed by a logic ‘1’, the resulting operation fails (MCR.PEG=0), and the 0s that are interlocked are merged (ORed) with 0s that are already present in the 64-bit ECC segment. Extreme care has to be taken when doing such an operation due to the high risk of producing ECC errors.

Addresses in locked blocks cannot be programmed. Register locked blocks cannot be programmed. Hardware locking is also available which only affects the program operation. Hardware locking is enabled by sideband signals, and if enabled, programs are prevented from accessing hardware locked blocks in the same way as program software locking.

The user may program the values in any or all of eight the words in a page with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. Only certain doublewords may be programmed within the page or the quad-page, without altering the content of the ones unselected via interlock.

The Program operation consists of the following sequence of events:

1. Change the value of MCR.PGM from ‘0’ to ‘1’.
2. Ensure the block that contains the address to be programmed is unlocked. Write the first address to be programmed with the program data. The Flash Memory module latches address bits (23:7) at this time, as well as written data. This Write is referred to as a Program Data Interlock Write. An Interlock Write may be as large as 64 bits, and as small as 32 bits (depending on the CPU bus).
3. If more than 1 word is to be programmed, write the additional address in the doubleword with data to be programmed. This is referred to as a Program Data Write. The Flash Memory modules ignore address bits (23:7) for program data writes. The eventual unwritten data word defaults to 0xFFFFFFFF.
4. Write a logic ‘1’ to the MCR.EHV to start the internal program sequence or terminate via step 9.
5. Wait until the MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to the MCR.EHV.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic ‘0’ to the MCR.PGM to terminate the program operation.

Programs may be initiated with the 0–1 transition of MCR.PGM or by clearing MCR.EHV at the end of a previous program. The first Write after a program is initiated determines the page address to be programmed. This first Write is referred to as an Interlock Write. The Interlock Write determines if the UTEST or normal array space will be programmed via MCR.PEAS.

In the case of an erase-suspended program, the values in MCR.PEAS may be modified via the Program Interlock Write, enabling erase-suspended programs to UTEST Nonvolatile Memory space and revert back to their original state (related to erase-suspended operation) once the erase-suspended program is completed.

An Interlock Write must be performed before setting MCR.EHV. An Interlock Write performed after setting MCR.EHV is forbidden and data and address passed through interlock is lost.The user may terminate a program sequence by clearing MCR.PGM prior to setting MCR.EHV.

After the Interlock Write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024 bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of

0xFFFF_FFFF. If multiple writes are performed on the same location, the data for the last Write is used in programming.

While MCR.DONE is low and MCR.EHV is high, the user may clear EHV, resulting in a Program Abort.

A Program Abort forces the module to step 8 of the program sequence.

An aborted program results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The data space being operated on before the Abort contains indeterminate data. This may be recovered by repeating the same program instruction or executing an Erase of the affected blocks.

The user may not abort a program sequence while in Program Suspend.

Figure 359. Doubleword program of data 0x55AA_55AA at address 0x00_AAA8 and data 0xAA55_AA55 at address 0x00_AAAC

```
MCR = 0x0000_0010;             /* Set PGM in MCR: Select Operation */
(0x00_AAA8) = 0x55AA_55AA;     /* Latch Address and 32 LSB data */
(0x00_AAAC) = 0xAA55_AA55;     /* Latch 32 MSB data */
MCR = 0x0000_0011;             /* Set EHV in MCR: Operation Start */
do                             /* Loop to wait for DONE=1 */
{ tmp = MCR;                   /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;    /* Check PEG flag */
MCR = 0x0000_0010;             /* Reset EHV in MCR: Operation End */
MCR = 0x0000_0000;             /* Reset PGM: Deselect Operation */
```

35.4.5.1.1 Program Suspend/Resume

The program sequence may be suspended to allow Read access to the Flash array. It is not possible to program or to erase during a Program Suspend. Read-While-Write operations may also be used to read the array during a program sequence providing the Read is to a different partition.

During Program Suspend, all reads to the doubleword targeted for program return indeterminate data.

A Program Suspend can be initiated by changing the value of MCR.PSUS from ‘0’ to ‘1’. MCR.PSUS can be set to ‘1’ at any time when MCR.PGM and MCR.EHV are high and MCR.ERS is low. 0–1 transition of MCR.PSUS causes the module to start the sequence which places it in Program Suspend.

It is possible to suspend a program performed during an Erase Suspend. The user must wait until MCR.DONE=1 before the module is suspended and further actions are attempted. MCR.DONE takes no more time than t_{PSUS} to go high after MCR.PSUS is set to ‘1’.

Once suspended, the array may be read. Flash memory reads while MCR.PSUS=1 from the doubleword being programmed return indeterminate data.

Figure 360. Doubleword Program Suspend

```
MCR = 0x0000_0019; /* Set PSUS in MCR: Program Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.PGM in order to perform reads during program suspend.

The Program sequence is resumed by writing a logic ‘0’ to MCR.PSUS.

MCR.EHV must be set to ‘1’ before MCR.PSUS can be cleared to resume the operation.

The module continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

Figure 361. Doubleword Program Resume

```
MCR = 0x0000_0011;/* Reset PSUS in MCR: Program Resume */
```

Repeated suspends at a high frequency may result in the operation timing out, and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Program Suspends to ensure this does not occur is t_{PSRT}.

35.4.5.1.2 Over-programming protection (OPP) enable

Over Programming Protection can be enabled on a block-by-block basis. In an OPP enabled block of code Flash, any quad-word which has already been programmed cannot be programmed again. The OPP enable does not affect the Erase operation. It is possible to independently set OPP and (hardware) erase protection in order to avoid any kind of overwrite. Using these protection mechanisms in conjunction with the Test mode disable feature gives even greater overwrite protection. Attempts to over-program result in MCR.PEG being cleared.

OPP can be enabled for 16 KB, 32 KB, 64 KB and 256 KB blocks.

OPP is enabled by sideband signals and, if enabled, the program operation is modified to check for programmed bits prior to undertaking a high voltage program event.

35.4.5.1.3 Successful program address

To enable the System to create logic to authenticate operations with a program (like in a diary operation), the Flash Memory module provides the last successful address programmed as a sideband signal. This value is held until the next successful program. A successful program is defined as a program operation of data that is not all 1s, to an unlocked block and the operation results in MCR.PEG returning a ‘1’. An all 1’s value is the default (and invalid) address after reset.

In case of page programming, the last successful address returned is the beginning of the page itself regardless of whether that specific address has not been passed through interlock. In case of quad-page programming, the last successful address returned is the beginning of the quad-page itself regardless of whether that specific address has not been passed through interlock.

35.4.5.2 Erase

Erase changes the value stored in all bits of the selected block(s) to logic ‘1’. An Erase sequence operates on any combination of blocks in the low, mid, high or 256K address space. The Test block cannot be erased.

The Erase sequence is fully automated within the Flash. The user only needs to select the blocks to be erased and initiate the Erase sequence.

Register locked blocks cannot be erased. Hardware locking, which only affects the Erase operation is also available. Hardware locking is enabled by sideband signals and, if enabled, erases are prohibited on hardware locked blocks in the same way as erase software locking. If multiple blocks are selected for erase during an Erase sequence, no specific operation order can be assumed.

The Erase operation consists of the following sequence of events:

1. Change the value in the MCR.ERS bit from ‘0’ to ‘1’.
2. Select the block(s) to be erased by writing 1’s to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers. Note that Lock and Select are independent. If a block is selected and locked, no erase occurs.
3. Write to any address in Flash. This is referred to as an Erase Interlock Write.
4. Write a logic ‘1’ to MCR.EHV to start the internal Erase sequence or skip to step 9 to terminate.
5. Wait until MCR.DONE goes high.
6. Confirm MCR.PEG=1.
7. Write a logic ‘0’ to MCR.EHV.
8. If more blocks are to be erased, return to step 2.
9. Write a logic ‘0’ to the MCR.ERS bit to terminate the Erase operation.

After setting MCR.ERS, one Write (referred to as an Interlock Write) must be performed before MCR.EHV can be set to ‘1’.

Data words written during Erase sequence Interlock Writes are ignored. As Flash functions in an System with an end2end ECC scheme, ECC parity bits are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC even if the value of the data is not meaningful for the Erase operation. If an inconsistency between data and parity is found, the whole operation is rejected and MCR.PEG=0 is set.

The user may terminate the Erase sequence by clearing ERS before setting EHV.

An Erase operation may be aborted by clearing MCR.EHV assuming MCR.DONE is low, MCR.EHV is high and MCR.ESUS is low. An Erase Abort forces the module to step 8 of the Erase sequence. An aborted Erase results in MCR.PEG being set low, indicating a failed operation. MCR.DONE must be checked to know when the aborting command has completed.

The block(s) being operated on before the Abort contain indeterminate data. This may be recovered by executing an Erase on the affected blocks. The user may not abort an Erase sequence while in Erase-Suspend.

Figure 362. Erase of blocks (example)

```
MCR = 0x0000_0004;            /* Set ERS in MCR: Select Operation */
SEL0 = 0x0006_0000;           /* Set the corresponding bit in SEL0: Select
Blocks */
(0x00_0000) = 0xFFFF_FFFF;    /* Latch a Flash Address */
MCR = 0x0000_0005;            /* Set EHV in MCR: Operation Start */
do                            /* Loop to wait for DONE=1 */
{ tmp = MCR;                  /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status = MCR & 0x0000_0200;   /* Check PEG flag */
MCR = 0x0000_0004;            /* Reset EHV in MCR: Operation End */
```

35.4.5.2.1 Erase Suspend/Resume

The Erase sequence may be suspended to allow Read access to the Flash array. It is possible to program another block in any Flash Memory module during Erase-Suspend. Programming a location subject to suspended Erase results in the program not being executed and PEG being set to 0.

It is not possible to erase any block during an Erase-Suspend.

During Erase-Suspend, all reads to blocks targeted for Erase return indeterminate data.

An Erase-Suspend can be initiated by changing the value of MCR.ESUS from ‘0’ to ‘1’. MCR.ESUS can be set to 1 at any time when MCR.ERS and MCR.EHV are high and MCR.PGM is low. A 0–1 transition of MCR.ESUS causes the module to start the sequence which places it in Erase-Suspend. The User must wait until MCR.DONE=1 before the module is suspended and further actions are attempted.

MCR.DONE takes no longer than t_{ESUS} to go high after MCR.ESUS is set to ‘1’.

Once suspended, it is not possible to alter the content of SEL0, SEL1, SEL2 and SEL3 registers. Once suspended, the array may be read. Flash memory reads while MCR.ESUS=1 from the block(s) being erased return indeterminate data.

Figure 363. Block Erase Suspend

```
MCR = 0x0000_0007; /* Set ESUS in MCR: Erase Suspend */
do                 /* Loop to wait for DONE=1 */
{ tmp = MCR;       /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.ERS in order to perform reads during Erase-Suspend.

The Erase sequence is resumed by writing a logic ‘0’ to MCR.ESUS.

MCR.EHV must be set to ‘1’ before MCR.ESUS can be cleared to resume the operation. The module continues the Erase sequence from one of a set of predefined points and this may extend the time required for the Erase operation.

Figure 364. Block Erase Resume

```
MCR= 0x0000_0005;/* Reset ESUS in MCR: Erase Resume */
```

Repeated suspends at a high frequency may result in the operation timing out and the embedded Flash memory responds by completing the operation with a fail code (MCR.PEG=0). The minimum time between Erase suspends to ensure this does not occur is t_{ESRT}.

35.4.5.3 Factory Mode

The Factory Mode feature can be used to improve Program and Erse Times and it is managed through a diary location mechanism. If location UTEST at offset +0x0020 is found virgin at the moment of the reset, MCR.FERS can be set, after rising MCR.ERS and before MCR.EHV. After setting MCR.EHV the FPEC recognizes the value of FERS and allows a fast Program and Erase Operation. Under those conditions a factory Mode can start and no Read-While-Write is allowed (all the flh_busy sideband signals are set high). If the diary location has been programmed by the user (having changed from being virgin at reset), the Factory Mode gets permanently disabled.

35.4.6 Alternate program and erase interface

A second Modify interface is provided on the Flash for program and erase operations. The intent is that a dedicated master can have private access to blocks through this interface.

The alternate interface includes an alternate MCR register and alternate lock registers. Any block in low, mid, or high address space may be accessible through the alternate interface. The UTest NVM Block is also accessible for program through the alternate interface. Blocks in 256K Address Space are not accessible through this interface.

The alternate interface supports programming of data sizes from one doubleword (64 bits) to four doublewords within a single page (256 bits). Within a page, up to eight words may be altered in a single program operation. It is recommended that programming operations through the alternate interface be from 64 bits to 256 bits, and be 64-bit aligned. Programming has the same constraints as for the Main interface concerning ECC boundaries: 64b for Data Flash and 128b for Code Flash.

The alternate interface supports erasing a single block at a time with each erase operation.

As with the main interface, erase suspend, program suspend, and erase-suspended programs are supported.

Program and Erase times for the alternate interface are the same as the main interface when programs and erases are done in isolation. If main interface and alternate interface are being utilized simultaneously, bandwidth sharing is utilized.

Note: It is possible for the UTest NVM block to exist in both the main program interface and alternate program interface. In the event of a conflict the first interface to do the program to an address will get priority, and all other attempts after this will result in an OTP over-program failure (MCR[PEG] or MCRA[PEGa] being set to 0).

35.4.6.1 Alternate program interface

The programming procedure follows exactly the same flow as the main interface, except that only page programming is allowed.

The alternate interface program is done at lower priority compared to the main interface. Based on the size of programming allowed, the main interface has a 4:1 ratio advantage over the alternate interface. Program operations are allowed to finish on the active interface prior to allowing the inactive interface to execute its operation. Suspends done on the active interface enable the inactive interface to begin its operation.

For alternate program while erase, there could be a latency of up to 5 ms in the program operation.

For more information on interaction between the alternate program interface and the main interface, see *Section 35.4.6.3: Alternate interface performance*.

If the alternate interface is the only interface active, then normal program times may be expected.

35.4.6.2 Alternate erase interface

For erases done through the alternate interface, the single block to be erased is selected based on the address that is received during the erase interlock write. Thus the Select registers are not valid for the alternate interface (step 2 of the erase flow in *Section 35.4.5.2: Erase*), and the interlock write address is used (step 3 of the erase flow in *Section 35.4.5.2: Erase*). All other features of the main interface apply to the alternate erase interface. The erase procedure is exactly the same as for the main interface. See *Section 35.4.5.2: Erase* for more information on erase.

The alternate interface erase is done at lower priority compared to the main interface. The time-slice ratio between the two interfaces is 10:1, with 50 ms of time given to the main erase for every 5 ms of alternate interface. Suspends done on the active interface enable the inactive interface to begin its operation.

For alternate erase while program, there can be a latency of up to 5 ms in the main program time. Once the alternate erase is interrupted, it will remain interrupted for main programs for a fixed time of 50 ms, at which time the alternate erase will restart. It should be noted that multiple interruptions of the alternate erase will significantly increase the total erase time.

For alternate erase while erase, the main erase has priority and receives 50 ms of erase for every 5 ms of alternate erase. This may result in a significant increase in the erase time for the alternate interface, and a minor increase in erase time for the main interface.

For more information on interaction between the alternate erase interface and the main interface, see *Section 35.4.6.3: Alternate interface performance*.

If the alternate interface is the only interface active, then normal erase times may be expected.

35.4.6.3 Alternate interface performance

Table 456 highlights the interactions between the alternate interface and the main interface for program, erase, suspend, and idle conditions.

Table 456. Alternate Program and Erase Characteristics

Alt PGM/ERS interface request	Main PGM/ERS interface request	Alt interface result on memory array	Main interface result on memory array
Idle	Idle	Idle	Idle
Idle/SUSP	PGM/ERS	Idle/SUSP	PGM/ERS
PGM/ERS	Idle/SUSP	PGM/ERS	Idle/SUSP

Table 456. Alternate Program and Erase Characteristics (continued)

Alt PGM/ERS interface request	Main PGM/ERS interface request	Alt interface result on memory array	Main interface result on memory array
PGM	PGM	PGM	Priority PGM (4:1 ratio)
PGM	ERS	PGM with 5ms latency	ERS (possible minimal increase to total ERS time)
ERS	PGM	ERS (significant increase in total ERS time expected)	Priority PGM (possible latency of 5 ms) Once PGM is granted, 50 ms time slice available for more programs
ERS	ERS	ERS (significant increase in total ERS time expected)	Priority ERS (10:1 ratio) (possible minimal increase to total ERS time) 50 ms Main ERS for every 5 ms alternate ERS

35.4.7 User Test mode

Customers can put the Flash Memory module in User Test mode to perform specific tests for the integrity of the Flash array.

Three kinds of test can be performed:

- Array Integrity Self Check
- Margin Read
- Vth Distribution

User Test mode is an exclusive operation—it cannot be run in conjunction with any other Flash mode (Read, Write, Low-Power and Power-Down), and Read-While-Write functionality is inapplicable. Read accesses attempted by the user during User Test mode generates a Read-While-Write Error (RWE of MCR set). Vth Distribution mode is conditioned by SoC Life Status (mode allowed only as Failure analysis)

It is not permitted to perform User Test operations on the Test blocks (including the UTEST section).

35.4.7.1 Array Integrity Self Check

Array integrity is checked using a predefined address sequence (proprietary), and this operation is executed on selected (SEL0, SEL1, SEL2 and SEL3) blocks. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Any random or non-random code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value (stored in UM0–UM9), to determine if an incorrect Read, or ECC detection was noted. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the frequency being used.

The internal MISR calculator is a 64 + 8 + 1-bit register.

The 256 data, the respective ECC parity data, and the uncorrectable ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location.

The whole check is done through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit/double-bit ECC correction and/or the uncorrectable error flag is set after any ECC detection. Single-bit and Double-bit corrections are always active and logging may be enabled (by UT0.SBCE1 and UT0.SBCE), resulting in the MCR.SBC and MCR.SBC1 flags and related address to be captured in ADR register, but this does not change the final signature in the UM0–UM9.

Only data from existing locations are captured by the MISR. The MISR can be seeded to any value by writing the UM0–UM9 registers.

The Array Integrity Self Check consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1’s to the appropriate field(s) in SEL0, SEL1, SEL2 and SEL3 registers. Blocks selected for Array Integrity Check do not need to be unlocked. It is not possible to perform Array Integrity operations on the UTEST Nonvolatile Memory block.
3. If desired, UT0.AIS can be set for sequential addressing only.
4. Seed the MISR UM0–UM9 with desired values.
5. If breakpoints are desired, set UT0.AIBPE to ‘1’, and ensure that MCR.EER, MCR.SBC and MCR.SBC1 are cleared. If breaking on single-bit correction is required, ensure that UT0.SBCE1 is set.
6. Write a logic ‘1’ to UT0.AIE to start the Array Integrity Check. Array integrity operations may be aborted prior to UT0.AID going high. This may be done by clearing UT0.AIE. It should be noted that in the event of an aborted Array Integrity check, the MISR registers contain a signature for the portion of the operation that was completed prior to the Abort, and is not definitive. Prior to performing further Array Integrity operations, the UM0–UM9 registers may require initialization to the desired seed value by performing register writes. Array Integrity operations may be suspended while UT0.AID is low. UT0.AISUS may be set to request an Array Integrity Suspend. Once UT0.AID has been set high, UT0.AISUS may be cleared to resume the Array Integrity sequence.
7. Wait until UT0.AID goes high.
8. Check that UT0.NAIBP is set to ‘1’ if breakpoints were previously enabled so that the MCR.EER, MCR.SBC, MCR.SBC1 and ADR registers may be checked to determine the cause and address of the break. Prior to resuming the operation, it necessary to clear MCR.SBC1, MCR.SBC or MCR.EER in order to preserve coherency of the flags and ADR updates with respect to any subsequent breakpoints. Operation may then be resumed by clearing UT0.NAIBP. Continue waiting until the UT0.AID bit goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
9. Compare UM0–UM9 content with the expected result.
10. Write a logic ‘0’ to the UT0.AIE bit.

Use sequential addressing for normal integrity checks of the Flash memory. If a more detailed check of the Read path is required (in diagnostic mode), leave UT0.AIS at ‘0’ and use the proprietary address sequence that checks the Read path more completely, however this sequence takes more time.

Caution: Do not modify the content of Block Select (SEL0, SEL1, SEL2 and SEL3) and Lock (LOCK0, LOCK1, LOCK2 and LOCK3) registers during execution of the Array Integrity Check operation or the MISR value may vary unpredictably.

User mode array reads requested during the Array Integrity test are ignored to ensure that the Array Integrity operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may clear AIE, resulting in an Array Integrity Check Abort. UT0.AID must be checked to know when the aborting command has completed.

Array Integrity Check can be suspended by setting UT0.AISUS while Array Integrity Check is running (UT0.AID=0). Once suspended (UT0.AID=1) Array Integrity Check cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 365. Array Integrity Check of blocks (example)

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set the corresponding bit in SEL0: Select Blocks
*/
SEL2 = 0x0000_0006;  /* Set the corresponding bit in SEL2: Select Blocks
*/
UT0 = 0x8000_0002;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
```

35.4.7.2 Margin Read

User Margin Read may be achieved using the Array Integrity interface and has all the associated features of the Array Integrity interface (MISR calculation, suspend capability and Breakpoints).

Margin Read procedure (either Margin 0 or Margin 1) can be run on selected blocks in order to unbalance the Sense Amplifiers with respect to standard Read conditions, so that all the Read accesses reduce the margin vs ‘0’ (UT0.MRV=0) or vs ‘1’ (UT0.MRV=1).

User Margin Read is a self timed event and is independent of system clocks or wait states selected. Margin Read can be run on selected (SEL0, SEL1, SEL2 and SEL3) blocks, generating checksum calculations on MISR and ECC flagging. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Once the operations are completed, the results of the Margin Reads can be checked, comparing checksum values in UM0–UM9 and reading MCR.EER and MCR.SBC to determine if zero, one or two bits are being detected by the Margin Read.

The MISR can be seeded to any value by writing the UM0–UM9 registers.

As with Array Integrity Check, the internal MISR calculator is a 64 + 8 + 1-bit register. The 256-bit data, the corresponding ECC parity data and the uncorrectable ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location. The whole check is accomplished through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction, and the double error flags are set after any ECC detection. Single-bit and Double-bit corrections are always active and logging may be enabled (by UT0.SBCE1 and UT0.SBCE), resulting in the MCR.SBC and MCR.SBC1 flags and related address to be captured in ADR register, but this does not change the final signature in the UM0–UM9.

In any case, the charge losses detected through the Margin Read cannot be considered device failures and no Failure Analysis is initiated on them.

The Margin Read Setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers. Blocks selected for Margin Read do not need to be unlocked. It is not possible to do Margin Read operations on the UTEST Nonvolatile Memory block.
3. Seed the MISR UM0–UM9 with desired values.
4. Ensure that MCR.EER, MCR.SBC and MCR.SBC1 are cleared.
5. Set UT0.SBCE1 to '1' to detect single bits during Margin Read. Set UT0.SBCE to '1' to detect double bits during Margin Read.
6. Change the value of UT0.MRE from '0' to '1'.
7. Select the Margin level: UT0.MRV=0 for 0's margin, UT0.MRV=1 for 1's margin.
8. Write a logic '1' to UT0.AIE to start the Margin Read.
9. Wait until UT0.AID goes high.
10. Check that UT0.NAIBP is set to '1' if breakpoints were previously enabled so that MCR.EER, MCR.SBC and ADR.ADDR may be checked to determine the cause and address of the break. Prior to resuming operation, clear MCR.SBC1, MCR.SBC or MCR.EER. Operation may then be resumed by clearing UT0.NAIBP. Continue to wait until UT0.AID goes high. If breakpoints were not enabled, or if UT0.NAIBP is low when UT0.AID goes high, then the operation is complete.
11. Compare UM0–UM9 content with the expected results.
12. Check MCR.EER, MCR.SBC and MCR.SBC1.
13. Write a logic '0' to UT0.AIE, UT0.MRE and UT0.MRV.
14. If more blocks are to be checked, return to step 2.

The linear address sequence is used regardless of the value of UT0.AIS.

Caution: Do not modify the content of Block Select (SEL0, SEL1, SEL2 and SEL3) and Lock (LOCK0, LOCK1, LOCK2 and LOCK3) registers during execution of the Margin Read operation, otherwise the MISR value may vary unpredictably.

User mode array reads requested during the Margin Read are ignored to ensure that the Margin Read operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0.AID is low and UT0.AIE is high, the user may abort Margin Read by clearing AIE. UT0.AID must be checked to know when the aborting command has completed. Margin Read can be suspended by setting UT0.AISUS while Margin Read is running (UT0.AID=0). Once suspended (UT0.AID=1), Margin Read cannot be aborted and clearing UT0.AISUS starts the Resume.

Figure 366. Margin Read Check versus 1's

```
UM0/9 = 0x0000_0000; /* Reset UM0/9 content */
UT0 = 0xF9F9_9999;   /* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;  /* Set LSL2-1 in SEL0: Select Blocks */
UT0 = 0x8000_0020;   /* Set MRE in UT0: Select Operation */
UT0 = 0x8000_0030;   /* Set MRV: Select Margin versus 1's */
UT0 = 0x8000_0032;   /* Set AIE in UT0: Operation Start */
do                   /* Loop to wait for AID=1 */
{ tmp = UT0;         /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9 = UM0/9;     /* Read UM0/9 content*/
UT0 = 0x8000_0030;   /* Reset AIE in UT0: Operation End */
UT0 = 0x0000_0000;   /* Reset UTE, MRE, MRV, AIS in UT0:
                        Deselect Operation */
```

35.4.7.3 Vth Distribution

Vth Distribution functionality can be used in case of Failure Analysis for quick assessment of cells status in terms of Vth. The functionality has bit register UTO.VTD as initiator. Writing of this bit is enabled by the Life Cycle state of the device. Life Cycles has to be in Failure Analysis (FA) condition to allow Vth Distribution mode.

Vth Distribution functionality works on selected blocks on the base of multi internal runs. Each run corresponds to an internal voltage step, where cells read as '1' (Vth lower than internal voltage level) are counted: the completion of each run provides on UMISR0 the count of these cells. Clearing UTO.NAIBP starts next voltage step run, till completion of the intended voltage range. Number of internal voltage step is fixed. Aim of the test is to sweep the range from the erased cells with the highest Vth to the programmed cells with the lowest Vth, therefore to provide an assessment of the effective distribution of the cells in the selected blocks.
Once all the cell counts, one per run, have been collected, distribution can be obtained as difference between counts collected through subsequent steps.
In every run, all the cell, including the ECC parity ones, are counted for the block selected.
Vth Distribution results are expected to be collected at room temperature (25C).

Vth Distribution Setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1, SEL2 and SEL3 registers.
3. Unlock blocks Blocks o be checked by writing 0's to the appropriate register(s) in LOCK0, LOCK1, LOCK2 and LOCK3 registers. Blocks selected for Vth Distribution need to be unlocked. It is not possible to do Vth Distribution operations on the UTEST Nonvolatile Memory block, neither on blocks protected through TMD SEAL Block Select.
4. Set UT0.VTD to '1' to select Vth Distribution mode.
5. Write a logic '1' to UT0.AIE to start the first internal run.
6. Wait until UT0.AID goes high.
7. Check that UT0.NAIBP is set to '1'. If NAIBP is at '1' it means current internal run has been completed and device is ready to increase voltage step. If NAIBP is at '0' the overall sweep has been completed.
8. Collect UM0 content for the current voltage step (run).
9. Clear UT0.NAIBP to increase voltage step and return to 6)

Caution: Voltage levels used during Vth distribution sweep may alter the intended reliability of the Cells as data retention. For this reason Vth distribution can be used no more than 10 times.

35.4.8 Protection strategy

Two kinds of protection are available: Modify Protection to avoid unwanted program/erase in Flash blocks and Test Mode Disable to avoid piracy.

35.4.8.1 Modify Protection

The Flash Modify Protection information is stored in nonvolatile Flash cells located in the UTEST region. This information is read once during the Flash Initialization phase following exit from reset and is stored in volatile registers that act as actuators at SoC level. The information is passed to the Flash Memory module through erase_lock and program_lock sidebands, and allows independent protection of each block of Low, Mid, High and 256K Address Space Block.

There are also Address Space Block Locking registers provided to independently lock/unlock each block of Low, Mid, High and 256K Address Space Block against program and erase. Locking is done through the LOCK0, LOCK1, LOCK2 and LOCK3 registers. These registers do not have a nonvolatile image stored in the UTEST area of TestFlash, so the locking information is kept on reset: volatile content is all 1's, meaning all blocks are locked.

All the volatile registers can be written to '0' or '1' at any time, therefore the user application can lock and unlock blocks when desired. Note, however, that overall protection is achieved by the combination of sidebands with Low, Mid, High and 256K Address Space Block Locking registers in such a way that a block can be programmed/erased only if both (sidebands and Locking registers) indicate an unlocked state. Sidebands independently control program protection, erase protection and over-programming protection (OPP) on a block-by-block basis.

35.4.8.2 Test Mode Disable

In the TestFlash area a mechanism is also available to disable entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected for protection in this way cannot be analyzed for possible failures by manufacture failure analysts.

Protection of this sort prevents all high voltage operations to the Flash executed by the internal FPEC as well as reads from FPEC, including Array Integrity Check or Margin Read, when using Test mode interfaces. Protection through other interfaces is managed through normal User mode protection mechanisms, that are System specific.

To disable manufacturer entry into Test mode, first program the Test Mode Disable Seal location to 0x5A4B_3C2D and once the next reset is asserted, Test mode is disabled.

It is possible to create a password to enable manufacturer entry into Test mode. This can be programmed into the Test Mode Disable Override Passcode. It is safest to do this prior to censoring the part to avoid unintended lockout. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and are not accepted for override. If the customer desires that override never be possible, one of the three invalid passcodes should be put into this location. Passcodes may be entered to authenticate entry (if enabled) by performing a register Write to offset address 0x90.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus is it possible for customers to select blocks for this type of protection, and render them ineligible for manufacturer failure analysis. Bits programmed to '0' in the Test Mode Disable Block Select field designate blocks that are controlled by Test Mode Disable feature. The TestFlash block, and thus the UTEST and BAF sections, is always protected once the Test Mode Disable Seal password is written. In order to permit two opportunities to select blocks for Test Mode disable, two regions are available, both in UTEST: one at offset 0x50, and the other at offset 0x60; both are 128-bit sized (only some may be effective, depending on actual sectorization). The bits of these two regions are logically ANDed in order to define which blocks are effectively selected for the Test Mode Disable feature.

The bit Block Select field is organized as follows, and aligned in the way blocks are defined in the LOCKx/SELx registers:

Table 457. Test Mode Disable block select

Block	Block selection bits
Blocks in Mid space	Data[16:31]
Blocks in Low space	Data[2:15]
Blocks in High space	Data[48:63]
Blocks in 256K space	Data[64:127]

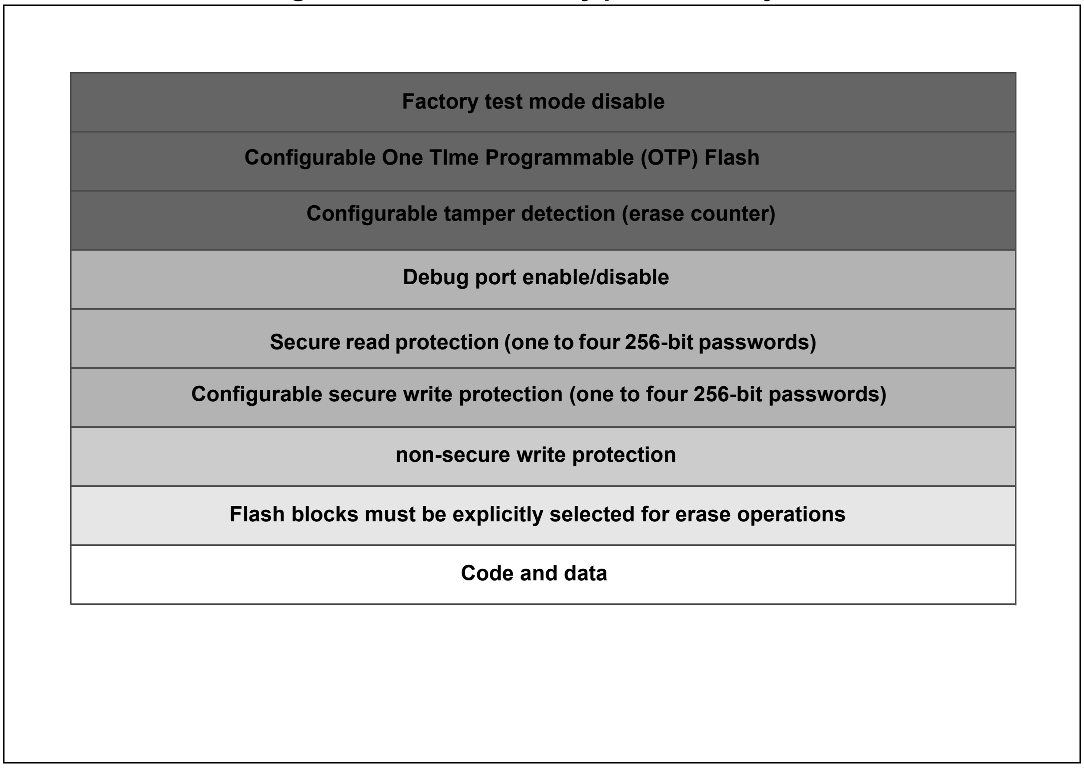
36 Flash Memory Programming and Configuration

This chapter provides basic guidance on activities related to configuring and programming the embedded Flash memory in the SPC584Bx microcontroller.

Multiple layers of protection are available to prevent unintended updates to Flash contents and unauthorized reads and writes to Flash contents. The protection mechanisms range from simple write-protect bits for individual Flash blocks to four levels of 256-bit password read/write protection and configuration of Flash memory blocks as One Time Programmable (OTP).

Additionally, the SPC584Bx microcontroller includes a tamper detection feature, debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

Figure 367. Flash memory protection layers



At the lowest layer of protection, all Flash erase operations require the explicit selection of one or more blocks of Flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual Flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual Flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of Flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The SPC584Bx microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected Flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection region if desired.

Another protection feature related to tamper detection is the ability to configure any Flash block as one-time programmable (OTP).

Finally, the microcontroller includes a feature that allows the customer to disable the ability to place the device in factory test mode.

The remainder of the chapter provides details regarding these protection mechanisms and gives a brief overview of security configuration planning.

Note: Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the Flash protection features work and relate to each other, please read the chapter in sequence from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection and tamper detection applied to groups of Flash memory blocks), which means that a custom level of access protection can be provided for each Flash memory block. This is accomplished through the use of registers containing bits that are mapped to individual Flash blocks. Understanding the mapping is key to understanding the implementation and use of the SPC584Bx microcontroller's Flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in *Section 36.1: Selection of Flash memory blocks for erase*. It is important to understand the topic before proceeding to other sections.

36.1 Selection of Flash memory blocks for erase

The registers used for selecting Flash blocks for erase operations are the Flash control registers named SEL0, SEL1, SEL2 and SEL3.

The SEL0–2 registers are 32-bit registers containing fields associated with specific address spaces: low, mid, high, and 256 KB. Each non-reserved bit in the fields is mapped to a specific Flash block.

For example, *Section 35.3.2.10: Select 0 register (SEL0)* shows the Select 0 (SEL0) register for the Flash module. This register provides a way of selecting blocks in the low and mid address spaces for erase operations.

Table 402: Flash memory partition 0 memory map shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual Flash blocks. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–11 (register bits 15–4) and MIDSEL bits 0–2 are mapped. Before any mapped block can be erased, it must be

selected by writing a ‘1’ to its corresponding bit in one of the SEL*n* registers. Refer to the device configuration chapter for the complete mapping.

Note: Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 327: Select 0 register (SEL0), all bits are reset to ‘0’. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Example 1 Selecting blocks for erase

Writing the value 0x0005_0000 to the SEL0 register (*Figure 327: Select 0 register (SEL0)*) selects the blocks in *Table 417: SEL0 field descriptions* for erase.

36.2 Non-secure write protection

Non-secure write protection refers to the chip’s ability to lock individual Flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip’s modules. The non-secure write protection feature detailed here applies only to embedded Flash memory.

Implementing non-secure write protection is almost identical to selecting specific Flash blocks for an erase operation—the only difference is the register used. To provide non-secure write protection for a block, write a ‘1’ to the corresponding mapped bit found in one of the LOCK0–3 Flash control registers.

Note: As indicated by the reset values shown in Section 35.3.2.4: Lock 0 register (LOCK0), after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

Example 2 Selecting blocks for write protection

Writing the value 0x0005_0000 (same value used in *Example 1*) to the LOCK0 register (*Section 35.3.2.4: Lock 0 register (LOCK0)*) locks the blocks in *Table 411* (same blocks selected in *Example 1*) so they cannot be programmed or erased, even if selected for erase.

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in *Section 36.3: Secure write protection*). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to ‘0’.

36.3 Secure write protection

Secure write protection refers to the chip’s ability to implement up to four levels of 256-bit password-secured *write* protection for individual Flash blocks. Use of this feature is optional but the default behavior of the SPC584Bx microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records. For details, please refer to *Section 78.4.2.1: JTAG Password Challenge* in the PASS chapter.

Note that the *secure* write protection settings override the non-secure write protection detailed in *Section 36.2: Non-secure write protection*.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each Flash block. The DCF records use a bit mapping scheme identical to the mapping in the Flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module—they distinguished by the PG*n* suffix. The PG*n* (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.

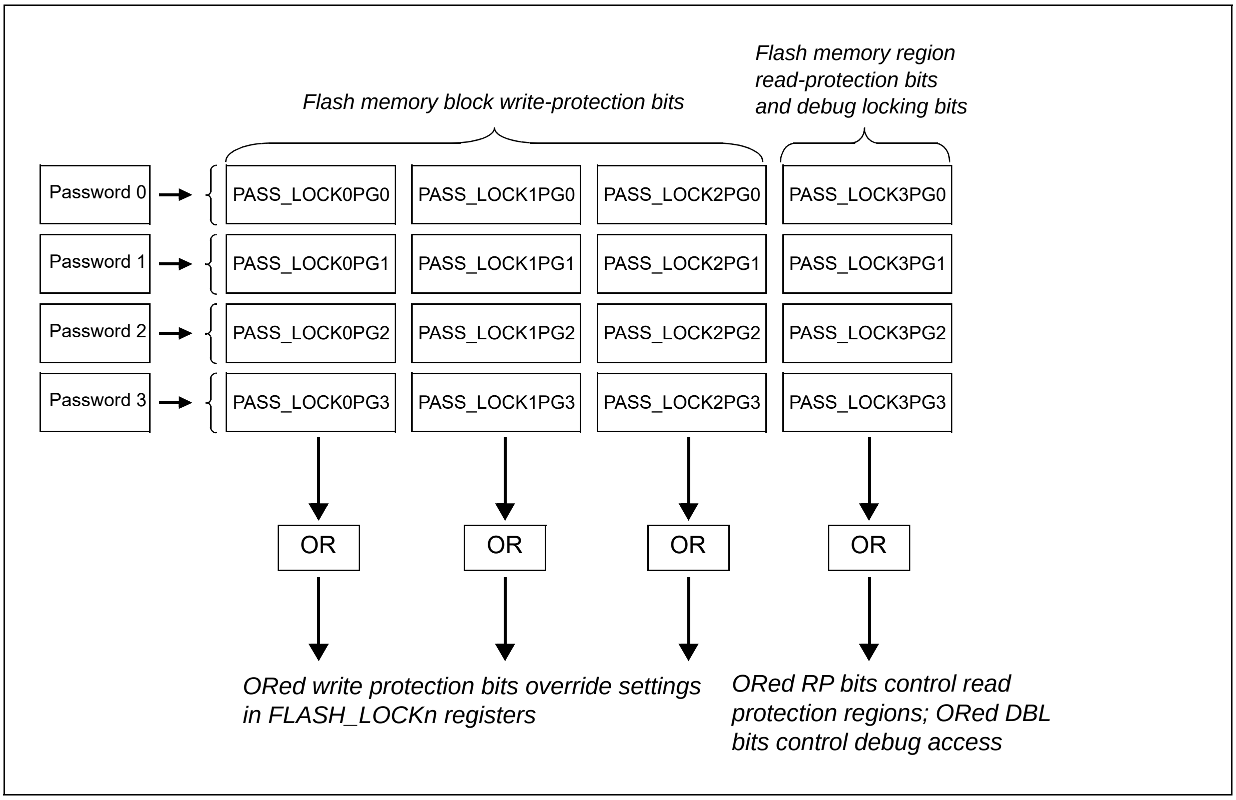
The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each Flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding Flash block.

Each set of registers contains the same mapping of bits to Flash blocks as the Flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a Flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the Flash block is available for programming or erase.

Figure 368 shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

Figure 368. Secure write protection



The next sections discuss implementing secure write protection and overriding secure write protection.

36.3.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers[k]. The DCF records have a structure that includes the same mapping of bits to Flash memory blocks as the Flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers.

Refer to *Chapter 9: Device Configuration Format (DCF) Records* for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to Flash memory blocks is identical to the mapping used for selecting Flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring Flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during

k. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

OEM production activities. The selection becomes a permanent part of the device configuration.

2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

Caution: Careful planning is required before writing DCF records. They are created in a write-once area of Flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table (*Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*). Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST Flash memory. The structure of a DCF Record is shown in *Figure 369*.

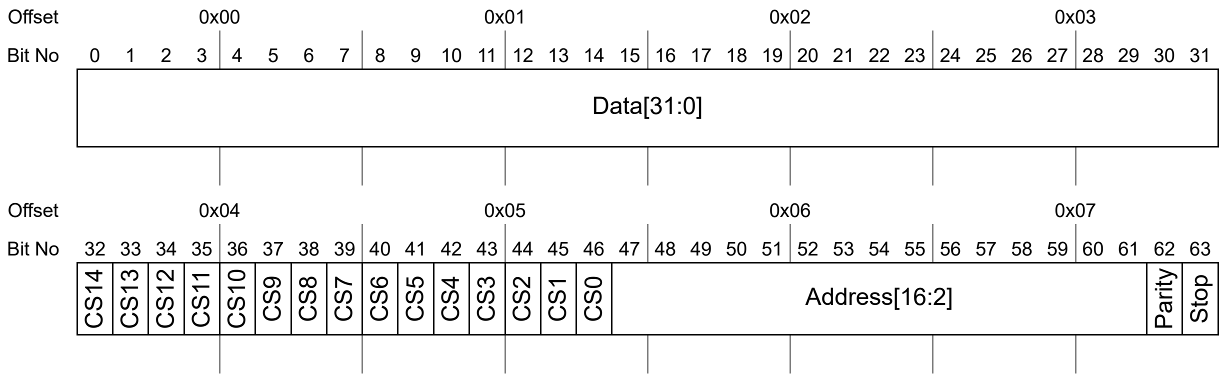


Figure 369. DCF record structure

Note: *The values in the PASS_LOCKxPGn registers should mirror the settings in the Flash module's LOCK0–3 registers.*

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated Flash block to be locked against programming or erase.

The PASS_LOCKxPGn bits take effect when the life cycle is matured to "OEM Production" or older.

Example 3 Implementing secure write protection

Implementation of secure write protection is done during initial Flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device Flash called UTEST Flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to Flash blocks as the Flash module's SEL0–3 registers and LOCK0–3 registers.
2. DCF records must be created to define which Flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2., determine the reset values of the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group: refer to Table 411

From the PASS section of Table 107: DCF client list in Chapter 9: Device Configuration Format (DCF) Records:

Table 458. DCF client list of PASS

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to Figure 369, the values for the DCF record are:

- Data[31:0] is 0x0005_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (refer to footnotes in Figure 370).

The following DCF record provides secure write protection for the blocks by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	X (1)	X (2)

Figure 370. Sample DCF record for secure write protection

1. Bit 62 indicates parity strategy, which is not used in the PASS DCF records so it is a “don’t care”.
2. Bit 63 indicates whether the current record is the last DCF. Generally, this should be written as ‘0’ so the first unprogrammed (all 1’s) DCF record acts as the stop record.

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to Flash blocks 4 and 5 set to ‘1’.

Caution: The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

Refer to the PASS section of DCF client list table (Table 107: DCF client list in Chapter 9: Device Configuration Format (DCF) Records) for details on the DCF records.

36.3.2 Overriding secure write protection

The “PG*n*” (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock

PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the Flash module's SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to '1', locking a Flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCK*x*PG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the Flash block is available for programming or erase.

Figure 371 shows the PASS_LOCK0_PG*n* register. It has the same structure as the Flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCK*x*_PG*n* registers and the Flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding Flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

Offset: 0x0100 LOCK0_PG0, 0x0110 LOCK0_PG1, 0x0120 LOCK0_PG2, 0x0130 LOCK0_PG3 — Access: Read/Write

Figure 371. LOCK0_PG*n* register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'

Note: The values in the PASS_LOCKxPGn registers should mirror the settings in the Flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated Flash block to be *locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.*

The PASS_LOCKxPGn bits take effect after the life cycle is matured to “OEM Production” or older.

Example 4 Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to ‘1’, causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the Flash module’s LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module’s LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to ‘0’ to make the desired Flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant 32 bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

As in the previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

36.4 Secure read protection

Read Protection is ability of the Flash controller to block read accesses to the Flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- SIPI reads
- All other types of bus master reads

When secure read protection is active, the affected Flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a Flash read protected region terminates with a bus error.

Most instances of Flash memory read protection in the SPC584Bx microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTEST Flash memory. Password-based read protection *is* customer-configurable[l] and is similar to the password-based write protection mechanism detailed in *Section 36.3: Secure write protection*.

There are two significant differences between password-based read protection and password-based write protection in the SPC584Bx microcontroller.

1. Read protection can only be applied to pre-defined groups of Flash memory blocks. These groups, called “Read Lock groups”, cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to “Failure Analysis”.

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

Note: The mappings of PASS_LOCK3_PGn register bits to Flash blocks vary with different microcontrollers. Refer to the Flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC584Bx microcontroller.

The next sections discuss implementing secure read protection and overriding secure write protection.

36.4.1 Implementing secure read protection

Implementation of secure read protection is done during initial Flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device Flash named UTEST Flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to Flash blocks as the Flash module’s SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which Flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers.

   Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.
   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in *Figure 372*. The fields relevant to implementing secure read protection are RL4–RL0.

l. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

Offset	0x010C LOCK3_PG0 0x011C LOCK3_PG1 0x012C LOCK3_PG2 0x013C LOCK3_PG3
Access: Read/Write

Reset	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)	x(2)

Figure 372. PASS_LOCK3_PG*n* Register

1. Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
2. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Example 5 Implementing secure read protection

Assume four passwords have been previously implemented.

Following is an example of a mapping of Flash blocks to Read Locking groups.

To provide two levels of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL*n* bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 459. DCF client list of PASS

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to *Figure 369*, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG2
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG3
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.

36.4.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG*n* registers (refer to *Figure 372*) contain five read protection fields, RP0–RP4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to ‘1’, causing the blocks associated with each read group to be read locked.

Example 6 Overriding secure read protection

Building on *Example 5: Implementing secure read protection*, where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to ‘0’ in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

36.5 Debug port enable/disable

The mechanism for temporarily enabling the SPC584Bx debug port after it has been locked by its life cycle state is similar to the Flash memory read protection mechanism detailed in *Section 36.4: Secure read protection*. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RP0–RP4 fields.

36.6 Tamper detection

The Tamper Detection Module (TDM) provides a type of Flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual Flash memory blocks to be selected for tamper detection.

Refer to *Chapter 79: Tamper Detection Module (TDM)*, for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, such as a Flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of DCF client list table (*Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) gives the CS and Address value combinations that correspond to groups of LOCK0–LOCK3 registers, similar to the Flash module's LOCK0–LOCK3 registers.

The mapping of individual Flash blocks to TDM DCF record data field bits is shown included in the detailed Flash block map in the Flash section of the Device Configuration chapter.

36.6.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections.

36.6.2 Creating the tamper detect diary

Tamper detection in the SPC584Bx microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called “tamper detect regions”, or TDRs, within the Flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the Flash module’s SEL*n* and LOCK*n* registers, which contain bits matched to specific Flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a “diary” that tracks Flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector.

Note: The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for SPC584Bx) multiplied by 4 KB, the portion of the diary allotted to records associated with each TDR.

The diary can be placed within any Flash block in the Flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section).
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be ‘0’.

Caution: The tamper detect diary base address DCF record is a “write once” record. All subsequent tamper detect diary base address DCF records created are ignored.

Example 7 Creating the tamper detect diary

If the total space required for a diary is 24 KB (as in the case of 6 TDRs), any Flash block in the SPC584Bx microcontroller but B0F0 and B0F1 whose size is not enough to allocate the diary total space can be used. Since the diary base address must be on a 4 KB, boundary, though, if the diary base address is within a 32 KB Flash block, it can be assigned to the base address of the block or the address given by the base address plus 4 KB or the address given by the base address plus 8 KB.

If the base address of the 32 KB block is 0x00FD000, the base address of the diary is given by:

32’b0000_0000_1111_1101_0000_0000_0000_0000 (32 KB base address)

or

32’b0000_0000_1111_1101_0001_0000_0000_0000 (32 KB base address + 4 KB)

or

32’b0000_0000_1111_1101_0010_0000_0000_0000 (32 KB base address + 8 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 16'b0000_0000_0000_0000
- TDR1 = Diary_Base_Address + 16'b0001_0000_0000_0000
- TDR2 = Diary_Base_Address + 16'b0010_0000_0000_0000
- TDR3 = Diary_Base_Address + 16'b0011_0000_0000_0000
- TDR4 = Diary_Base_Address + 16'b0100_0000_0000_0000
- TDR5 = Diary_Base_Address + 16'b0101_0000_0000_0000
- End of the diary = Diary_Base_Address + 16'b0110_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 460. DCF client list of Tamper Detect

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to *Figure 369*, the values for the DCF record are:

- For LOCK0_PG0
  - Data[31:0] is 0x00FC4000 (the base address).
  - CS[14:0] is 0b000_0000_0001_0000 (bits 32–46).
  - Address[16:2] is 0b000_0000_0000_0000 (bits 47–61).
  - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62).
  - Preferred Stop value is 0.

Refer to the Tamper Detect section of DCF client list table (*Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details.

Note: User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in Section 36.6.4: Overriding tamper detection.

36.6.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDR*x*_LOCK*n* DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDRxLOCK*n* DCF records mapped in exactly the same way as the Flash module's SEL*n* and LOCK*n* registers (refer to the detailed Flash block map in the Flash section of the Device Configuration chapter for the mapping).

In the TDRxLOCK*n* DCF records:

- A bit set to '1' means the corresponding Flash block is assigned to this TDR.
- A bit set to '0' means the corresponding Flash block is NOT assigned to this TDR.

The default state (no TDRs defined) is defined as "Block NOT assigned to the TDR".

36.6.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in *Figure 373*.

Caution: Bits in this DCF record are writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
W	0	0	0	0	0	0	0	0	0	0	TOE5	TOE4	TOE3	TOE2	TOE1	TOE0

Figure 373. Data portion of Tamper Region Override (TO) DCF record

Example 8 Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full.

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 461. DCF client list of Tamper Detect

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to *Figure 369*, the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3).
- CS[14:0] is 0b000_0000_0001_0000 (bits 32–46).
- Address[16:2] is 0b000_0000_0000_0001 (bits 47–61).
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

Refer to the Tamper Detect section of DCF client list table (*Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details.

36.7 Implementing OTP

Any Flash block within the Flash array can be assigned, at any time, to be OTP. OTP means that Flash erase of the entire block is disabled and only 128-bit quad-words that are already erased (Flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

Caution: After a Flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*. Refer to the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

36.8 Implementing test mode disable

The SPC584Bx Flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the Flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

36.8.1 Unconditional test mode disable seal

Warning: This process is not reversible. After completing these steps the SPC584Bx microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual Flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST Flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTEST Flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST Flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

Note: The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.8.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual Flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST Flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTEST Flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST Flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

Note: The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.8.3 Selecting Flash memory blocks for test mode disable seal

Selecting Flash memory blocks for test mode disable seal protection is similar to selecting blocks for tamper detection in that it involves writing to non-register Flash locations. In the case of the test mode disable seal function, there are two areas of UTEST Flash memory that have identical mapping to Flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

The mapping of bits to blocks for this function is identical to the mapping used for other functions. Refer to *Chapter 35: Embedded Flash Memory* for the map.

Note: Selecting a block for test mode disable requires a '0' in the mapped bit—not a '1' as with other functions.

36.9 Security configuration planning

At minimum, designing the Flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

In devices containing a Hardware Security Module (HSM), significant planning must go into the implementation of HSM functions. The HSM is an independent software platform within the microcontroller. It is intended to be used to implement advanced security functions that are defined by customer software.

Note: Details of advanced security features, including the advanced security architecture is and the Hardware Security Module (HSM) are contained in the SPC584Bx Microcontroller Security Reference Manual. Distribution of the document is restricted to qualified customers.

The basic security features available in the SPC584Bx microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) Flash memory block assignment
- Factory test mode disable

36.9.1 Hardware Security Module (HSM)

Details of the HSM are included in the *SPC584Bx Microcontroller Security Reference Manual*. It is mentioned here because the Flash memory module includes blocks that can be configured for exclusive access by the HSM. If the HSM is to be used in an application it is advisable to protect HSM code by configuring it for exclusive access by the HSM. The blocks configurable for exclusive access by the HSM appear in *Figure 5* in *Chapter 3: Embedded memories*. They are labeled as secure code Flash or secure EEPROM emulation blocks. They are not configured for HSM-exclusive access by default, though—they are available to act as secure Flash areas but must be explicitly configured for that purpose. Refer to *SPC584Bx Microcontroller Security Reference Manual* for details.

36.9.2 Creating password groups

Most basic security features in the SPC584Bx microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTEST memory map (refer to the Memory Map chapter).

The UTEST memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Passwords must not be one of the following, which are considered insecure and therefore invalid:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

Caution: The password fields are in OTP UTEST Flash, so they can only be written once.

36.9.3 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user Flash are write protected, so this could be more accurately viewed as planning which blocks of user Flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the Flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in *Section 36.3.1: Implementing secure write protection* and *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.9.4 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to Flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user Flash are read protected, so this could be more accurately viewed as planning which blocks of user Flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the Flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in *Section 36.4.1: Implementing secure read protection* and *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.9.5 Planning debug port enable/disable

Refer to *Section 36.5: Debug port enable/disable* and *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.9.6 Planning OTP Flash memory block assignment

Any block of user Flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a Flash block as OTP is not reversible.

Before creating DCF records to implemented OTP Flash blocks, please thoroughly review the implementation steps detailed in *Section 36.7: Implementing OTP* and *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.9.7 Planning factory test mode disable

Refer to *Section 36.8: Implementing test mode disable* and *Table 107: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

37 Decorated Storage Memory Controller (DSMC)

37.1 Introduction

This section details hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rA,rB` where the data size specifier is defined as 8-bit (b = byte), 16-bit (h = halfword) or 32-bit (w = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rA,rB` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `"x"` mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in *Figure 374*.

Figure 374. Power Architecture Decorated Load and Store Instruction Formats

	0	1	2	3	4	5	6–10	11–15	16–20	21	22	23	24	25	26	27	28	29	30	31

lwdx	0	1	1	1	1	1	**r**T	**r**A	**r**B	1	0	0	1	0	0	0	0	1	1	/
lbdcbx	0	1	1	1	1	1	**r**T	**r**A	**r**B	1	0	0	0	0	0	0	0	1	0	/
lhdcbx	0	1	1	1	1	1	**r**T	**r**A	**r**B	1	0	0	0	1	0	0	0	1	0	/
lwdcbx	0	1	1	1	1	1	**r**T	**r**A	**r**B	1	0	0	1	0	0	0	0	1	0	/

	0	1	2	3	4	5	6–10	11–15	16–20	21	22	23	24	25	26	27	28	29	30	31
stbdx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	0	0	0	0	0	1	1	/
sthdx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	0	1	0	0	0	1	1	/
stwdx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	1	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	0	1	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S	**r**A	**r**B	1	0	1	1	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit “decoration”. The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and operand data for the command or both.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

37.2 Decorated Stores: `st[b,h,w]d{cb}x rS,rB,rA`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

37.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container

Figure 375. Decoration Format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read

if bfw == 0
   then bfw = container

if ((srtbit + bfw) <= container)// generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp   & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp// memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

37.2.2 Compare-and-Store (CAST)

Figure 376. Decoration Format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8							
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16															
cast.w	1	0	0	1	CD28																											

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read

if (size == 8)// define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand)// compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

37.2.3 Logical AND (AND)

Figure 377. Decoration Format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
and.{b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata// modify
mem[accessAddress, size] = tmp// memory write
```

37.2.4 Logical OR (OR)

Figure 378. Decoration Format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or.{b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata// modify
mem[accessAddress, size] = tmp// memory write
```

37.2.5 Logical Exclusive-OR (XOR)

Figure 379. Decoration Format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor.{b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata// modify
mem[accessAddress, size] = tmp// memory write
```

37.3 Decorated Loads: `l[b,h,w]d{cb}x rT,rB,rA`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an “extract”) operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

37.3.1 Simple Load (SLD)

Figure 380. Decoration Format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld.{b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

37.3.2 Registers-and-Memory Exchange (SWAP)

Figure 381. Decoration Format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
cast.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	WD16															
cast.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core’s rT register and stores the source operand from the core’s rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)// store_operand - "modify"
    store_operand = WD8
else if (size == 16)
          store_operand = WD16
     else store_operand = {0x0, WD28}// zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32-bit store operand.

37.3.3 Load-and-Set-1(Bit) (LAS1)

Figure 382. Decoration Format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp
mask  = 1 << (container - bit - 1)// generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

37.4 DSMC Instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the data port of the cores and the master ports of the crossbar.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the targeted slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

38 Analog-to-Digital Converters (ADC) Configuration

This chapter is organized as follows:

- *Section 38.1: ADC overview*
  - *Section 38.1.1: ADC subsystem block diagram*
  - *Section 38.1.2: Analog input pin multiplexing*
- *Section 38.2: Configuration of ADC modules*
  - *Section 38.2.1: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*

38.1 ADC overview

SPC584Bx contains the following analog-to-digital converters (ADCs):

- three independent 12-bit and one independent 10-bit Successive Approximation Register Analog-to-Digital Converters (SARADCs)

Note: SARADC instances naming in some figures of this chapter may differ from the naming provided in Table 462 in order to simplify these figures.

Table 462. ADC implementation

Converter Type	12-bit SAR ADC			10-bit SAR ADC
Special Function	**Supervisor SAR ADC**	**Fast SAR ADC**		**STDBY & Fast Comparator**
Name	SAR_ADC_12bit_SUPERVISOR (SAR_ADC_B)	SAR_ADC_12bit_0	SAR_ADC_12bit_1	SAR_ADC_10bit_STDBY
Number of internal channels(1)	63	11	11	9

1. This is the maximum number of available channels per dedicated silicon but the available number of channels per package might be different (see the IO_Definition document)

The internal channels of each ADC are connected to analog input pads. The analog pads include programmable pull-up / pull-down resistors.

These ADCs interface to external analog input pins. The number of external analog input pins for each package is available in the IO_Definition.xls file attached to the IO_Definition document.

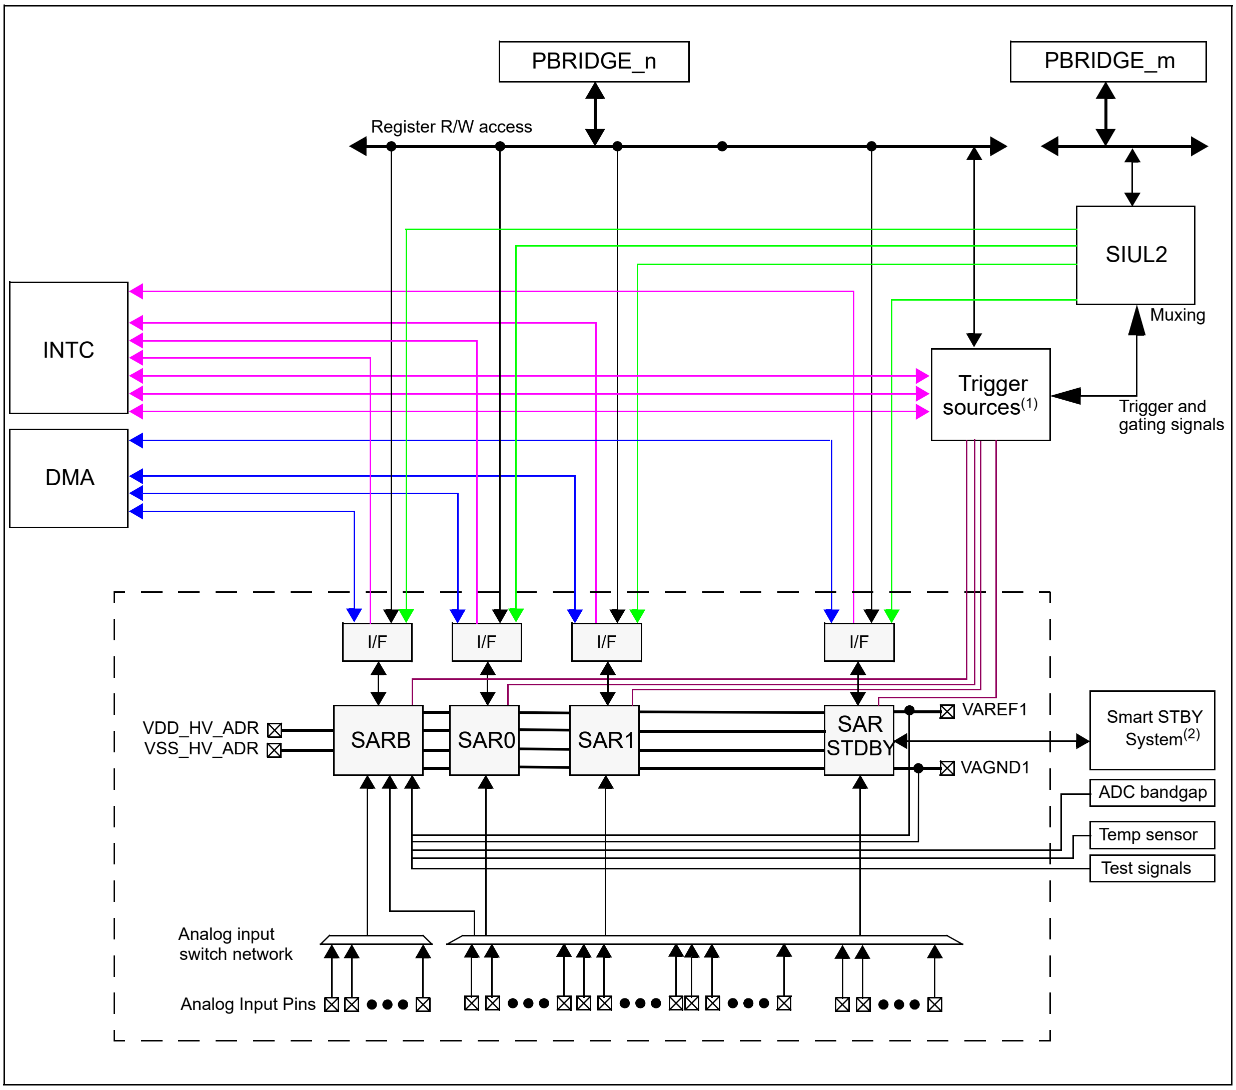
Each SARADC instance has independent analog input, register interface, trigger and clock inputs, independent interrupt, and DMA capability. Each SARADC has a dedicated peripheral bridge (PBRIDGE) interface for CPU access to the registers.

All SARADCs share the same supply pins (VDD_HV_ADV/VSS_HV_ADV). This is true for all packages.

38.1.1 ADC subsystem block diagram

Figure 383 gives the block diagram for the high-level integration of the ADC sub-system for SPC584Bx. The primary intent of the diagram is to show that each ADC has independent register interfaces, interrupt/DMA requests, and trigger source selection.

Figure 383. SPC584Bx ADC subsystem



1. The different trigger sources are detailed in the *Section 38.2.1.5: SAR ADC triggering*
2. SAR_ADC_10bit_STDBY interactions with the Smart STBY System are described in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*

38.1.2 Analog input pin multiplexing

For analog input pin multiplexing please refer to the IO_Definition.xls file attached to the IO_Definition document.

38.2 Configuration of ADC modules

The following sections describe device-specific details for the following module:

- *Section 38.2.1: Successive Approximation Register Analog-to-Digital Converter (SAR ADC)*

38.2.1 Successive Approximation Register Analog-to-Digital Converter (SAR ADC)

There are three independent 12-bit and one independent 10-bit SAR ADCs on SPC584Bx. Refer to *Figure 383* for the ADC sub-system block diagram.

The following sections describe configuration details:

- *Section 38.2.1.1: SAR ADC configuration overview*
- *Section 38.2.1.2: SAR ADC integration diagram*
- *Section 38.2.1.3: SAR ADC analog input*
- *Section 38.2.1.4: SAR ADC clock sources*
- *Section 38.2.1.5: SAR ADC triggering*
- *Section 38.2.1.6: SAR ADC Standby*
- *Section 38.2.1.7: SAR absolute voltage reference*

For detailed module information, refer to the Successive Approximation Register Analog-to-Digital Converter (SAR ADC) Digital Interface chapter.

38.2.1.1 SAR ADC configuration overview

38.2.1.1.1 12-bit Fast SAR ADC

Two 12-bit Fast SAR ADC instances are implemented with:

- 12-bit and 10-bit conversion mode selectable by software on a per conversion basis
  - 11 analog input channels for each SAR_ADC_12bit_0, SAR_ADC_12bit_1
- 4 watchdogs

38.2.1.1.2 12-bit SAR ADC B0

One 12-bit SARADC B0 (SAR_ADC_12BIT_B0) instance with diagnosis is implemented with:

- 12-bit and 10-bit conversion mode selectable by software on a per conversion basis
- 63 analog input channels (called internal channels)
- 64 external multiplexed channels (called external channels)
- All analog internal channels from other ADCs are also connected to SAR_ADC_12bit_B0
- 9 internal test channels (called "test channels") to be used for self-diagnosis of the converter and diagnosis of the analog signal path up to the external circuitry. This includes:
  - an internal bandgap reference from temperature sensor
  - an internal analog ground signal for software offset cancellation
  - four internal voltage references with 20 kOhm source impedance
- 8 watchdogs
- Body Cross Triggering Unit (BCTU) support to trigger ADC conversion

38.2.1.1.3 10-bit Fast SAR ADC STDBY

One fast 10-bit SAR ADC STDBY instance with 9 internal channels with fast comparator capability and supporting STAND-BY feature is implemented with:

- 10-bit and 8-bit conversion mode selectable by software on a per conversion basis (all standard SAR ADC functionalities are present)
- 8 external channels needed for data register and watchdog functionality
- 4 analog watchdogs
- Cross Triggering Unit (STBY eCTU) support. In Standby mode, ADC operation is controlled by STBY eCTU. Refer to the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* for details on STAND-BY feature
- In RUNTIME, 10-bit Fast ADC STDBY can be used as the other 10-bit Fast SAR ADC instances

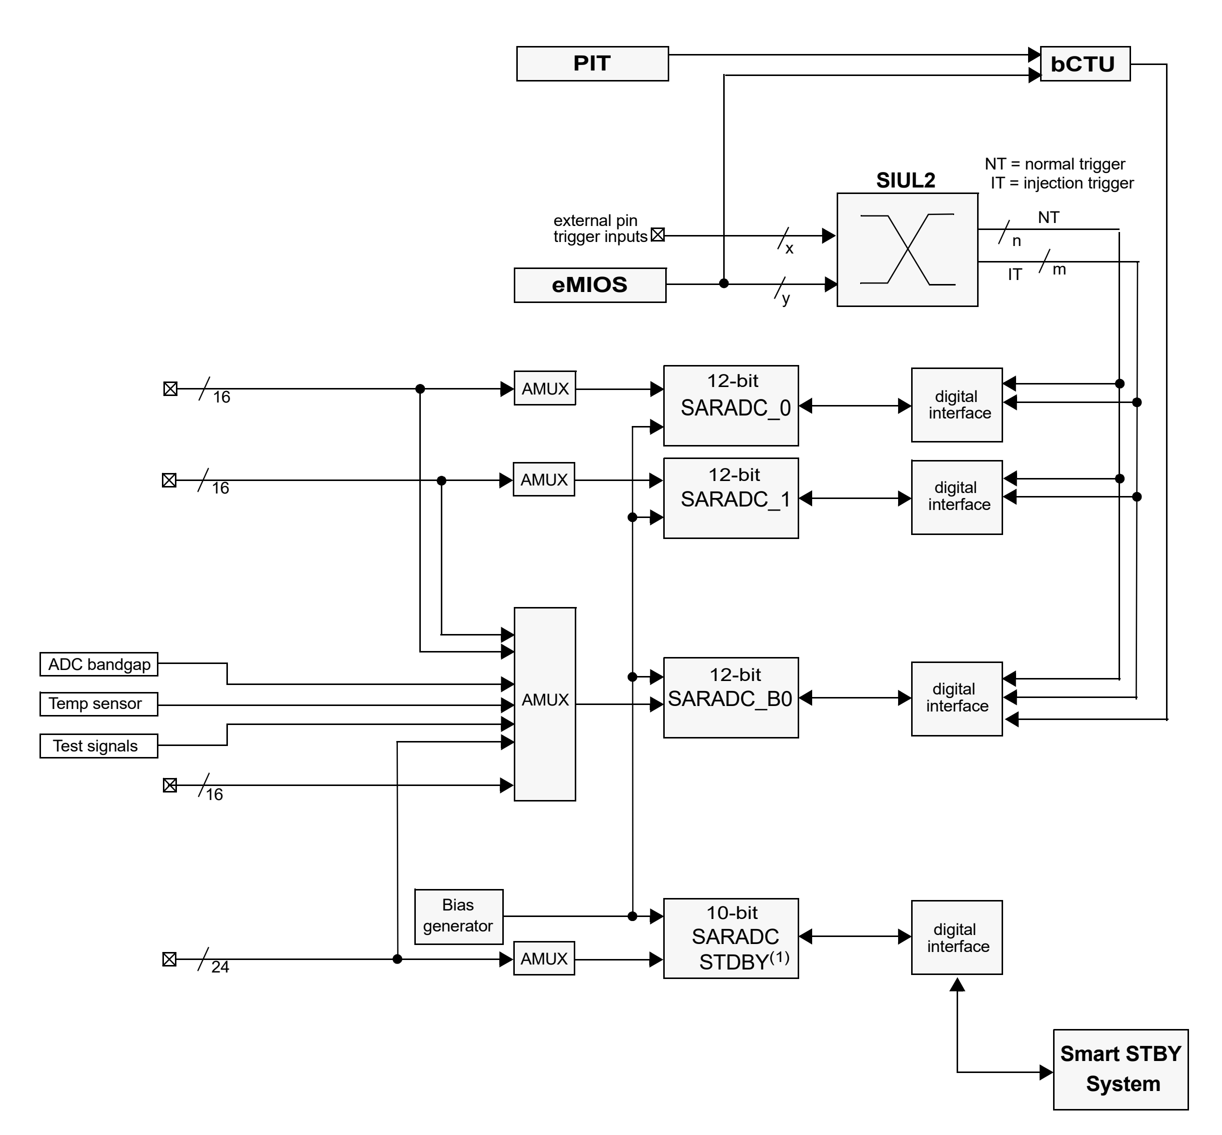
Note: Refer to SPC584Bx datasheet for SAR ADC analog performances.

38.2.1.2 SAR ADC integration diagram

Figure 384 shows the block diagram of the integration of the four 12-bit and one 10-bit SAR ADCs on SPC584Bx.

The bias generator provides 4 reference points (VDD_HV_ADR_S, 1/3 VDD_HV_ADR_S, 2/3 VDD_HV_ADR_S, and VSS_HV_ADR_S) which are provided to SAR_ADC_12bit_B0 via an internal 20 kΩ impedance. See the SAR ADC block diagram in the *Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC)*.

Figure 384. SAR ADC integration diagram(1)(2)



1. SAR_ADC_10bit_STDBY instance is implemented on a special low-power domain. Further information is provided in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*
2. No normal and injection trigger for SAR_ADC_STDBY

38.2.1.3 SAR ADC analog input

All analog input pins are routed to SAR_ADC_12bit_B0 and another fast SAR ADC Analog input (AMUX) is implemented in the SAR ADC subsystem.

Note: Simultaneous sampling of two SAR ADCs on the same analog channel is possible under certain conditions:

Both ADCs need synchronized start of sampling (both ADCs have to be triggered by the same trigger signal)

Both ADCs need synchronized end of sampling (both ADCs have to be configured with the same sampling time)

External circuitry on the analog input has to be chosen accordingly (effective internal capacity on analog signal path during sampling time is doubled versus single conversion as given in the device data sheet)

The mapping of analog input pins to the SAR converters is given in *Section 38.1.2*.

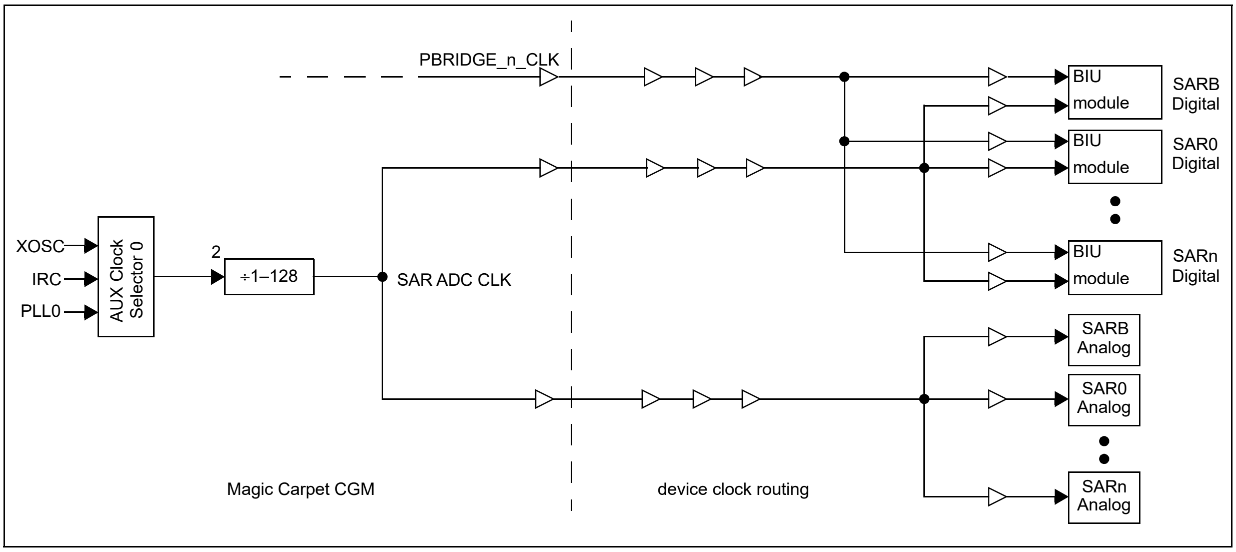
38.2.1.4 SAR ADC clock sources

Each SAR ADC digital interface on SPC584Bx has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE*n*_CLK. The module clock is sourced by the ADC clock (SAR ADC CLK). See *Chapter 25: Clocking* for more detail on the clock sources.

The input clock for the SAR ADC analog blocks is clocked by the SAR ADC CLK. *Figure 385* shows a block diagram of the SAR ADC clock architecture.

To avoid crosstalk issues, all SAR ADCs run at the same clock frequency. The SAR digital interface is clocked from the PBRIDGE*n*_CLK clock. All SAR analog blocks are clocked from the output of a single divider of the SAR ADC CLK at the device level.

Figure 385. SAR ADC clock diagram



38.2.1.5 SAR ADC triggering

Each SAR ADC has 2 independent trigger inputs for starting normal conversion or injected conversion on an analog input. One trigger source can be selected among a list of available signals and connected to the trigger inputs independently for each SAR ADC.

The trigger sources for each SAR ADC on the device are either external input pins or eMIOS channels. Each external input can selectively trigger any of the SAR ADCs on the device. The synchronization to the PBRIDGE clock and digital filtering of the external input pin triggers is done in the system integration logic.

Each trigger input supports software selectable options for rising edge, falling edge, rising and falling edge, or level-based trigger assertion. The trigger selection for each SAR ADC and edge/level selection is located in the SIUL2.

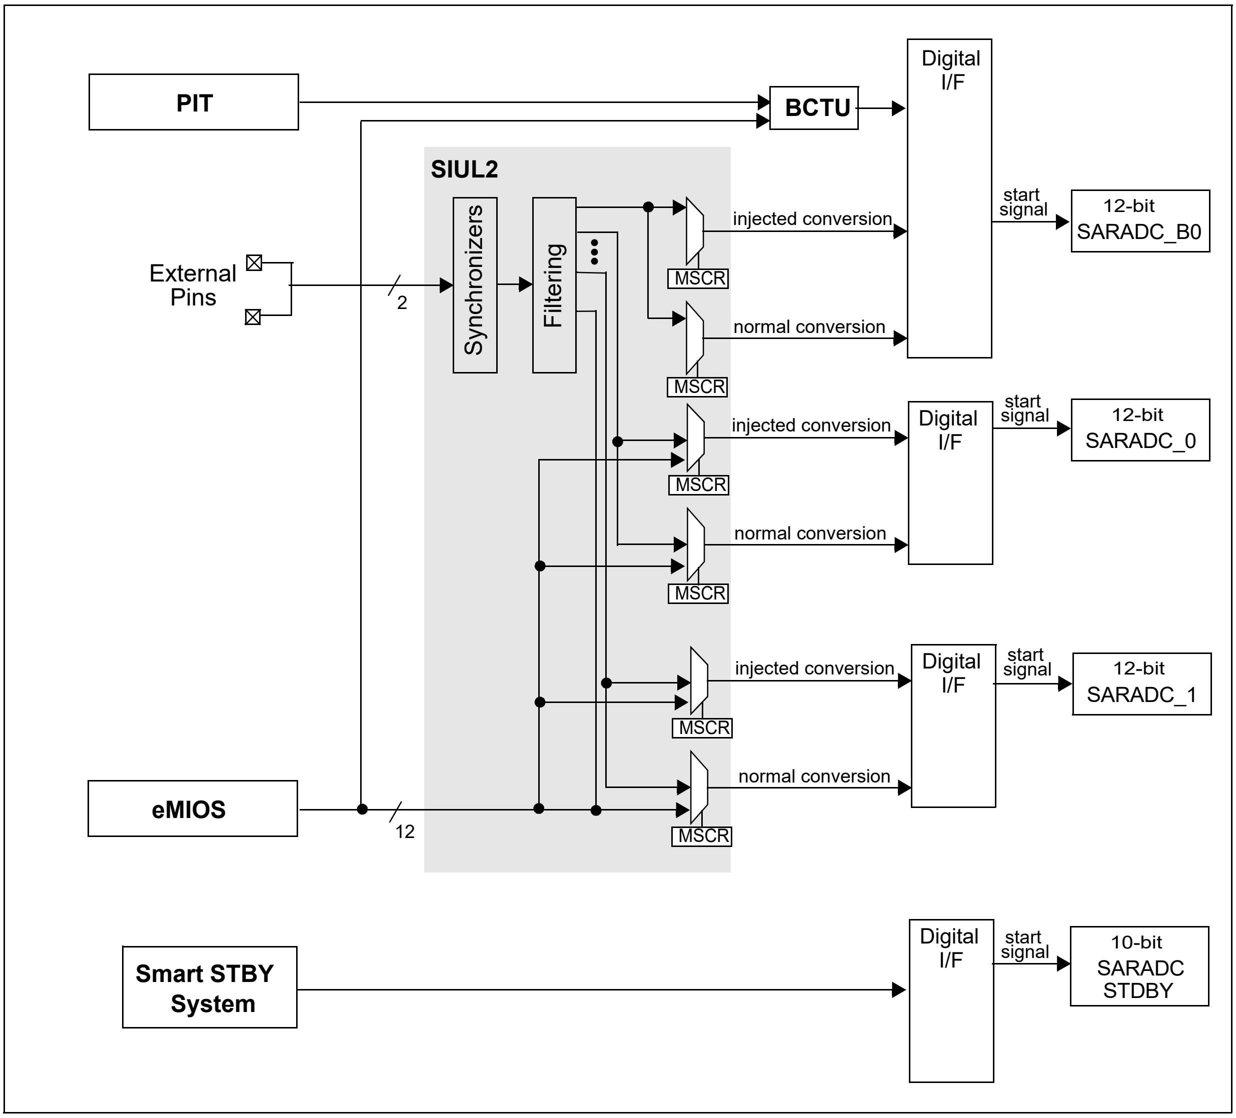
The BCTU module is connected to SAR_ADC_12bit_B0 (SAR_ADC parameter CTSEN = 0). This module receives trigger requests from the timer module (PIT_RTI)or from EMIOS. It translates those trigger requests into ADC measurement commands.

The STBY eCTU module is connected to SAR_ADC_10bit_STDBY (SAR_ADC parameter CTSEN = 2). It receives trigger requests from the real time clock module (RTC) and translates them into ADC commands. The STBY eCTU is used for the Smart Standby feature. Please refer to the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* for more data about this feature.

The SPC584Bx SoC diagram for the SAR ADC trigger inputs is given in *Figure 386*.

Note: Please refer to the MS Excel file attached to SPC584Bx IO_Definition document (I/O signal table) to get the exhaustive list of signals source able to trigger ADC conversion.

Figure 386. SAR ADC input trigger diagram(1)



1. No normal and injection triggers for SARADC_STDBY

Trigger source selection for each SAR ADC is given in the *Chapter 16: System Integration Unit Lite2 (SIUL2)*.

Each SAR ADC digital interface, except SAR_ADC_12bit_B0, provides 4 watchdog Threshold Crossover event trigger signals which are mapped to the interrupt controller.*Chapter 16: System Integration Unit Lite2 (SIUL2)*

38.2.1.6 SAR ADC Standby

SAR_ADC_10bit_STDBY interactions with the Smart STBY System are described in the *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)*

38.2.1.7 SAR absolute voltage reference

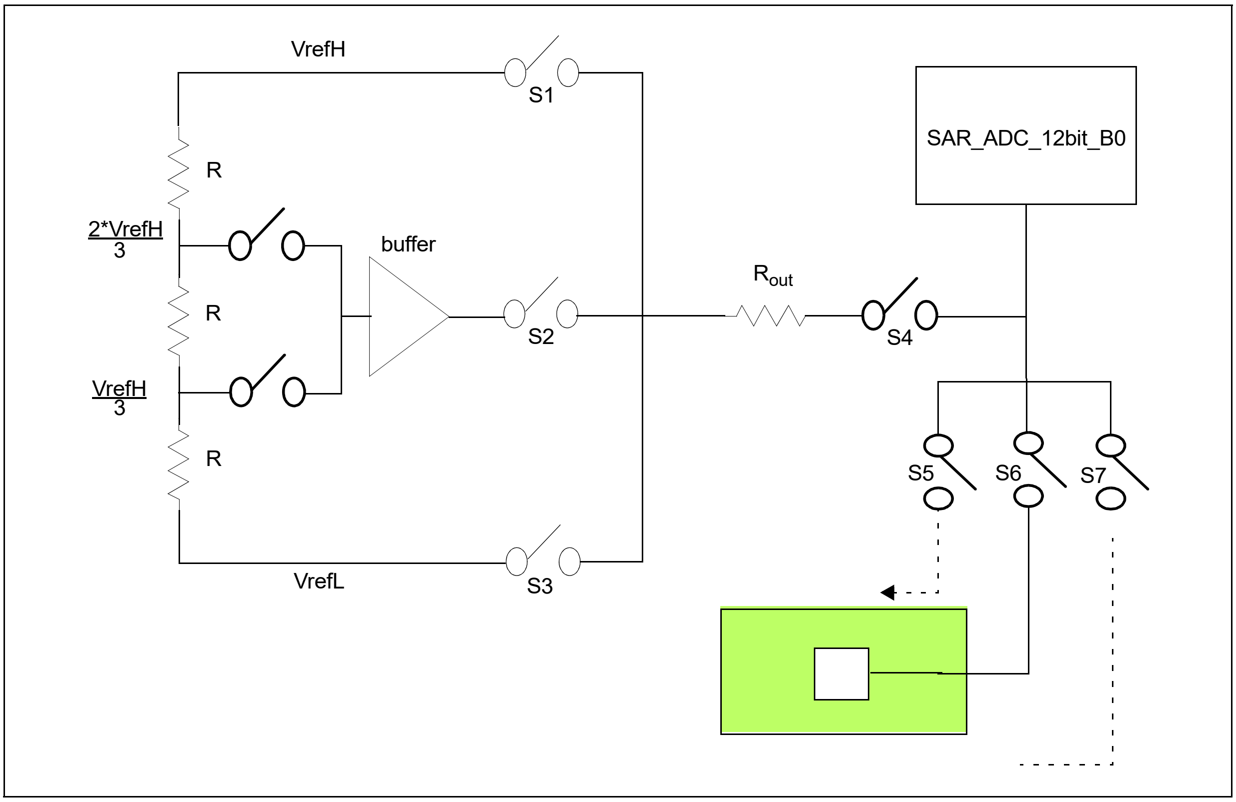
SPC584Bx provides an internal, absolute voltage reference that can be calculated from two digital temperature sensor signal values. The temperature sensor signal values can be read by SAR_ADC_12bit_B0. For further information refer to *Chapter 40: Temperature Sensor*. The ADC conversion channel numbers for the temperature sensor signals are given in *Table 464*.

38.2.1.8 SAR ADC diagnostic

38.2.1.8.1 Self Test features

- The ADCBIAS provides four different voltage levels defined as GND, $V_{ref}/3$, $2*V_{ref}/3$ and V_{ref}. The self test internal reference voltage precision is provided in the SAR ADC electrical specification table of the device datasheet.
- For the impedance requirements please refer to SPC584Bx datasheet.
- The impedance of the switches that are connecting the different references to the ADC input has not been considered in the impedance calculation.
- The impedance of the switches from the reference generation to the ADC input has been matched with the one of the switches that are connecting the device pin to the ADC input.
- The sampling time of SAR_ADC_12bit_B0 needs to be extended due to long settling time induced by the high impedance of the source. For sampling time adjustment, please refer to SPC584Bx datasheet.
- The SAR ADC Digital Interface provides the necessary control to select the required switches S1–S7 (shown in *Figure 387*) to perform the Self Test.

Figure 387. Self Test implementation



38.2.1.8.2 Internal reference

SAR_ADC_12bit_B0 provides the ability to sample and convert four internal voltages through a 20 kΩ source impedance. These voltages are as follows:

- $V_{DD\_HV\_ADR\_S}$
- 1/3 $V_{DD\_HV\_ADR\_S}$
- 2/3 $V_{DD\_HV\_ADR\_S}$
- $V_{SS\_HV\_ADR\_S}$

Conversion of an internal reference voltage works the same as that for a normal conversion, with the exception of the conversion time. Due to the 20 kΩ source impedance, the sampling time is much higher than the normal time.

Enabling the sampling and selection of an internal reference is independent of input channel selection for SAR_ADC_12bit_B0.

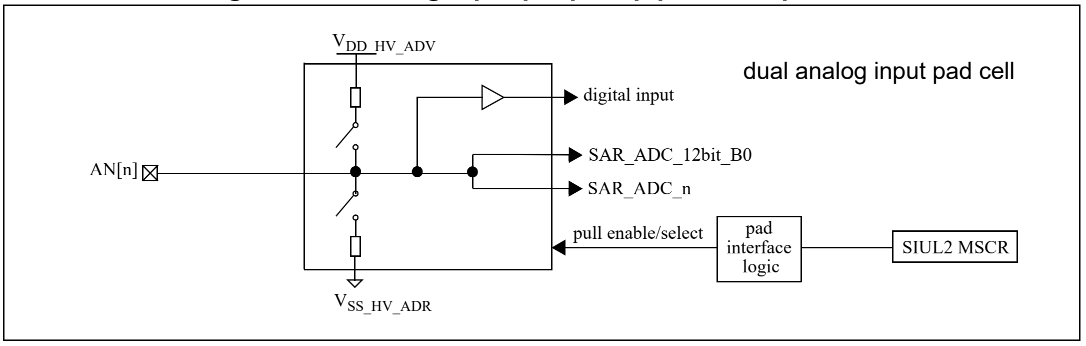
38.2.1.8.3 Analog input pin programmable pullup/pulldown

An open or short circuit condition is detectable within the device for analog input pins. There is a programmable pullup/pulldown pad cell at the input pad. This allows for application testing of the mux input logic. The analog input pin diagram with the pullup/pulldown is shown in *Figure 388*. The pullup/pulldown is included inside the analog input pad cell.

Control of the pullup/pulldown is independently done in the SIUL2 MSCR registers for each analog input pin.

Only the analog input pins specified in *Section 38.1.2* have the pullup/pulldown feature.

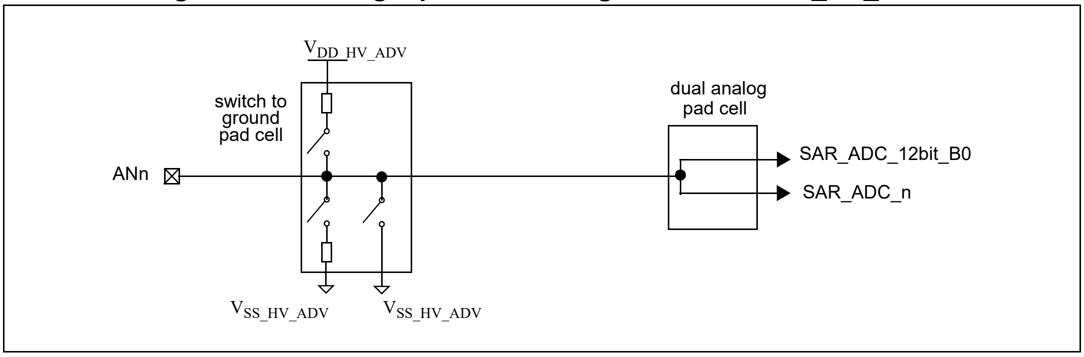
Figure 388. Analog input pin pullup/pulldown pad cell



38.2.1.8.4 Analog input pin switch to $V_{SS\_HV\_ADV}$

All analog input-only pins on SPC584Bx have in addition to the weak pullup/pulldown a programmable switch to $V_{SS\_HV\_ADV}$ to discharge the input. The analog input diagram is given in *Figure 389*. The default state of the switch for both inputs is OFF.

Figure 389. Analog input — discharge switch to VSS_HV_ADV



The ground switches are controlled independently from the input switch to the ADC. The ground switch is controlled in input multiplexing MSCR registers (MSCR[WPDE], MSCR[WPUE]) in the SIUL2. The MSCR register provides selection between open or closed switch, with open being the default state.

The ground switches can be used to periodically discharge the associated channels.

38.2.1.9 SAR ADC channel assignment

38.2.1.9.1 Internal channel assignment

The input multiplexer channel assignments for the SAR ADCs are provided in *Table 463*.

Table 463. SAR analog input channel assignment

39 Successive Approximation Register Analog-to-Digital Converter (SARADC)

39.1 Introduction

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for the application. It provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has its corresponding digital interface implemented at the chip level.

39.2 Overview

The SARADC digital interface contains advanced features for normal or injected conversion modes of operation. The conversion can be triggered by software or hardware. For advanced cross triggering functions, it provides a CTU interface with an on-chip Cross Triggering Unit (CTU) which can support two different CTU modes: CTU “trigger mode” and CTU “control mode” (refer to details in *Section 39.4.5: Cross Triggering Unit (CTU) interface*).

The digital interface can be configured to control up to 256 multiplexed analog input channels. There are three types of input channels:

- Internal channels, mapped to index ranging from 0 to 95.
- Test channels, mapped to index ranging from 96 to 127.
- External channels, mapped to index ranging from 128 to 255.

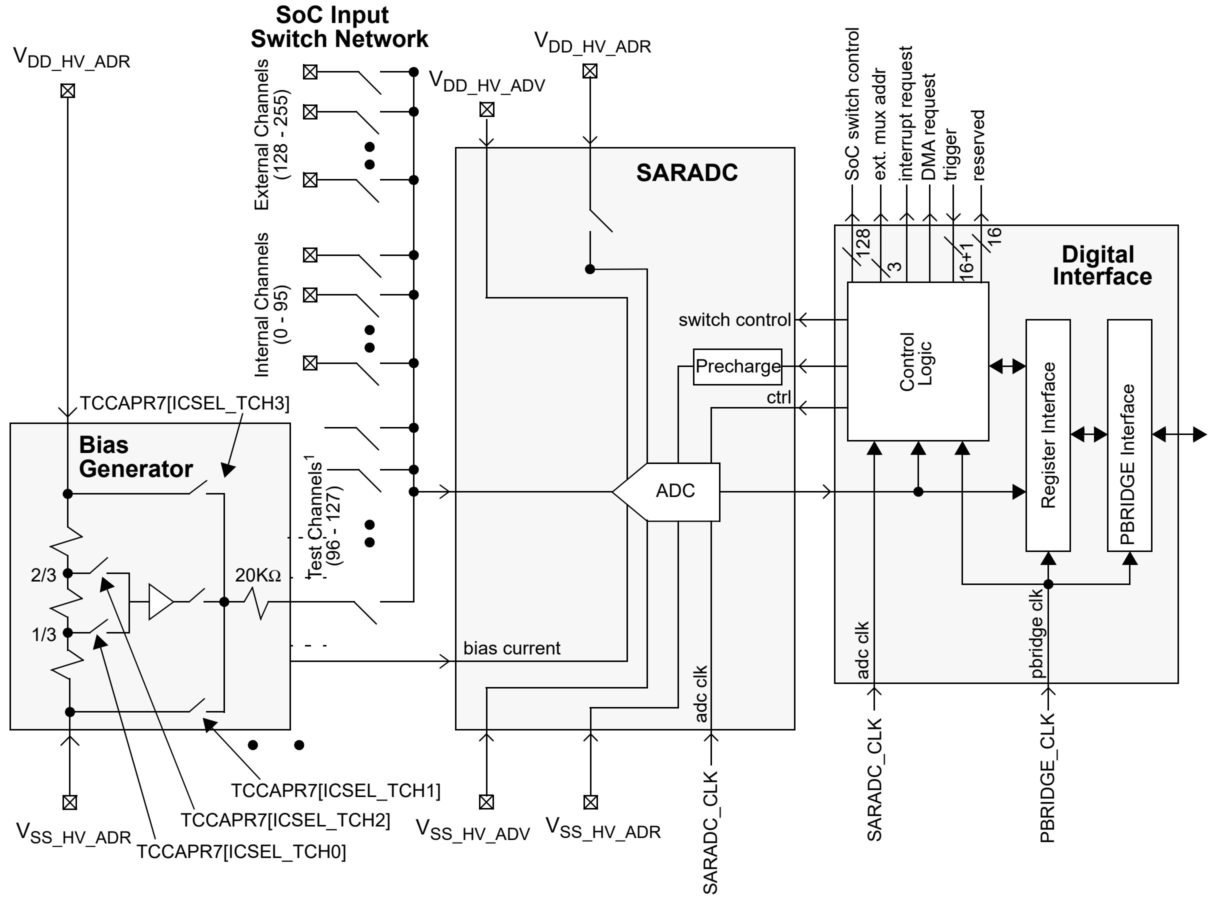
Note: The number of input channels and their mapping depend on the device configuration. Refer to the device-specific Analog-to-Digital Converters (ADC) Configuration section (analog input pin multiplexing and SAR ADC channel assignment) for a channel mapping table.

The mask registers present within the digital interface can be properly programed to configure which channel has to be converted. External channel selection is provided through external decode signals and are available as alternate functions on GPIO. Each set of eight external channels can be mapped to any internal analog channel via static software programming in specific registers.

Four conversion timing registers allow configuration of different precharging and sampling durations, one of which can then be assigned to each channel. Analog Watchdogs allow continuous hardware monitoring of analog input channels. The digital interface also provides for interrupt/DMA support for various conditions related to end of channel conversions.

Figure 390 shows the SARADC block diagram.

Figure 390. SARADC block diagram



Note1: Test channels are mapped to internal analog channels via the TCCAPRn registers of SAR ADC supervisor.

39.3 Feature description

Note: Not all features are implemented on all SARADC instances: refer to the ADC Configuration chapter for further information.

39.3.1 Main features

- Selectable 10-bit or 12-bit data resolution output for 12-bit SARADC
- Selectable 8-bit or 10-bit data resolution output for 10-bit SARADC
- Up to 96 internal channels, 32 test channels, 128 external channels supported; variable number of analog channels of each type controlled by parameters
- 4 different conversion timing registers selectable for any channel
- Mapping of external channel to any internal channel through static programming by software
- Shorting of test channel with internal channel through static programming by software
- External decode signals (3 signals) for selection of external analog mux inputs
- Normal conversion with One Shot/Scan modes
- Injected conversion with One Shot mode
- Normal conversion with dedicated trigger input
- Injected conversion with dedicated trigger input
- 2 different abort features that allow to abort either a single channel conversion or chain conversion
- Power Down Mode
- Dedicated data register for each channel, containing the following information:
  - Conversion result in one half-word:
10-bit or 12-bit for 12-bit SARADC
8-bit or 10-bit for 10-bit SARADC
  - Status byte which provides some conversion information such as mode of operation (Normal, Injected, or CTU), data valid, data overwritten status
  - Control byte for conversion timing parameter selection
- Configurable number of analog watchdogs.
- 2 different CTU modes (CTU Control mode and CTU “trigger mode”) available when CTU feature is present in SARADC instance.
- Fast Comparator Mode Conversion available when Fast Comparator feature is present in SARADC instance
- Smart Standby Wakeup Support available when Smart Standby Wakeup feature is present on SARADC instance
- Interrupt/DMA support for the following conditions
  - End of conversion of single channel for both normal, injected conversions
  - End of conversion chain for both normal, injected conversions
  - End of CTU conversion
  - Watchdog thresholds crossover

39.4 Functional description

Two main conversion types are available within the SARADC digital interface:

- Normal conversion
- Injected conversion

Note: "Precharge" option on this device means "de-charge" to reference ground VSS_HV_ADR_S.

39.4.1 Normal channel conversion

This is the normal conversion that the user programs by configuring the normal conversion mask registers (ICNCMR0–2, TCNCMR, ECNCMR0–3). Each channel can be individually enabled by setting '1' in the corresponding field of these registers. Mask registers must be programed before starting the conversion and cannot be changed until the conversion of all the selected channels ends (MSR[NSTART] bit is reset).

39.4.1.1 Start of normal conversion

The normal conversion can be started as follows:

- By software
  - The normal conversion chain starts when the MCR[NSTART] bit is set. It is recommended that the normal trigger enable MCR[NTRGEN] bit is reset during conversions started by software. Once normal conversion has started, any further write operation of MCR[NSTART] bit has no effect during ongoing conversion, but the conversion is enqueued after completion of current conversion in one shot mode.
- By normal trigger
  - A normal trigger valid edge or level is detected to start the conversion.The normal trigger is enabled by setting the NTRGEN bit in MCR and two options are available. A programed event (rising, falling or both edges depending on NEDGESEL bit field of MCR) on the normal trigger input starts the normal conversion. Once normal conversion has started, any further valid trigger edge will be ignored during ongoing conversion. If the trigger mode is enabled (MCR[NTRGEN] bit is set) and a conversion is in progress, no conversion request should be given by programming MCR[NSTART] bit.
  - An appropriate gap should be maintained between any two consecutive triggers such that next trigger is received only after the completion of the current conversion. This gap value can be calculated as a sum of total conversion time as programed using CTR0-3 registers for each channel in the chain.

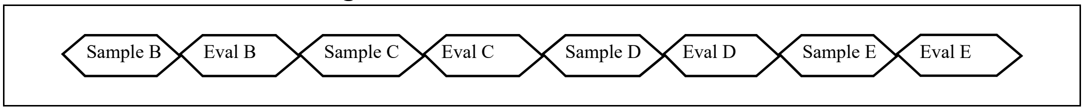
39.4.1.2 Normal conversion operating modes

Two operating modes are available for the normal conversion:

- One Shot Mode
- Scan Mode

To enter one of these modes, it is necessary to program the MCR[MODE] bit. The first phase of the conversion process involves sampling the analog channel and the next phase involves the conversion phase when the sampled analog value is converted to digital as shown in *Figure 391*.

Figure 391. Normal conversion flow



In **One Shot Mode** (MODE = 0), a sequential conversion specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored into the corresponding data register.

For Example, channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the One Shot Mode. MODE = 0 is set for One Shot mode. Conversion starts from the channel B followed by conversion of channels D-E. At the end of conversion of channel E, the scanning of channels stops.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time MCR[NSTART] bit is reset if the conversion is started by software.

Once the normal conversion operation starts in one shot mode and another software conversion request is made writing the MCR[NSTART] bit and before MSR[NSTART] is cleared, one additional conversion is initiated with the same channel mask register settings after the current conversion is finished. This is called **enqueuing**. Enqueuing can help in removing the delay between two consecutive one shot chains and uncertainty caused by metastability between MCR[NSTART] bit written at system clock and generation of start pulse on ADC clock before every chain execution.

In **Scan Mode** (MODE = 1), a sequential conversion of N channels specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 registers is continuously performed. As in the previous case, at the end of each conversion the digital result of the conversion is stored into the corresponding data register.

In this mode, the software can start conversion by writing ‘1’ to MCR[NSTART] bit or a valid normal trigger edge is detected which also sets MCR[NSTART] bit. The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One Shot Mode, the MCR[NSTART] bit is not reset. It can be reset by software when the user needs to stop scan mode. In this case, the current scan conversion is completed and MSR[NSTART] bit is also reset after the last conversion of the chain.

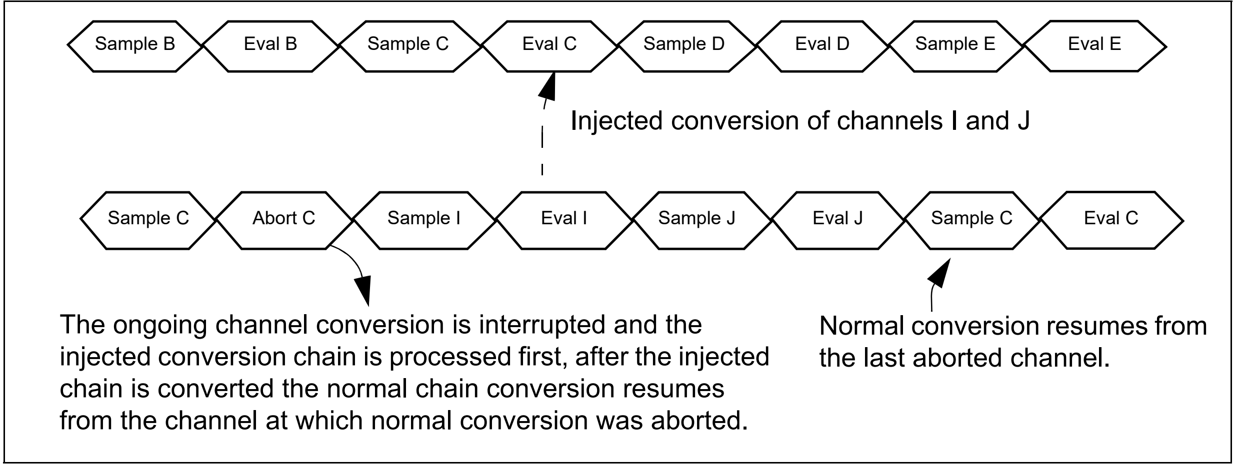
For Example, channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *Scan Mode*. MODE = 1 is set for Scan Mode. Conversion starts from the channel B followed by conversion of the channels D-E. At the end of conversion of channel E the scanning of channel B starts followed by conversion of the channels D-E. This sequence repeats itself until the MCR[NSTART] bit is reset by software.

In both modes, at the end of each channel conversion an End Of Conversion interrupt is issued (if enabled by the corresponding mask bit), and at the end of the conversion sequence an End Of Chain interrupt is issued (if enabled by the corresponding mask bit). The End Of Chain interrupt is issued for each pass of scan mode.

39.4.2 Injected channel conversion

A conversion chain can be injected into the current normal conversion by configuring the injected mask registers (ICJCMR0–2, TCJCMR, ECJCMR0–3). As in normal conversion, each internal, test or external channel can be individually selected. This injected conversion can only be in one shot mode and interrupts the normal conversion. When an injected conversion is inserted, ongoing channel conversion is aborted and the injected channel request is processed. After the last channel in the injected chain is converted, normal conversion resumes from the channel at which the normal conversion was stopped, as shown in *Figure 392*.

Figure 392. Injected sample/conversion sequence



The injected conversion can be started as follows:

- By software
  - The injected conversion chain starts when the MCR[JSTART] bit is set. The current conversion is suspended and the injected chain is converted. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed. It is recommended that the injection trigger enable MCR[JTRGEN] bit is reset during conversions started by software. Once injected conversion has started, any further write operation of MCR[JSTART] bit will not have any effect during ongoing conversion and the new request will get enqueued and executed after current injected chain finishes.
- By injection trigger
  - The injection trigger is enabled by setting the JTRGEN bit in MCR. A programed event (rising, falling or both edges depending on JEDGESEL bit field of MCR) on the injection external trigger starts the injected conversion and also sets the MSR[JSTART] bit. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed.
  - When JTRGSEQ bit is set, the injection trigger sequence feature is enabled. In this mode, each valid edge of injection trigger input will convert one analog channel. First valid edge will convert the first analog channel enabled through ICJCMR0–2, TCJCMR, ECJCMR0–3 registers. The next valid edge converts the next enabled analog input and so on. Once all the enabled channels are converted, the channel selection loops back to the first enabled channel for next trigger edge. If the JTRGSEQ is reset, the channel selection is reset again to first channel enabled through ICJCMR0–2, TCJCMR, ECJCMR0–3 registers. If JTRGSEQ is reset before completing the injected chain, the remaining channels are completed in one-shot after receiving next valid trigger edge.
  - An appropriate gap should be maintained between any two consecutive injected triggers such that next injected trigger is received only after the completion of ongoing injected conversion. This gap value can calculated as a sum of total conversion time as programed using CTR0-3 registers for each channel in the injected chain.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time MSR[JSTART] is reset if the conversion is started by software.

At the end of each injected conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit) and at the end of the sequence an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit).

39.4.3 Abort conversion

Two different abort functions are provided:

- The user can abort the ongoing conversion by setting the ABORT bit in the MCR. The current conversion is aborted and the conversion of the next channel of the chain is immediately started (generating a new start pulse to the SARADC). In the case of an abort operation, the NSTART/JSTART bit remains set and the ABORT bit is reset after the conversion of the next channel starts. The EOC corresponding to the aborted channel is not generated. This behavior is true for normal or triggered/Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported generating an ECH interrupt. ABORT function should not be used when only single channel is selected in a conversion chain, instead ABORTCHAIN can be used.
- It is also possible to abort the current chain conversion by setting the ABORTCHAIN bit in the MCR. In that case the behavior of the ADC depends on the MODE bit. In fact, if scan mode is disabled, the NSTART bit is automatically reset together with the ABORTCHAIN bit. Otherwise, if the MODE bit is set to ‘1’, a new chain conversion is started. The EOC of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

  When a chain conversion abort is requested (ABORTCHAIN bit is set) while an injected conversion is running over a suspended Normal conversion, there are 2 cases. If One Shot Mode is enabled (MODE=0 in MCR register) then both injected chain and Normal conversion chain are aborted (both the NSTART and JSTART bits are also reset). If the Scan Mode is enabled (MODE=1 in MCR register) then injected conversion is stopped and the suspended Normal conversion is restarting. (only JSTART bit is reset).

Note: ABORT/ABORTCHAIN functions are not supported during CTU initiated conversions.

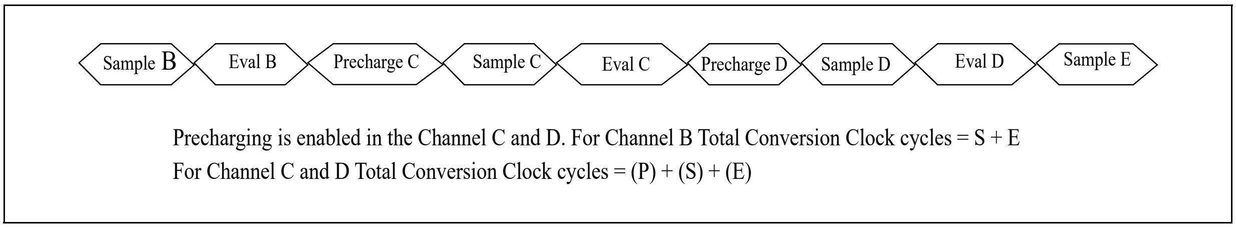
39.4.4 Analog conversion timings

39.4.4.1 Conversion timings

In order to support different loadings and switching times (in particular for the external channel types) four different Conversion Timing registers are present (CTR0–3). Each conversion timing register contains PRECHG and INPSAMP bit fields to program the required duration for precharging and sampling phases. The selection of these registers for each channel is done by the CTSEL bit field of corresponding channel data register.

Precharging phase allows to precharge or discharge the internal capacitor to a fixed internal voltage for duration determined by PRECHG bit field prior to actual analog channel sampling start. This is useful for resetting information regarding the last converted data. Precharging feature can be enabled or disabled for each channel by programming the PCE bit of corresponding channel data register. If precharging is enabled for a given channel, the normal sequence of operation is precharging, then sampling, then evaluation, as shown in *Figure 393*. Refer to device datasheet for the minimum precharge and sample durations required.

Figure 393. Analog conversion sequence



Bit fields PRECHG and INPSAMP are used to define the total conversion duration (t_{conv}) and in particular the partition among precharge duration (t_{prechg}), sampling phase duration (t_{sample}) and evaluation phase duration (t_{eval}).

The precharging phase duration is given by

$$t_{prechg} = PRECHG * t_{ck}$$

where PRECHG is the configured precharging phase duration and PCE bit of channel data register is ‘1’. If the PCE bit is ‘0’, the precharging phase is skipped and conversion starts with sampling phase directly.

The sampling phase duration is given by the following equation:

$$t_{sample} = INPSAMP * t_{ck}$$

where INPSAMP must be greater than or equal to 5 (hardware requirement). In case the value of INPSAMP is found to be less than 5, it is automatically set to 5 inside SARADC. The total evaluation phase duration is given by the following equation:

$$t_{eval} = EVAL * t_{ck}$$

In this phase, the internal sampling capacitor is disconnected from the analog channel and ADC estimates the digitized value of the sampled input using successive approximation algorithm. In the evaluation phase, all the bits are estimated sequentially to provide the conversion result.

The total conversion duration is (not including external multiplexing) is given by the following:

$$t_{conv} = t_{prechg} + t_{sample} + t_{eval}$$

The timings refer to the unit t_{ck} which is the inverse of f_{ck}, where f_{ck} = SARADC peripheral clock. Refer to the device data sheet for the total conversion time.

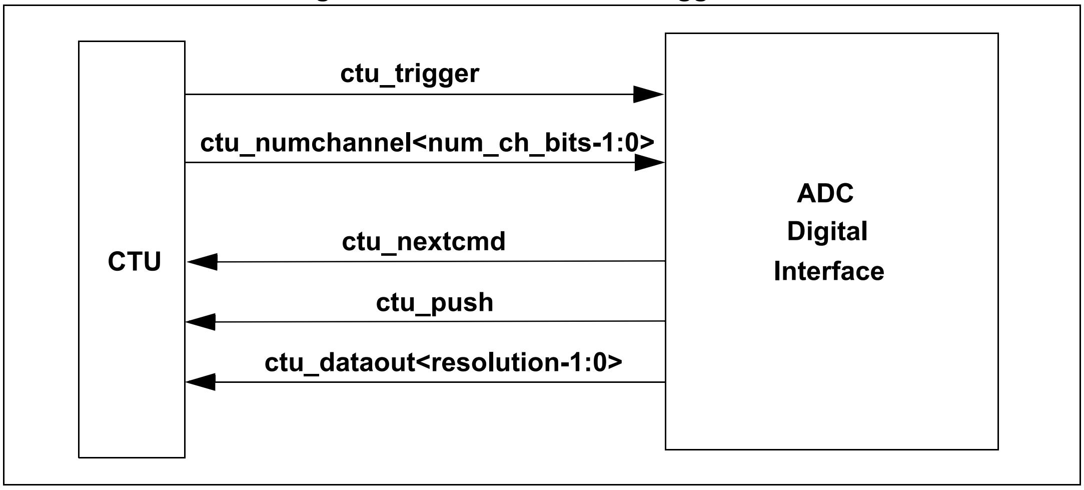
Note: The current implementation of ADCDIG does not support hardware restriction over values of PRECHG and INPSAMP fields. As minimum values for these fields are product specific and need to be managed through software.

39.4.5 Cross Triggering Unit (CTU) interface

The Cross Triggering Unit (CTU) is added to enhance the injected conversion capability of the SARADC. The CTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. In Figure 394 the CTU/ADC interface is shown.The CTU generates a trigger output pulse of one clock cycle and outputs onto a data bus which channel has to be converted. A single channel is converted for each request. After performing the conversion, the digital interface returns the conversion result to CTU. The conversion result is also saved in the corresponding channel data register and it is compared with watchdog thresholds if requested. Together with the converted data, it also sends a request for next command and a control which can be used to push the conversion result into CTU data storage registers/FIFO.

These two pulses named *ctu_nextcmd* and *ctu_push* spaced of one or two clock cycle (of analog ADC clock). The ctu_nextcmd is set to ‘1’ during the last clock cycle or last but one of ADC evaluation phase (depending on ADC type used). The ctu_push is asserted when the conversion is finished meaning that the ctu_dataout is valid.

Figure 394. SARADC Cross Trigger Unit



Different CTU modes can be selected programming the CTUEN and CTU_MODE fields of the MCR with respect of CTSEN SARADC parameter as described in the following table.

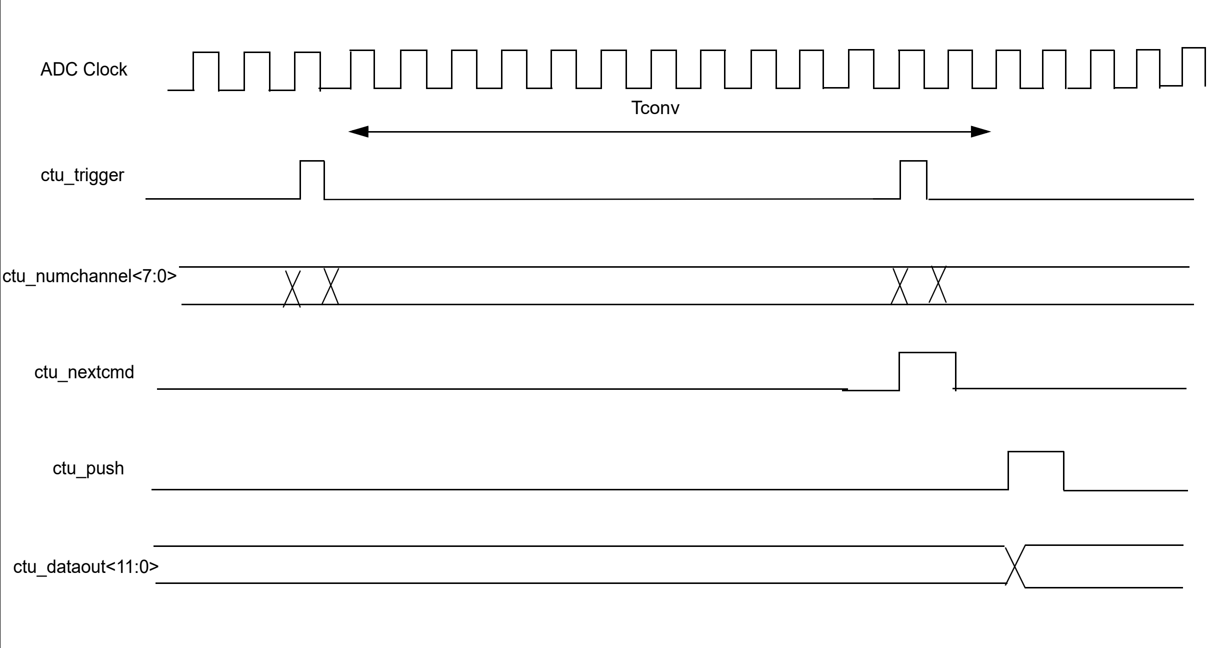
Table 465. CTU modes

CTSEN(1)	CTUEN	CTU_MODE	CTU mode
—	0	—	CTU is disabled
0	1	—	CTU trigger mode is enabled
1	1	—	CTU control mode is enabled
2	1	1	CTU trigger mode is selected
2	1	0	CTU control mode is selected

1. Refer to SAR ADC triggering section of chapter Analog-to-Digital Converters (ADC) Configuration for CTSEN value applicable on each SAR_ADC instance. CTSEN is hardware implemented, no bit register available.

The CTU, SARADC analog block and digital Interface are synchronous to each other, the CTU clock and ADC clock post division should be synchronous and phase aligned to ensure jitter free start pulses to ADC analog. Timings of CTU Interface signals are described in *Figure 395*.

Figure 395. CTU interface timings



39.4.5.1 CTU trigger mode

In CTU trigger mode, normal and injected conversions triggered by the CPU are still enabled. When a trigger pulse and the injected channel are received internally by the ADCDig, the conversion starts. The CTUSTART bit in the MSR is set automatically at this point and it is also automatically reset when the triggered injected conversion is completed.

In CTU trigger mode if an injected conversion (programed by the user by setting the JSTART bit) is ongoing and a pulse is received on the CTU trigger input line, then the injected channel conversion chain is aborted and only the triggered CTU injected conversion proceeds. Aborting the injected conversion, the JSTART bit in the MSR is reset to ‘0’. The JECH and JEOC are also reset to '0'. That abort is signaled through the status bit JABORTCHAIN in the MSR.

IN CTU trigger mode if normal conversion is ongoing and a pulse is received on the CTU trigger input line, then ongoing channel conversion is aborted and the triggered injected conversion is processed. When it is finished, normal conversion resumes from the channel at which the normal conversion was aborted.

If another CTU trigger pulse is received before the end of conversion, that request is discarded and this error condition is reported by CTUTRGERR bit in ISR.

When a normal conversion is requested during CTU conversion (CTUSTART bit = ‘1’), the normal conversion starts when CTU conversion is completed (CTUSTART reset). Otherwise, when an Injected conversion is requested during CTU conversion, that conversion is discarded and the JSTART bit in the MCR is immediately reset.

CTU trigger mode can be entered by setting CTUMODE=’1’ during power-down and CTUEN=’1’ any time after the power-down is exited. CTU trigger mode can be exited by clearing the CTUEN bit, But care must be taken not to exit the CTU mode when some CTU initiated conversion is ongoing. Also power down request (by setting MCR[PWDN] bit) should not be made while CTU transactions are ongoing.

39.4.5.2 CTU control mode

When CTU control mode is enabled, the CPU is able to write in the ADC registers but it cannot start any conversion. Conversion requests can be generated only by the CTU trigger pulse. If a normal or injected conversion is requested, it is automatically discarded.

When a CTU sends trigger pulse and channel number to be converted to SARADC digital interface, triggered injected conversion starts. The MSR[CTUSTART] bit is set automatically on the first received trigger pulse and it can be reset only when CTU is disabled (CTUEN bit to ‘0’).

CTU control mode can be entered by setting CTUMODE=’0’ during power-down and CTUEN=’1’ any time after the power-down is exited. CTU control mode can be exited by clearing the CTUEN bit, But care should be taken not to enter or exit the CTU mode when some conversion is ongoing. Also power down request (by setting MCR[PWDN] bit) should not be made while CTU transactions are ongoing.

39.4.6 Test channel connection with internal analog channel

The test channels are meant for monitoring various on-chip analog signals coming from temperature sensor, bandgap, voltage regulator and different voltage levels available on the chip. These analog signals can be interfaced to SARADC SUPERVISOR through test channels for testing purpose. Test channels are mapped from 96 to 127. Each test channel is controlled in the same way as normal internal channel.

FAST SAR ADC self-testing method: the test channel[127:124] is also mapped to various V_ref voltages (4 voltages) selection switches in the ADCBIAS block. The decoding of these channels to switch on and select a particular V_ref voltage is done in SoC level muxing logic. Refer ADC configuration for detailed mapping/control description of Self Test feature.(SAR_ADC_10bit_STDBY has no test channels)

It is also possible to perform test channel conversions with and without shorting the normal analog channel pin with the internal test voltage.

For analog test channel assignment, refer to the device configuration or ADC configuration section.

After the conversion is performed on a test channel the converted data is stored at two CDR locations at the end of conversion, first location is the CDR belonging to the test channel on which conversion is performed and second location is the CDR belonging to internal channel on which test channel is mapped.

39.4.7 External channel mapping to internal analog channel

External channels are supposed to be used in conjunction with a given internal analog channel along with an 8:1 external mux outside the device. Each input of the external mux can be mapped to a unique channel number, thus allowing it to perform conversions like any other channel of the ADC. External channels are mapped from 128 to 255.

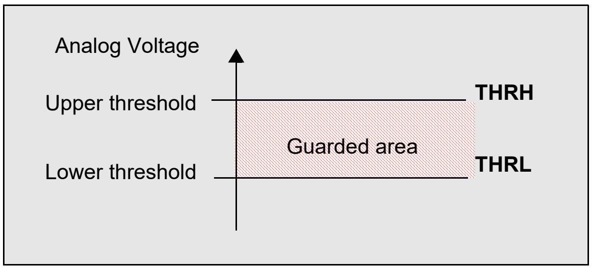
External channels are implemented in the multiples of 8. Each slice of eight channels can be associated to any physical internal analog channel mapped from 0 to 95. This external-to-internal channel mapping is determined by the ICSEL_ECx_x bit field of ECMICR0–3 registers. For example, when external multiplexer is planned to be used on internal channel 5, and the external inputs need to be mapped to channels 128 to 135, then this channel number 5 must be written to the ICSEL_ECH128_135 bit field of the ECMICR0 register. After reset, all external channels are mapped to internal analog channel 0. If a conversion on a single external channel (out of group of 8) mapped to a particular internal channel has to be performed than only that particular channel should be enabled in the Conversion Mask Register (ECNCMR or ECJCMR).

After the conversion is performed on a external channel, the converted data is stored at two CDR locations at the end of conversion. The first location is the CDR belonging to the external channel on which conversion is performed and the second location is the CDR belonging to the internal channel on which the external channel is mapped.

39.4.8 Programmable analog watchdog

Analog watchdogs are used for determining whether the result of the conversion of a channel lies within a given guard area (as shown in the *Figure 396*) bounded by upper and a lower threshold values named THRH and THRL respectively.

Figure 396. Analog watchdog guarded area



Following conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside that guard area, then corresponding threshold violation interrupts are generated. The comparison result is stored as WDGxH and WDGxL bits in the WTISR as explained in *Table 466*. Depending on the MSKWDGxL and MSKWDGxH mask bits in the WTIMR, an interrupt is generated on threshold violation.

Table 466. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

The lower and higher threshold values for the analog watchdog are programed using THRHLR0–15 registers. Analog watchdog functionality for each channel can be enabled independently from ICWENR0–2, TCWENR, ECWEN0–3 registers and can select the watchdog threshold registers (THRHLR0–15) to be used by programming ICWSELR0–11, TCWSELR0–3, ECWSELR0–15 registers. The threshold registers selected by WSEL_CHx field of watchdog threshold selection registers will provide the threshold values.

For example, if channel 30 is to be monitored with the threshold values in register THRHLR12, then WSEL_CH30 is programed to select THRHLR12 register to provide threshold values. Enabling is done by setting the bit corresponding to channel 30 in ICWENR0 register.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in ICAWORR0–2, TCAWORR, ECAWORR0–3 registers. In this case, a set of threshold registers (THRHLR0–15) can be linked to several analog channels. The threshold values to be selected for a channel needs be programed only once in ICWSELR, TCWSELR, ECWSELR registers.

Note: If the higher threshold for the analog watchdog is programed lower than the lower threshold and the converted value is less than the lower threshold, then the WDGxL interrupt for the low threshold violation is set, else if the converted value is greater than the lower threshold (consequently also greater than the higher threshold) then the interrupt WDGxH for high threshold violation is set. The user should therefore take care to avoid this situation as it could lead to misinterpretation of the watchdog interrupts.

39.4.9 DMA functionality

A Direct Memory Access (DMA) request can be programed after the conversion of every channel by setting the respective masking bit in ICDSR0–2, TCDSR and ECDSR0–3 registers. The DMA masking registers must be programed before starting any conversion. The DMA transfers can be enabled using the DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

39.4.10 Interrupts

The SARADC digital interface generates the following maskable interrupt signals:

- End Of Conversion interrupts
  - NEOC (end of normal conversion of each channel)
  - NECH (end of normal chain)
  - JEOC (end of injected conversion of each channel)
  - JECH (end of injected chain)
  - EOCTU (End of CTU Conversion)

The EOC_CH[x] bit of interrupt pending registers (ICIPR0–2, TCIPR, ECIPR0–3) is set when channel x completes the conversion (normal or injection). This pending status is qualified when the corresponding mask bit IM_CH[x] is also set in the interrupt mask registers (ICIMR0–2, TCIMR, ECIMR0–3).

The NEOC interrupt is generated only if the following conditions are met

- ISR[NEOC] bit is set after the normal conversion completion for any channel x.
- IMR[MSKNEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The JEOC interrupt is generated only if the following conditions are met

- ISR[JEOC] bit is set after the injected conversion completion for any channel x.
- IMR[MSKJEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The EOCTU interrupt is generated only if the following conditions are met

- ISR[EOCTU] bit is set after the CTU triggered conversion completion for any channel x.
- IMR[MSKEOCTU] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

It is recommended to clear the NEOC/JEOC/EOCTU bits of ISR and all the individual channel pending bits which are not masked while servicing the interrupt.

The ISR[NECH] bit is set when a normal channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

The ISR[JECH] bit is set when an injected channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

- WDGxL and WDGxH (Watchdog threshold) interrupt requests

The interrupts generated due to the analog watchdog are handled by registers WTISR and WTIMR in order to check and enable the interrupt requests to external interrupt controller module. The watchdog interrupt source sets two pending bits WDGxH and WDGxL for each channel being monitored in the WTISR. The interrupt request is generated if at least one of the following conditions are met:

- WTISR[WDGxL] bit is set and the corresponding mask bit MSKWDGxL is also set in WTIMR for at least one channel.
- WTISR[WDGxH] bit is set and the corresponding mask bit MSKWDGxH is also set in WTIMR for at least one channel.

The ISR and WTISR contain the interrupt pending request status flags. In case the user wants to clear a particular interrupt event status, writing a ‘1’ to the corresponding status bit clears the pending interrupt flag. (At this write operation, all other bits of the ISR must be maintained at ‘0’.)

The ADC module provides dedicated interrupt outputs for all interrupt sources. Also, all interrupt lines are OR-ed together to provide a single output to the external interrupt controller if a combined interrupt is required.

Conversion should not be initiated unless the required conversion mask bits (ECNCMR or ECJCMR) are set.

39.4.11 External decode signals selection and delay

The ADC provides three external decode signals used as select lines for 8:1 external mux. For each set of 8 external channels (for example [CH128:CH135], [CH136:CH143], and so on), the same 3-bit decode signals output are used to select the inputs of external mux. These external mux select lines change in grey code sequence for each increment of channel selection. This ensures that only one line changes and avoids any current spikes or leakage if more than one line changes simultaneously.

In order to take into account the control switching time of the external analog mux, a Decode Signals Delay register is provided. Writing that register allows programming of the delay between the decoding signal selection and the actual start of conversion.

39.4.12 Power down mode

The SARADC analog block can be put in low current consumption mode by setting the PWDN bit in MCR. This is the default mode after exiting from reset. This state must be exited before starting any operation by resetting the PWDN bit in the MCR. When in power-down mode, no conversion should be started. Bit ADCSTATUS[0] in the MSR is set only when ADC enters power-down mode.

The power-down mode can be requested by setting the PWDN bit in the MCR. If a one-shot conversion is ongoing, the SARADC cannot immediately enter the power-down mode. In fact, the SARADC enters power-down mode only after completing the ongoing conversion. If a scan conversion is ongoing, the ongoing operation shall be first aborted manually by resetting the NSTART bit and using the ABORTCHAIN bit. A power Down request while scan mode conversion is ongoing is ignored.

After the power down phase is completed, the process ongoing before the power down phase must be restarted manually (by setting the appropriate START bit). Resetting PWDN bit and setting NSTART or JSTART bit during the same cycle is forbidden.

CTU triggered conversion should not be initiated during power down mode. In both CTU modes, to request power down mode the application has to wait for the end of the current CTU conversion (CTUSTART bit automatically reset when conversion finishes). Additionally, when SARADC is in CTU control mode the application needs to exit the CTU control mode (by resetting the CTUEN bit) before requesting the power down mode.

39.4.13 Stop mode

The SARADC can be requested to enter this low power mode anytime during the operation. If stop mode is requested while some Normal/Injected mode chained conversions are ongoing, the current channel conversion will be completed and upon stop mode exit the conversion will be resumed from next channel. However, stop mode should not be requested while CTU triggered conversions are ongoing.

39.4.14 Fast Comparator mode conversion

In this mode the SARADC analog block/sequencer can be requested to work as a fast comparator instead of a regular data converter for the initiated conversion (single/chain). Here, the sample phase remains unchanged, but the evaluation phase is reduced to just two cycles of fast comparison of the sampled channel value with regards to the corresponding threshold pair values (THRL,THRH) provided at the start of each conversion.

39.4.14.1 Execution order

The programming sequence and execution order when SARADC works in Fast Comparator mode is as follows:

1. The user must configure and program the required SARADC configuration and control registers like MCR, Channel Conversion Mask (CMRs), CTRs in the same way and order as if normal or injected conversion were initiated. CDR/CTR programming constraint is the following:
   CTR[INPSAMP] >= 2. Value of 2 for the minimum sampling duration.
2. Enable the Fast Comparator feature by programming the Fast Comparator Enable (MCR[FCE]) bit.
3. Associate and select (program WSELR) 1 out of maximum 16 watchdog threshold pairs (program WTHRHLR[THRL,THRH]) for each of the channels selected for fast

comparison and enable (WENR). WTHTHLR[THRL,THRH] programming constraints are as follows:

a) THRH > THRL

b) THRH < Maximum value of converted analog signal, that is $2^{resolution}-1$

c) THRL > Minimum value of converted analog signal, that is 0

4. Initiate the conversion by setting MCR[NSTART/JSTART].
5. The result of fast comparison from ADC analog block {THRH+1, THRL-1 or (THRH+THRL)/2} and the comparator error status are stored as normal conversion results in the CDR registers.
6. The conversion results are again compared by the watchdog monitor inside the ADC digital interface and resulting violation is reported back to the system by WTISR[WDG0-15L/H] status bits, corresponding interrupts and two external signals (upper threshold violation, lower threshold violation).
7. For additional requirements about smart standby wake up using fast comparator mode, refer to the below *Section 39.4.15* for more details.

39.4.15 Smart standby wake up support

Here, the SARADC in conjunction with the CTU and the smart standby wake up unit (SSWU) can be used to wake up the system by regularly checking the sampled values. This is done with respect to the programed thresholds on certain selected channels.

39.4.15.1 Execution order

The programming sequence and execution order when SARADC works in conjunction with the SSWU is as follows:

1. User must configure and program the required SARADC configuration and control registers like MCR, Channel Conversion Mask (CMRs), CTRs.
2. Associate and select (program WSELR) 1 out of maximum 16 watchdog threshold pairs (program WTHRHLR[THRL,THRH]) for each of the channels selected through CMRs and enable (WENR).
3. Set MCR[FCE]; if fast comparator mode conversion is required (optional), the steps 1, 2 and 3 should be performed before the system enters in standby mode.
4. The CTU and SSWU exit the power down mode of SARADC by de-asserting the power down request signal.
5. CTU Initiates conversion providing CTU triggers. The minimum gap between the power down request signal pulse and the first CTU trigger pulse should be greater than 2 to 3 ADC clock cycles.
6. The result of conversion is available in CDR after the end of conversion pulse arrives from SARADC analog block; If MCR[FCE] is set, comparison results are stored as either THRH+1, THRL-1 or (THRH+THRL)/2 in the CDR registers.
7. The conversion results are again compared by the watchdog monitor inside the ADC digital interface and the resulting violation is reported back to the SSWU by two external signals (upper threshold violation, lower threshold violation).
8. SSWU can request for SARADC power-down mode entry by asserting the power down request signal (rising edge) port.

39.5 Memory map and registers

This section provides memory map for the SARADC digital interface.

Note: The actual availability and number of registers and their configuration are chip-specific. For this information, refer to "ADC Configuration" chapter.

Figure 397. Main Configuration Register (MCR)

Table 468. MCR field descriptions

Field	Description
0 OWREN	Overwrite enable This bit enables or disables the functionality to overwrite unread converted data in ICDR, TCDR, ECDR registers. 0 Prevents overwrite of unread converted data, new result is discarded. 1 Enables converted data to be overwritten by a new conversion.
1 WLSIDE	Write left/right-aligned 0 The conversion data in ICDR, TCDR, ECDR registers is written right-aligned. 1 Conversion data is left-aligned (from 15 to (15 – resolution + 1))
2 MODE	One Shot/Scan 0 One Shot Mode: Configures the normal conversion of one chain. 1 Scan Mode: Configures continuous chain conversion mode; when the programed chain conversion is finished it restarts immediately

Table 468. MCR field descriptions (continued)

Field	Description
4 NSTART	Normal Start conversion Setting this bit starts the chain or scan conversion. Resetting this bit during scan mode causes the current chain conversion to finish, then stops the operation. 0 Causes the current chain conversion to finish and stops the operation. 1 Starts the chain or scan conversion **Note:** The application relies on the corresponding bit in MSR (MSR[NSTART]) to confirm that any changes to this bit has taken effect. Example with NSTART bit: MCR[NSTART] = 1; // Register to start normal conversion while(MSR[NSTART]==0); // Ensure normal conversion is completed before raising new request
5 NTRGEN	Normal trigger enable 0 Normal trigger disabled to start a normal conversion. 1 Normal trigger enabled to start a normal conversion.
6:7 NEDGESEL	Normal trigger edge selection 00 Falling edge of normal trigger is selected. 01 Rising edge of normal trigger is selected. 10 Both rising and falling edges of normal trigger are selected. (*x* = 0,1). 11 Both rising and falling edges of normal trigger are selected. (*x* = 0,1)
8 JSTART	Injected Start conversion Setting this bit will start the configured injected analog channels to be converted by software. Resetting this bit has no effect, as the injected chain conversion cannot be interrupted. 0 Writing ‘0’ has no effect. 1 Starts the injected chain conversion. **Note:** The application should rely on the corresponding bit in MSR (MSR[JSTART]) to confirm that any changes to this bit have taken effect.
9 JTRGEN	Injection trigger enable 0 Injection trigger disabled for channel injection (injected conversion cannot be started using an injection trigger) 1 Injection trigger enabled for channel injection
10:11 JEDGESEL	Injection trigger edge selection 00 Falling edge of injection trigger is selected 01 Rising edge of injection trigger is selected 10 Both rising and falling edges of injection trigger are selected. (*x* = 0,1) 11 Both rising and falling edges of injection trigger are selected. (*x* = 0,1)
12 JTRGSEQ	Injection trigger sequence enable 0 Injection trigger sequence mode is disabled 1 Injection trigger sequence mode is enabled
14 CTUEN	Cross Trigger Unit Enable 0 The cross triggering unit is disabled and the triggered injected conversion cannot take place 1 The cross triggering unit is enabled and the triggered injected conversion can take place **Note:** Can be set or cleared anytime with some restriction mentioned in CTU trigger/control mode section.

Table 468. MCR field descriptions (continued)

Field	Description
15 CTU_MODE	Cross Trigger Unit Mode This bit is present only if generic parameter CTSEN = 2, otherwise this bit is a reserved bit and always read as 0. This should be set only when ADC Digital is in power-down mode. 0 CTU control mode is selected 1 CTU trigger mode is selected
20:23 JTRGSEL	Injection Trigger Input Selection This bit field selects which trigger input to be selected to start injected conversion. 0000 Trigger input 0 is selected. 0001 Trigger input 1 is selected ... 1111 Trigger input 15 is selected **Note:** JTRGSEL[3:0] must be 0000 when only one trigger input (input 0) is supported
24 ABORTCHAIN	Abort Chain When this bit is set, the ongoing Chain Conversion is aborted. This bit is reset by hardware as soon as a new conversion is requested. 0 Conversion is not affected 1 Aborts the ongoing chain conversion **Note:** Behavior of this request during CTU mode is mentioned in CTU trigger/control mode section.
25 ABORT	Abort Conversion When this bit is set, the ongoing conversion is aborted and a new conversion is invoked. This bit is reset by hardware as soon as a new conversion is invoked. 0 Conversion is not affected 1 Aborts the ongoing conversion **Note:** Behavior of this request during CTU mode is mentioned in CTU trigger/control mode section.
27 FRZ	Freeze This bit enables to stop the SARADC conversions at the end of current channel conversion when SoC enters debug mode. 0 Conversions are not stopped 1 When SoC enters debug mode, further conversions by SARADC analog block will be stopped. The ongoing channel conversion will be completed and the converted data is stored. When the SoC exits debug mode, SARADC resumes the job that was left before halting the conversions. Changing configuration registers during halted condition may cause a pending operation to fail when normal operation is resumed
29 FCE	Fast Comparator Enable This bit enables the fast comparison mode for upcoming channel conversions. 0 Fast Comparison mode disabled 1 Fast Comparison mode enabled

Table 468. MCR field descriptions (continued)

Field	Description
30 EDCSELF	External Decode Channel Format Select (EDCSELF) This bit selects the format for 3-bit output port ipp_decode_extch used as select line for external decode channel 8:1 muxes. The last three bits of external channel number are passed as is (if value 0) or converted to gray code (if value 1) and passed to this port. 0 Binary format 1 Gray Code format
31 PWDN	Power-down enable When this bit is set, the analog module is requested to enter Power Down mode. When SARADC status is PWDN, resetting this bit starts SARADC transition to IDLE mode. 0 SARADC is in normal mode. 1 SARADC has been requested to power down. **Note:** When requesting a power mode transition, the application should rely on the MSR[ADCSTATUS] bit field in order to confirm that the transition has taken effect.

39.5.1.2 Main Status Register (MSR)

Offset: 0x004 Access: User Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Only available with cross-triggering unit (CTU) feature.

Figure 398. Main Status Register (MSR)

Table 469. MSR field descriptions

Field	Description
4 NSTART	This status bit is used to signal that a normal conversion is ongoing. 0 Normal conversion is not taking place. 1 Normal conversion is ongoing or the normal conversion is pending due to injected conversion or CTU triggered injected conversion.
8 JSTART	This status bit is used to signal that an injected conversion is ongoing. 0 Injected conversion is not taking place. 1 Injected conversion is ongoing.
13 JABORTCHAIN	This status bit is used to signal that an Injected conversion chain has been aborted. This bit is reset when a new conversion starts. 0 Last injected conversion chain has not been aborted. 1 Last injected conversion chain has been aborted.
15 CTUSTART	This status bit is used to signal that a CTU conversion is ongoing. This bit is set when a CTU trigger pulse is received and the CTU conversion starts. When CTU trigger mode is enabled this bit is automatically reset when the conversion is completed. Otherwise, if Control Mode is enabled this bit can be reset only when the CTU is disabled (CTUEN set to ‘0’). 0 CTU triggered injected conversion is not taking place. 1 CTU triggered injected conversion is ongoing.
16:23 CHADDR	Channel under measure address This status bit is used to signal which channel is under measure.
29:31 ADCSTATUS	The value of this parameter depends on ADC status. While requesting an external channel conversion, SARADC digital interface needs to wait for a fixed time determined by DSD bit field of DSDR before proceeding to actual sampling phase. This is known as wait state. 000 IDLE 001 Power-down 010 Wait state 011 — 100 Sample 101 — 110 Conversion 111 —

1. Only available with cross-triggering unit (CTU) feature.

Figure 399. Interrupt Status Register (ISR)

Table 470. ISR field descriptions

Field	Description
26 CTUTRGERR	CTU Trigger Error Flag This Error Flag indicates that the next CTU trigger has been discarded as it overlapped during execution of current CTU conversion. This indicated that CTU sampling duration is less than programed conversion time of ADC. 0 No CTU trigger overlap error condition since last CTU conversion. 1 CTU trigger overlap error has occurred.
27 EOCTU	End of CTU channel conversion interrupt flag This bit indicates the end of conversion for a CTU injected channel. 0 End of conversion of CTU triggered channel has not occurred since the last time the flag is cleared. 1 End of conversion of CTU triggered channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
28 JEOC	End of injected channel conversion interrupt flag This bit indicates the end of conversion for an injected channel. 0 End of conversion of injected channel has not occurred since the last time the flag is cleared. 1 End of conversion of injected channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
29 JECH	End of injected chain conversion interrupt flag This bit indicates the end of conversion for an injected chain. 0 End of conversion of injected chain has not occurred since the last time the flag is cleared. 1 End of conversion of injected chain has occurred or the flag has not been cleared since the last end of conversion occurrence.

Table 470. ISR field descriptions (continued)

Field	Description
30 NEOC	End of normal channel conversion interrupt flag This bit indicates the end of conversion for a normal channel. 0 End of conversion of normal channel has not occurred since the last time the flag is cleared. 1 End of conversion of normal channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
31 NECH	End of normal chain conversion interrupt flag This bit indicates the end of conversion for an normal chain. 0 End of conversion of normal chain has not occurred since the last time the flag is cleared. 1 End of conversion of normal chain has occurred or the flag has not been cleared since the last end of conversion occurrence.

39.5.1.4 Internal Channel Interrupt Pending Register *n* (ICIPR*n*)

The interrupt channel register to channel association is described in *Table 472*.

Offset: 0x014 + *n**0x4 (*n* = 0 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 DS_CH[x]	DMA select for channel x 0 CH[x] is disabled to transfer data in DMA mode. 1 CH[x] is enabled to transfer data in DMA mode.

Table 480. Internal Channel DMA Select Registers to Channel Association

Register	Register bits 0:31
ICDSR0	DS_CH[31:0]
ICDSR1	DS_CH[63:32]
ICDSR2	DS_CH[95:64]

Note: If channel CH[x] is not existing then the corresponding bit field DS_CH[x] is reserved and returns 0.

If all channels CH[x] are not existing, the full register is not existing and any attempt to access this space generates a transfer error.

39.5.1.11 Watchdog Threshold Register *n* (WTHRHLR*n*)

Note: The number of WTHRHLR registers corresponds to the number of analogs watchdogs implemented in the ADC module.

The length of the threshold field depends on the SARADC resolution. For 10-bit SARADC, the bits 4, 5, 20 and 21 are reserved.

Note: The reset value of the bits 4 and 5 is 0 instead of 1 in case SARADC resolution is 10-bit.

Offset: 0x060 + *n**0x4 (*n* = 0 to 3) Access: User Read/Write

Figure 411. Power Down Exit Delay Register (PDEDR)

Table 487. PDEDR field descriptions

Field	Description
24:31 PDED	Power down exit delay duration Defines the delay between the power-down bit reset and the starting of conversion. The power-down delay is calculated as [PDED × 1/(SARADC clock frequency)]. The minimum required power down delay is the sum of $t_{ADCBIASINIT}$ (time required by ADCBIAS to generate correct value of bias current for all ADCs) and $t_{ADCINIT}$ (initialization time for ADC after the generation of bias current). Both values are provided in the device datasheet.

39.5.1.16 Internal Channel Data Register n (ICDR*n*)

The conversion results for each channel are loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid, timing parameter selection for each channel.

This register should be accessed via 32-bit R/W.

Offset: 0x100 + *n**0x4 (*n* = 0 to 95) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 412. Internal Channel Data Register *n* (ICDR*n*)

Table 488. ICDR*n* field descriptions

Field	Description
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled. 1 Precharge phase is enabled.
6:7 CTSEL	This bit field selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected. 01 CTR1 is selected. 10 CTR2 is selected. 11 CTR3 is selected.
11 FCERR	Fast Comparator Error Flag This bit is used to notify error condition on current fast comparator operation inside ADC analog block. It is automatically cleared when data is read. 0 Cleared by reading the Converted by software. 1 Fast Comparator Error Condition has occurred in current conversion.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten. 1 Previous converted data has been overwritten before having been read.

Table 488. ICDRn field descriptions (continued)

Field	Description
14:15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode. 01 Data is a result of Injected conversion mode. 10 Data is a result of CTU conversion mode. 11 Reserved
16:31 CDATA	Channel converted data **Note:** The data organization inside the CDATA field is dependent on: – The SARADC type which can either be a 12-bit type, a 10-bit type or a 9-bit type. – The setting of CTRx.CRES which selects if conversion is done with full resolution or with reduced resolution. – The setting of MCR.WLSIDE which selects the read data alignment. The valid data bits position is summarized in *Table 489*.

Table 489. Valid data bit organization

39.5.1.17 Watchdog Threshold Register *n* (WTHRHLR*n*)

Note: The number of WTHRHLR registers corresponds to the number of analogs watchdogs implemented in the ADC module.

The length of the threshold field depends on the SARADC resolution.

For 10-bit SARADC, the bits 4, 5, 20 and 21 are reserved.

Offset: 0x280 + n*0x4 (n = 4 to 15) Access: User Read/Write

Table 492. Internal Channel Watchdog Enable Registers to Channel Association

Register	Register bits 0:31
ICWSELRn (n = 0 to 11)	WSEL_CH[(8*n)+7] … WSEL_CH[8*n]

The number of bits implemented for each WSEL_CHx depends on Watchdog number:

- If Watchdog number > 8, the number of bits implemented is 4 (WSEL_CHx[3:0])
- If 4 < Watchdog number <= 8, the number of bits implemented is 3 (WSEL_CHx[3] is reserved).
- If 1 < Watchdog number <= 4, the number of bits implemented is 2 (WSEL_CHx[3:2] is reserved).
- If Watchdog number = 1, only 1 bit is present.

Each nibble (WSEL_CHx) has a positional correspondence to the Internal Channel number (each channel has a 1:1 nibble correspondence), so each word ICWSELRx corresponds to eight internal Channels for a total of twelve 32-bit registers to covering all 96 test channels.

If an Internal channel is not defined, the corresponding WSEL_CHx nibble is not implemented. For the implemented nibbles, width of WSEL_CHx field within the nibble is dependent on the Watchdog number. For example, if Watchdog number is 4 than only two LSBs of each WSEL_CHx are implemented and remaining two will remain unimplemented. If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

39.5.1.19 Internal Channel Watchdog Enable Register *n* (ICWENR*n*)

The Watchdog enable registers to channel association is described in *Table 494*.

Offset: 0x2E0 + *n**0x4 (*n* = 0 to 2) Access: User Read/Write

16:19 WSEL_CH[(8*n)+99]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
20:23 WSEL_CH[(8*n)+98]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
24:27 WSEL_CH[(8*n)+97]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
28:31 WSEL_CH[(8*n)+96]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. … 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.

Table 508. Test Channel Watchdog Select Registers to Channel Association

Register	Register bits 0:31
TCWSELR0	WSEL_CH[103] … WSEL_CH[96]
TCWSELR1	WSEL_CH[111] … WSEL_CH[104]
TCWSELR2	WSEL_CH[119] … WSEL_CH[112]
TCWSELR3	WSEL_CH[127] … WSEL_CH[120]

The number of bits implemented for each WSEL_CHx depends on Watchdog number:

- If Watchdog number > 8, the number of bits implemented is 4 (WSEL_CHx[3:0])
- If 4 < Watchdog number <= 8, the number of bits implemented is 3 (WSEL_CHx[3] is reserved).
- If 1 < Watchdog number <= 4, the number of bits implemented is 2 (WSEL_CHx[3:2] is reserved).
- If Watchdog number = 1, only 1 bit is present.

Each such nibble (WSEL_CHx) has positional correspondence to Test Channel number (each channel has a 1:1 nibble correspondence), so each word TCWSELRx corresponds to eight test Channels, thus requiring total four 32-bit registers to cover all 32 test channels.

If a Test channel is not defined, the corresponding WSEL_CHx nibble is not implemented. For the implemented nibbles, width of WSEL_CHx field within the nibble is dependent on the Watchdog number. For example, if Watchdog number is 4 than only two LSBs of each WSEL_CHx are implemented and remaining two will remain unimplemented. If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

39.5.1.27 Test Channel Watchdog Enable Register (TCWENR)

The Watchdog enable registers to channel association is described in *Table 510*.

Offset: 0x424 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	WEN_CH[x]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WEN_CH[x]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 423. Test Channel Watchdog Enable Register (TCWENR)

Table 509. TCWENR field descriptions

Field	Description
0:31 WEN_CH[x]	Watchdog enable for channel x 0 Watchdog feature is disabled for CH[x]. 1 Watchdog feature is enabled for CH[x].

Table 510. Test Channel Watchdog Enable Registers to Channel Association

Register	Register bits 0:31
TCWENR	WEN_CH[127:96]

Note: If channel CH[x] is not existing then the corresponding bit field WEN_CH[x] is reserved and returns 0.

If all channels CH[x] are not existing, the full register is not existing and any attempt to access this space generates a transfer error.

39.5.1.28 Test Channel Analog Watchdog Out of Range Register (TCAWORR)

The analog watchdog registers to channel association is described in *Table 512*.

Offset: 0x0428 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 424. Test Channel Analog Watchdog Out of Range Register (TCAWORR)

Table 511. TCAWORR field descriptions

Field	Description
0:31 AWOR_CH[x]	Analog watchdog out of range status for channel x, provided corresponding WEN_CHx bit is set. 0 CH[x] converted data is not out of range determined by its thresholds. 1 CH[x] converted data is out of range determined by its thresholds.

Table 512. Analog Watchdog Register to Channel Association

Register	Register bits 0:31
TCAWORR	AWOR_CH[127:96]

Note: If channel CH[x] is not existing then the corresponding bit field AWOR_CH[x] is reserved and returns 0.

If all channels CH[x] are not existing, the full register is not existing and any attempt to access this space generates a transfer error.

39.5.1.29 Test Channel Connection with Analog Pin Register *n* (TCCAPR*n*)

Test channels connected through a 20 kΩ source impedance can be shorted with any internal analog channel using the configuration programed in these registers.

Test channel short registers to channel association is described in *Table 514*.

For analog test channel assignment, refer to the table SAR_ADC analog test channel assignment of chapter Analog-to-Digital Converters (ADC) Configuration.

Offset: 0x430 + *n**0x4 (*n* = 0 to 7) Access: User Read/Write

39.5.1.30 Test Channel Data Register *n* (TCDR*n*)

The conversion results for each channel are loaded into data registers. Each data register contains:

- the conversion result
- status information related to ADC mode
- data valid
- timing parameter selection for each channel.

These registers are accessed 32-bit R/W.

Offset: 0x2D0 + *n**0x4 (*n* = 96 to 127) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 426. Test Channel Data Register *n* (TCDR*n*)

Table 515. TCDR*n* field descriptions

Field	Description
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled 1 Precharge phase is enabled
6:7 CTSEL	This bit field selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
11 FCERR	Fast Comparator Error Flag This bit is used to notify error condition on current fast comparator operation inside ADC analog block. It is automatically cleared when data is read. 0 Cleared by reading the Converted by software. 1 Fast Comparator Error Condition has occurred in current conversion.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software 1 Converted data is valid and has not been read yet
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14:15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16:31 CDATA	Channel converted data **Note:** If MCR[WLSIDE] is set to ‘0’ than the converted data is read right aligned with lower 12/10 bits representing the actual converted data (width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining upper 4/6 bits are read as zeros. Whereas if the MCR[WLSIDE] is set as ‘1’ than the converted data is read left aligned with upper 12/10 bits representing the actual converted data (width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining lower 4/6 bits are read as zeros.

39.5.1.31 External Channel Decode Signals Delay Register (ECDSDR)

Table 527. ECWSELRn field descriptions (continued)

Field	Description
20:23 WSEL_CH[(8*n)+130]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. ... 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
24:27 WSEL_CH[(8*n)+129]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. ... 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.
28:31 WSEL_CH[(8*n)+128]	Watchdog select for channel x 0000 THRHLR0 register is selected. 0001 THRHLR1 register is selected. 0010 THRHLR2 register is selected. ... 1110 THRHLR14 register is selected. 1111 THRHLR15 register is selected.

Table 528. External Channel Watchdog Enable Registers to Channel Association

Register	Register bits 0:31
ECWSELRn (n = 0 to 15)	WSEL_CH[(8*n)+135] ... WSEL_CH[(8*n)+128]

The number of bits implemented for each WSEL_CHx depends on Watchdog number:

- If Watchdog number > 8, the number of bits implemented is 4 (WSEL_CHx[3:0])
- If 4 < Watchdog number <= 8, the number of bits implemented is 3 (WSEL_CHx[3] is reserved).
- If 1 < Watchdog number <= 4, the number of bits implemented is 2 (WSEL_CHx[3:2] is reserved).
- If Watchdog number = 1, only 1 bit is present.

Each nibble (WSEL_CHx) has positional correspondence to the External Channel number (each channel has a 1:1 nibble correspondence), so each word ECWSELRx corresponds to eight external channels, thus requiring a total of sixteen 32-bit registers to cover all 128 external channels.

If an External channel is not defined, the corresponding WSEL_CHx nibble is not implemented. For the implemented nibbles, width of WSEL_CHx field within the nibble is dependent on the Watchdog number. For example, if Watchdog number is 4, then only two LSBs of each WSEL_CHx are implemented and the remaining two will remain unimplemented. If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

39.5.1.38 External Channel Watchdog Enable Register *n* (ECWENR*n*)

The Watchdog enable registers to channel association is described in *Table 530*.

Offset: 0x5A0 + n*0x4 (n = 0 to 3) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	WEN_CH[x]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WEN_CH[x]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 437. External Channel Data Register *n* (ECDR*n*)

Table 535. ECDR*n* field descriptions

Field	Description
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled. 1 Precharge phase is enabled.
6:7 CTSEL	This bit field selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected. 01 CTR1 is selected. 10 CTR2 is selected. 11 CTR3 is selected.
11 FCERR	Fast Comparator Error Flag This bit is used to notify error condition on current fast comparator operation inside ADC analog block. It is automatically cleared when data is read. 0 Cleared by reading the Converted by software. 1 Fast Comparator Error Condition has occurred in current conversion.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten. 1 Previous converted data has been overwritten before having been read.

Table 535. ECDRn field descriptions (continued)

Field	Description
14:15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode. 01 Data is a result of Injected conversion mode. 10 Data is a result of CTU conversion mode. 11 Reserved
16:31 CDATA	Channel converted data **Note:** If MCR[WLSIDE] is set to ‘0’ than the converted data is read right aligned with lower 12/10 bits representing the actual converted data (width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining upper 4/6 bits are read as zeros. Whereas if the MCR[WLSIDE] is set as ‘1’ than the converted data is read left aligned with upper 12/10 bits representing the actual converted data (width of actual converted data depends on selected resolution of current conversion, selectable by CTRx[CRES] bit) and remaining lower 4/6 bits are read as zeros.

39.6 Start of conversion pulse delay

The following table lists the delays between various trigger points (initiation request for conversion as registered at system clock) and the actual issue of start pulse (adc_start[(m)]) to the ADC hard-macrocell. Here, each possible trigger source is described with the number of clock cycles required for different operations until the trigger of adc_start. This table does not take into account any software delay involved in programming or polling of any bit in order to measure conversion timing.

Table 536. Start of conversion pulse delay table

Trigger source	Register control (PBRIDGE_ CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_ CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Normal conversion triggered by software (setting of NSTART of MCR)	1	—	2	1-2[(3)]	Cumulative delay from wen (byte_en) assertion to actual issue of adc_start pulse = 3-4 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Normal conversion triggered by external trigger (hardware trigger through)	—	—	2	1–2[(3)]	Cumulative delay from the triggering edge (rising or falling) to the actual issue of adc_start pulse = 3–4 SARADC_CLK cycles.

m. adc_start is the start of conversion indication to ADC hard-macrocell to start the conversion.

Table 536. Start of conversion pulse delay table (continued)

Trigger source	Register control (PBRIDGE_ CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_ CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Normal conversion within a chain	—	—	0 (from EOC(1) of previous conversion)	—	Delay from the EOC(1) of last conversion, The start of next conversion is issued exactly on the same cycle when EOC(1) is expected for previous conversion.
Injected conversion triggered by software (setting of JSTART bit of MCR)	1	—	3	1–2(3)	Cumulative delay from wen (byte_en) assertion. Here delay for first start pulse of the injected chain execution when FSM was originally in IDLE state is considered = 4–5 SARADC_CLK cycles + 1 PBRIDGE_CLK cycle.
Injected conversion triggered by external Trigger (hardware trigger)	—	—	3	1–2(3)	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Injected conversion within a chain (delay between consecutive conversion of injected chain)	—	—	0 (from EOC(1) of previous conversion)	—	Delay from EOC(1) of last injected channel and adc_start pulse of next injected channel. The start of next conversion is issued exactly on the same cycle when EOC(1) is expected for previous conversion
Injected conversion over normal conversion (software injected conversion chain)	1	1–2(3)	3–5(2)	1–2(3)	Cumulative delay from wen (byte_en) assertion to actual trigger of first injected channel, when the FSM was in conversion cycle of previous normal conversion = 4–7 SARADC_CLK cycles + 2-3 PBRIDGE_CLK cycles.

Table 536. Start of conversion pulse delay table (continued)

Trigger source	Register control (PBRIDGE_ CLK)	Inter domain synchronization (PBRIDGE_CLK)	ADC state machine (SARADC_ CLK)	Inter domain synchronization (SARADC_CLK)	Comments
Injection of conversion over normal conversion in JTRGSEQ mode	—	—	3	1–2(3)	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 SARADC_CLK cycles.
Abort of a Normal/Injected Channel conversion during Normal Chain/Injected Chain execution (setting of MCR[ABORT] bit)	1	1–2(3)	3–5(2)	1–2(3)	Delay from writing of ABORT bit (wen/byte_en assertion) to actual issue of adc_start pulse for the next channel conversion = 4–7 SARADC_CLK cycles + 2–3 PBRIDGE_CLK cycles.

1. EOC is the end of conversion from ADC hard macrocell
2. The above delay values are calculated over a range of system and ADC clock frequencies. With PBRIDGE_CLK(max) = 50 MHz to PBRIDGE_CLK(min) = 40 MHz and SARADC_CLK(max) = 16 MHz to SARADC_CLK(min) = 14 MHz. L.H.S value corresponds to max frequencies and RHS corresponds to min frequencies.
3. The above variation is owing to inter domain synchronization.

39.7 Initialization information

To initialize the SARADC registers for data conversion, the following programming sequence is required:

1. Program the PDEDR register with appropriate power down exit delay value and required CTU mode (MCR[CTU_MODE]) in case CTU mode has to be entered later on by setting CTUEN bit.
2. Exit the power down mode by clearing the MCR[PWDN] bit. After the power down mode is exited the SARADC enters the IDLE state, this can be checked by polling for MSR[ADCSTATUS] bits. Note that steps 3-7 can also be executed before step 2.
3. Program the required conversion mode and control options for example one-shot mode or scan mode, hardware trigger enable and selection for normal or injected conversions, hardware trigger edge select, overwrite enable, and so on, in MCR register.
4. Program the conversion mask registers ({I,T,E}C{N,J}CMR) for channels to be converted. If required, enable and select watchdog monitors ({I,T,E}CWENR, {I,T,E}CWSELR) as applicable for each channel, program the watchdog threshold values (WTHRHLR) for each watchdog monitor.
5. If required, Enable and select the External to Internal channel mapping by programming the ECMICR registers, Test to internal channel mapping by programming the TCCAPR registers.
6. Program the required Interrupt/DMA mask registers (DMAE, {I,T,E}CDSR, IMR, {I,T,E}C{N,J}MR, WTIMR) for each of the selected channels.

7. Program the Conversion timing registers(CTR0-3) for the required conversion durations. Enable the precharge phase, CTR selection per channel basis by programming the {I,T,E}CDR registers.
8. To initiate CTU mode conversion enter the selected CTU mode by setting the MCR[CTUEN] bit and program the CTU module accordingly to start the conversions. To initiate Normal/Injected mode conversions by software set the MCR[NSTART/JSTART] bit. To initiate hardware triggered Normal/Injected conversions program the external trigger module to provide the required triggers.
9. Read the conversion data and status in {I,T,E}CDR registers.

40 Temperature Sensor

40.1 Introduction

The device includes an onboard temperature sensor that monitors device temperature and delivers two analog outputs signals and three digital output signals.

The analog outputs consist of two voltage signals which vary linearly with the internal junction temperature: a voltage signal that is linearly increasing (PTAT: proportional to absolute temperature) and a voltage signal that is linearly decreasing (CTAT: complementary proportional to absolute temperature). The analog outputs are connected to an input channel of an ADC on the device. The internal junction temperature must be calculated by software based on the converted temperature values.

The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions. These signals notify the device to take action to appropriately adjust the device temperature in response to an out of specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

40.1.1 Signal Descriptions

This module has no external signals.

40.2 Functional description

The temperature sensor generates two analog outputs voltage, PTAT and CTAT which are proportional to the absolute current junction temperature of the device.

An on-chip ADC module is used to convert the analog outputs voltage, PTAT and CTAT, into a digital representation. These values, along with parameter values stored in onboard flash memory, are used by software to calculate the device junction temperature.

40.2.1 Linear temperature sensor (analog output generation)

The temperature sensor outputs two voltage proportional and complementary proportional to the internal junction temperature of the chip. These analog voltage signals are converted into digital values by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programed into flash memory.

40.3 Temperature formula

40.3.1 Equations for converting TSENS voltages to junction temperature

Table 537. Calibration constants [1] [2]

Constant	Description
P1	Code from the ADC converting PTAT output voltage at 150 °C
P2	Code from the ADC converting PTAT output voltage at -40 °C
C1	Code from the ADC converting CTAT output voltage at 150 °C
C2	Code from the ADC converting CTAT output voltage at -40 °C

1. It is mandatory to keep the ADC reference constant while measuring P1, P2, C1, and C2
2. Flash locations for P2, C2, P1 and C1 are respectively 0x400000, 0x400002, 0x400004 and 0x400006.

In the equations below:

- Pn and Cn are the calibration constants described in *Table 537*.
- T is the unknown device temperature in °C.
- Px is the code from the ADC converting PTAT output voltage at the temperature T with any ADC reference voltage Vref
- Cx is the code from the ADC converting CTAT output voltage at the temperature T with the same ADC reference voltage Vref.
- T2 = -40 °C
- T1 = 150 °C

Equation 24 $A = Px \cdot C2 - (Cx \cdot P2)$

Equation 25 $B = Cx \cdot P1 - (Px \cdot C1)$

The temperature T is calculated as

Equation 26 $T = T2 + \frac{A \cdot (T1 - T2)}{A + B}$

Caution: It is mandatory to have the same value as the ADC reference, while measuring Px and Cx.

40.3.2 Equations for converting TSENS voltages into constant reference (Digital Bandgap Voltage)

By converting the two outputs of the Temperature Sensor through ADC, one can find out a constant reference code (REFCODE) which does not change with temperature.

- Pn and Cn are the calibration constants described in *Table 537*.
- Px is the code from the ADC converting PTAT output voltage at any temperature T with any ADC reference voltage Vref.
- Cx is the code from the ADC converting CTAT output voltage at the same temperature T with the same ADC reference voltage Vref.

Equation 27

$$REFCODE = Px + \left(\frac{(P2 - P1)}{(C1 - C2)}\right) \times Cx$$

Caution: It is mandatory to measure Px and Cx at the same ADC reference voltage and at the same temperature.

Note: Software calculation must be made with negligible precision loss associated with limited bit representation of intermediate calculated results.

41 Body Cross Triggering Unit (BCTU)

41.1 Introduction

The Body Cross Triggering Unit (BCTU) allows to synchronize an ADC conversion with a timer event from eMIOS (every mode which can generate a DMA request can trigger BCTU), or PIT_RTI. To select which ADC channel must be converted on a particular timer event, the BCTU provides the ADC with a 7-bit channel number. This channel number can be configured for each timer channel event by the application.

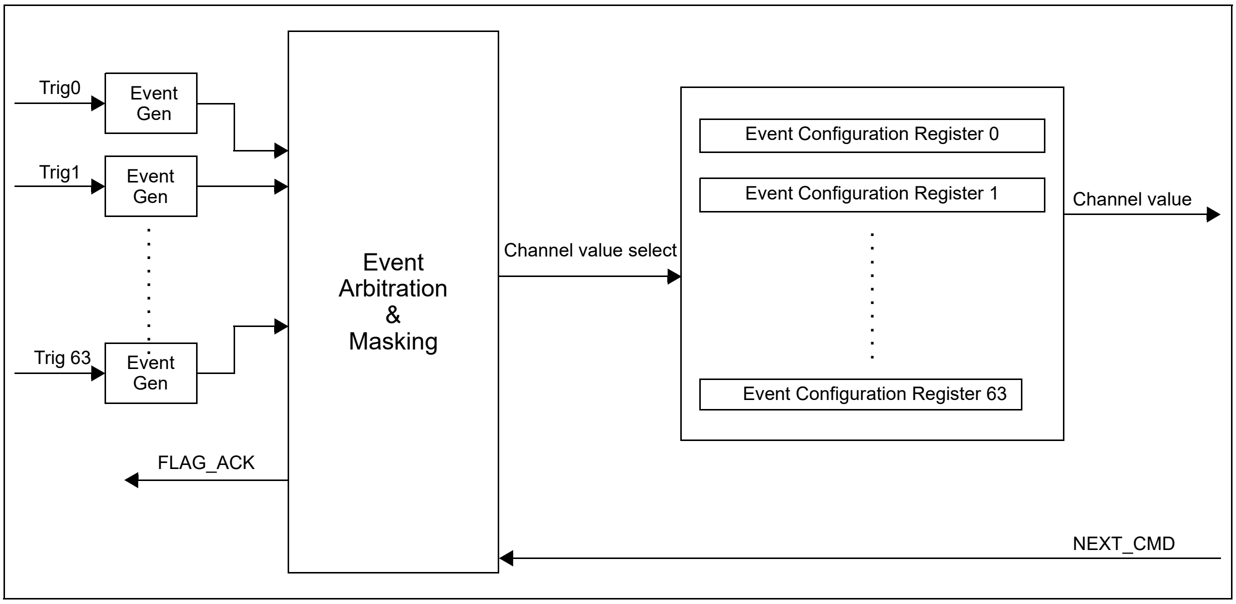
41.2 Main features

- Single cycle delayed trigger output. The trigger output is a combination of 64 (generic value) input flags/events connected to different timers in the system.
- One event configuration register dedicated to each timer event allows to define the corresponding ADC channel.
- Acknowledgment signal to eMIOS/PIT_RTI for clearing the flag
- Synchronization with ADC to avoid collision

41.3 Block diagram

The BCTU block diagram is shown in *Figure 438*.

Figure 438. Body Cross Triggering Unit block diagram



41.4 Memory map and register descriptions

The BCTU registers are listed in *Table 538*.

Table 538. BCTU memory map

Offset	Register	Location

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit implementation is generic based and implemented only for inputs mapped to PIT_RTI event flags.

Figure 440. Event Configuration Register *n* (BCTU_EVTCFGR*n*)

Table 540. BCTU_EVTCFGR*n* field descriptions

Field	Description
16 TM	Trigger Mask 0 Trigger masked 1 Trigger enabled
17 CLR_FLAG	To provide flag_ack through software 1 Flag_ack is forced to '1' for the particular event 0 Flag_ack is dependent on flag servicing
25:31 CHANNEL_VALUE	0xxxxxx ADC internal channel number from 0 to 63 1xxxxxx ADC external channel number from 128 to 191 **Note:** When bit 25 = 1 an offset of 128 is added to the value defined by bits 26:31 : that allows to address external channels inside ADC module.

These registers contain the ADC channel number to be converted when the timer event occurs.

When CLR_FLAG is set, BCTU ignores any event from PIT_RTI if some triggered conversion is going on in ADC (conversion from BCTU to ADC). But if BCTU is not busy in sending any trigger to ADC, then it will send the trigger to ADC for conversion of configured channel in BCTU_EVTCFGR register. In that case, setting CLR_FLAG bit would not provide flag_ack through software.

The CLR_FLAG bit has to be used cautiously as setting this bit may result in a loss of events.

The event input can be masked by writing '0' to bit TM of the BCTU_EVTCFGR register. Writing '1' to bit TM enables the BCTU triggering and automatically disables the DMA connection for the corresponding eMIOS channel.

Note: The BCTU tracks issued conversion requests to the ADC. When the ADC is being triggered by the BCTU and there is a need to shut down the ADC, the ADC must be allowed to complete conversions before being shut down. This ensures that the BCTU is notified of completion; if the ADC is shut down while performing a BCTU-triggered conversion, the BCTU is not notified and will not be able to trigger further conversions until the device is reset.

41.5 Functional description

This peripheral is used to synchronize ADC conversions with timer events (from eMIOS or PIT_RTI). When a timer event occurs, the BCTU triggers an ADC conversion providing the ADC channel number to be converted. In case concurrent events occur the priority is managed according to the index of the timer event. The trigger output is a single cycle pulse used to trigger ADC conversion of the channel number provided by the BCTU.

Each trigger input from the BCTU is connected to the Event Trigger signal of an eMIOS channel. The assignment between eMIOS outputs and BCTU trigger inputs of the device is defined in the *Chapter 7: Device configuration*.

Each event has a dedicated configuration register (BCTU_EVTCFGR). These registers store a channel number which is used to communicate which channel needs to be converted.

In case several events are pending for ADC request, the priority is managed according to the timer event index. The lowest index has the highest priority. Once an event has been serviced (conversion requested to ADC) the eMIOS flag is cleared by the BCTU and next prior event is handled.

The acknowledgment signal can be forced to ‘1’ by setting the CLR_FLAG bit of the BCTU_EVTCFGR register. These bits are implemented for only those input flags to which PIT_RTI flags are connected. Providing these bits offers the option of clearing PIT_RTI flags by software.

42 System Timer Module (STM)

42.1 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

Note: For chip-specific implementation details of this module's instances, see the chip configuration information.

42.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the HPBM_CLK divided by an 8-bit prescale value (1 to 256).

42.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

42.1.3 Modes of operation

The STM supports two device modes of operation: Normal and Debug. When the STM is enabled in Normal mode, its counter runs continuously. In Debug mode, operation of the counter is controlled by the FRZ bit in the STM Control Register (STM_CR). If STM_CR[FRZ] is set, the counter is stopped in Debug mode, otherwise it continues to run.

42.2 External signal description

The STM does not have any external interface signals.

42.3 Memory map and register definition

The STM programming model includes a group of 32-bit registers: a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

42.3.1 Memory map

The STM memory map is shown in *Table 541*.

Table 541. STM memory map

Address offset	Register	Location
0x0000	STM Control Register (STM_CR)	*Section 42.3.2.1*

42.4 Functional description

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the HPBM_CLK frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode the counter operation is controlled by the STM_CR[FRZ] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode, otherwise it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*) and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing a 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

Note: The STM counter does not advance when the HPBM_CLK is stopped.

43 Software Watchdog Timer (SWT)

43.1 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

Note: For chip-specific implementation details of this module's instances, refer to the chip configuration information.

43.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

Note: The SWT runs over all device mode except the STANDBY mode where it is not powered.

43.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

43.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR *Section 43.2.1.1: SWT Control Register (SWT_CR)*. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit of the SWT_CR register. Refer to *Section 43.2.1.1: SWT Control Register (SWT_CR)*. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

43.2 Memory map and register definition

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access, otherwise a bus error is generated. If either the HLK or

SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in *Table 547*.

Table 547. SWT memory map

1. SWT_CO will reflect the internal value of the counter when WEN=0, and will be read as 0x0000_0000 when WEN=1

Figure 451. SWT Counter Output Register (SWT_CO)

Table 553. SWT_CO field descriptions

Field	Description
0:31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

43.2.1.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Offset: 0x0018 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 554. SWT_SK field descriptions

Field	Description
16:31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] = 01, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^16.

43.3 Functional description

43.3.1 Introduction

The SWT is a 32-bit timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- A control register (SWT_CR)
- An interrupt register (SWT_IR)
- A time-out register (SWT_TO)
- A window register (SWT_WN)
- A service register (SWT_SR)
- A counter output register (SWT_CO)
- A service key register (SWT_SK)

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

43.3.1.1 SWR_CR register

The SWT_CR register includes bits to enable the timer, set configuration options and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific[n]. If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

43.3.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100 in which case the time-out period is set to 0x100.When the SWT is enabled, this time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed.The source used to drive the down counter and the reset value of the SWT_TO register is device specific, refer to the device configuration chapter.

43.3.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

n. Refer to SWT section in device configuration chapter.

43.3.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

43.3.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

43.3.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

43.3.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

43.3.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation which is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- Fixed service sequence
- Keyed service sequence
- Fixed execution address
- Incremental execution address

43.3.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected which requires writing 0xA602, 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

43.3.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected which requires writing two pseudo-random keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudo-random key generator defined in *Equation 28*. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

Equation 28

$$SK_{n+1} = (17*SK_n+3) \bmod 2^{16}$$

43.3.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

43.3.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected in which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

43.3.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to ‘1000’ then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

43.3.5 Time-out

The SWT_CR[ITR] (“Interrupt Then Reset” bit) controls the action taken when a time-out occurs. If the SWT_CR[ITR] bit is not set, a reset is generated immediately on a time-out. If the SWT_CR[ITR] bit is set, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period. If the service sequence is not written before the second consecutive time-out, the SWT generates a system reset. The interrupt is indicated by the time-out interrupt flag (SWT_IR[TIF]). The interrupt request is cleared by writing a one to the SWT_IR[TIF] bit.

43.3.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

44 Periodic Interrupt Timer (PIT)

44.1 Introduction

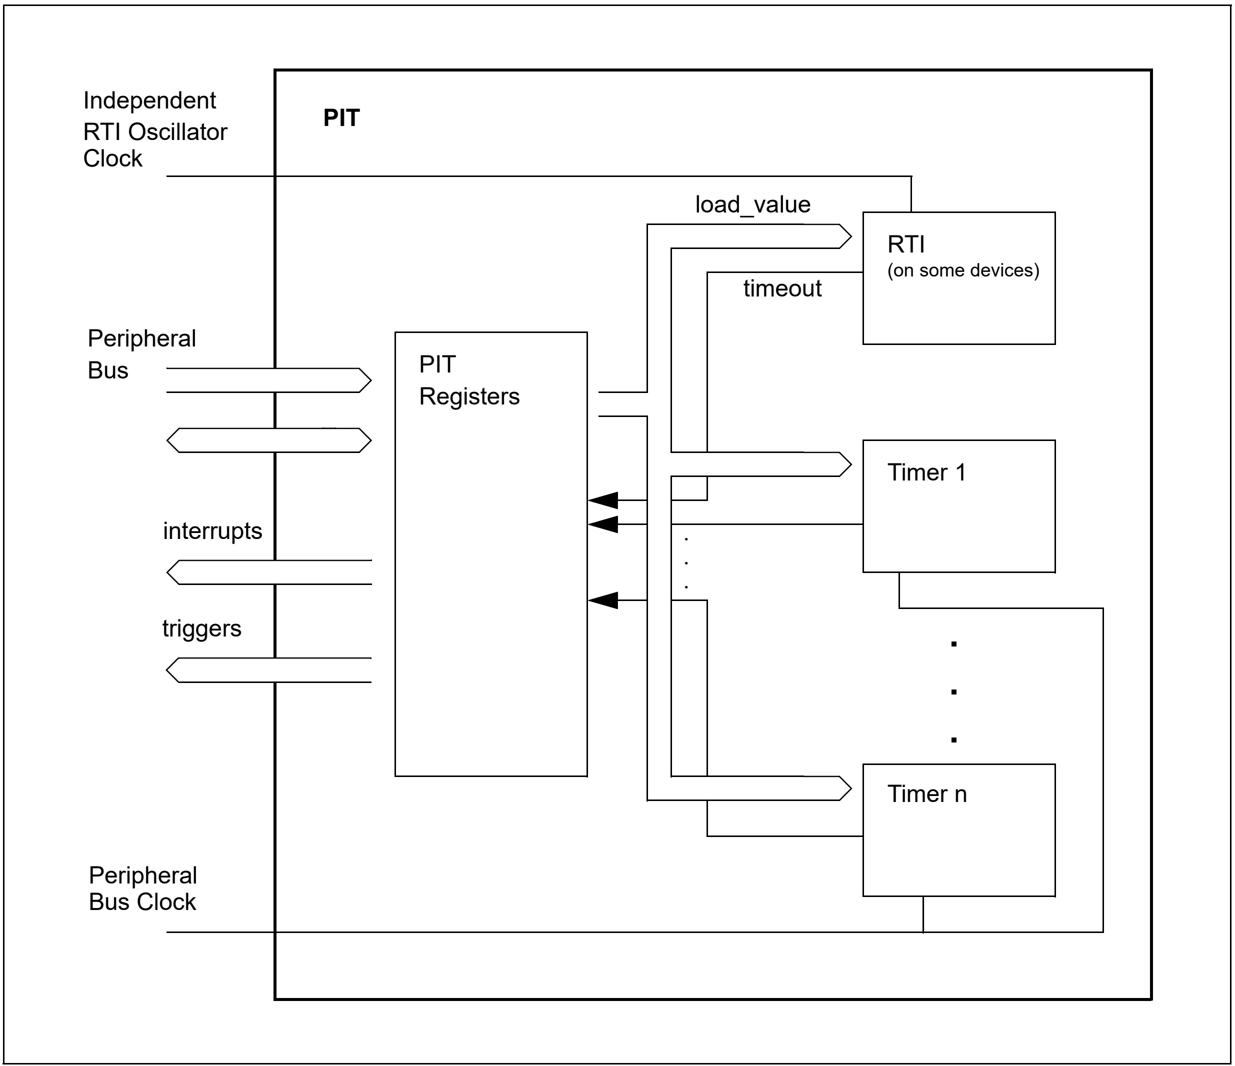
The PIT timer module is an array of timers that can be used to raise interrupts and trigger DMA channels. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup.

Note: For the chip-specific implementation details of this module's instances refer to the Device Configuration chapter.

44.1.1 Block diagram

Figure 453 shows the PIT block diagram.

Figure 453. Block diagram of the PIT



Note: Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

44.1.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wake up the CPU in Stop mode
- Timers can generate DMA trigger pulses
- Timers can generate interrupts
- All interrupts are maskable
- RTI interrupt can be raised, even when the bus clock is switched off
- Power saving with a separate input clock for the RTI timer (all other timers share one common core clock)
- Independent timeout periods for each timer

44.2 Signal description

This module has no external pins.

44.2.1 Memory map/register description

This section provides a detailed description of all registers accessible in this module.

Note: Reserved registers will read as 0, writes will have no effect.

Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

The RTI registers should be programed only when the RTI clock is running.

30 MDIS	Module Disable This is used to disable the module clock. The RTI timer is not affected by this bit. This bit must be enabled before any other setup is done. 0 Clock for PIT timers is enabled. 1 Clock for PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters debug mode. 0 Timers continue to run in debug mode. 1 Timers are stopped in debug mode.

44.2.1.2 PIT Upper Lifetime Timer Register (LTMR64H)

The PIT Upper Lifetime Timer Register (LTMR64H) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

Offset: 0x00E0 Access: User read-only

Field	Description
0:31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

44.2.1.3 PIT Lower Lifetime Timer Register (LTMR64L)

The PIT Lower Lifetime Timer Register (LTMR64L) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

44.2.1.4 PIT RTI Timer Load Value Register (RTI_LDVAL)

This register selects the timeout period for the timer interrupts.

In case of the RTI, it takes several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronization mechanism allows 0 wait states for RTI in this case.

Offset: 0x00F0 Access: User read/write

Table 559. RTI_LDVAL field descriptions

Field	Description
0:31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. **Note:** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.

44.2.1.5 PIT RTI Current Timer Value Register (RTI_CVAL)

This register indicates the current timer position.

For the RTI timers, it shows a value which is several cycles old, since it originates from a potentially different clock domain.

31 TIF	Timer Interrupt Flag TIF is set to '1' at the end of the timer period. This flag can be cleared only by writing it with 1. Writing 0 has no effect. If enabled (TIE = 1), TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

44.3 Functional description

This section provides the functional description of the module.

44.3.1 General

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses as well as to generate interrupts. Each interrupt is available on a separate interrupt line.

44.3.1.1 Timers/RTI

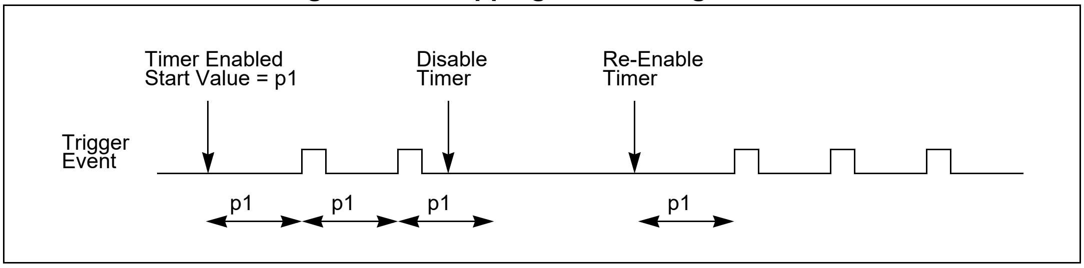
The timers generate triggers at periodic intervals, when enabled. They load their start values, as specified in their LDVAL registers, then count down until they reach 0. Then they load their respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked (by setting the TIE bits in the TCTRL registers). A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 should be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

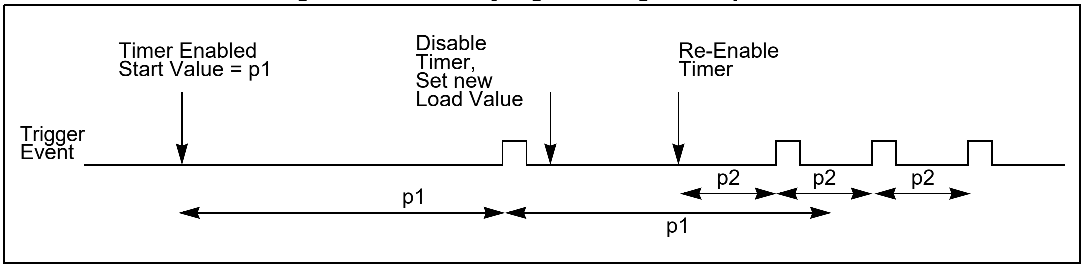
The counter period can be restarted, by first disabling, then enabling the timer with the TEN bit (refer to the following figure).

Figure 465. Stopping and starting a timer



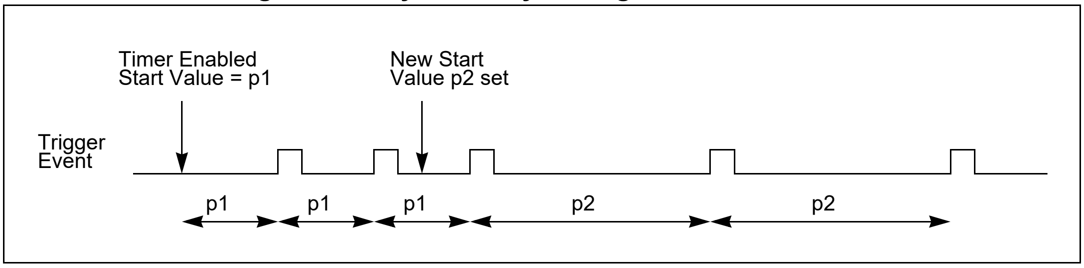
The counter period of a running timer can be modified, by first disabling the timer, setting a new load value and then enabling the timer again (refer to the following figure).

Figure 466. Modifying running timer period



It is also possible to change the counter period without restarting the timer by writing the LDVAL register with the new load value. This value will then be loaded after the next trigger event (refer to the following figure).

Figure 467. Dynamically setting a new load value



44.3.1.2 Debug mode

In debug mode, the timers will be frozen based on field MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system (for example, the timer values) and then continue the operation.

44.3.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. Refer to the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting the TIE bits. The timer interrupt flags (TIF) are set to ‘1’ when a timeout occurs on the associated timer, and are cleared to ‘0’ by writing a ‘1’ to that TIF bit.

The PIT RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting the TIE bit to zero. The real time interrupt flag (TIF) is set to ‘1’ when a timeout occurs, and is cleared by writing a ‘1’ to the TIF bit. (The flag will be set regardless whether the interrupt is enabled.)

The RTI can be used for periodic wakeup from a low power mode. It can also be used to generate a general purpose interrupt.

44.3.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer *n*-1 has counted down to 0, counter *n* will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

44.4 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

First the PIT module must be activated by writing a 0 to field MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5000000 cycles.

Timer 1 needs to trigger every 5.12 ms/20 ns = 256000 cycles and timer 3 every 30 ms/20 ns = 1500000 cycles.

The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) - 1

This means RTI_LDVAL will be written with 004C4B3F hex, LDVAL1 should be written with 0x0003E7FF, and LDVAL3 should be written with 0x0016E35F.

To generate the wakeup interrupt, the interrupt line must be enabled by writing a ‘1’ to bit RTI_TCTRL[TIE]. To start the RTI, bit RTI_TCTRL[TEN] must also be set.

The interrupt for Timer 1 is enabled by setting bit TCTRL1[TIE]. The timer is started by writing ‘1’ to bit TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore Timer 3 is started by writing a ‘1’ to bit TCTRL3[TEN]; bit TIE stays at 0.

The following example code matches the described setup:

Example 9

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE;    // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN;   // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;        // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;         // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3for 1500000 cycles
PIT_TCTRL3 |= TEN;         // start Timer 3
```

44.5 Example Configuration for the Lifetime Timer

To configure the life timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a ‘0’ to field MCR[MDIS], then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

Example 10

```
// turn on PIT
PIT_CTRL = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0;        // disable timer 2 interrupts
PIT_TCTRL1 |= CHN;       // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN;         // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0for maximum counting period
PIT_TCTRL0 = TEN;          // start timer 0
```

To access the lifetime read first LTMR64H then LTMR64L.

Equation 29

current_uptime = PIT_LTMR64H << 32;

current_uptime = current_uptime + PIT_LTMR64L

The timer is a down counter.

45 Enhanced Modular IO Subsystem (eMIOS)

45.1 Introduction

45.1.1 Overview of the eMIOS module

The eMIOS provides functionality to generate or measure time events on up to 32 unified channels (UCs). Each UC provides a set of functional modes, 16-bit timer resolution, and provides a user interface that is consistent with previous eMIOS implementations.

45.1.2 Features of the eMIOS module

- Two eMIOS blocks with 32 channels
- eMIOS blocks can be synchronized from outside
- One global prescaler
- 16-bit data registers
- 16-bit wide counter buses
  - Counter buses B, C, D, and E can be driven by Unified Channel 0, 8, 16, and 24, respectively
  - Counter bus A is driven by the Unified Channel 23
  - Several channels have their own time base, alternative to the counter buses
  - Shared timebases through the counter buses
  - Synchronization among timebases
- Control and Status bits grouped in a single register
- Shadow FLAG register
- Flag outputs of channels 8-11 of eMIOSs are used to disable the outputs of other channels. They form the ODIS bits
- State of the UC can be frozen for debug purposes
- Motor control capability

45.1.3 Modes of operation

The Unified Channels can be configured to operate in the following modes:

- General purpose input/output
- Single Action Input Capture
- Single Action Output Compare
- Input Pulse Width Measurement
- Input Period Measurement
- Double Action Output Compare
- Modulus Counter
- Modulus Counter Buffered
- Output Pulse Width and Frequency Modulation Buffered
- Output Pulse Width Modulation Buffered
- Output Pulse Width Modulation with Trigger
- Center Aligned Output Pulse Width Modulation Buffered

These modes are described in *UC modes of operation*.

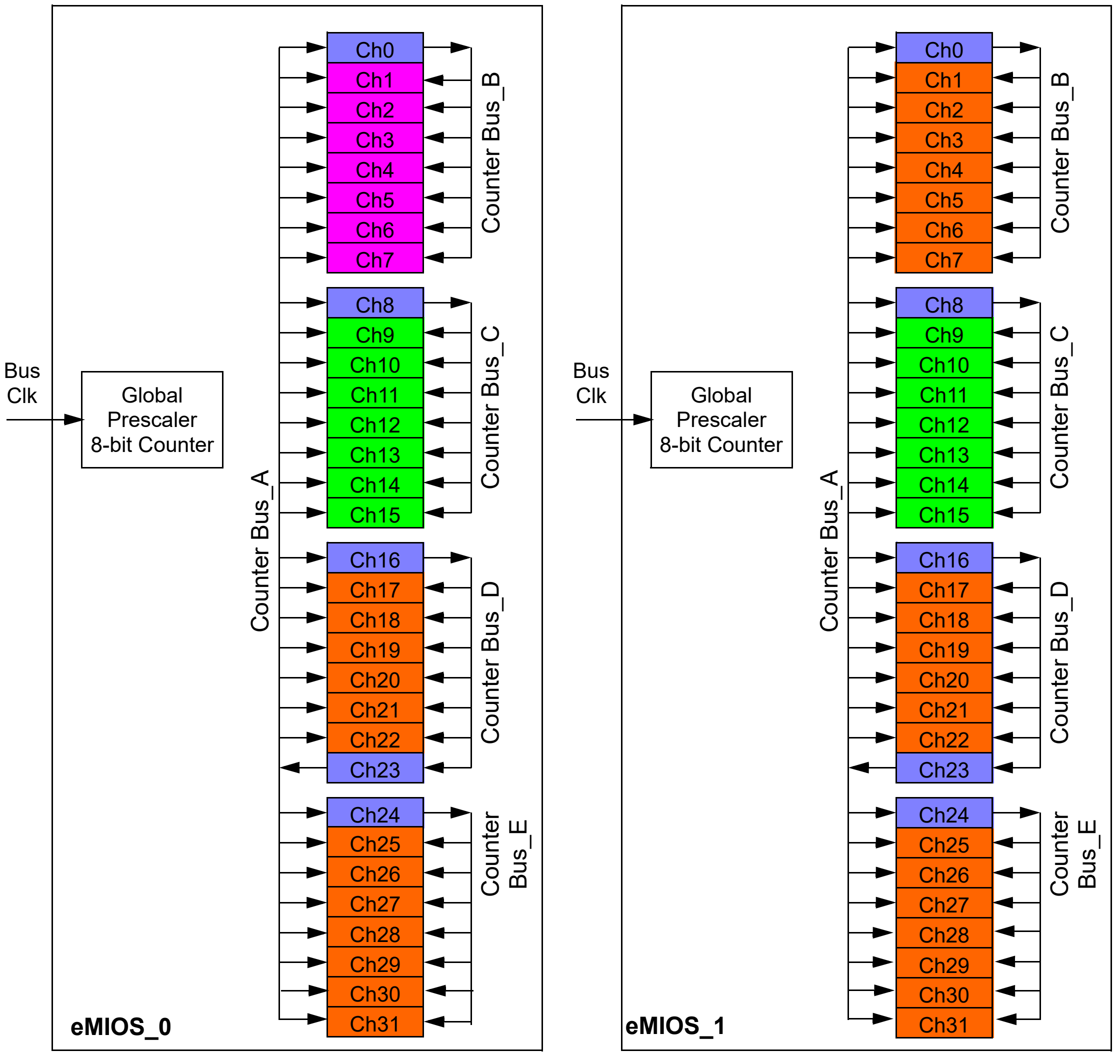
Each channel can have a specific set of modes implemented, according to device requirements.

If an unimplemented mode (reserved) is selected, the results are unpredictable such as writing a reserved value to MODE[25:31] in *eMIOS UC Control Register (EMIOSCn)*.

45.1.4 Channel implementation

Figure 468 shows the channel configuration of the eMIOS blocks.

Figure 468. Channel configuration



Channel Functionality

IPWM	Input Pulse Width Measurement	OPWMCB	Center Aligned Output PWM Buffered with Dead-Time
MC	Modulus Counter	SAIC	Single Action Input Capture
MCB	Buffered Modulus Counter	SAOC	Single Action Output Compare

45.1.4.1 Channel mode selection

Channel modes are selected using the mode selection bits MODE[25:31] in the *eMIOS UC Control Register (EMIOSCn)*. *Table 583* provides the specific mode selection settings for the eMIOS implementation on this device.

45.2 External signal description

For information on eMIOS external signals on this device, refer to the signal description chapter of the reference manual.

45.3 Memory map and register description

45.3.1 Memory maps

The overall address map organization is shown in *Table 567*.

45.3.1.1 Unified Channel memory map

Table 567. eMIOS memory map

Address offset	Register	Location
0x0000	eMIOS Module Configuration (EMIOSMCR)	*Section 45.3.2.1*

45.3.2 Register description

All control registers are 32 bits wide. Data registers and counter registers are 16 bits wide.

45.3.2.1 eMIOS Module Configuration Register (EMIOSMCR)

The EMIOSMCR contains global control bits for the eMIOS block.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	MDIS	FRZ	GTBE	0	GPREN	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 469. eMIOS Module Configuration Register (EMIOSMCR)

Table 569. EMIOSMCR field descriptions

Field	Description
1 MDIS	Module Disable Puts the eMIOS in low power mode. The MDIS bit is used to stop the clock of the block, except the access to registers EMIOSMCR, EMIOSOUDIS and EMIOSUCDIS. 0 Clock is running 1 Enter low power mode
2 FRZ	Freeze Enables the eMIOS to freeze the registers of the Unified Channels when Debug Mode is requested at MCU level. Each Unified Channel should have FREN bit set in order to enter freeze state. While in Freeze state, the eMIOS continues to operate to allow the MCU access to the Unified Channels registers. The Unified Channel will remain frozen until the FRZ bit is written to ‘0’ or the MCU exits Debug mode or the Unified Channel FREN bit is cleared. 0 Exit freeze state 1 Stops Unified Channels operation when in Debug mode and the FREN bit is set in the EMIOSC*n* register
3 GTBE	Global Time Base Enable The GTBE bit is used to export a Global Time Base Enable from the module and provide a method to start time bases of several blocks simultaneously. 0 Global Time Base Enable Out signal negated 1 Global Time Base Enable Out signal asserted **Note:** The Global Time Base Enable Out signals of all eMIOS blocks are combined (ORed) together to generate one Global Time Base Enable Input signal that controls the internal counters of all eMIOS blocks. When asserted, internal counter are enable. When negated, internal counters are disabled.
5 GPREN	Global Prescaler Enable The GPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) and prescaler counter is cleared 1 Prescaler enabled
16:23 GPRE	Global Prescaler The GPRE bits select the clock divider value for the global prescaler, as shown in *Table 570*.

Table 570. Global prescaler clock divider

GPRE	Divide ratio

…	…
11111110	255
11111111	256

45.3.2.2 eMIOS Global FLAG (EMIOSGFLAG) Register

The EMIOSGFLAG is a read-only register that groups the flag bits (F[31:0]) from all unified channels.These bits are mirrors of the FLAG bits in each EMIOSS*n* register. This organization improves interrupt handling on simpler devices. Each bit relates to one channel.

45.3.2.5 eMIOS UC A Register (EMIOSA*n*)

Depending on the mode of operation, internal registers A1 or A2, used for matches and captures, can be assigned to the EMIOSA*n* register. Both A1 and A2 are cleared by reset. *Table 576* summarizes the EMIOSA*n* writing and reading accesses for all operation modes. For more information, refer to *UC modes of operation*.

Offset: 0x0020 + n * 0x20 (n = 0 to 31) Access: Read/Write

OPWMB	A2	A1	B2	B1	—	—

1. In these modes, the register EMIOSB*n* is not used, but B2 can be accessed.

45.3.2.7 eMIOS UC Counter Register (EMIOSCNT*n*)

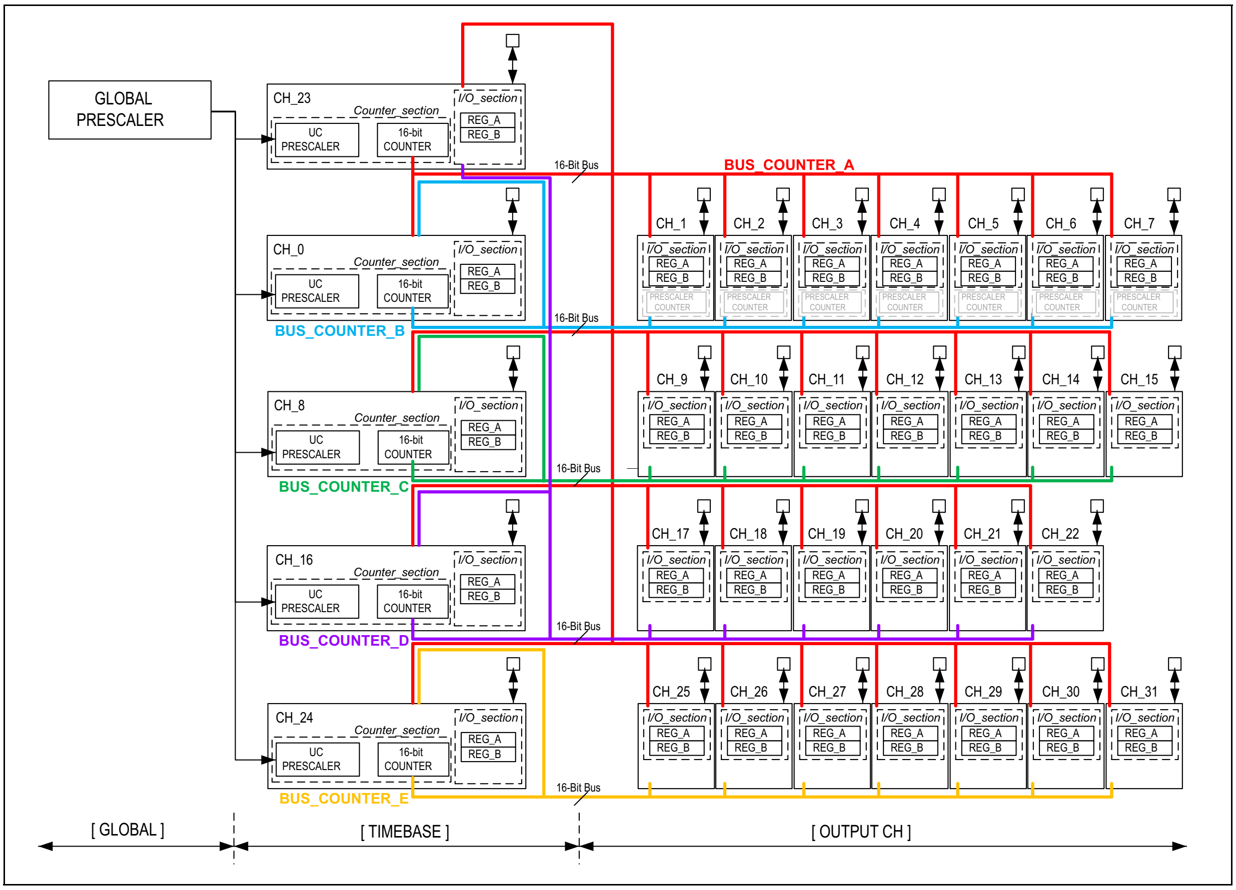
The EMIOSCNT*n* register contains the value of the internal counter. When GPIO mode is selected or the channel is frozen, the EMIOSCNT*n* register is read/write. For all other modes, the EMIOSCNT*n* is a read-only register. When entering some operation modes, this register is automatically cleared (refer to *UC modes of operation* for details).

Depending on the channel configuration it may have an internal counter or not. It means that if at least one mode that requires the counter is implemented, then the counter is present; otherwise it is absent.

Channels of type X and G have the internal counter enabled, so their timebase can be selected by channel's BSL[21:22] = 11:eMIOS_A - channels 0 to 8, 16, 23 and 24, eMIOS_B = channels 0, 8, 16, 23 and 24. Other channels from the above list do not have internal counters.

Figure 475 shows the bus counter choices for the unified channels.

Figure 475. eMIOS bus counters



Note: EMIOS_0: counter_section is implemented in CH_0/8/16/23/24 and CH_1 to 7

Note: EMIOS_1: counter_section is implemented in CH_0/8/16/23/24

Figure 477. eMIOS UC Control Register (EMIOSC*n*)

Table 578. EMIOSC*n* field descriptions

Field	Description
0 FREN	Freeze Enable bit The FREN bit, if set and validated by FRZ bit in EMIOSMCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values
1 ODIS	Output Disable bit The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode. 1 If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally. 0 The output pin operates normally.
2:3 ODISSL	Output Disable Select bits The ODISSL[1:0] bits select one of the four output disable input signals, as shown in *Table 579*.

Table 578. EMIOSC*n* field descriptions (continued)

Field	Description
4:5 UCPRE	Prescaler bits The UCPRE bits select the clock divider value for the internal prescaler of Unified Channel, as shown in *Table 580*.
6 UCPREN	Prescaler Enable bit The UCPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) 1 Prescaler enabled
7 DMA	Direct Memory Access bit The DMA bit selects if the FLAG signal will be used as an interrupt request, as a DMA request or as a CTU trigger. The choice between a DMA request or a CTU trigger is determined by the value of bit TM in the register CTU_EVTCFGRx (refer to the CTU chapter of the reference manual). 0 Flag/overrun assigned to interrupt request 1 Flag/overrun assigned to DMA request or CTU trigger
9:12 IF	Input Filter The IF field controls the programmable input filter, selecting the minimum input pulse width that can pass through the filter, as shown in *Table 581*. For output modes, these bits have no meaning.
13 FCK	Filter Clock select bit The FCK bit selects the clock source for the programmable input filter. 0 Prescaled clock 1 Main clock
14 FEN	FLAG Enable bit The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal or a CTU trigger signal (The type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request or DMA request or a CTU trigger) 1 Enable (FLAG will generate an interrupt request or DMA request or a CTU trigger)
18 FORCMA	Force Match A bit For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. 0 Has no effect 1 Force a match at comparator A **Note:** For input modes, the FORCMA bit is not used and writing to it has no effect.
19 FORCMB	Force Match B bit For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has no effect 1 Force a match at comparator B **Note:** For input modes, the FORCMB bit is not used and writing to it has no effect.

Table 578. EMIOSC*n* field descriptions (continued)

Field	Description
21:22 BSL	Bus Select The BSL field is used to select either one of the counter buses or the internal counter (if present) to be used by the Unified Channel. Refer to *Table 582* for details.
23 EDSEL	Edge Selection bit For input modes, the EDSEL bit selects whether the internal counter is triggered by both edges of a pulse or just by a single edge as defined by the EDPOL bit. When not shown in the mode of operation description, this bit has no effect. 0 [All input modes]: single edge triggering defined by the EDPOL bit; [GPIO input mode]: a FLAG is generated as defined by the EDPOL bit; [SAOC mode]: the output flip-flop is toggled at each match. 1 [All input modes]: both edges triggering; [GPIO input mode]: no FLAG is generated; [SAOC mode]: the output flip-flop is toggled at each match.
24 EDPOL	Edge Polarity bit For input modes, the EDPOL bit asserts which edge triggers either the internal counter or an input capture or a FLAG. When not shown in the mode of operation description, this bit has no effect. 0 [All input modes]: trigger on a falling edge; [All output modes]: a match on comparator A clears the output flip-flop, while a match on comparator B sets it 1 [All input modes]: trigger on a rising edge; [All output modes]: a match on comparator A sets the output flip-flop, while a match on comparator B clears it
25:31 MODE	Mode selection The MODE field selects the mode of operation of the Unified Channel, as shown in *Table 583*. **Note:** If a reserved value is written to mode the results are unpredictable.

45.3.2.10 eMIOS UC Alternate A Register (EMIOSALTA*n*)

The EMIOSALTA*n* register provides an alternate register to access A2 channel registers in restricted modes (GPIO, OPWMT) only. If EMIOSA*n* register is used along with EMIOSALTA*n*, both A1 and A2 registers can be accessed in these modes. *Figure 576* summarizes the EMIOSALTA*n* writing and reading accesses for all operation modes. Refer to *General purpose Input/Output (GPIO) mode*, *Output Pulse Width Modulation with Trigger (OPWMT) mode* for a more detailed description of the use of EMIOSALTA*n* register.

45.4 Functional description

The four types of channels of the eMIOS (types X, Y, G and H) can operate in the modes as listed in *Figure 468*. The eMIOS provides independently operating unified channels (UC) that can be configured and accessed by a host MCU. Up to three time bases(o) can be shared by the channels through five counter buses[p] and each unified channel can generate its own time base[q]. The eMIOS block is reset at positive edge of the clock (synchronous reset). All registers are cleared on reset.

45.4.1 Unified Channel (UC)

Each Unified Channel consists of:

- Counter bus selector, which selects the time base to be used by the channel for all timing functions
- A programmable clock prescaler
- Two double buffered data registers A and B that allow up to two input capture and/or output compare events to occur before software intervention is needed
- Two comparators (equal only) A and B, which compare the selected counter bus with the value in the data registers
- Internal counter, which can be used as a local time base or to count input events
- Programmable input filter, which ensures that only valid pin transitions are received by channel
- Programmable input edge detector, which detects the rising, falling or either edges
- An output flip-flop, which holds the logic level to be applied to the output pin
- eMIOS Status and Control register

45.4.1.1 UC modes of operation

The mode of operation of the Unified Channel is determined by the mode select bits MODE[25:31] in the *eMIOS UC Control Register (EMIOSCn)* (refer to *Figure 477* for details).

As the internal counter EMIOSCNT*n* continues to run in all modes (except for GPIO mode), it is possible to use this local counter as a timebase for other UCs if it is not used for the current local mode.

In order to provide smooth waveform generation, a few specific modes allow A and B registers to be changed on the fly. These modes are suffixed with a “B” (MCB, OPWFMB, OPWMB and OPWMCB), meaning that in these modes A and B registers are double buffered.

45.4.1.1.1 General purpose Input/Output (GPIO) mode

In GPIO mode, all input capture and output compare functions of the UC are disabled, the internal counter (EMIOSCNT*n* register) is cleared and disabled. All control bits remain

---

o. Time bases can be supplied by:
i) channel 23 to all unified channels
ii) channel 0 to channels 0 to 7, by channel 8 to channels 8 to 15, by channel 16 to channels 16 to 23, by channel 24 to channels 24 to 31
iii) channel's internal counter when available.

p. Internal eMIOS architecture has one global counter bus A and four local counter buses B, C, D, and E, that distribute the time bases described in footnote *o.* (i) and (ii).

q. Channels of type X and G have the internal counter enabled, so their timebase can be selected by channel's BSL[21:22]=11: eMIOS_A - channels 0 to 8, 16, 23 and 24 eMIOS_B = channels 0, 8, 16, 23 and 24.

accessible. In order to prepare the UC for a new operation mode, writing to registers EMIOSA*n* or EMIOSB*n* stores the same value in registers A1/A2 or B1/B2, respectively. Writing to register EMIOSALTA*n* stores a value only in register A2.

MODE[31] bit selects between input (MODE[31] = 0) and output (MODE[31] = 1) modes.

It is required that when changing MODE[25:31], the application software goes to GPIO mode first in order to reset the UC's internal functions properly. Failure to do this could lead to invalid and unexpected output compare or input capture results or the FLAGs being set incorrectly.

In GPIO input mode (MODE[25:31] = 0000000), the FLAG generation is determined according to EDPOL and EDSEL bits and the input pin status can be determined by reading the UCIN bit.

In GPIO output mode (MODE[25:31] = 0000001), the Unified Channel is used as a single output port pin and the value of the EDPOL bit is permanently transferred to the output flip-flop.

45.4.1.1.2 Single Action Input Capture (SAIC) mode

In SAIC mode (MODE[25:31] = 0000010), when a triggering event occurs on the input pin, the value on the selected time base is captured into register A2. The FLAG bit is set along with the capture event to indicate that an input capture has occurred. Register EMIOSA*n* returns the value of register A2. As soon as the SAIC mode is entered coming out from GPIO mode the channel is ready to capture events. The events are captured as soon as they occur thus reading register A always returns the value of the latest captured event. Subsequent captures are enabled with no need of further reads from EMIOSA*n* register. The FLAG is set at any time a new event is captured.

The input capture is triggered by a rising, falling or either edges in the input pin, as configured by EDPOL and EDSEL bits in EMIOSC*n* register.

Figure 480 and *Figure 481* show how the Unified Channel can be used for input capture.

Figure 480. Single action input capture with rising edge triggering example

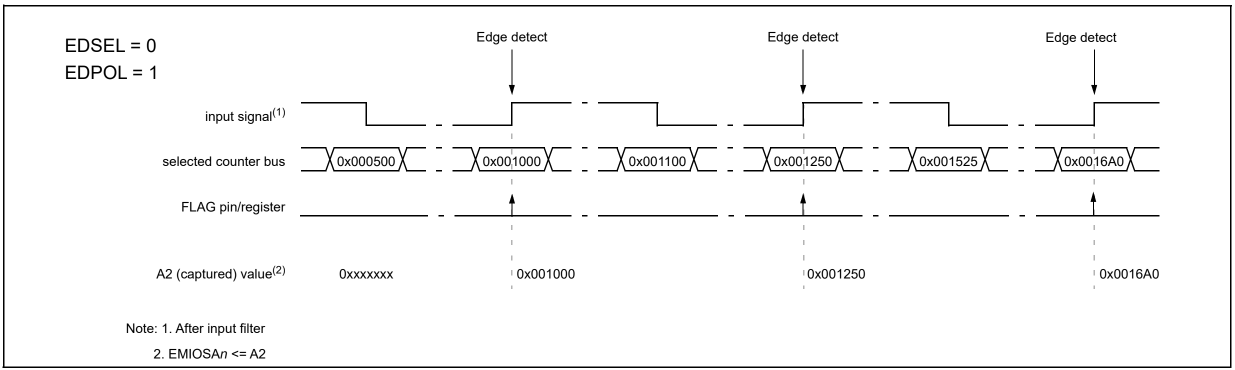

Figure 481. Single action input capture with both edges triggering example

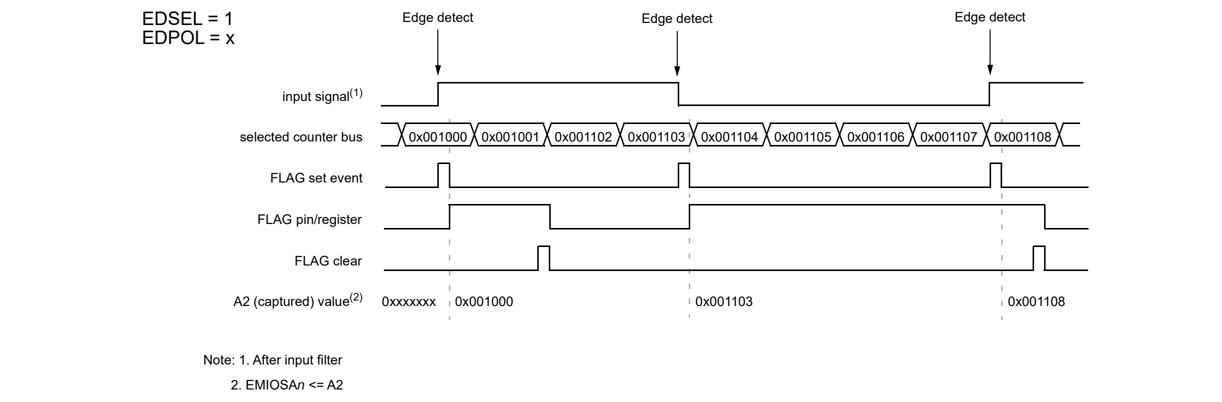

45.4.1.1.3 Single Action Output Compare (SAOC) mode

In SAOC mode (MODE[25:31] = 0000011) a match value is loaded in register A2 and then immediately transferred to register A1 to be compared with the selected time base. When a match occurs, the EDSEL bit selects whether the output flip-flop is toggled or the value in EDPOL is transferred to it. Along with the match the FLAG bit is set to indicate that the output compare match has occurred. Writing to register EMIOSA*n* stores the value in register A2 and reading to register EMIOSA*n* returns the value of register A1.

An output compare match can be simulated in software by setting the FORCMA bit in EMIOSC*n* register. In this case, the FLAG bit is not set.

When SAOC mode is entered coming out from GPIO mode the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC*n* register.

Counter bus can be either internal or external and is selected through bits BSL[21:22].

Figure 482 and *Figure 483* show how the Unified Channel can be used to perform a single output compare with EDPOL value being transferred to the output flip-flop and toggling the output flip-flop at each match, respectively. Note that once in SAOC mode the matches are enabled thus the desired match value on register A1 must be written before the mode is entered. A1 register can be updated at any time thus modifying the match value which will reflect in the output signal generated by the channel. Subsequent matches are enabled with no need of further writes to EMIOSA*n* register. The FLAG is set at the same time a match occurs (refer to *Figure 484*).

Note: The channel internal counter in SAOC mode is free-running. It starts counting as soon as the SAOC mode is entered.

Figure 482. SAOC example with EDPOL value being transferred to the output flip-flop

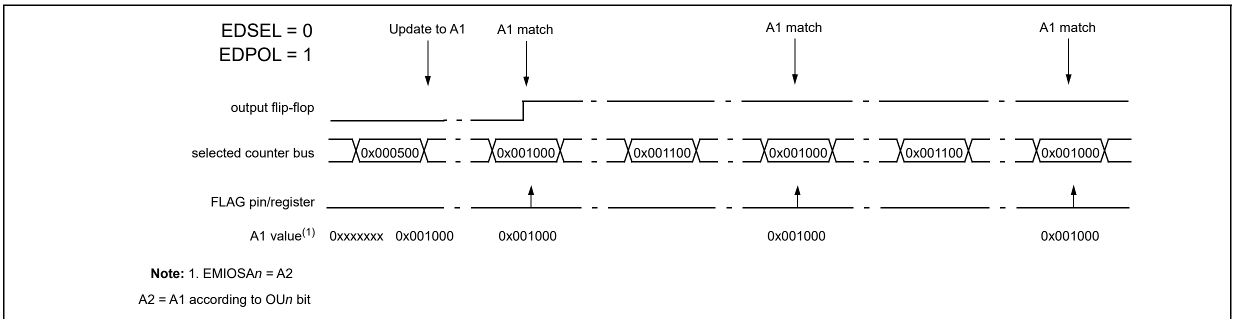

Figure 483. SAOC example toggling the output flip-flop

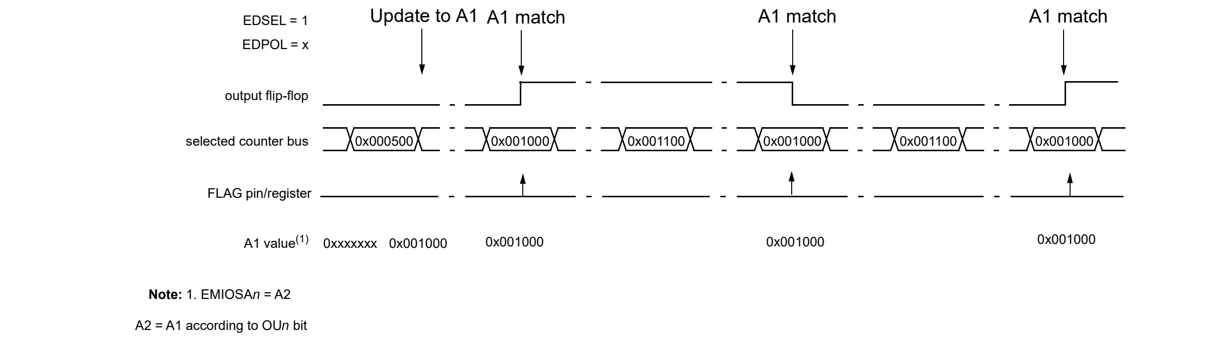

Figure 484. SAOC example with flag behavior

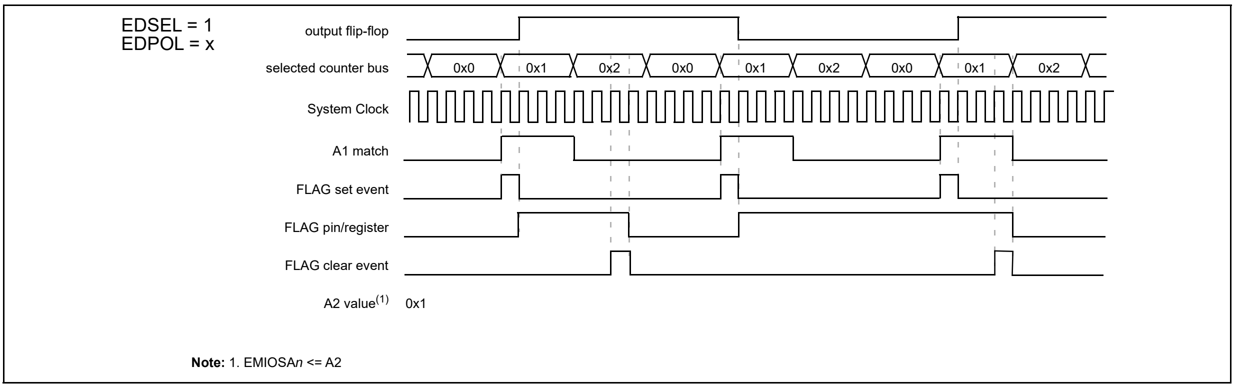

45.4.1.1.4 Input Pulse Width Measurement (IPWM) Mode

The IPWM mode (MODE[25:31] = 0000100) allows the measurement of the width of a positive or negative pulse by capturing the leading edge on register B1 and the trailing edge on register A2. Successive captures are done on consecutive edges of opposite polarity. The leading edge sensitivity (that is, pulse polarity) is selected by EDPOL bit in the EMIOSC*n* register. Registers EMIOSA*n* and EMIOSB*n* return the values in register A2 and B1, respectively.

The capture function of register A2 remains disabled until the first leading edge triggers the first input capture on register B2. When this leading edge is detected, the count value of the selected time base is latched into register B2; the FLAG bit is not set. When the trailing edge is detected, the count value of the selected time base is latched into register A2 and, at the same time, the FLAG bit is set and the content of register B2 is transferred to register B1 and to register A1.

If subsequent input capture events occur while the corresponding FLAG bit is set, registers A2, B1 and A1 will be updated with the latest captured values and the FLAG will remain set. Registers EMIOSA*n* and EMIOSB*n* return the value in registers A2 and B1, respectively.

In order to guarantee coherent access, reading EMIOSA*n* forces B1 be updated with the content of register A1. At the same time transfers between B2 and B1 are disabled until the next read of EMIOSB*n* register. Reading EMIOSB*n* register forces B1 be updated with A1 register content and re-enables transfers from B2 to B1, to take effect at the next trailing edge capture. Transfers from B2 to A1 are not blocked at any time.

The input pulse width is calculated by subtracting the value in B1 from A2.

Figure 485 shows how the Unified Channel can be used for input pulse width measurement.

Figure 485. Input pulse width measurement example

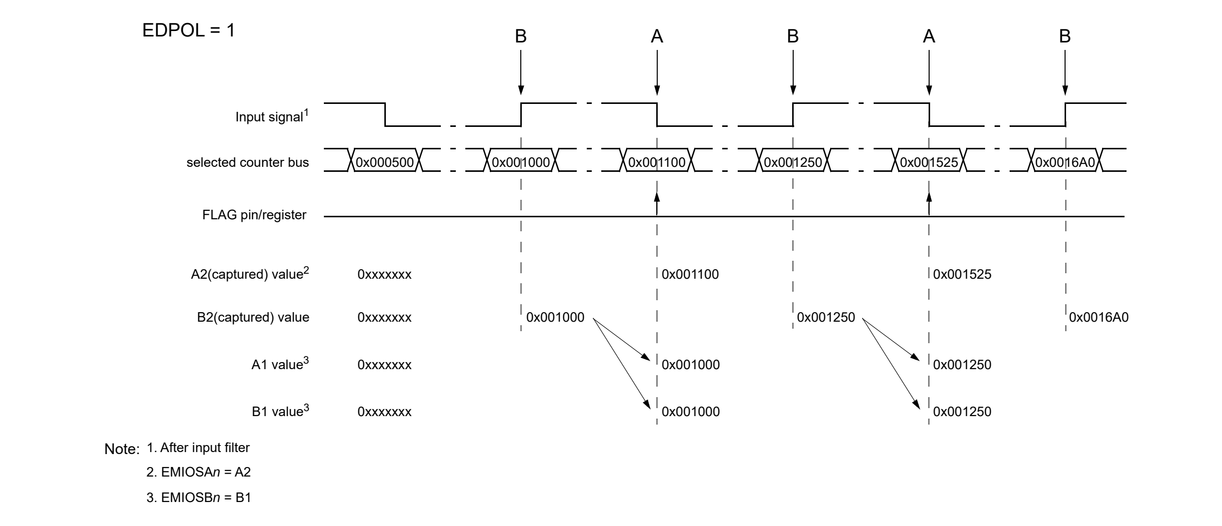

Figure 486 shows the A1 and B1 updates when EMIOSA*n* and EMIOSB*n* register reads occur. Note that A1 register has always coherent data related to A2 register. Note also that when EMIOSA*n* read is performed B1 register is loaded with A1 register content. This guarantees that the data in register B1 has always the coherent data related to the last EMIOSA*n* read. The B1 register updates remain locked until EMIOSB*n* read occurs. If EMIOSA*n* read is performed B1 is updated with A1 register content, even if B1 update is locked by a previous EMIOSA*n* read operation.

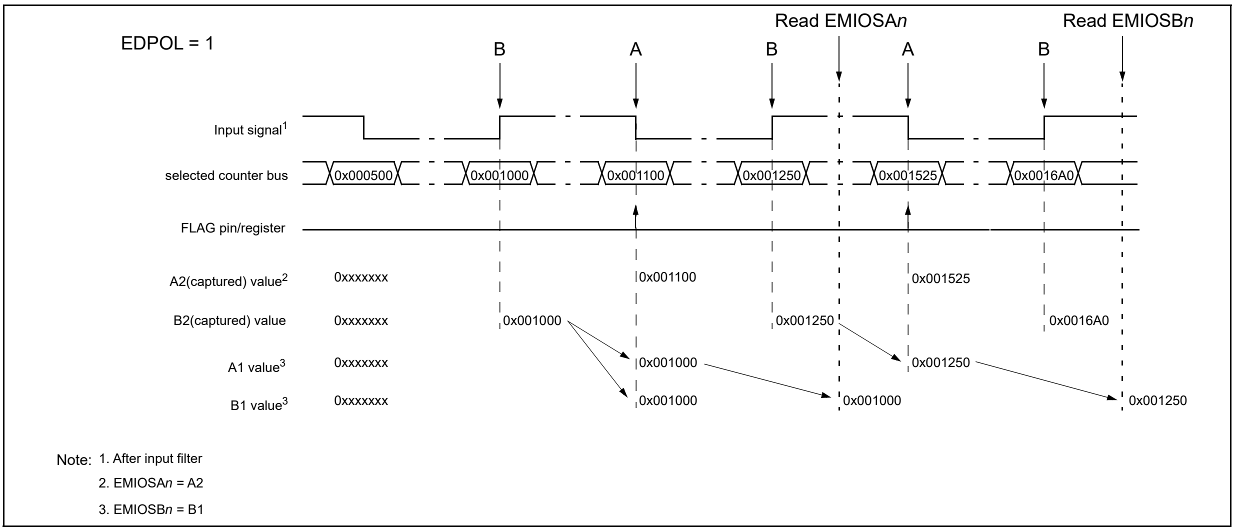
Figure 486. B1 and A1 updates at EMIOSA*n* and EMIOSB*n* reads



Reading EMIOSA*n* followed by EMIOSB*n* always provides coherent data. If not coherent data is required for any reason, the sequence of reads should be inverted, therefore EMIOSB*n* should be read prior to EMIOSA*n* register. Note that even in this case B1 register updates will be blocked after EMIOSA*n* read, thus a second EMIOSB*n* is required in order to release B1 register updates.

45.4.1.1.5 Input Period Measurement (IPM) mode

The IPM mode (MODE[25:31] = 0000101) allows the measurement of the period of an input signal by capturing two consecutive rising edges or two consecutive falling edges. Successive input captures are done on consecutive edges of the same polarity. The edge polarity is defined by the EDPOL bit in the EMIOSC*n* register.

Note: The input signal must have at least four system clock cycles period in order to be properly captured by the synchronization logic at the channel input even if the input filter is in by-pass mode.

When the first edge of selected polarity is detected, the selected time base is latched into the registers A2 and B2, and the data previously held in register B2 is transferred to register B1. On this first capture the FLAG line is not set, and the values in registers B1 is meaningless. On the second and subsequent captures, the FLAG line is set and data in register B2 is transferred to register B1.

When the second edge of the same polarity is detected, the counter bus value is latched into registers A2 and B2, the data previously held in register B2 is transferred to data register B1 and to register A1. The FLAG bit is set to indicate the start and end points of a complete period have been captured. This sequence of events is repeated for each subsequent capture. Registers EMIOSA*n* and EMIOSB*n* return the values in register A2 and B1, respectively.

In order to allow coherent data, reading EMIOSA*n* forces A1 content be transferred to B1 register and disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOSB*n* register. Reading EMIOSB*n* register forces A1 content to be transferred to B1 and re-enables transfers from B2 to B1, to take effect at the next edge capture.

The input pulse period is calculated by subtracting the value in B1 from A2.

Figure 487 shows how the Unified Channel can be used for input period measurement.

Figure 487. Input period measurement example

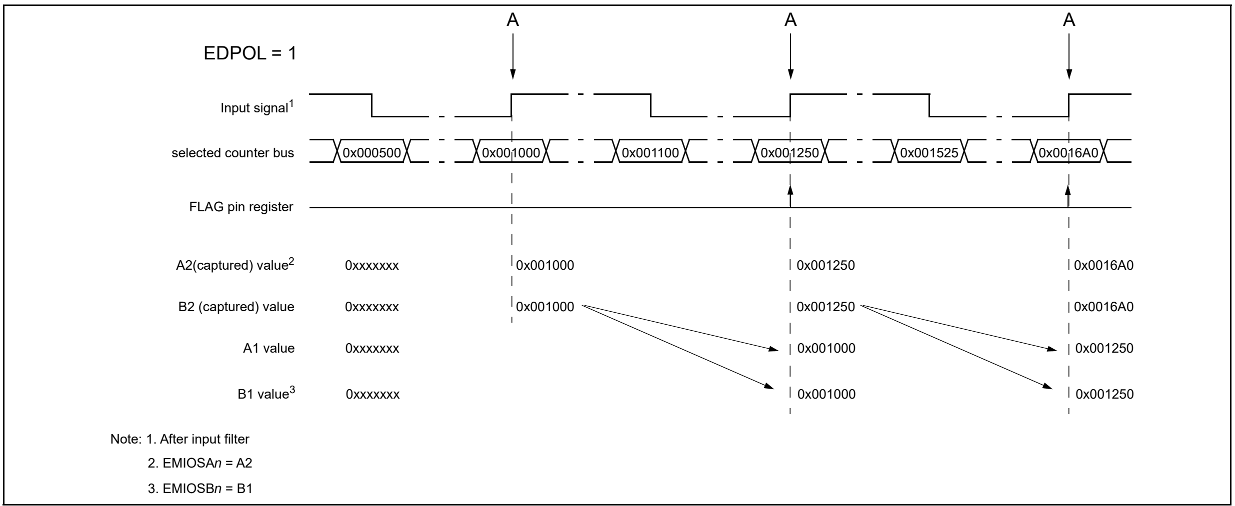


Figure 488 describes the A1 and B1 register updates when EMIOSA*n* and EMIOSB*n* read operations are performed. When EMIOSA*n* read occurs the content of A1 is transferred to B1 thus providing coherent data in A2 and B1 registers. Transfers from B2 to B1 are then blocked until EMIOSB*n* is read. After EMIOSB*n* is read, register A1 content is transferred to

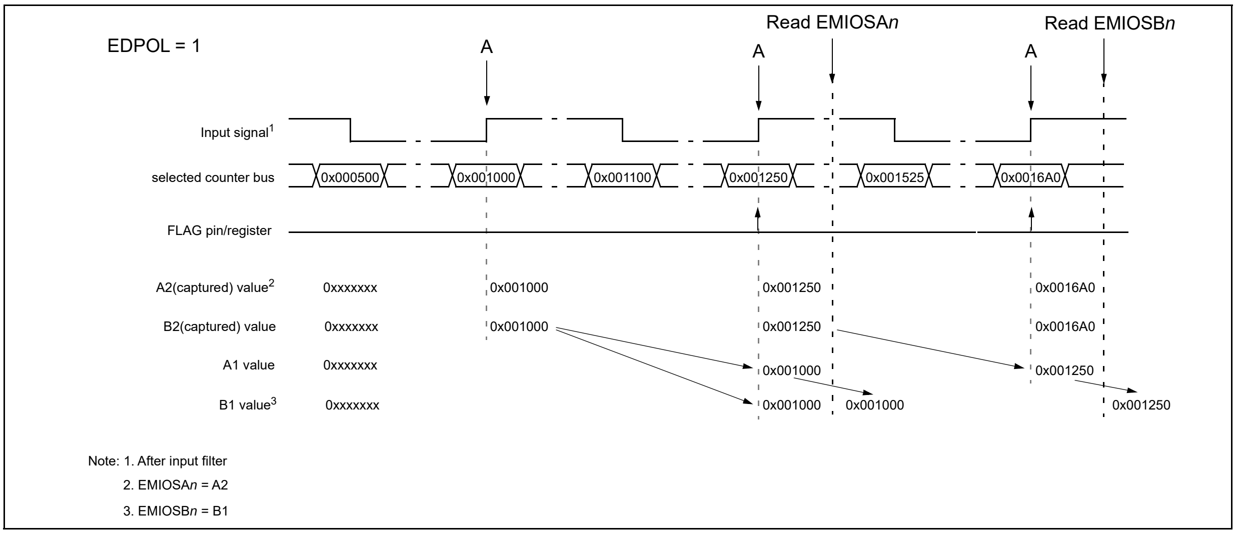
register B1 and the transfers from B2 to B1 are re-enabled to occur at the transfer edges, which is the leading edge in the *Figure 488* example.

Figure 488. A1 and B1 updates at EMIOSA*n* and EMIOSB*n* reads



45.4.1.1.6 Double Action Output Compare (DAOC) mode

In the DAOC mode the leading and trailing edges of the variable pulse width output are generated by matches occurring on comparators A and B. There is no restriction concerning the order in which A and B matches occur.

When the DAOC mode is entered, coming out from GPIO mode both comparators are disabled and the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC*n* register.

Data written to A2 and B2 are transferred to A1 and B1, respectively, on the next system clock cycle if bit OU*n* of the EMIOSOUDIS register is cleared (refer to *Figure 491*). The transfer is blocked if bit OU*n* is set. Comparator A is enabled only after the transfer to A1 register occurs and is disabled on the next A match. Comparator B is enabled only after the transfer to B1 register occurs and is disabled on the next B match. Comparators A and B are enabled and disabled independently.

The output flip-flop is set to the value of EDPOL when a match occurs on comparator A and to the complement of EDPOL when a match occurs on comparator B.

MODE[31] controls if the FLAG is set on both matches (MODE[25:31] = 0000111) or just on the B match (MODE[25:31] = 0000110). FLAG bit assertion depends on comparator enabling.

If subsequent enabled output compares occur on registers A1 and B1, pulses will continue to be generated, regardless of the state of the FLAG bit.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a comparison event in comparator A or B, respectively. Note that the FLAG bit is not affected by these forced operations.

Note: If both registers (A1 and B1) are loaded with the same value, the B match prevails concerning the output pin state (output flip-flop is set to the complement of EDPOL), the FLAG bit is set and both comparators are disabled.

Figure 489 and *Figure 490* show how the Unified Channel can be used to generate a single output pulse with FLAG bit being set on the second match or on both matches, respectively.

Figure 489. Double action output compare with FLAG set on the second match

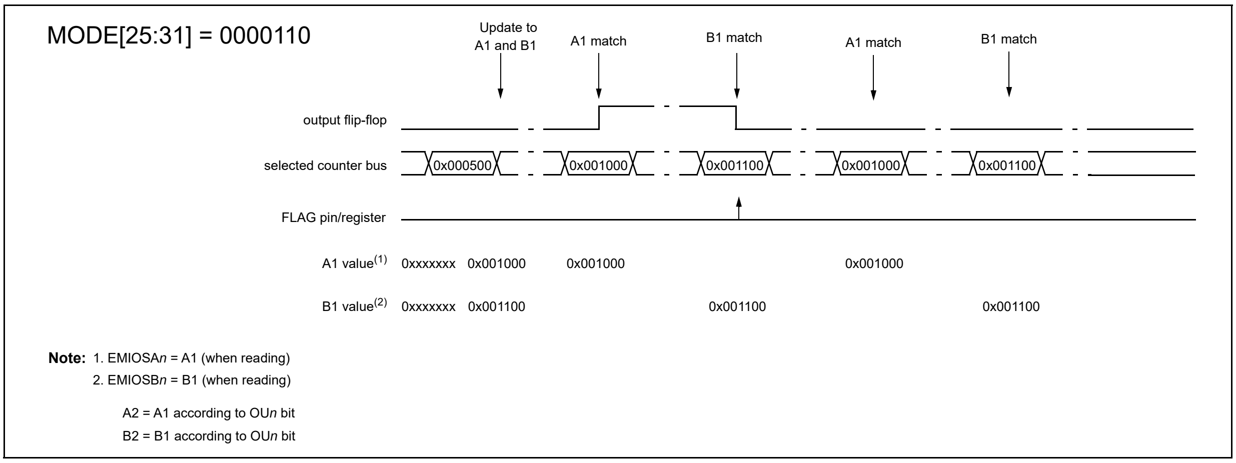


Figure 490. Double action output compare with FLAG set on both matches

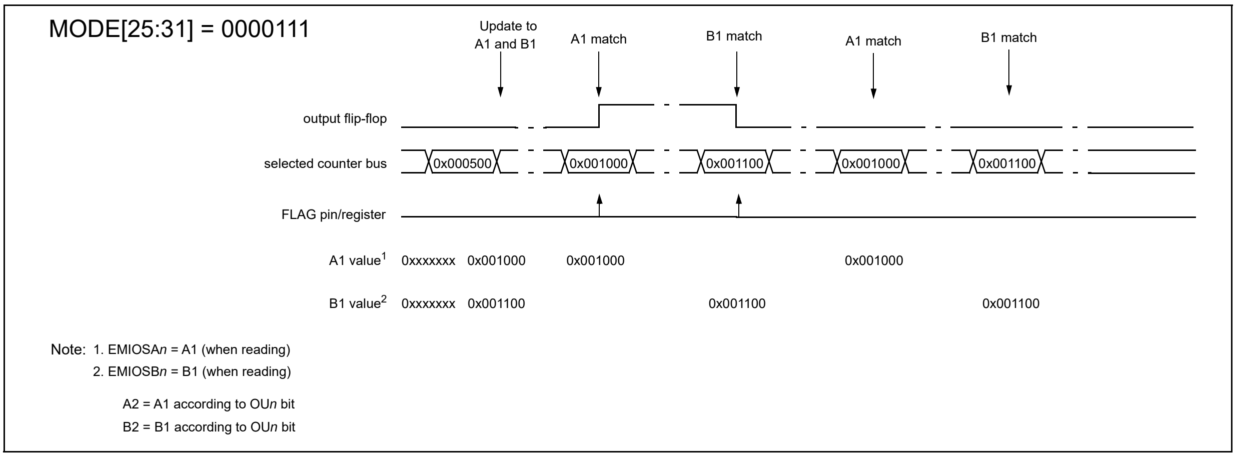

Figure 491. DAOC with transfer disabling example

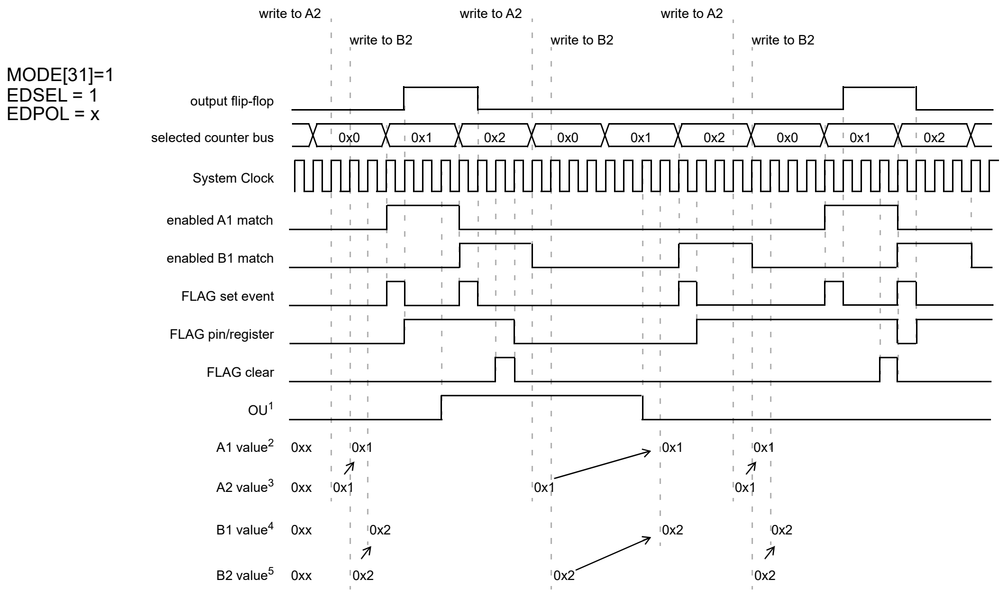

Note: 1. OU*n* bit of EMIOSOUDIS register
2. EMIOSA*n* = A1 (when reading)
3. EMIOSA*n* = A2 (when writing)
4. EMIOSB*n* = B1 (when reading)
5. EMIOSB*n* = B2 (when writing)

45.4.1.1.7 Modulus Counter (MC) mode

The MC mode can be used to provide a time base for a counter bus or as a general purpose timer.

Bit MODE[31] selects internal or external clock source when cleared or set, respectively. When external clock is selected, the input signal pin is used as the source and the triggering polarity edge is selected by the EDPOL and EDSEL in the EMIOSC*n* register.

The internal counter counts up from the current value until it matches the value in register A1. Register B1 is cleared and is not accessible to the MCU. Bit MODE[29] selects up mode or up/down mode, when cleared or set, respectively.

When in up count mode, a match between the internal counter and register A1 sets the FLAG and clears the internal counter. The timing of those events varies according to the MC mode setup as follows:

- Internal counter clearing on match start (MODE[25:31] = 001000b)
  - External clock is selected if MODE[31] is set. In this case the internal counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. Note that by having the internal counter cleared as soon as the match occurs and incremented at the next input event a shorter zero count is generated. Refer to *Figure 514* and *Figure 515*.
  - Internal clock source is selected if MODE[31] is cleared. In this case the counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. At the next prescaler tick after the match the internal

counter remains at zero and only resumes counting on the following tick. Refer to *Figure 514* and *Figure 516*.

- Internal counter clearing on match end (MODE[25:31] = 001001b)
  – External clock is selected if MODE[31] is set. In this case the internal counter clears when the match signal is asserted and the input event occurs. The channel FLAG is set at the same time the counter is cleared. Refer to *Figure 514* and *Figure 517*.
  – Internal clock source is selected if MODE[31] is cleared. In this case the internal counter clears when the match signal is asserted and the prescaler tick occurs. The channel FLAG is set at the same time the counter is cleared. Refer to *Figure 514* and *Figure 517*.

Note: If the internal clock source is selected and the prescaler of the internal counter is set to '1', the MC mode behaves the same way even in Clear on Match Start or Clear on Match End submodes.

When in up/down count mode (MODE[25:31] = 00101bb), a match between the internal counter and register A1 sets the FLAG and changes the counter direction from increment to decrement. A match between register B1 and the internal counter changes the counter direction from decrement to increment and sets the FLAG only if MODE[30] bit is set.

Only values different than 0x0 must be written at A register. Loading 0x0 leads to unpredictable results.

Updates on A register or counter in MC mode may cause loss of match in the current cycle if the transfer occurs near the match. In this case, the counter may rollover and resume operation in the next cycle.

Register B2 has no effect in MC mode. Nevertheless, register B2 can be accessed for reads and writes by addressing EMIOSB.

Figure 492 and *Figure 493* show how the Unified Channel can be used as modulus counter in up mode and up/down mode, respectively.

Figure 492. Modulus Counter Up mode example

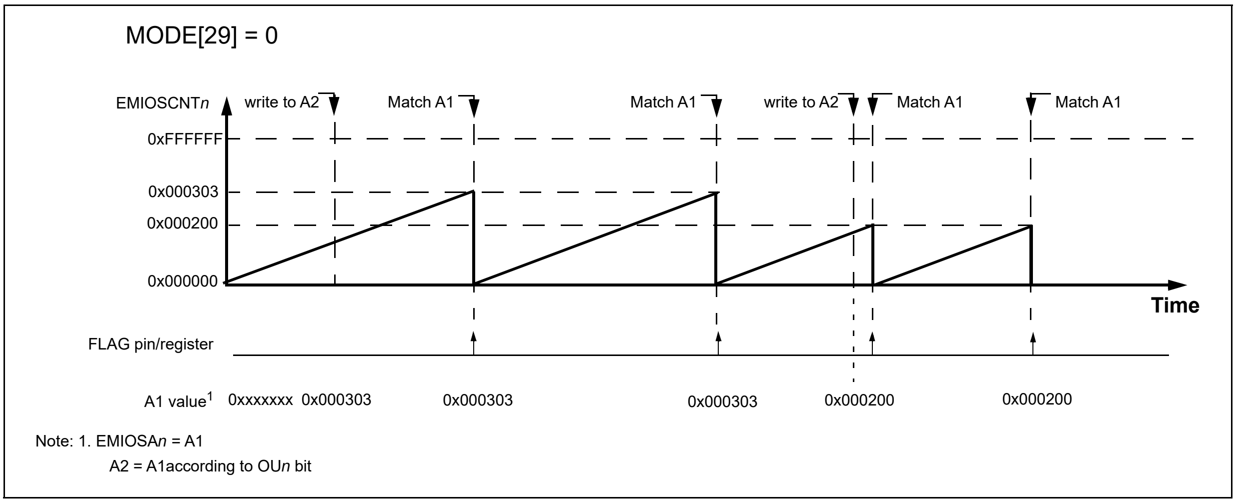

Figure 493. Modulus Counter Up/Down mode example

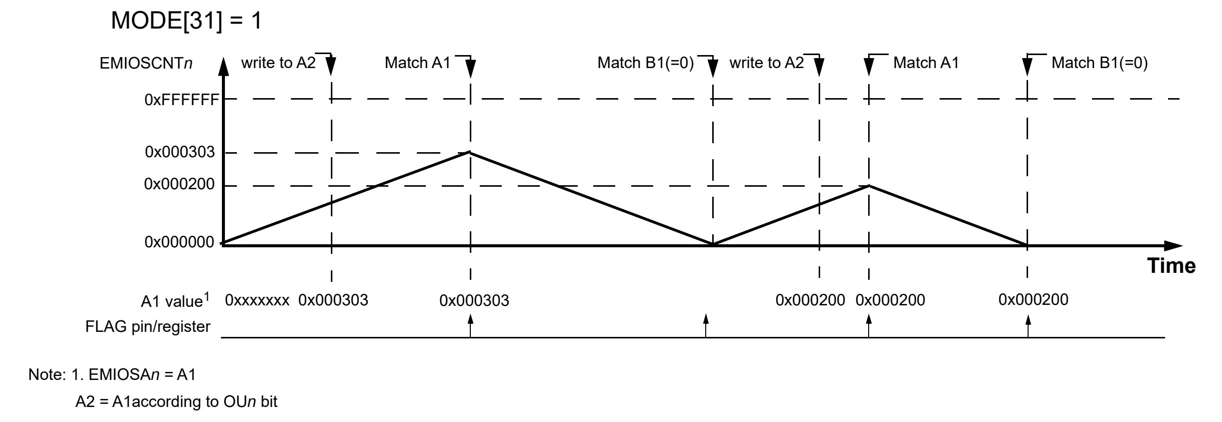

45.4.1.1.8 Modulus Counter Buffered (MCB) mode

The MCB mode provides a time base which can be shared with other channels through the internal counter buses. Register A1 is double buffered thus allowing smooth transitions between cycles when changing A2 register value on the fly. A1 register is updated at the cycle boundary, which is defined as when the internal counter transitions to 0x1.

The internal counter values operates within a range from 0x1 up to register A1 value. If when entering MCB mode coming out from GPIO mode the internal counter value is not within that range then the A match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xFFFF for a 16-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal MCB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to A1 register value range when the MCB mode is entered.

Bit MODE[31] selects internal clock source if cleared or external if set. When external clock is selected the input channel pin is used as the channel clock source. The active edge of this clock is defined by EDPOL and EDSEL bits in the EMIOSC*n* channel register.

When entering in MCB mode, if up counter is selected by MODE[29] = 0 (MODE[25:31] = 101000b), the internal counter starts counting from its current value to up direction until A1 match occurs. The internal counter is set to 0x1 when its value matches A1 value and a clock tick occurs (either prescaled clock or input pin event).

If up/down counter is selected by setting MODE[29] = 1, the counter changes direction at A1 match and counts down until it reaches the value 0x1. After it has reached 0x1 it is set to count in up direction again. B1 register is used to generate a match in order to set the internal counter in up-count direction if up/down mode is selected. Register B1 cannot be changed while this mode is selected.

Note that differently from the MC mode, the MCB mode counts between 0x1 and A1 register value. Only values greater than 0x1 must be written at A1 register. Loading values other than those leads to unpredictable results. The counter cycle period is equal to A1 value in up counter mode. If in up/down counter mode the period is defined by the expression: (2*A1)-2.

Figure 494 describes the counter cycle for several A1 values. Register A1 is loaded with A2 register value at the cycle boundary. Thus any value written to A2 register within cycle **n** will be updated to A1 at the next cycle boundary and therefore will be used on cycle **n+1**. The cycle boundary between cycle **n** and cycle **n+1** is defined as when the internal counter transitions from A1 value in cycle **n** to 0x1 in cycle **n+1**. Note that the FLAG is generated at the cycle boundary and has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

Figure 494. Modulus Counter Buffered (MCB) Up Count mode

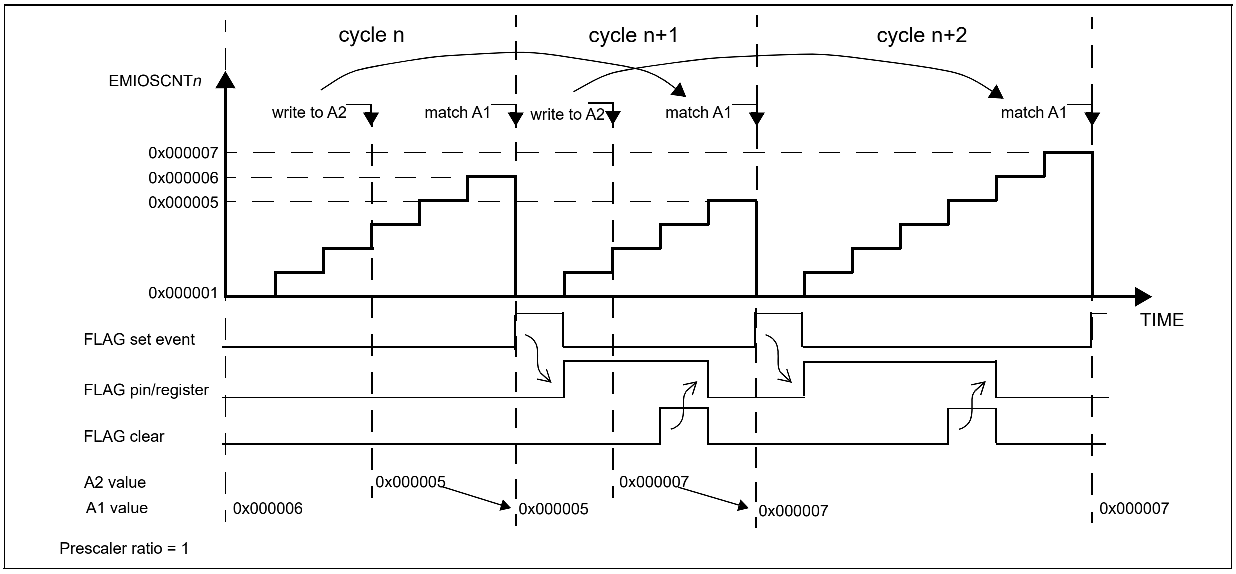

Figure 495 describes the MCB in up/down counter mode (MODE[25:31] = 10101bb). A1 register is updated at the cycle boundary. If A2 is written in cycle **n**, this new value will be used in cycle **n+1** for A1 match. Flags are generated only at A1 match start if MODE[30] is 0. If MODE[30] is set to 1 flags are also generated at the cycle boundary.

Figure 495. Modulus Counter Buffered (MCB) Up/Down mode

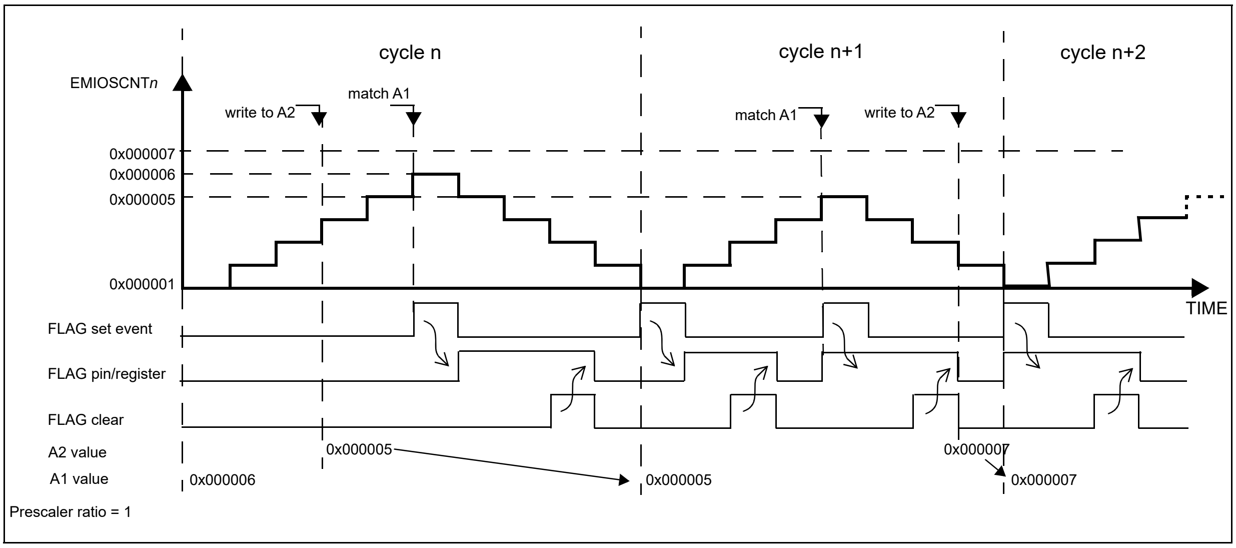

Figure 496 describes in more detail the A1 register update process in up counter mode. The A1 load signal is generated at the last system clock period of a counter cycle. Thus, A1 is updated with A2 value at the same time that the counter (EMIOSCNT*n*) is loaded with 0x1. The load signal pulse has the duration of one system clock period. If A2 is written within cycle **n** its value is available at A1 at the first clock of cycle **n+1** and the new value is used

for match at cycle **n+1**. The update disable bits OU*n* of EMIOSOUDIS register can be used to control the update of this register, thus allowing to delay the A1 register update for synchronization purposes.

Figure 496. MCB Mode A1 Register Update in Up Counter mode

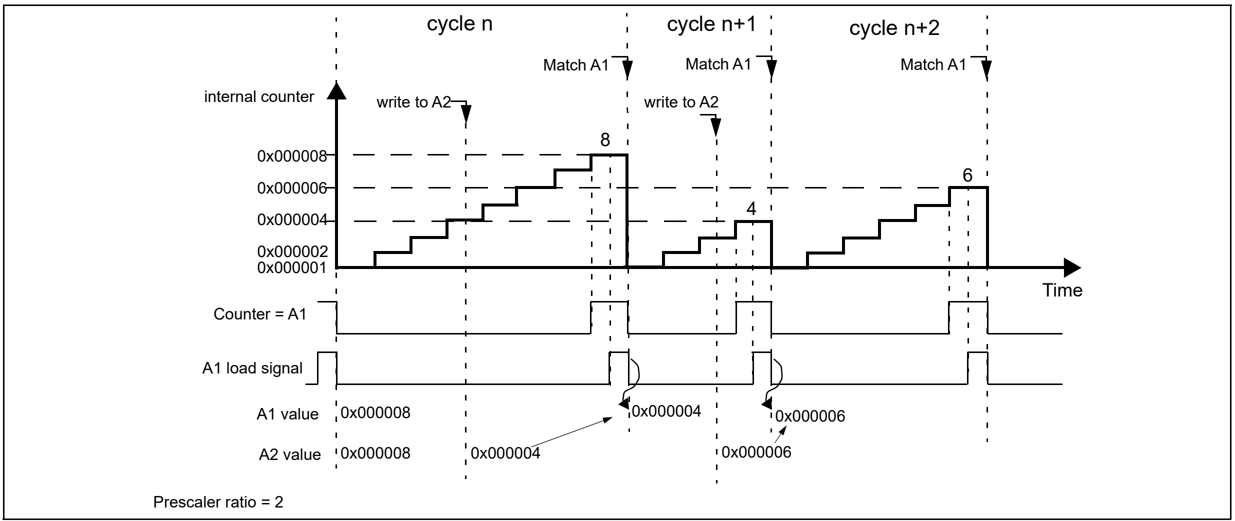

Figure 497 describes the A1 register update in up/down counter mode. Note that A2 can be written at any time within cycle **n** in order to be used in cycle **n+1**. Thus A1 receives this new value at the next cycle boundary. Note that the update disable bits OU*n* of EMIOSOUDIS register can be used to disable the update of A1 register.

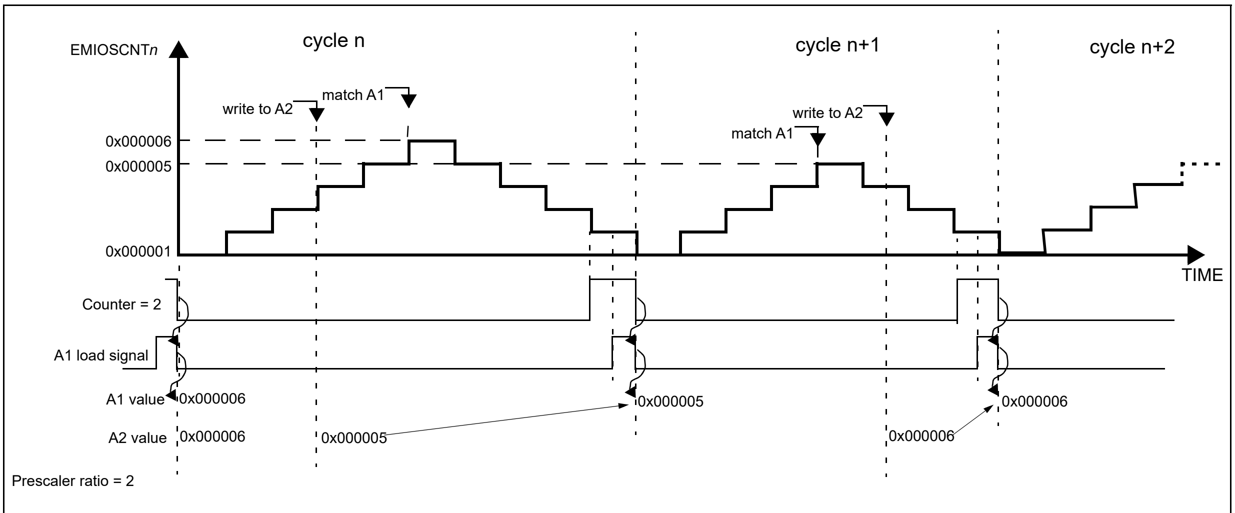
Figure 497. MCB Mode A1 Register Update in Up/Down Counter mode



45.4.1.1.9 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

This mode (MODE[25:31] = 10110b0) provides waveforms with variable duty cycle and frequency. The internal channel counter is automatically selected as the time base when this mode is selected. A1 register indicates the duty cycle and B1 register the frequency. Both A1 and B1 registers are double buffered to allow smooth signal generation when changing the registers values on the fly. 0% and 100% duty cycles are supported.

At OPWFMB mode entry the output flip-flop is set to the value of the EDPOL bit in the EMIOSC*n* register.

If when entering OPWFMB mode coming out from GPIO mode the internal counter value is not within that range then the B match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xFFFF for a 16-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal OPWFMB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to B1 register value range when the OPWFMB mode is entered.

When a match on comparator A occurs the output register is set to the value of EDPOL. When a match on comparator B occurs the output register is set to the complement of EDPOL. B1 match also causes the internal counter to transition to 0x1, thus restarting the counter cycle.

Only values greater than 0x1 are allowed to be written to B1 register. Loading values other than those leads to unpredictable results. If you want to configure the module for OPWFMB mode, ensure that the B1 register is modified before the mode is set.

Figure 498 describes the operation of the OPWFMB mode regarding output pin transitions and A1/B1 registers match events. Note that the output pin transition occurs when the A1 or B1 match signal is deasserted which is indicated by the A1 match negedge detection signal. If register A1 is set to 0x4 the output pin transitions 4 counter periods after the cycle had started, plus one system clock cycle. Note that in the example shown in *Figure 498* the internal counter prescaler has a ratio of two.

Figure 498. OPWFMB A1 and B1 match to Output Register Delay

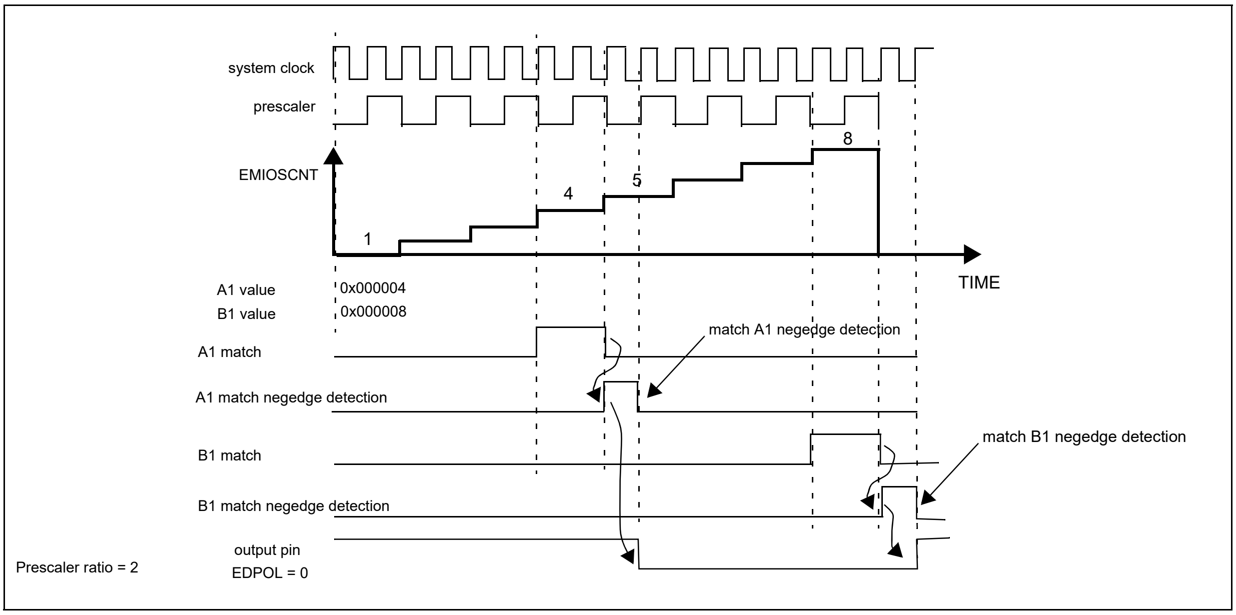


Figure 499 describes the generated output signal if A1 is set to 0x0. Since the counter does not reach zero in this mode, the channel internal logic infers a match as if A1 = 0x1 with the difference that in this case, the posedge of the match signal is used to trigger the output pin transition instead of the negedge used when A1 = 0x1. Note that A1 posedge match signal from cycle **n+1** occurs at the same time as B1 negedge match signal from cycle **n**. This allows to use the A1 posedge match to mask the B1 negedge match when they occur at the same time. The result is that no transition occurs on the output flip-flop and a 0% duty cycle is generated.

Figure 499. OPWFMB Mode with A1 = 0 (0% duty cycle)

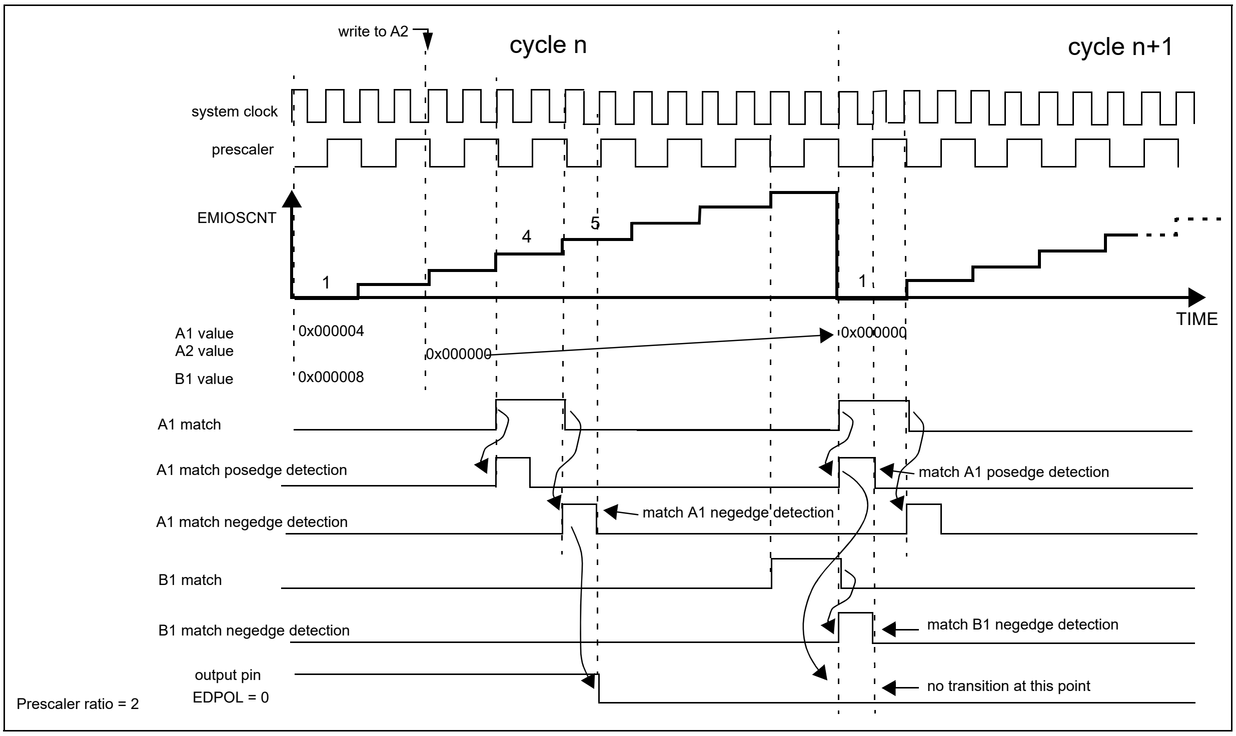

Figure 500 describes the timing for the A1 and B1 registers load. The A1 and B1 load use the same signal which is generated at the last system clock period of a counter cycle. Thus, A1 and B1 are updated respectively with A2 and B2 values at the same time that the counter (EMIOSCNT*n*) is loaded with 0x1. This event is defined as the cycle boundary. The load signal pulse has the duration of one system clock period. If A2 and B2 are written within cycle **n** their values are available at A1 and B1, respectively, at the first clock of cycle **n+1** and the new values are used for matches at cycle **n+1**. The update disable bits OU*n* of EMIOSOUDIS register can be used to control the update of these registers, thus allowing to delay the A1 and B1 registers update for synchronization purposes.

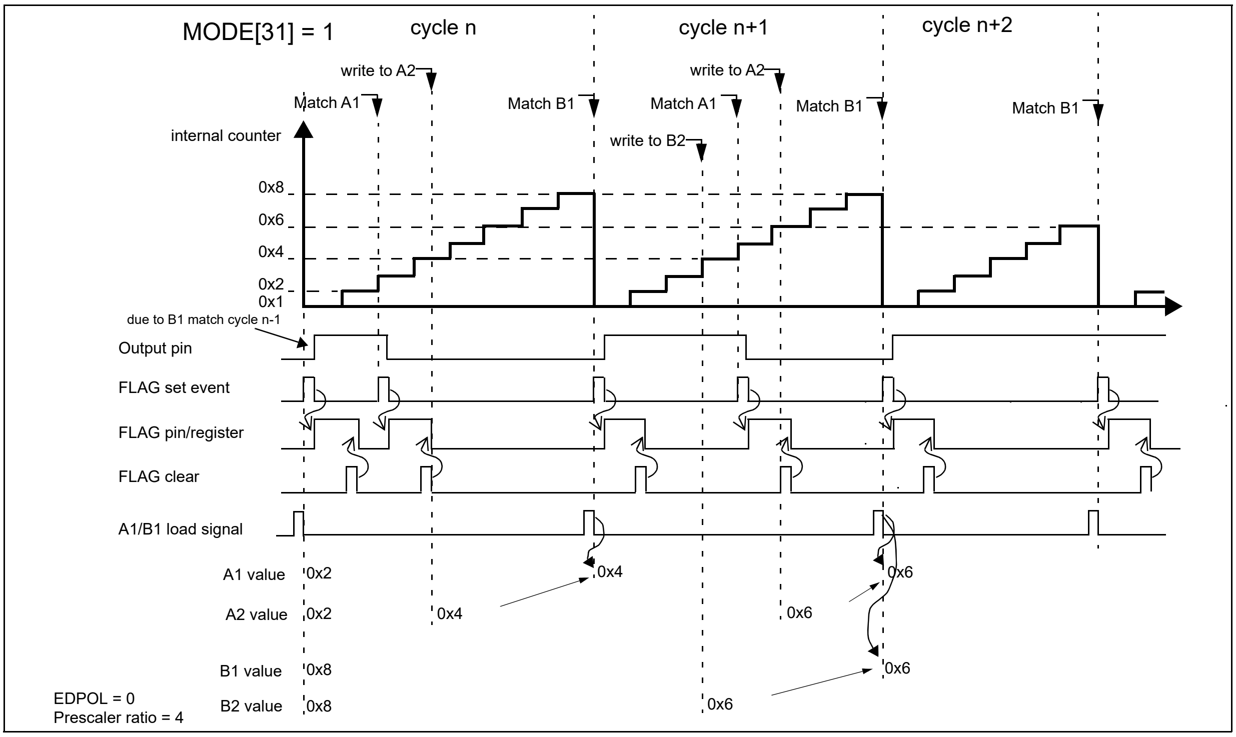
In *Figure 500* it is assumed that both the channel and global prescalers are set to 0x1 (each divide ratio is two), meaning that the channel internal counter transitions at every four system clock cycles. FLAGs can be generated only on B1 matches when MODE[30] is cleared, or on both A1 and B1 matches when MODE[30] is set. Since B1 flag occurs at the cycle boundary, this flag can be used to indicate that A2 or B2 data written on cycle **n** were loaded to A1 or B1, respectively, thus generating matches in cycle **n+1**. Note that the FLAG has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

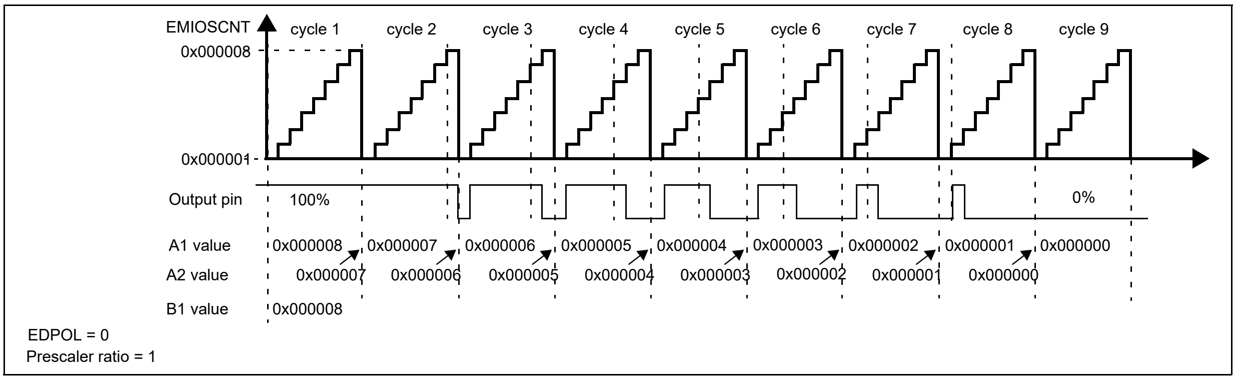
Figure 500. OPWFMB A1 and B1 registers update and flags



The FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on comparators A or B respectively. Similarly to a B1 match FORCMB sets the internal counter to 0x1. The FLAG bit is not set by the FORCMA or FORCMB bits being asserted.

Figure 501 describes the generation of 100% and 0% duty cycle signals. It is assumed EDPOL = 0 and the resultant prescaler value is 1. Initially A1 = 0x8 and B1 = 0x8. In this case, B1 match has precedence over A1 match, thus the output flip-flop is set to the complement of EDPOL bit. This cycle corresponds to a 100% duty cycle signal. The same output signal can be generated for any A1 value greater than or equal to B1.

Figure 501. OPWFMB mode from 100% to 0% duty cycle



A 0% duty cycle signal is generated if A1 = 0x0 as shown in *Figure 501* cycle 9. In this case B1 = 0x8 match from cycle 8 occurs at the same time as the A1 = 0x0 match from cycle 9. Refer to *Figure 499* for a description of the A1 and B1 match generation. In this case A1 match has precedence over B1 match and the output signal transitions to EDPOL.

45.4.1.1.10 Center Aligned Output PWM Buffered with Dead-Time (OPWMCB) mode

This operation mode generates a center aligned PWM with dead time insertion to the leading (MODE[25:31] = 10111b1) or trailing edge (MODE[25:31] = 10111b0). A1 and B1 registers are double buffered to allow smooth output signal generation when changing A2 or B2 registers values on the fly.

Bits BSL[21:22] select the time base. The time base selected for a channel configured to OPWMCB mode should be a channel configured to MCB Up/Down mode, as shown in *Figure 495*. It is recommended to start the MCB channel time base after the OPWMCB mode is entered in order to avoid missing A matches at the very first duty cycle.

Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base.

Register B1 contains the dead time value and is compared against the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Bit Mode[31] selects between trailing and leading dead time insertion, respectively.

Note: The internal counter runs in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio.

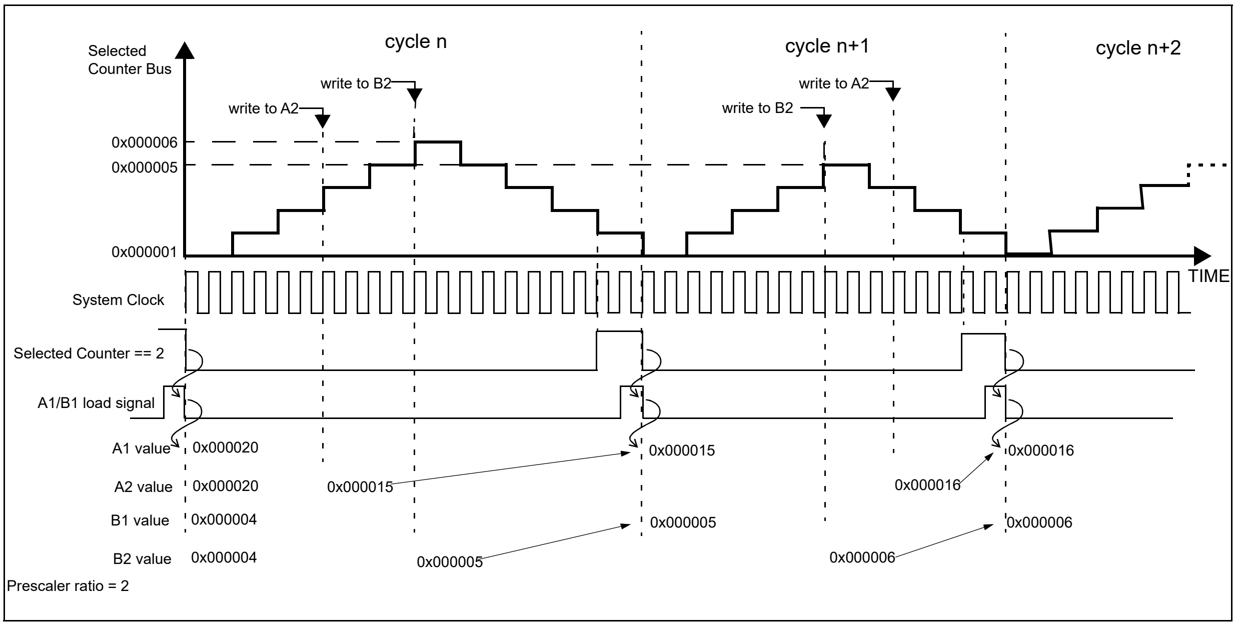
When OPWMCB mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC*n* register.

The following basic steps summarize the proper OPWMCB startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler;
2. *[MCB channel]* Disable Channel Prescaler;
3. *[MCB channel]* Write 0x1 at internal counter;
4. *[MCB channel]* Set A register;
5. *[MCB channel]* Set channel to MCB Up mode;
6. *[MCB channel]* Set prescaler ratio;
7. *[MCB channel]* Enable Channel Prescaler;
8. *[OPWMCB channel]* Disable Channel Prescaler;
9. *[OPWMCB channel]* Set A register;
10. *[OPWMCB channel]* Set B register;
11. *[OPWMCB channel]* Select time base input through BSL[21:22] bits;
12. *[OPWMCB channel]* Enter OPWMCB mode;
13. *[OPWMCB channel]* Set prescaler ratio;
14. *[OPWMCB channel]* Enable Channel Prescaler;
15. *[global]* Enable Global Prescaler.

Figure 502 describes the load of A1 and B1 registers which occurs when the selected counter bus transitions from 0x2 to 0x1. This event defines the cycle boundary. Note that values written to A2 or B2 within cycle **n** are loaded into A1 or B1 registers, respectively, and used to generate matches in cycle **n+1**.

Figure 502. OPWMCB A1 and B1 registers load

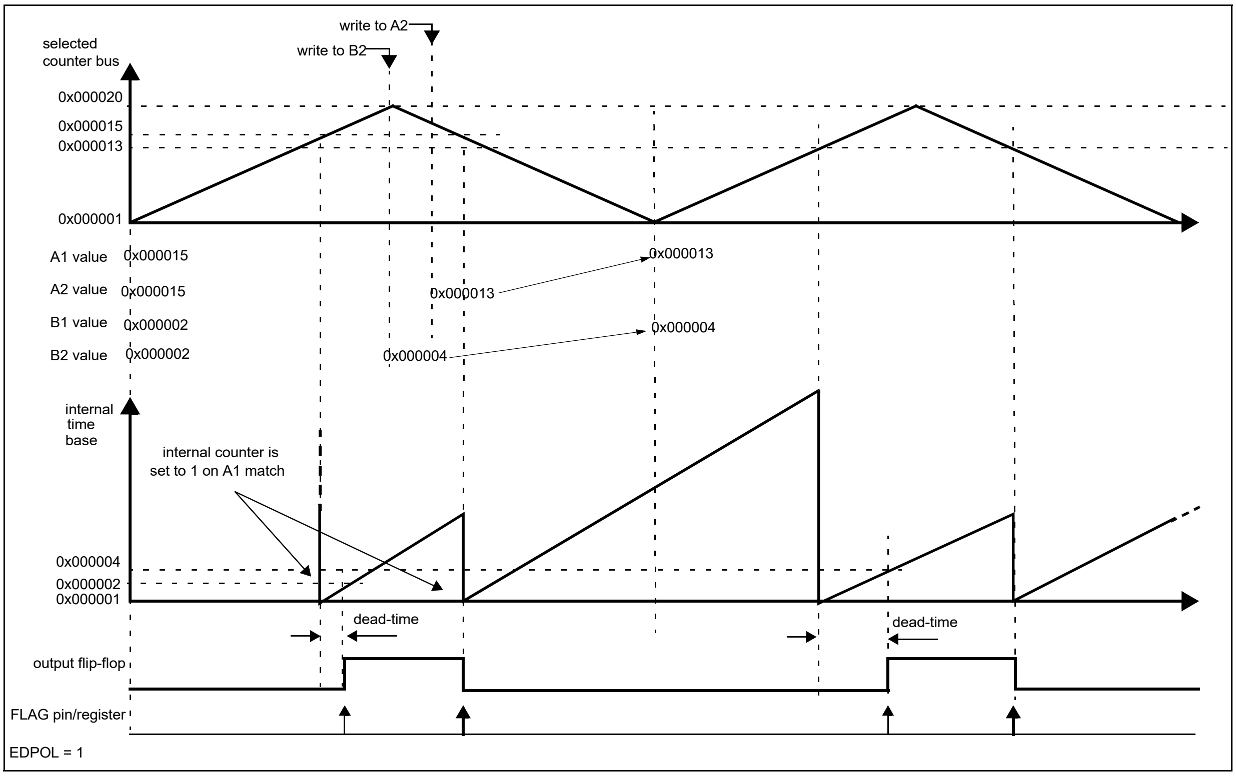


Bit OU*n* of the EMIOSOUDIS register can be used to disable the A1 and B1 updates, thus allowing to synchronize the load on these registers with the load of A1 or B1 registers in others channels. Note that, using the update disable bit A1 and B1 registers can be updated at the same counter cycle thus allowing to change both registers at the same time.

In this mode, A1 matches always set the internal counter to 0x1. When operating with leading edge dead time insertion the first A1 match sets the internal counter to 0x1. When a match occurs between register B1 and the internal time base, the output flip-flop is set to the value of the EDPOL bit. In the following match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously. The internal counter should not reach 0x0 as a consequence of a rollover. In order to avoid it, the user should not write to the EMIOSB register a value greater than twice the difference between external count up limit and EMIOSA value.

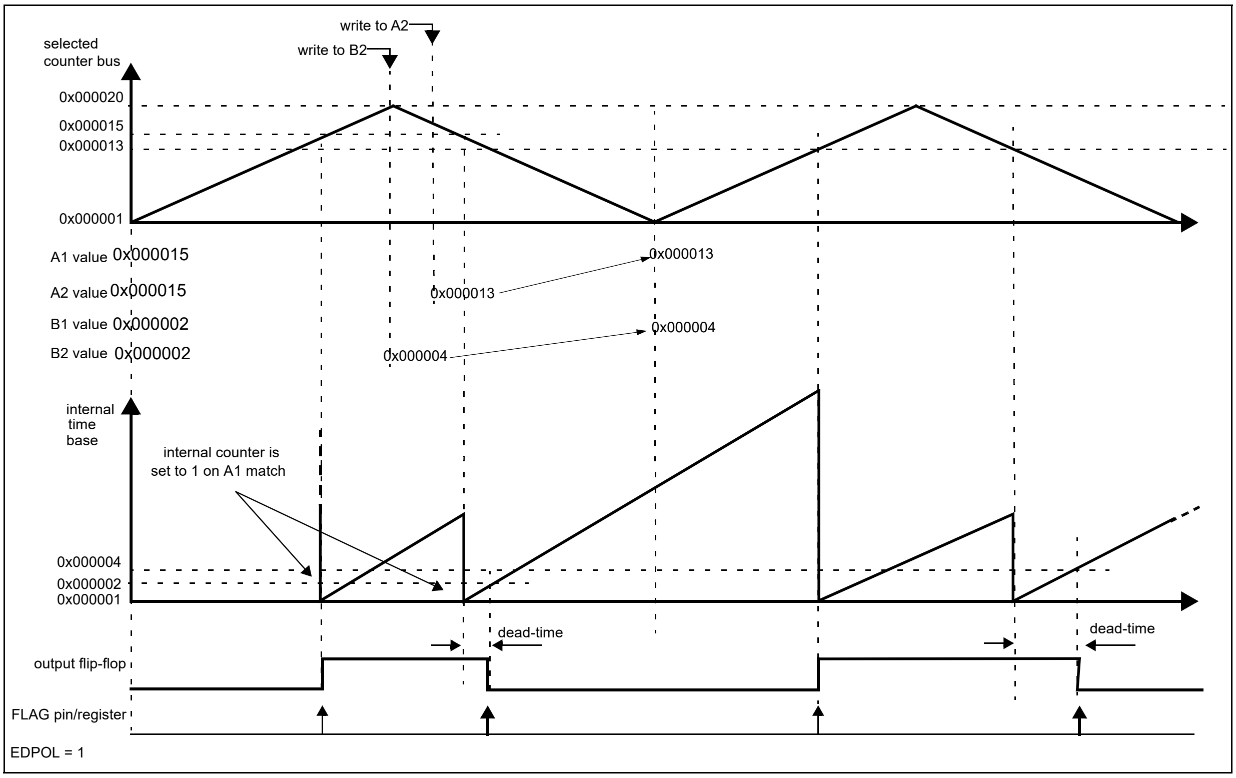
Figure 503 shows two cycles of a Center Aligned PWM signal. Note that, both A1 and B1 register values are changing within the same cycle which allows to vary at the same time the duty cycle and dead time values.

Figure 503. OPWMCB with lead dead time insertion



When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit and sets the internal counter to 0x1. In the second match between register A1 and the selected time base, the internal counter is set to 0x1 and B1 matches are enabled. When the match between register B1 and the selected time base occurs the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

Figure 504. OPWMCB with trail dead time insertion



FLAG can be generated in the trailing edge of the output PWM signal when MODE[30] is cleared, or in both edges, when MODE[30] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

Note: *In OPWMCB mode, FORCMA and FORCMB do not have the same behavior as a regular match. Instead, they force the output flip-flop to constant value which depends upon the selected dead time insertion mode, lead or trail, and the value of the EDPOL bit.*

FORCMA has different behaviors depending upon the selected dead time insertion mode, lead or trail. In lead dead time insertion FORCMA force a transition in the output flip-flop to the opposite of EDPOL. In trail dead time insertion the output flip-flop is forced to the value of EDPOL bit.

If bit FORCMB is set, the output flip-flop value depends upon the selected dead time insertion mode. In lead dead time insertion FORCMB forces the output flip-flop to transition to EDPOL bit value. In trail dead time insertion the output flip-flop is forced to the opposite of EDPOL bit value.

Note: *FORCMA bit set does not set the internal time-base to 0x1 as a regular A1 match.*

The FLAG bit is not set either in case of a FORCMA or FORCMB or even if both forces are issued at the same time.

Note: *FORCMA and FORCMB have the same behavior even in Freeze or normal mode regarding the output pin transition.*

When FORCMA is issued along with FORCMB the output flip-flop is set to the opposite of EDPOL bit value. This is equivalent of saying that.FORCMA has precedence over FORCMB when lead dead time insertion is selected and FORCMB has precedence over FORCMA when trail dead time insertion is selected.

Duty cycle from 0% to 100% can be generated by setting appropriate values to A1 and B1 registers relatively to the period of the external time base. Setting A1 = 1 generates a 100% duty cycle waveform. Assuming EDPOL is set to ‘1’ and OPWMCB mode with trail dead time insertion, 100% duty cycle signals can be generated if B1 occurs at or after the cycle boundary (external counter = 1). If A1 is greater than the maximum value of the selected counter bus period, then a 0% duty cycle is produced, only if the pin starts the current cycle in the opposite of EDPOL value. In case of 100% duty cycle, the transition from EDPOL to the opposite of EDPOL may be obtained by forcing pin, using FORCMA or FORCMB, or both.

Note: If A1 is set to 0x1 at OPWMCB entry the 100% duty cycle may not be obtained in the very first PWM cycle due to the pin condition at mode entry.

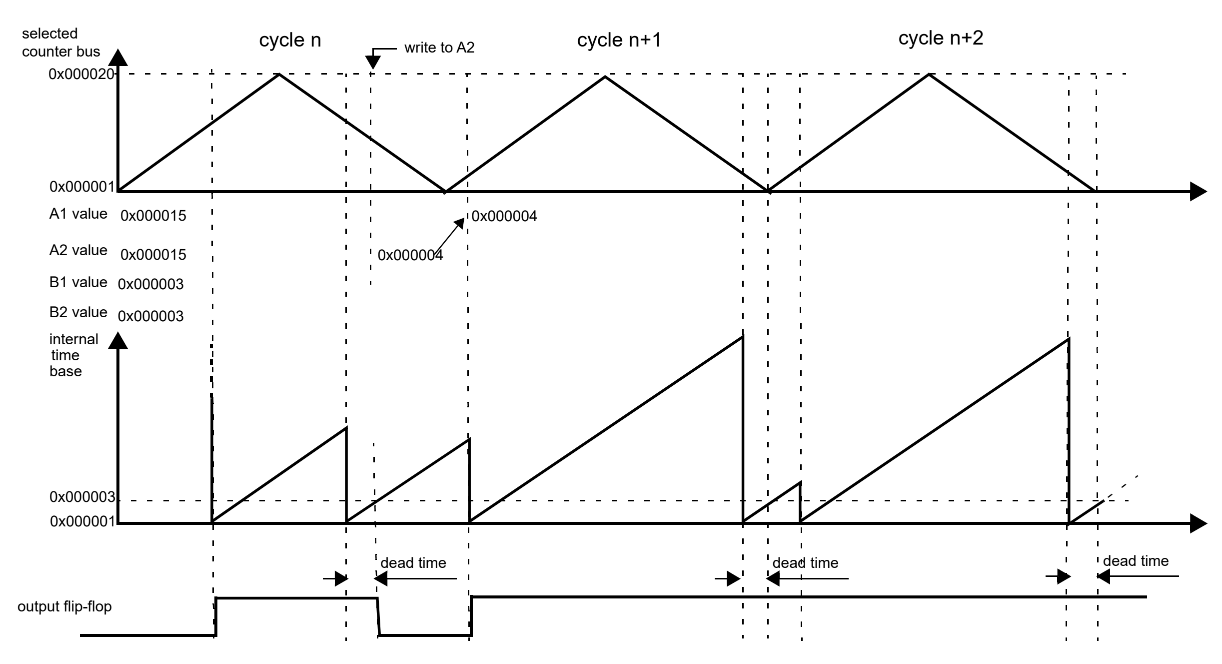
Only values different than 0x0 are allowed to be written to A1 register. If 0x0 is loaded to A1 the results are unpredictable.

Note: A special case occurs when A1 is set to (external counter bus period)/2, which is the maximum value of the external counter. In this case the output flip-flop is constantly set to the EDPOL bit value.

The internal channel logic prevents matches from one cycle to propagate to the next cycle. In trail dead time insertion B1 match from cycle **n** could eventually cross the cycle boundary and occur in cycle **n+1**. In this case B1 match is masked out and does not cause the output flip-flop to transition. Therefore matches in cycle **n+1** are not affected by the late B1 matches from cycle **n**.

Figure 505 shows a 100% duty cycle output signal generated by setting A1 = 4 and B1 = 3. In this case the trailing edge is positioned at the boundary of cycle **n+1**, which is actually considered to belong to cycle **n+2** and therefore does not cause the output flip-flip to transition.

Figure 505. OPWMCB with 100% Duty Cycle (A1 = 4 and B1 = 3)



It is important to notice that, such as in OPWMB and OPWFMB modes, the match signal used to set or clear the channel output flip-flop is generated on the deassertion of the channel combinational comparator output signal which compares the selected time base with A1 or B1 register values. Refer to *Figure 498* which describes the delay from matches to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB regarding matches and output pin transition.

45.4.1.1.11 Output Pulse Width Modulation Buffered (OPWMB) Mode

OPWMB mode (MODE[25:31] = 11000b0) is used to generate pulses with programmable leading and trailing edge placement. An external counter driven in MCB Up mode must be selected from one of the counter buses. A1 register value defines the first edge and B1 the second edge. The output signal polarity is defined by the EDPOL bit. If EDPOL is zero, a negative edge occurs when A1 matches the selected counter bus and a positive edge occurs when B1 matches the selected counter bus.

The A1 and B1 registers are double buffered and updated from A2 and B2, respectively, at the cycle boundary. The load operation is similar to the OPWFMB mode. Refer to *Figure 500* for more information about A1 and B1 registers update.

FLAG can be generated at B1 matches, when MODE[30] is cleared, or in both A1 and B1 matches, when MODE[30] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A1 or B1 respectively. FLAG bit is not set by the FORCMA and FORCMB operations.

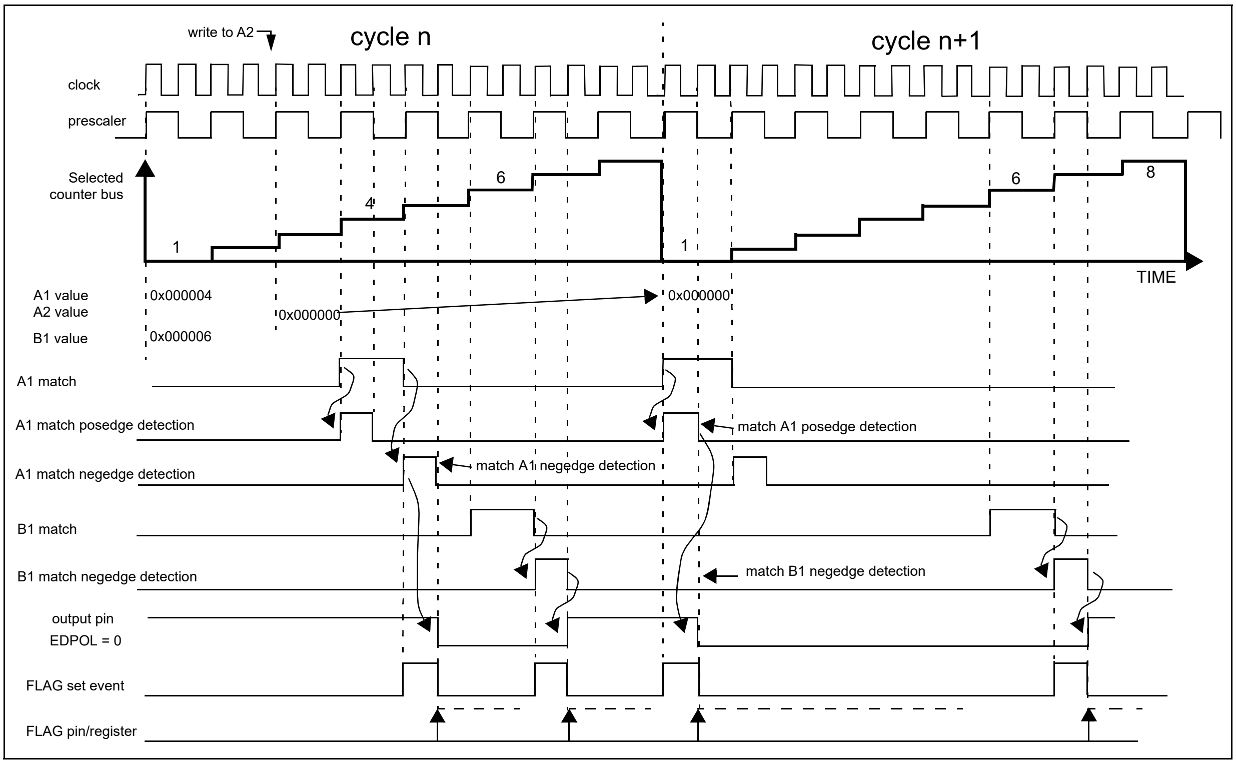
At OPWMB mode entry the output flip-flop is set to the value of the EDPOL bit in the EMIOSC*n* register.

Some rules applicable to the OPWMB mode are:

- B1 matches have precedence over A1 matches if they occur at the same time within the same counter cycle
- A1 = 0 match from cycle **n** has precedence over B1 match from cycle **n-1**
- A1 matches are masked out if they occur after B1 match within the same cycle
- Any value written to A2 or B2 on cycle **n** is loaded to A1 and B1 registers at the following cycle boundary (assuming OU*n* bit of EMIOSOUDIS register is not asserted). Thus the new values will be used for A1 and B1 matches in cycle **n+1**

Figure 506 describes the operation of the OPWMB mode regarding A1 and B1 matches and the transition of the channel output pin. In this example EDPOL is set to ‘0’.

Figure 506. OPWMB mode matches and flags



Note that the output pin transitions are based on the negedges of the A1 and B1 match signals. *Figure 506* shows in cycle **n+1** the value of A1 register being set to ‘0’. In this case the match posedge is used instead of the negedge to transition the output flip-flop.

Figure 507 describes the channel operation for 0% duty cycle. Note that the A1 match posedge signal occurs at the same time as the B1 = 0x8 negedge signal. In this case A1 match has precedence over B1 match, causing the output pin to remain at EDPOL bit value, thus generating a 0% duty cycle signal.

Figure 507. OPWMB mode with 0% duty cycle

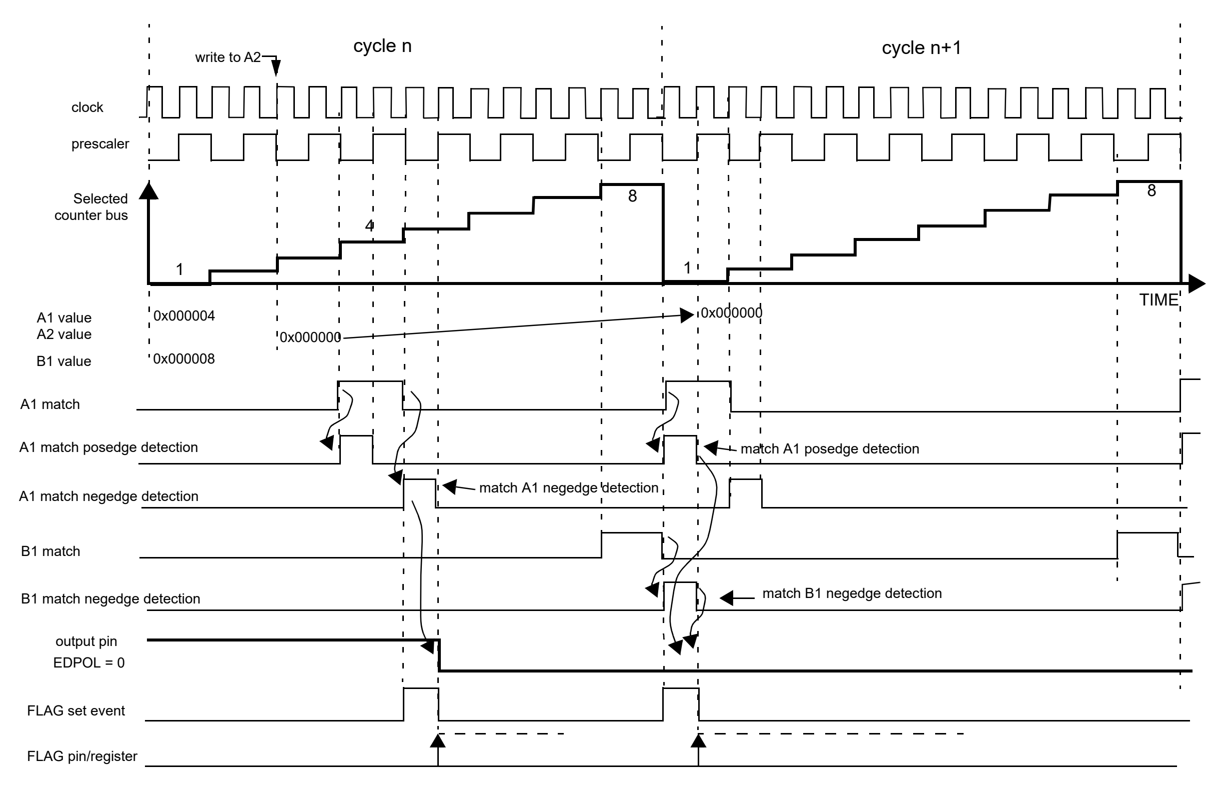


Figure 508 shows a waveform changing from 100% to 0% duty cycle. EDPOL in this case is zero. In this example B1 is programmed to the same value as the period of the external selected time base.

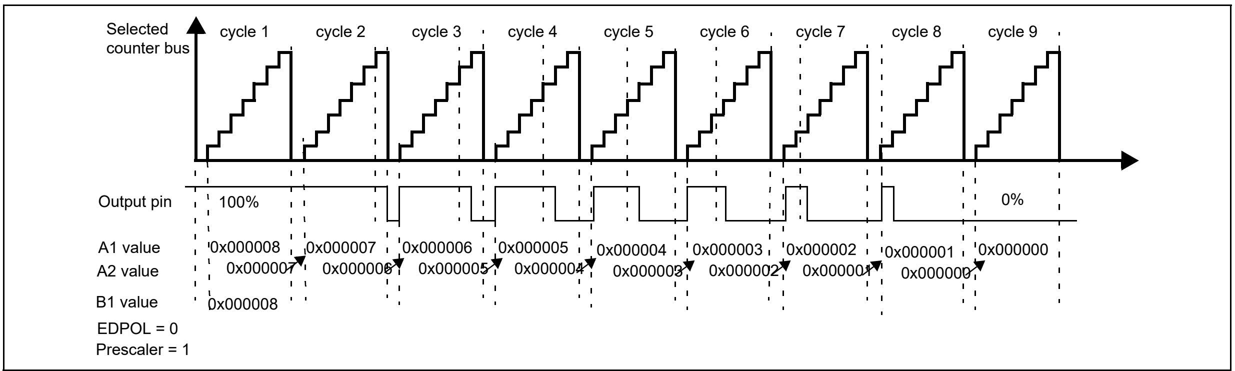
Figure 508. OPWMB mode from 100% to 0% duty cycle



In *Figure 508* if B1 is set to a value lower than 0x8 it is not possible to achieve 0% duty cycle by only changing A1 register value. Since B1 matches have precedence over A1 matches the output pin transitions to the opposite of EDPOL bit at B1 match. Note also that if B1 is set to 0x9, for instance, B1 match does not occur, thus a 0% duty cycle signal is generated.

45.4.1.1.12 Output Pulse Width Modulation with Trigger (OPWMT) mode

OPWMT mode (MODE[25:31] = 0100110) is intended to support the generation of pulse width modulation signals where the period is not modified while the signal is being output, but where the duty cycle will be varied and must not create glitches. The mode is intended to be used in conjunction with other channels executing in the same mode and sharing a common timebase. It will support each channel with a fixed PWM leading edge position with respect to the other channels and the ability to generate a trigger signal at any point in the period that can be output from the module to initiate activity in other parts of the device such as starting ADC conversions.

An external counter driven in either MC Up or MCB Up mode must be selected from one of the counter buses.

Register A1 defines the leading edge of the PWM output pulse and as such the beginning of the PWM's period. This makes it possible to insure that the leading edge of multiple channels in OPWMT mode can occur at a specific time with respect to the other channels when using a shared timebase. This can allow the introduction of a fixed offset for each channel which can be particularly useful in the generation of lighting PWM control signals where it is desirable that edges are not coincident with each other to help eliminate noise generation. The value of register A1 represents the shift of the PWM channel with respect to the selected timebase. A1 can be configured with any value within the range of the selected time base. Note that registers loaded with 0x0 will not produce matches if the timebase is driven by a channel in MCB mode.

A1 is not buffered as the shift of a PWM channel must not be modified while the PWM signal is being generated. In case A1 is modified it is immediately updated and one PWM pulse could be lost.

EMIOSB*n* address gives access to B2 register for write and B1 register for read. Register B1 defines the trailing edge of the PWM output pulse and as such the duty cycle of the PWM signal. To synchronize B1 update with the PWM signal and so ensure a correct output pulse generation the transfer from B2 to B1 is done at every match of register A1.

EMIOSOUDIS register affects transfers between B2 and B1 only.

In order to account for the shift in the leading edge of the waveform defined by register A1 it will be necessary that the trailing edge, held in register B1, can roll over into the next period. This means that a match against the B1 register should not have to be qualified by a match in the A1 register. The impact of this would mean that incorrectly setting register B1 to a value less that register A1 will result in the output being held over a cycle boundary until the B1 value is encountered.

This mode provides a buffered update of the trailing edge by updating register B1 with register B2 contents only at a match of register A1.

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A1 occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

Note that the output pin and flag transitions are based on the posedges of the A1, B1 and A2 match signals. Refer to *Figure 506* at *Output Pulse Width Modulation Buffered (OPWMB) Mode* for details on match posedge.

Register A2 defines the generation of a trigger event within the PWM period and A2 should be configured with any value within the range of the selected time base, otherwise no trigger will be generated. A match on the comparator will generate the FLAG signal but it has no effect on the PWM output signal generation. The typical setup to obtain a trigger with FLAG is to enable DMA and to drive the channel's ipd_done input high.

A2 is not buffered and therefore its update is immediate. If the channel is running when a change is made this could cause either the loss of one trigger event or the generation of two trigger events within the same period. Register A2 can be accessed by reading or writing the eMIOS UC Alternate A Register (EMIOSALTA) at UC*n* base address +0x14.

FLAG signal is set only at match on the comparator with A2. A match on the comparator with A1 or B1 or B2 has no effect on FLAG.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Any FORCMA and/or FORCMB has priority over any simultaneous match regarding to output pin transitions. Note that the load of B2 content on B1 register at an A match is not inhibited due to a simultaneous FORCMA/FORCMB assertion. If both FORCMA and FORCMB are asserted simultaneously the output pin goes to the opposite of EDPOL value such as if A1 and B1 registers had the same value. FORCMA assertion causes the transfer from register B2 to B1 such as a regular A match, regardless of FORCMB assertion.

If subsequent matches occur on comparators A1 and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

At OPWMT mode entry the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC*n* register.

In order to achieve 0% duty cycle both registers A1 and B must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the complement value of EDPOL.

In order to achieve 100% duty cycle the register B1 must be set to a value greater than maximum value of the selected time base. As a consequence, if 100% duty cycle must be implemented, the maximum counter value for the time base is 0xFFFE for a 16-bit counter. When a match on comparator A1 occurs the output flip-flop is set at every period to the value of EDPOL bit. The transfer from register B2 to B1 is still triggered by the match at comparator A.

Figure 509 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and duty cycle update on next period update.

Figure 509. OPWMT example

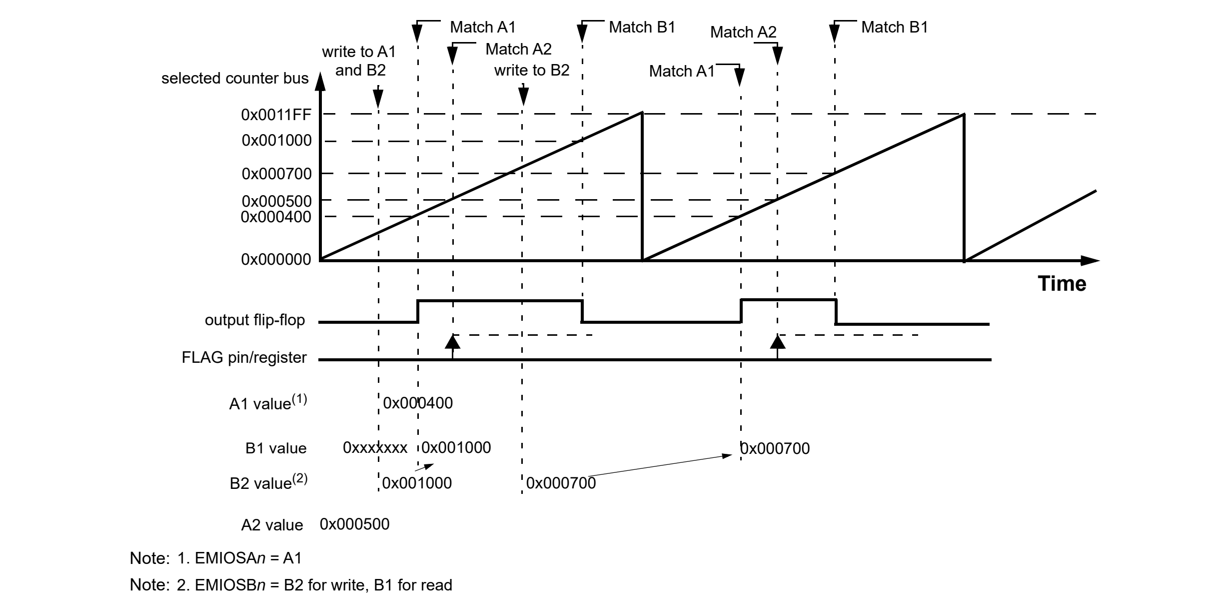


Figure 510 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 0% duty.

Figure 510. OPWMT with 0% Duty Cycle

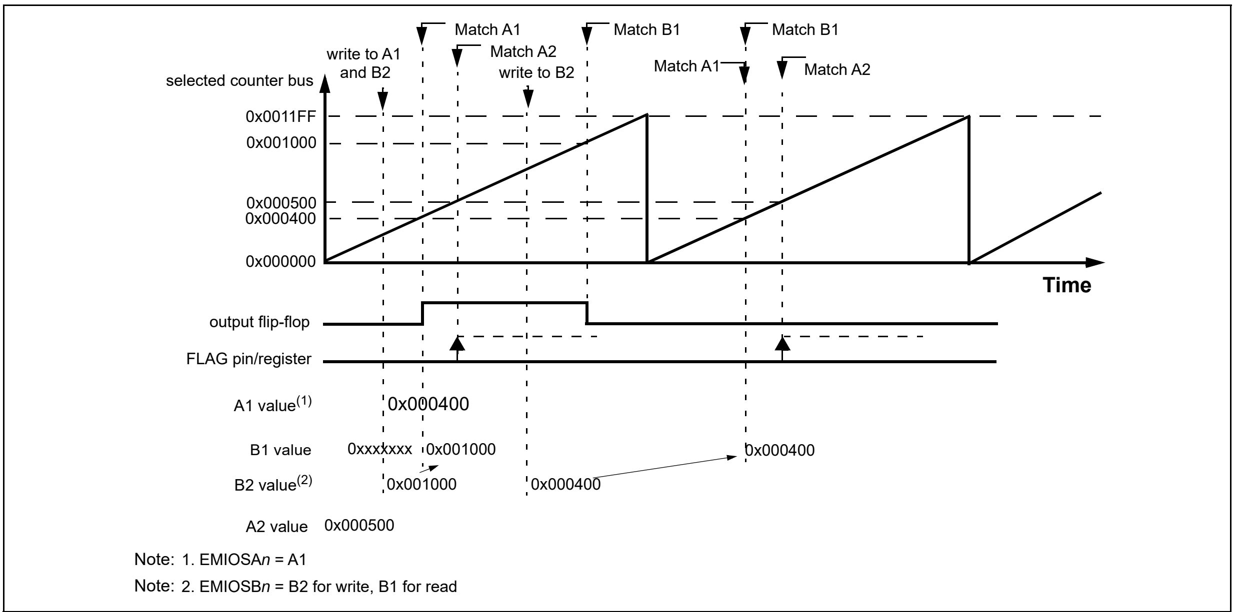

Figure 511 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 100% duty cycle.

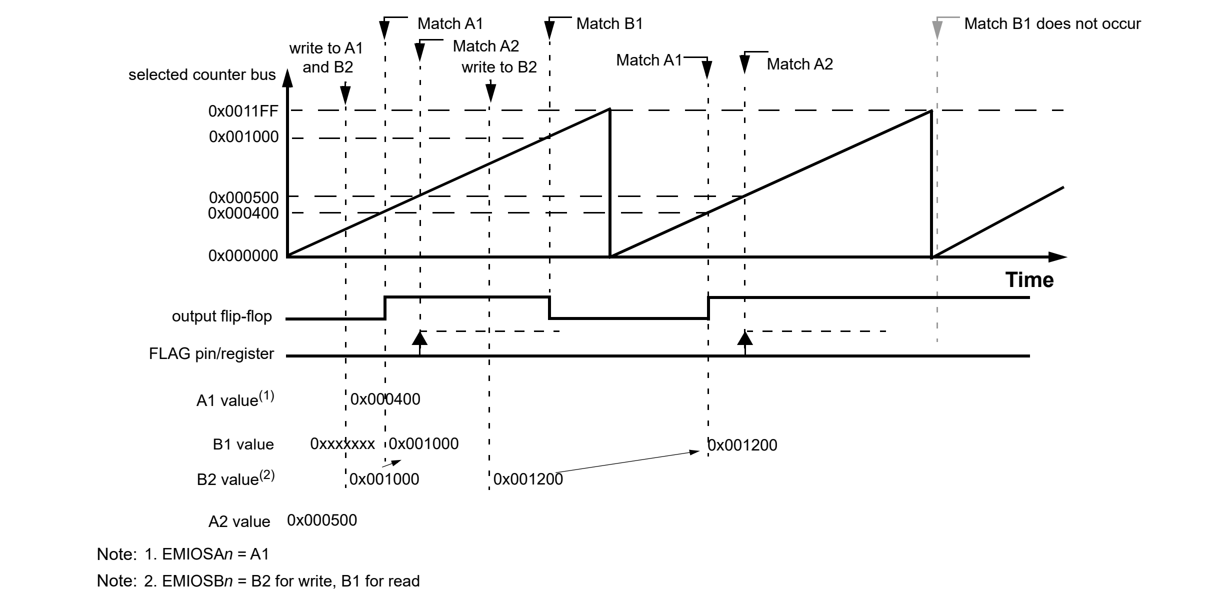
Figure 511. OPWMT with 100% duty cycle

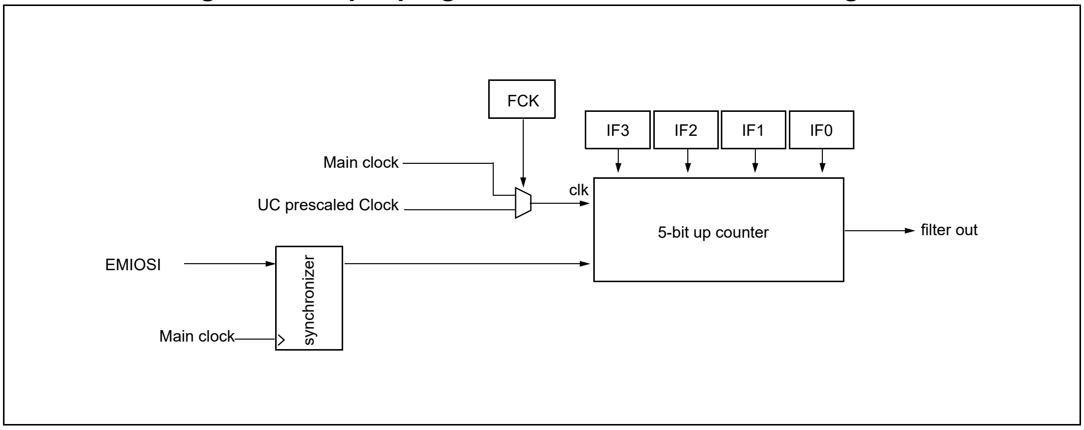


45.4.1.2 Input Programmable Filter (IPF)

The IPF ensures that only valid input pin transitions are received by the Unified Channel edge detector. A block diagram of the IPF is shown in *Figure 512*.

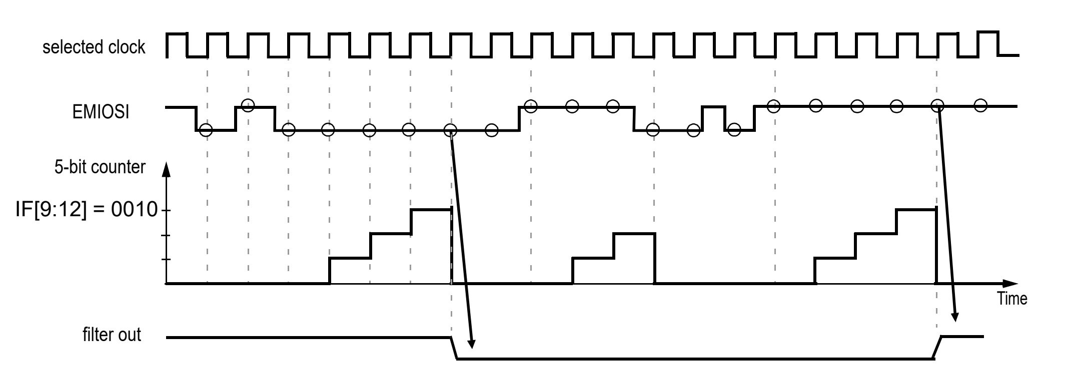
The IPF is a 5-bit programmable up counter that is incremented by the selected clock source, according to bits IF[9:12] in EMIOSC*n* register.

Figure 512. input programmable filter submodule diagram



The input signal is synchronized by the main clock. When a state change occurs in this signal, the 5-bit counter starts counting up. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value is validated. In this case, it is transmitted as a pulse edge to the edge detector. If the opposite edge appears on the pin before validation (overflow), the counter is reset. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the edge detector. A timing diagram of the input filter is shown in *Figure 513*.

Figure 513. Input programmable filter example



The filter is not disabled during either freeze state or negated GTBE input.

45.4.1.3 Clock Prescaler (CP)

The CP divides the GCP output signal to generate a clock enable for the internal counter of the Unified Channels. The GCP output signal is prescaled by the value defined in *Figure 580* according to the UCPRE[4:5] bits in EMIOSC*n* register. The prescaler is enabled by setting the UCPREN bit in the EMIOSC*n* and can be stopped at any time by clearing this bit, thereby stopping the internal counter in the Unified Channel.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at both GPREN bit in EMIOSMCR register and UCPREN bit in EMIOSC*n* register, thus disabling prescalers;
2. Write the desired value for prescaling rate at UCPRE[4:5] bits in EMIOSC*n* register;
3. Enable channel prescaler by writing 1 at UCPREN bit in EMIOSC*n* register;
4. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

45.4.1.4 Effect of Freeze on the Unified Channel

When in debug mode, bit FRZ in the EMIOSMCR and bit FREN in the EMIOSC*n* register are both set, the internal counter and Unified Channel capture and compare functions are halted. The UC is frozen in its current state.

During freeze, all registers are accessible. When the Unified Channel is operating in an output mode, the force match functions remain available, allowing the software to force the output to the desired level.

Note that for input modes, any input events that may occur while the channel is frozen are ignored.

When exiting debug mode or freeze enable bit is cleared (FRZ in the EMIOSMCR or FREN in the EMIOSC*n* register) the channel actions resume, but may be inconsistent until channel enters GPIO mode again.

45.4.2 IP Bus Interface Unit (BIU)

The BIU provides the interface between the Internal Interface Bus (IIB) and the Peripheral Bus, allowing communication among all submodules and this IP interface.

The BIU allows 8, 16 and 32-bit access. They are performed over a 32-bit data bus in a single cycle clock.

45.4.2.1 Effect of Freeze on the BIU

When the FRZ bit in the EMIOSMCR is set and the module is in debug mode, the operation of BIU is not affected.

45.4.3 Global Clock Prescaler Submodule (GCP)

The GCP divides the system clock to generate a clock for the CPs of the channels. The main clock signal is prescaled by the value defined in *Figure 570* according to bits GPRE[16:23] in the EMIOSMCR. The global prescaler is enabled by setting the GPREN bit in the EMIOSMCR and can be stopped at any time by clearing this bit, thereby stopping the internal counters in all the channels.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write ‘0’ at GPREN bit in EMIOSMCR, thus disabling global prescaler;
2. Write the desired value for prescaling rate at GPRE[16:23] bits in EMIOSMCR;
3. Enable global prescaler by writing ‘1’ at GPREN bit in EMIOSMCR.

The prescaler is not disabled during either freeze state or negated GTBE input.

45.4.3.1 Effect of Freeze on the GCP

When the FRZ bit in the EMIOSMCR is set and the module is in debug mode, the operation of GCP submodule is not affected, that is, there is no freeze function in this submodule.

45.5 Initialization/Application information

On resetting the eMIOS the Unified Channels enter GPIO input mode.

45.5.1 Considerations

Before changing an operating mode, the UC must be programmed to GPIO mode and EMIOSA*n* and EMIOSB*n* registers must be updated with the correct values for the next operating mode. Then the EMIOSC*n* register can be written with the new operating mode. If a UC is changed from one mode to another without performing this procedure, the first operation cycle of the selected time base can be random, that is, matches can occur in random time if the contents of EMIOSA*n* or EMIOSB*n* were not updated with the correct value before the time base matches the previous contents of EMIOSA*n* or EMIOSB*n*.

When interrupts are enabled, the software must clear the FLAG bits before exiting the interrupt service routine.

45.5.2 Application information

Correlated output signals can be generated by all output operation modes. Bits OU*n* of the EMIOSOUDIS register can be used to control the update of these output signals.

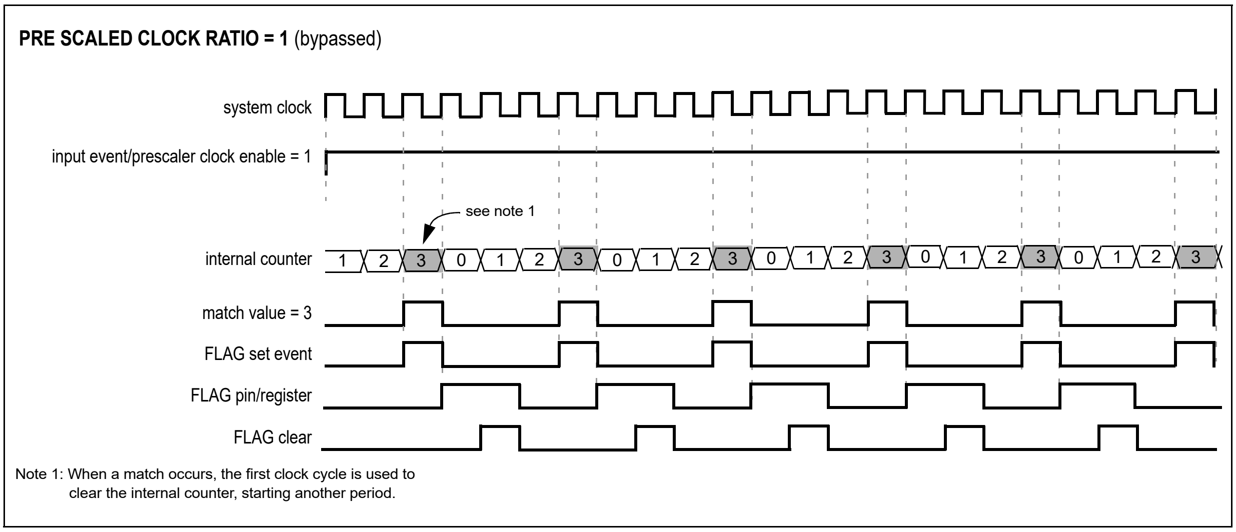
In order to guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters may increment in the same ratio, but at a different clock cycle.

45.5.2.1 Time base generation

For MC with internal clock source operation modes, the internal counter rate can be modified by configuring the clock prescaler ratio. *Figure 514* shows an example of a time base with prescaler ratio equal to one.

Note: MCB and OPWFMB modes have a different behavior.

Figure 514. Time base period when running in the fastest prescaler ratio

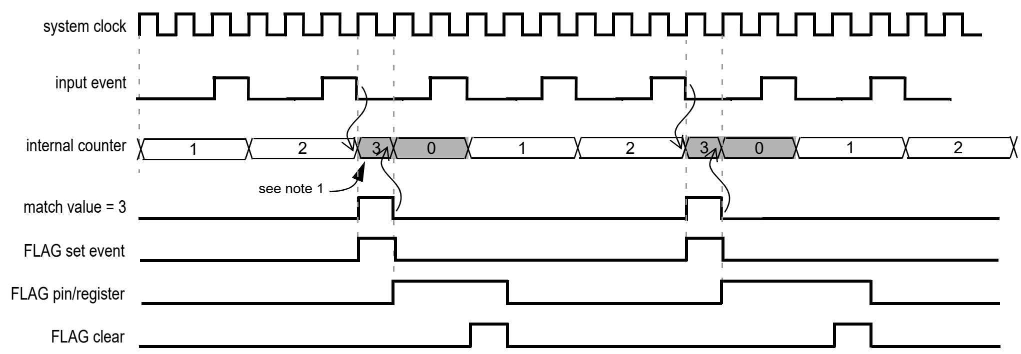


If the prescaler ratio is greater than one or external clock is selected, the counter may behave in three different ways depending on the channel mode:

- If MC mode and Clear on Match Start and External Clock source are selected the internal counter behaves as described in *Figure 515*.
- If MC mode and Clear on Match Start and Internal Clock source are selected the internal counter behaves as described in *Figure 516*.
- If MC mode and Clear on Match End are selected the internal counter behaves as described in *Figure 517*.

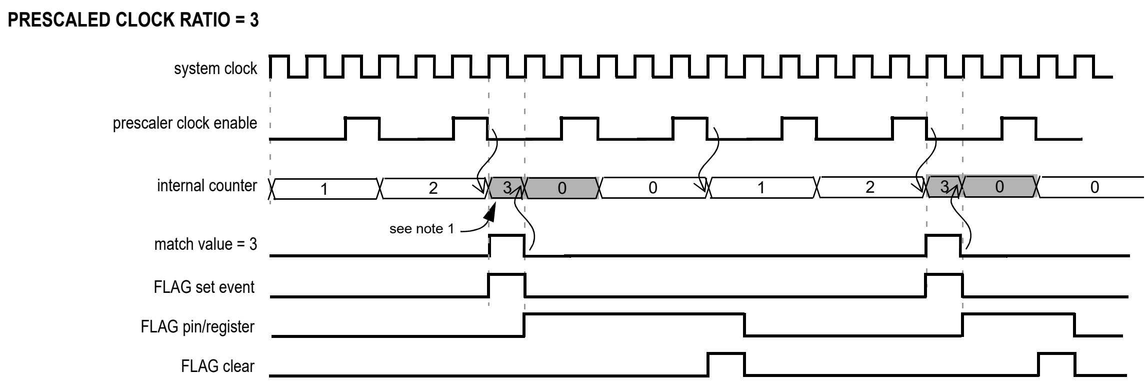
Note: MCB and OPWFMB modes have a different behavior.

Figure 515. Time base generation with external clock and clear on match start



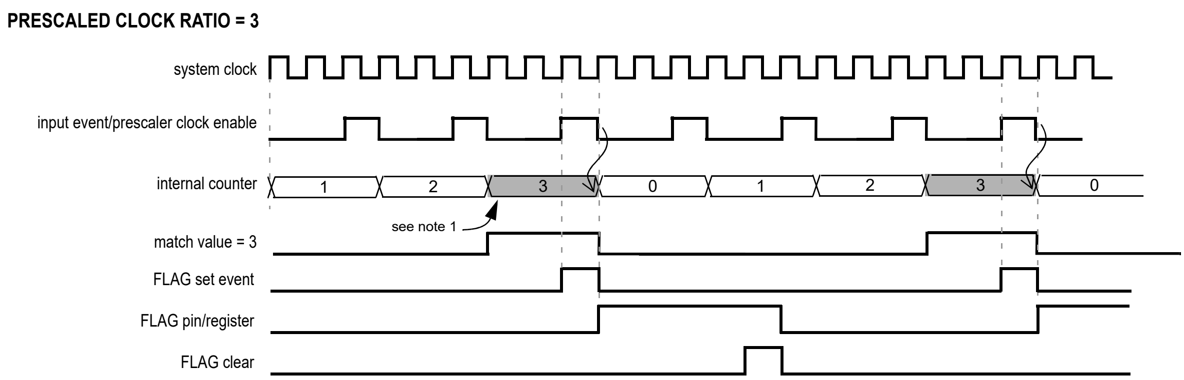
Note 1: When a match occurs, the first system clock cycle is used to clear the internal counter, and at the next edge of prescaler clock enable the counter will start counting.

Figure 516. Time base generation with internal clock and clear on match start



Note 1: When a match occurs, the first clock cycle is used to clear the internal counter, and only after a second edge of pre scaled clock the counter will start counting.

Figure 517. Time base generation with clear on match end



Note 1: The match occurs only when the input event/prescaler clock enable is active. Then, the internal counter is immediately cleared.

45.5.2.2 Coherent accesses

It is highly recommended that the software waits for a new FLAG set event before starting to read the EMIOSA*n* and EMIOSB*n* registers to get a new measurement. The FLAG indicates that new data has been captured and it is the only way to assure data coherency.

The FLAG set event can be detected by polling the FLAG bit or by enabling the interrupt request or CTU trigger generation.

Reading the EMIOSA*n* register again in the same period of the last read of EMIOSB*n* register may lead to incoherent results. This will occur if the last read of EMIOSB*n* register occurred after a disabled B2 to B1 transfer.

45.5.2.3 Channel/Modes initialization

The following basic steps summarize basic output mode startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[timebase channel]* Disable Channel Prescaler.
3. *[timebase channel]* Write initial value at internal counter.
4. *[timebase channel]* Set A/B register.
5. *[timebase channel]* Set channel to MC(B) Up mode.
6. *[timebase channel]* Set prescaler ratio.
7. *[timebase channel]* Enable Channel Prescaler.
8. *[output channel]* Disable Channel Prescaler.
9. *[output channel]* Set A/B register.
10. *[output channel]* Select timebase input through bits BSL[21:22].
11. *[output channel]* Enter output mode.
12. *[output channel]* Set prescaler ratio (same ratio as timebase channel).
13. *[output channel]* Enable Channel Prescaler.
14. *[global]* Enable Global Prescaler.
15. *[global]* Enable Global Time Base.

The timebase channel and the output channel may be the same for some applications such as in OPWFM(B) mode or whenever the output channel is intended to run the timebase itself.

The flags can be configured at any time.

46 CAN subsystem

46.1 Introduction

SPC584Bx has two CAN subsystems implemented:

- CAN Subsystem 0
- CAN Subsystem 1

Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the subsystems implementation.

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection from CPU write access. The subsystem follows the little endian format.

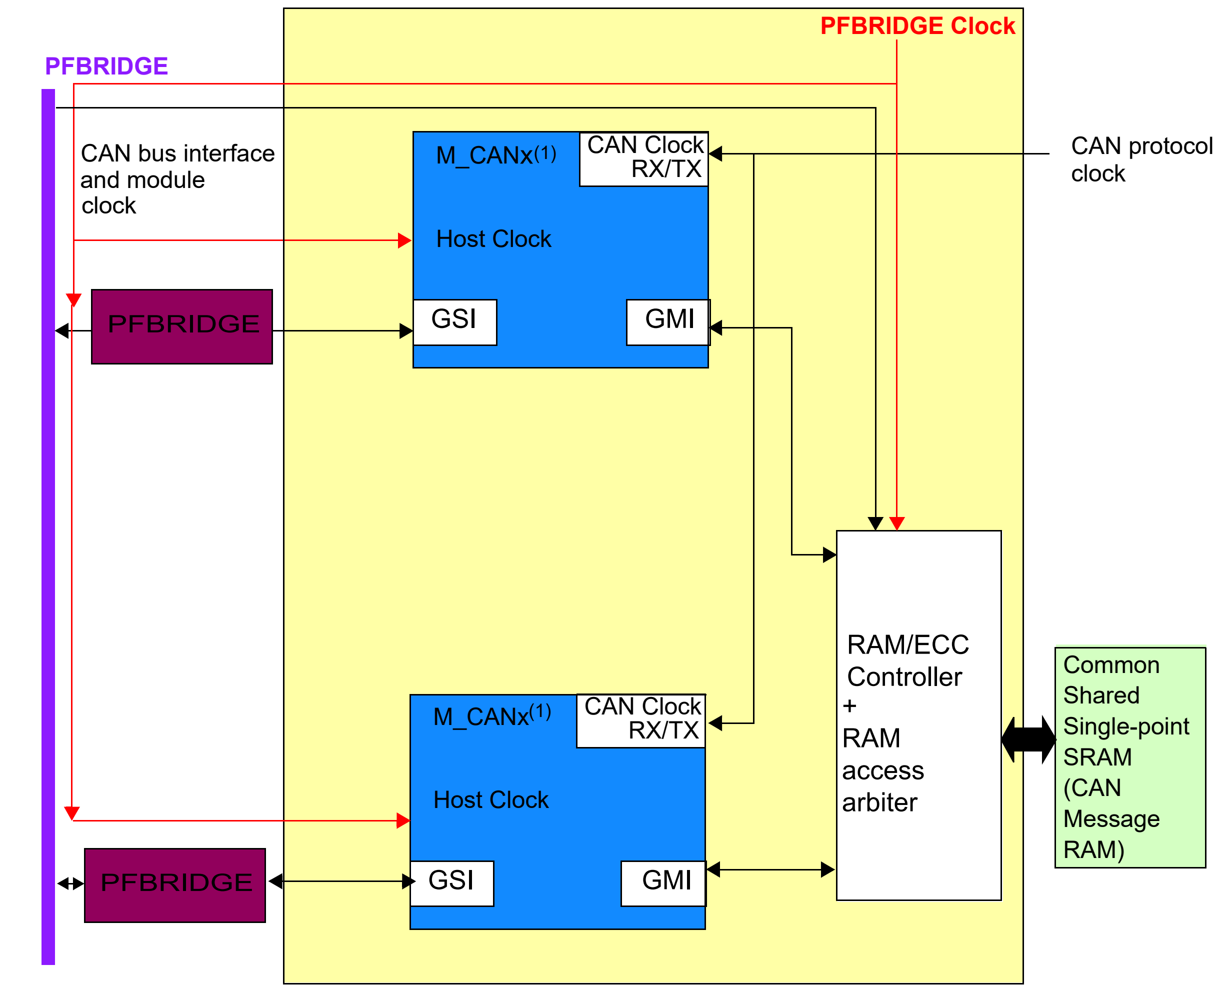
Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the number of CAN nodes used in the device.

Table 586. IP user manual versions

IP Name	Version
M_CAN IP	Revision 3.2.1

The general CAN subsystem implementation is shown in *Section 46.2*. It interfaces with the Host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.

Figure 518. CAN subsystem generic block diagram



1: Number of M_CAN nodes (M_CANx) varies per device. Please refer to Device Configuration chapter to see the number of M_CAN nodes used in the device.

46.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller

46.3 Modular CAN (M_CAN) cores

M_CAN functionality conforms to CAN specification V2.0B active for each M_CAN node.The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0.Flexible assignment of Message Objects to nodes.
The bit rate can be programmed to values up to 1 Mbit/s for standard CAN frames. High bit rates are possible in CAN FD mode. Additional transceiver hardware is required for connection to the physical layer.

Note: Implemented CAN nodes are fully compliant to ISO CAN FD specification ISO 11898-1: 2015.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.

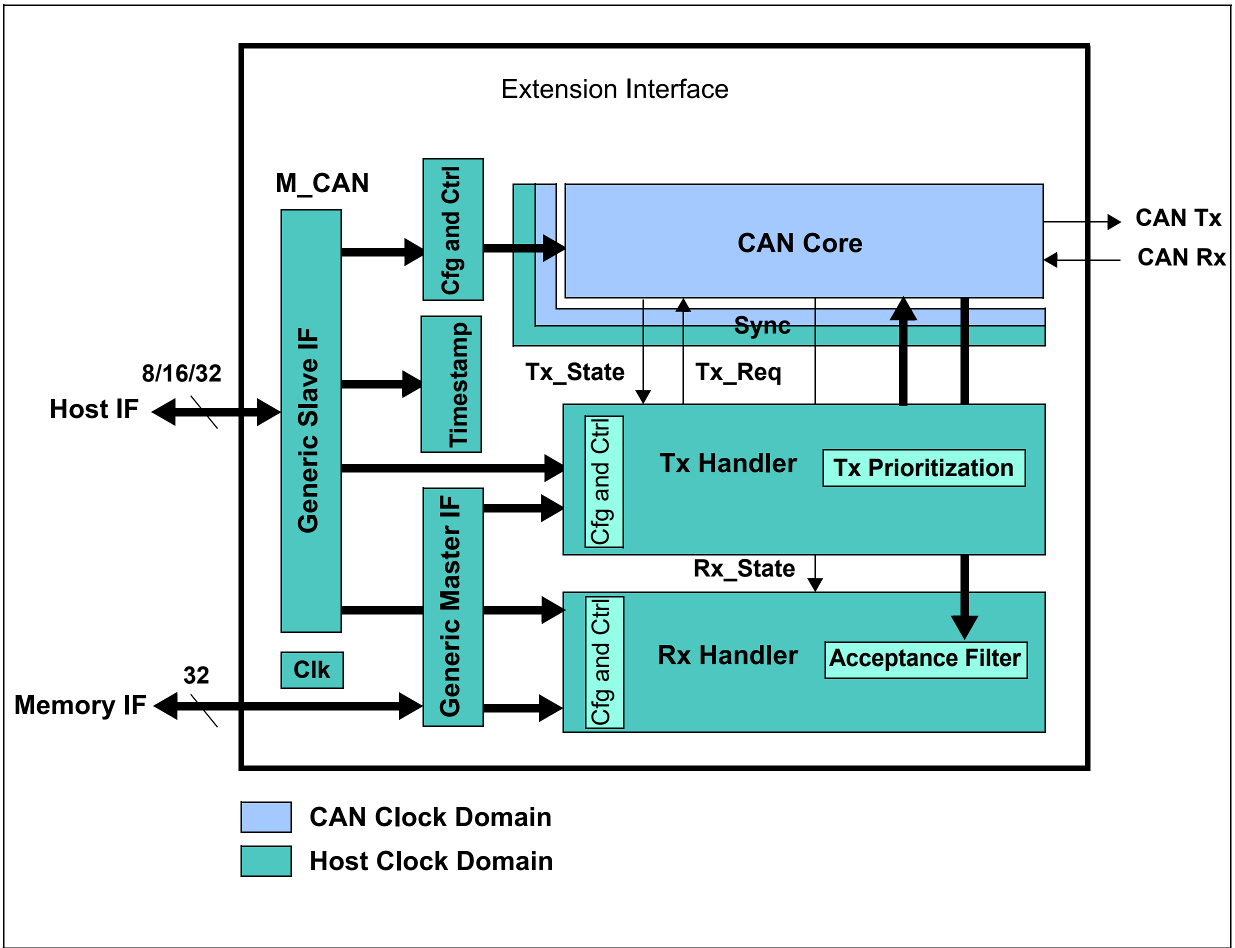
46.3.1 Features

The following are the features of Modular CAN cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015
- CAN Flexible data-rate (ISO CAN FD) protocol with 64 data bytes on M_CAN is supported
- Bit rates up to 1 Mbit/s in standard CAN mode
- Bit rates up to 8 Mbit/s in ISO CAN FD mode
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bits Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN
- Clock calibration over M_CAN is supported

46.3.2 Block diagram

Figure 519. M_CAN core block diagram



- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.
- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored

together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable of connecting to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB $\times$ 32 bits.
- Extension Interface: All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

46.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

46.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to EINT0 or to EINT1. By default all interrupts are routed to interrupt line EINT0. By programming EINT0 and EINT1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

46.3.5 Memory map and register descriptions

46.3.5.1 Hardware reset description

After hardware reset, the registers of the M_CAN hold the reset values listed in *Table 587*. Additionally the *Bus_Off* state is reset and the M_CAN Tx output is set to *recessive* (HIGH). The value 0x0001 (bit 0 [INIT] of the CCCR register = ‘1’) in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets bit 0 [INIT] of the CCCR register = ‘0’.

46.3.5.2 Register map

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR register is set to '1'.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

Caution: Any write access to reserved or not implemented registers in the 16 KB slot assigned by the peripherals bridge to the M_CAN IP will not generate any bus access error.

46.3.5.2.3 Data Bit Timing and Prescaler Register (DBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_CAN clock periods. tq = (FBRP + 1) M_CAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (programmed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning that the data for the next bit is available at the first clock edge after the sample point.

Figure 522. Data Bit Timing and Prescaler Register (DBTP)

Table 590. DBTP field descriptions

Field	Description
8 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
11:15 DBRP	Data Baud Rate Prescaler (0x00–0x1F) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
19:23 DTSEG1	Data time segment before sample point (0x0–0x1F) Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 DTSEG2	Data time segment after sample point (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 DSJW	Data (Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via DBTP must be higher than or equal to the bit rate configured for the arbitration phase via NBTP.

To achieve high bit rates in CAN FD mode for the data phase up to 8 Mbit/s the number of time quanta bits per CAN bit can be chosen down to 4 time quanta per bit time.

46.3.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting CCCR[TEST] to ‘1’. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back mode and software control of M_CAN Tx pin are hardware test modes. Programming of **TX** ≠ ‘00’ may disturb the message transfer on the CAN bus.

46.3.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR is set. The RAM Watchdog Counter is clocked by the Host clock .

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.
2. These are protected set (p) bits.

Figure 525. CC Control register (CCCR)

Table 593. CCCR field descriptions

Field	Description
16 NISO	Non ISO Operation If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame. 0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	Edge Filtering during Bus Integration 0 Edge filtering disabled 1 Two consecutive dominant tq required to detect an edge for hard synchronization
19 PXHD	Protocol Exception Handling Disable 0 Protocol exception handling enabled 1 Protocol exception handling disabled **Note:** When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
22 BRSE	Bit Rate Switch Enable 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled **Note:** When CAN FD operation is disabled FDOE = ‘0’, BRSE is not evaluated.
23 FDOE	FD Operation Enable 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping Host clock and core clock

Table 593. CCCR field descriptions (continued)

Field	Description
29 ASM	Restricted Operation Mode Bit ASM is only set by the Host when both CCE and INIT are set to ‘1’. The bit is reset by the Host at any time. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = ‘1’)
31 INIT	Initialization 0 Normal Operation 1 Initialization is started **Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

46.3.5.2.7 Nominal Bit Timing and Prescaler Register (NBTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of [4…385] time quanta. The CAN time quantum may be programmed in the range of [1…512] M_CAN clock periods.

Equation 30 **tq = (NBRP + 1) M_CAN clock period**

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Offset: 0x001C Access: Read Protected

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 526. Nominal Bit Timing and Prescaler Register (NBTP)

Table 594. NBTP field descriptions

Field	Description
0:6 NSJW	(Re) Synchronization Jump Width (0x00–0x7F) Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
7:15 NBRP	Baud Rate Prescaler (0x000–0x1FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16:23 NTSEG1	Time segment before sample point (0x01–0xFF) Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
25:31 NTSEG2	The time segment after the sample point (0x00–0x7F) Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the M_CAN for a bit rate of 500 kbit/s.

46.3.5.2.8 Timestamp Counter Configuration Register (TSCC)

Offset: 0x0020 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	TCP(1)

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 527. Timestamp Counter Configuration Register (TSCC)

Table 595. TSCC field descriptions

Field	Description
12:15 TCP	Timestamp Counter Prescaler (0x0–0xF) Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 to16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
30:31 TSS	Timestamp Select 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to Timestamp Counter Prescaler (TCP) 10 Reserved 11 Same as ‘00’ **Note:** In case of CAN FD mode the absolute duration of a bit time does change in one CAN message due to the different baud rates for arbitration phase and data phase. Therefore the timestamp counter does still reflect increasing number on bit times but the fix relationship to absolute time is not given any more. Anyway, it is possible to establish in which order the frames are received.

46.3.5.2.9 Timestamp Counter Value Register (TSCV)

Offset: 0x0024 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 528. Timestamp Counter Value Register (TSCV)

Table 596. TSCV field descriptions

Field	Description
16:31 TSC	Timestamp Counter The internal Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = ‘01’, the Timestamp Counter is incremented in multiples of CAN bit times [1 to 16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero.

Note: A “wrap around” is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

46.3.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter, refer to *Section 46.3.9*.

Offset: 0x0028 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Figure 531. Error Counter Register (ECR)

Table 599. ECR field descriptions

Field	Description
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR register.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

46.3.5.2.13 Protocol Status Register (PSR)

Offset: 0x0044 Access: RXS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

1. Access type is RX: reset on read.
2. Access type is RS: set on read.

Figure 532. Protocol Status Register (PSR)

Table 600. PSR field descriptions

Field	Description
9:15 TDCV	Transmitter Delay Compensation Value (0x00-0x7F) Position of the secondary sample point, defined by the sum of the measured delay from CAN Tx to CAN Rx and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
17 PXE	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state

Table 600. PSR field descriptions (continued)

Field	Description
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing – node is synchronizing on CAN communication 01 Idle-node is neither receiver nor transmitter 10 Receiver-node is operating as receiver 11 Transmitter-node is operating as transmitter
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

The Bus_Off recovery sequence (refer to CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT.] If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 $\times$ 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

46.3.5.2.14 Transmitter Delay compensation Register (TDCR)

Offset: 0x0048 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	TDCO(1)							0	TDCF(1)						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 533. Transmitter Delay compensation Register (TDCR)

Table 601. TDCR field descriptions

Field	Description
17:23 TDCO	Transmitter Delay Compensation Offset (0x00-0x7F) Offset value defining the distance between the measured delay from CAN Tx to CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.
25:31 TDCF	Transmitter Delay Compensation Filter Window Length (0x00-0x7F) Defines the minimum value for the SSP position, dominant edges on CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

46.3.5.2.15 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred

Table 602. IR field descriptions (continued)

Field	Description
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to ‘1’. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (for example parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (for example ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler – has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. – was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler is not able to read a message from the Message RAM in time. In this case message transmission is aborted. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full

Table 602. IR field descriptions (continued)

Field	Description

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 541. Extended ID and Mask Register (XIDAM)

Table 609. XIDAM field descriptions

Field	Description
3:31 EIDM	Extended ID Mask For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.

46.3.5.2.23 High Priority Message Status Register (HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Offset: 0x0094 Access: R

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 556. Tx Buffer Request Pending Register (TXBRP)

Table 624. TXBRP field descriptions

Field	Description
0:31 TRP[31:0]	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – after successful transmission together with the corresponding TXBTO bit – when the transmission has not yet been started at the point of cancellation – when the transmission has been aborted due to lost arbitration – when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

46.3.5.2.38 Tx Buffer Add Request Register (TXBAR)

Offset: 0x00D0 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 565. Tx Event FIFO Acknowledge Register (TXEFA)

Table 633. TXEFA field descriptions

Field	Description
27:31 EFAI	Event FIFO Acknowledge Index After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

46.3.6 Message RAM

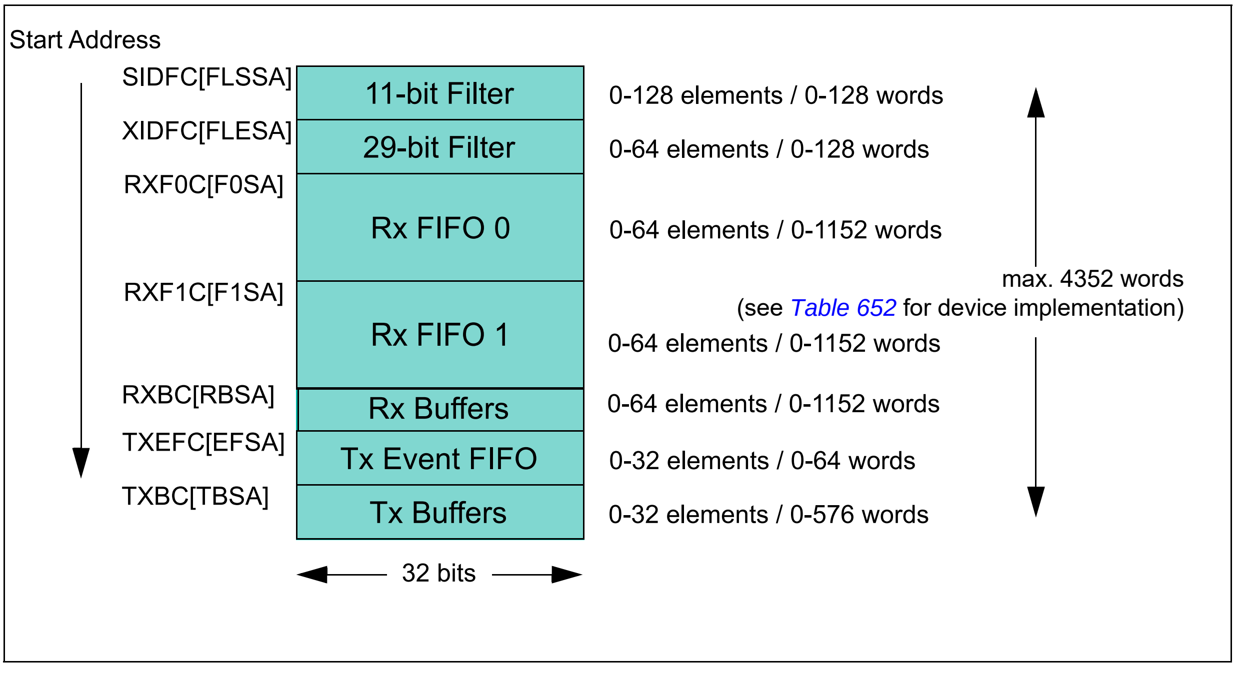
For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_CAN module.

Note: Because the Message RAM is equipped with ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing, for example, 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 4352 words in the Message RAM (for the chip-specific implementation details of each module's instance, refer to device configuration chapter). It is not necessary to configure each of the sections listed in *Figure 566*, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC.F0DS, RXESC.F1DS, RXESC.RBDS, and TXESC.TBDS.

Figure 566. Message RAM Configuration



When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses such as only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Note: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

46.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

	0 … 7	8 … 15	16 … 23	24 … 31

Figure 567. Rx Buffer and FIFO element

Table 634. Rx Buffer and FIFO element descriptions

Field	Description
R0 bit 0 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 bit 1 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 bit 2 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (EDL = ‘1’), bit RTR reflects the state of the reserved bit r1.
R0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 bit 0 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element

Table 634. Rx Buffer and FIFO element descriptions (continued)

Field	Description
R1 bits 1:7 FIDX[6:0]: Filter Index	0-127=Index of matching Rx acceptance filter element (invalid if ANMF = ‘1’). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 bit 10 EDL: Extended Data Length	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
R1 bit 11 BRS: Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 bits 12:15 DLC[3:0]: Data Length Code	0-8 CAN + CAN FD: Received frame has 0-8 data bytes 9-15 CAN: Received frame has 8 data bytes 9-15 CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
R1 bits 16:31 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 bits 0:7	DB3[7:0]: Data Byte 3
R2 bits 8:15	DB2[7:0]: Data Byte 2
R2 bits 16:23	DB1[7:0]: Data Byte 1
R2 bits 24:31	DB0[7:0]: Data Byte 0
R3 bits 0:7	DB7[7:0]: Data Byte 7
R3 bits 8:15	DB6[7:0]: Data Byte 6
R3 bits 16:23	DB5[7:0]: Data Byte 5
R3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Rn bits 0:7	DBm[7:0]: Data Byte m
Rn bits 8:15	DBm-1[7:0]: Data Byte m-1
Rn bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 to 17) are used for storage of a CAN message’s data field.

46.3.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

Tn bits 8:15	DBm-1[7:0]: Data Byte m-1
Tn bits 16:23	DBm-2[7:0]: Data Byte m-2
Tn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.

46.3.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

	0 ... 7	8 ... 15				16 ... 23	24 ... 31
E0	ESI | XTD | RTR | ID[28:0]	ID[28:0]				ID[28:0]	ID[28:0]

Figure 569. Tx Event FIFO element

Table 636. Tx Event FIFO element descriptions

Field	Description
E0 bit 0 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 bit 1 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.
E1 bit 8:9 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching

Table 636. Tx Event FIFO element descriptions (continued)

Field	Description
E1 bits 12:15 DLC[3:0]	Data Length Code 0-8 CAN + CAN FD: frame with 0-8 data bytes transmitted 9-15 CAN: frame with 8 data bytes transmitted 9-15 CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
E1 bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

46.3.6.4 Standard Message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0 to 127).

	0		7 | 8	15 | 16	23 | 24 31
S0	SFT[1:0]	SFEC[2:0]	SFID1[10:0]	res	SFID2[10:0]

Figure 570. Standard Message ID Filter element

Table 637. Standard Message ID Filter element descriptions

Field	Description
Bits 0:1 SFT[1:0]	Standard Filter Type 00 Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 01 Dual ID filter for SFID1 or SFID2 10 Classic filter: SFID1 = filter, SFID2 = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored

Table 637. Standard Message ID Filter element descriptions (continued)

Field	Description
Bits 5:15 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31 SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: 1) SFEC = ‘001’...‘110’ Second ID of standard ID filter element 2) SFEC = ‘111’ Filter for Rx Buffers or for debug messages
	SFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN Host clock period in case the filter matches.
	SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

46.3.6.5 Extended Message ID Filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0 to 63).

	0		7 | 8 … 15 | 16 … 23 | 24 … 31
F0	EFEC[2:0]		EFID1[28:0]
F1	EFT[1:0]	res	EFID2[28:0]

Figure 571. Extended Message ID Filter element

Table 638. Extended Message ID Filter element description

Field	Description
F0 bits 0:2 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 bits 3:31 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (refer to *Section 46.3.10.1.5*) is used.
F1 bits 0:1 EFT[1:0]	Extended Filter Type 00 Range filter from EFID1 to EFID1 (EFID2 ≥ EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
F1 bits 3:31 EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = ‘001’...‘110’ Second ID of extended ID filter element 2) EFEC = ‘111’ Filter for Rx Buffers or for debug messages EFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6] is used to control the filter event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

46.3.7 M_CAN functional description

46.3.7.1 Operating modes

46.3.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = ‘1’. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS–High Priority Message Status
- RXF0S–Rx FIFO 0 Status
- RXF1S–Rx FIFO 1 Status
- TXFQS–Tx FIFO/Queue Status
- TXBRP–Tx Buffer Request Pending
- TXBTO–Tx Buffer Transmission Occurred
- TXBCF–Tx Buffer Cancellation Finished
- TXEFS–Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writable while CCCR[CCE] = ‘0’

- TXBAR–Tx Buffer Add Request
- TXBCR–Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

The following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
      while (read_data != 0x003){
         write(M_CAN0,0xF,driver.regs.can0_cccr.addr,0x003);
            read_data = read(M_CAN0,0xF,driver.regs.can0_cccr.addr);
      };
```

```
-- Configuring the time stamp and timeout registers
     write(M_CAN0,0xF,driver.regs.can0_tscc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_tocc.addr,0x000);

-- Configuring the interrupt registers
     write(M_CAN0,0xF,driver.regs.can0_ie.addr,0xFFFFFFFF);
     write(M_CAN0,0xF,driver.regs.can0_ils.addr,0x00000002);
     write(M_CAN0,0xF,driver.regs.can0_ile.addr,0x00000003);

     write(M_CAN0,0xF,driver.regs.can0_gfc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_xidam.addr,0x00FFFFFF);

-- Writing the start addresses of all the M_CAN Buffers
     generate and drive M_CAN0 can0_rxf0c keeping {
                                         .f0sa == 0x100;

```

46.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, the received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers or a Tx FIFO, or both, or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

46.3.7.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = *recessive* signifies a CAN FD frame, FDF = *dominant* signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = *dominant* and BRS = *recessive*. The coding of res = *recessive* is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = *recessive* and res = *recessive*, it will signal a Protocol Exception Event by setting bit PSR.PXE. When Protocol Exception Handling is enabled (CCCR.PXHD = ‘0’), this causes the operation state to change from Receiver (PSR.ACT = “10”) to Integrating (PSR.ACT = “00”) at the next sample point. In case Protocol Exception Handling is disabled (CCCR.PXHD = ‘1’), the M_CAN will treat a *recessive* res bit as a form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = ‘1’, transmission and reception of CAN FD frames are enabled. Transmission and reception of Classic CAN frames are always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = ‘0’, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = ‘0’, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘0’, only bit FDF of a Tx Buffer element is evaluated. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘1’, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to *Table 639*.

Table 639. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is *recessive*. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing and Prescaler Register NBTP. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing and Prescaler Register DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (CAN clock). Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit ESI (Error Status Indicator) is determined by the transmitter’s error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted *recessive*, else it is transmitted *dominant*.

46.3.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via CAN Tx output pin the M_CAN the transmitted data from its local CAN transceiver via CAN Rx input pin. The received data is delayed by the transmitter delay. In case this delay is greater than NTSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

46.3.7.4.1 Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration the transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_CAN's Tx output through the transceiver to the CAN Rx input plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.

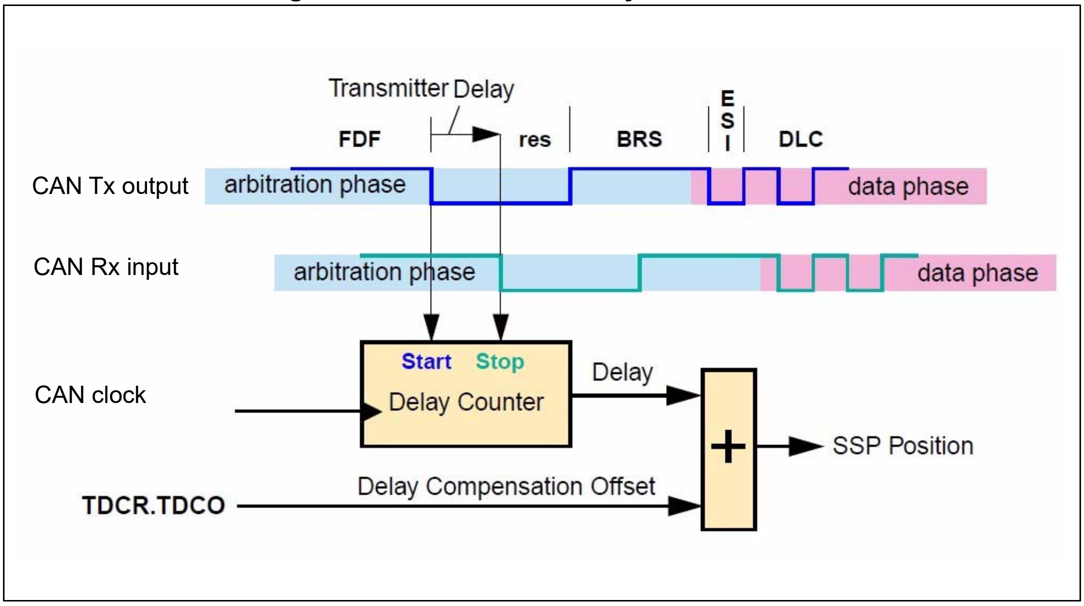
The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than 6 bit times in the data phase
- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

Figure 572 below describes how the Transceiver Delay Compensation measurement.

If transmitter delay compensation is enabled by programming DBTP.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input CAN Rx input of the transmitter. The resolution of this measurement is one mtq.

Figure 572. Transceiver Delay measurement



To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on CAN Rx input, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF AND CAN Rx input is low.

46.3.7.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCR.ASM. The bit can only be set by the Host when both CCCR.CCE and CCCR.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

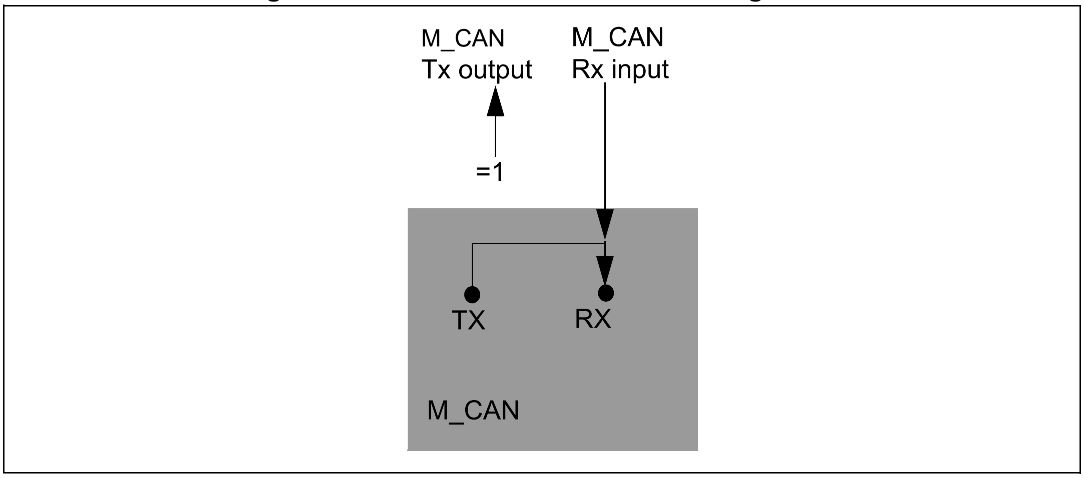
If the M_CAN is connected to a Clock Calibration on CAN Unit, CCCR.ASM is controlled by “calibration OK” input. In case “calibration OK” switches to ‘0’, bit CCCR.ASM is set. When “calibration OK” switches back to ‘1’, bit CCCR.ASM returns to the previously written value. The state of CCCR.ASM is the written value while “calibration OK” input is at ‘1’. The input is hardwired to ‘1’ when there is no Clock Calibration on CAN Unit connected.

46.3.7.6 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (refer to ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

Figure 573 shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

Figure 573. Pin control in Bus Monitoring mode



46.3.7.7 Disabled automatic retransmission

According to the CAN Specification (refer to ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

46.3.7.7.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = ‘10’ (transmission in spite of cancellation).

46.3.7.8 Power down (Sleep mode)

The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and Host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

46.3.7.9 Test modes

To enable write access to register TEST (refer to *Section 46.3.5.2.4: Test Register (TEST)*), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN Tx output pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN’s bit timing and it can drive constant dominant or recessive values. The actual value at M_CAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].

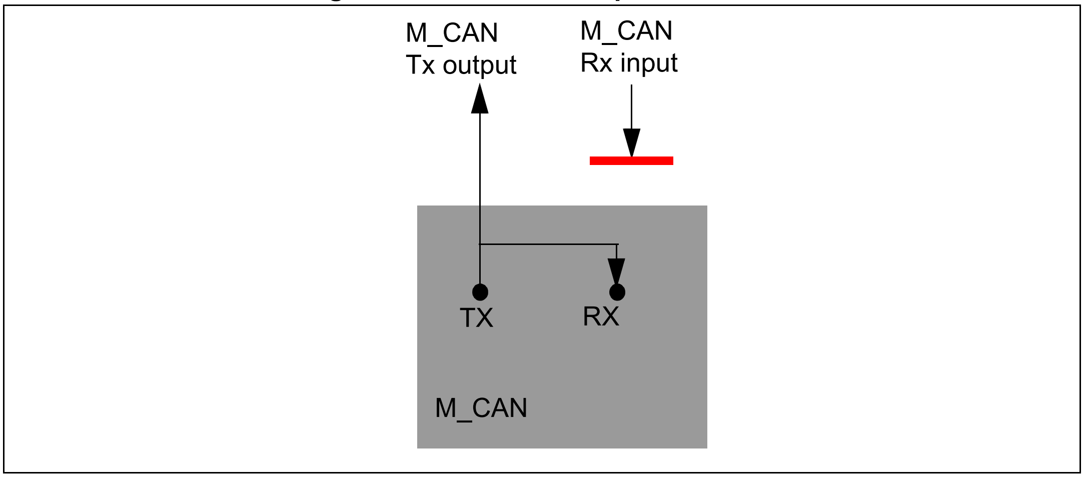
Note: Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

46.3.7.9.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. *Figure 574* shows the connection of Tx and Rx signals to the M_CAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the CAN Tx output pin.

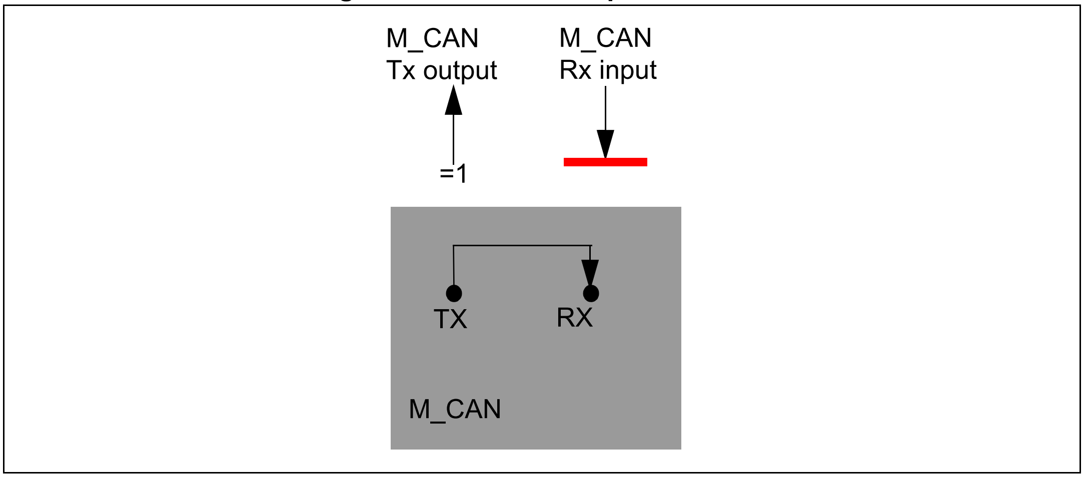
Figure 574. External Loop Back mode



46.3.7.9.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the CAN Tx output and Rx input pins. In this mode M_CAN Tx pin is disconnected from the M_CAN and M_CAN Tx pin is held recessive. *Figure 575* shows the connection of M_CAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

Figure 575. Internal loop back mode



46.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer /Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

46.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = ‘0’. It is stopped when CCCR[INIT] = ‘1’, for example when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core’s sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

46.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indexes.

46.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (such as CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC.

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Section 46.3.10.2.2: Rx FIFO Overwrite Mode* have to be considered.

Note: When an accepted message is written to one of the two Rx FIFOs, or into a Rx Buffer, the unmodified received identifier is stored independently of the filter(s) used. The result of the acceptance filter process strongly depends on the sequence of configured filter elements.

46.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SFID1/SFID2 resp. EFID1/EFID2. There are two possibilities when range filtering is used together with extended frames:

- EFT = ‘00’: The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = ‘11’: The Extended ID AND Mask (XIDAM) is not used for range filtering

46.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1 = SFID2 resp. EFID1 =EFID2.

46.3.10.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1/EFID2 is used as Message ID filter, while SFID2/EFID2 is used as filter mask.

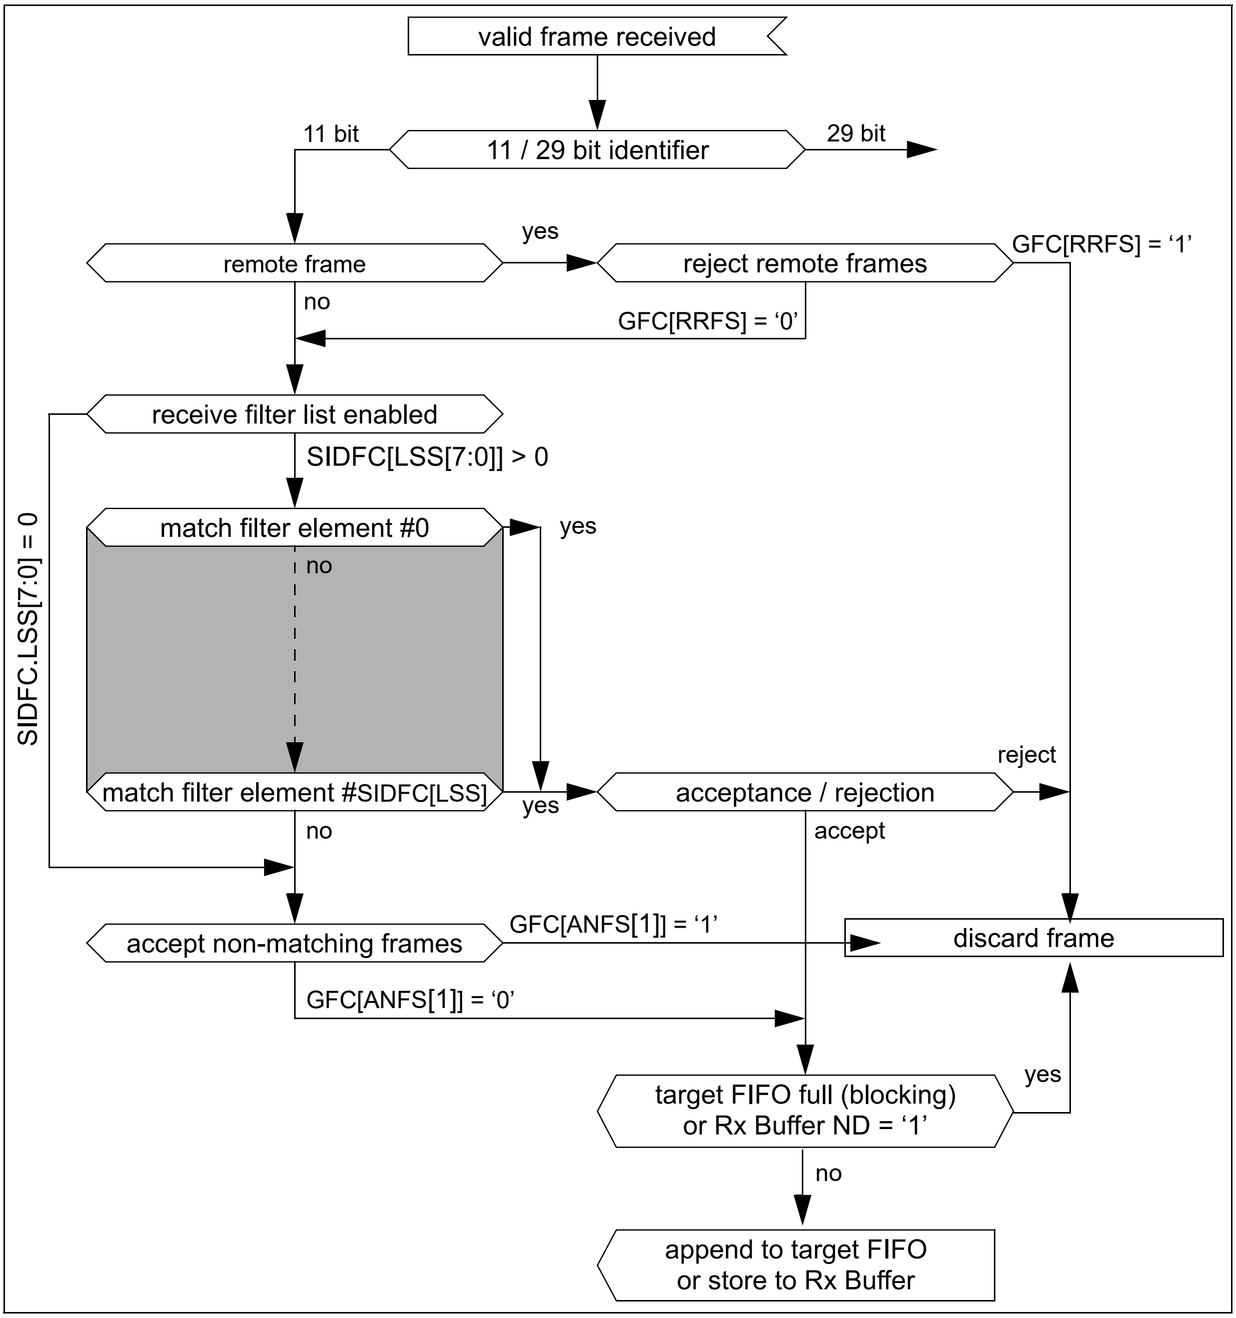
A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

46.3.10.1.4 Standard message ID filtering

Figure 576 shows the flow for standard message ID (11-bit Identifier) filtering.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 576. Standard Message ID Filter Path



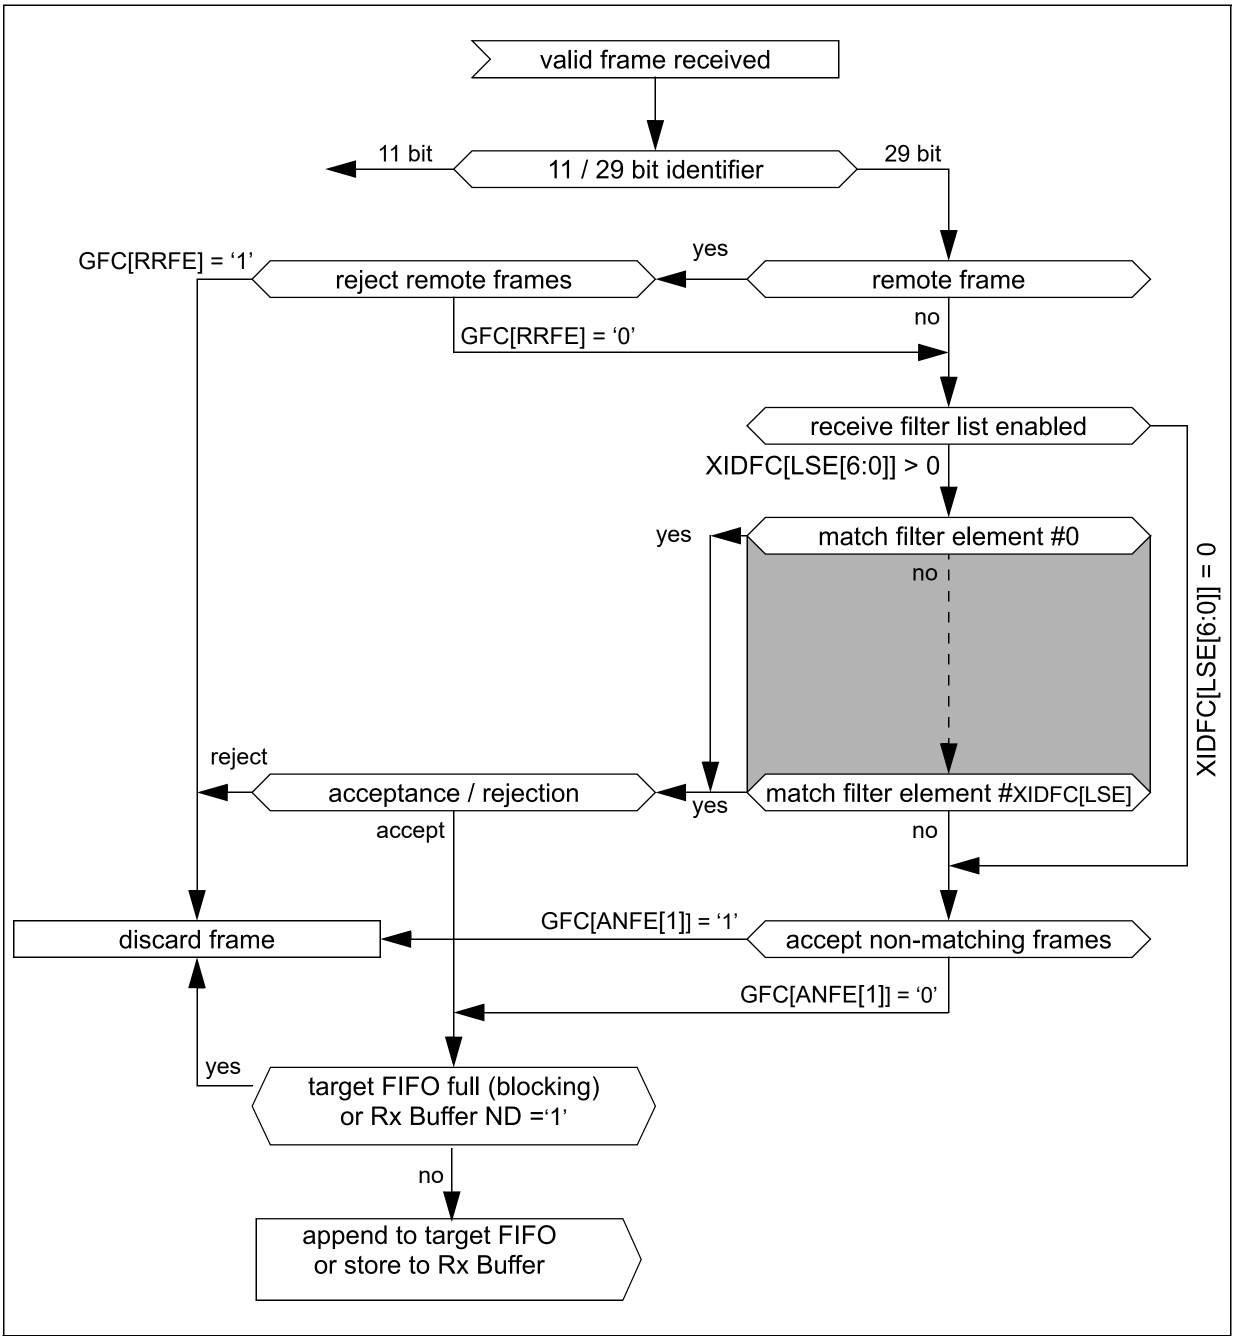
46.3.10.1.5 Extended message ID filtering

Figure 577 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in *Section 46.3.5.2.21: Extended ID Filter Configuration Register (XIDFC)*.

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the

Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 577. Extended Message ID Filter Path



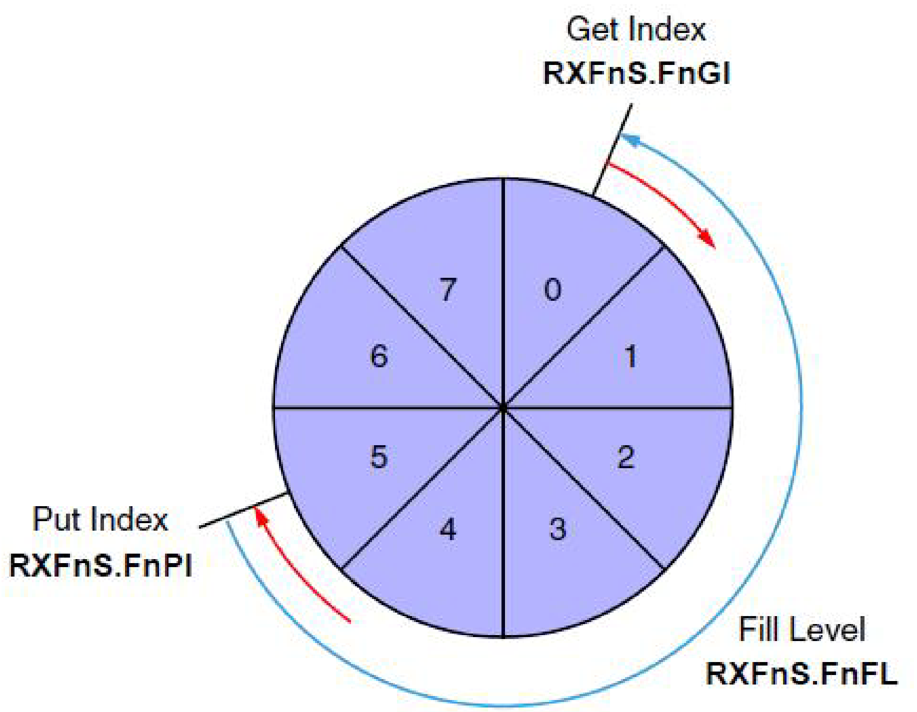
46.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 refer to *Section 46.3.10.1: Acceptance filtering*. The Rx FIFO element is described in *Section 46.3.6.1: Rx Buffer and FIFO element*.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IR.RFnW is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag IR.RFnF is set.

Figure 578. Rx FIFO Status



When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI × FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 640. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10

Table 640. Rx Buffer / FIFO Element Size (continued)

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
110	48	14
111	64	18

46.3.10.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IR.RFnL is set.

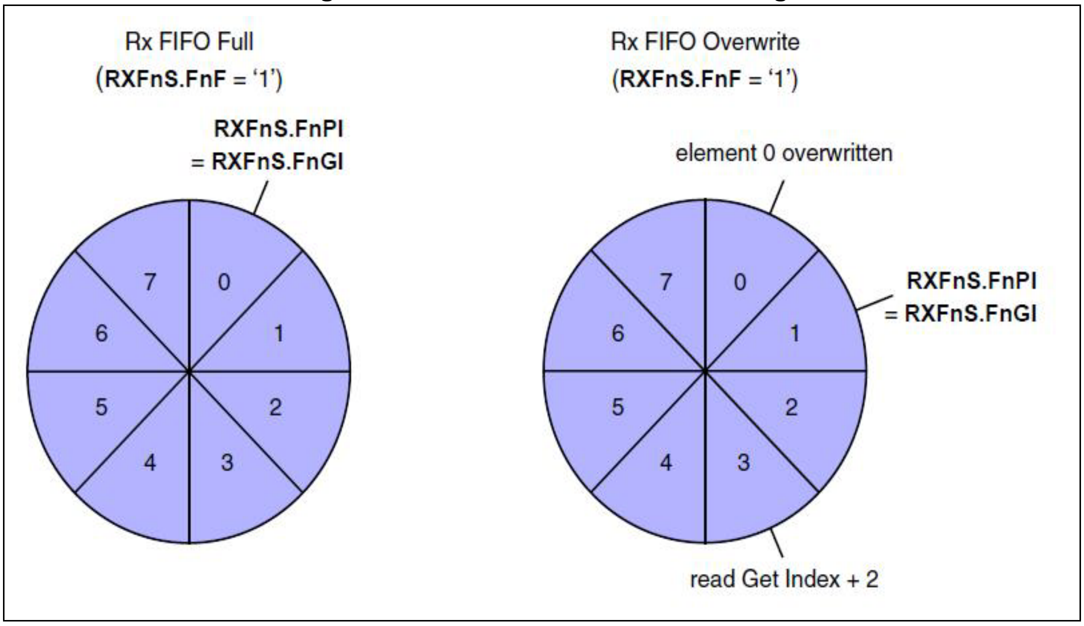
46.3.10.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. *Figure 579* shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 579. Rx FIFO Overflow Handling



After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = '0').

46.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (refer to *Section 46.3.6.4: Standard Message ID Filter element* and *Section 46.3.6.5: Extended Message ID Filter element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 641. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a ‘1’ to the respective bit position.

While an Rx Buffer’s New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

46.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

46.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (for example #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (refer to *Section 46.3.6.1: Rx Buffer and FIFO element*).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = ‘111’ have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while DMA request output is activated. The behavior is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets the DMA acknowledge input . This resets the DMA request output. Now the M_CAN is prepared to receive the next set of debug messages.

46.3.12.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to ‘111’. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 /EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 642. Example Filter Configuration for debug messages

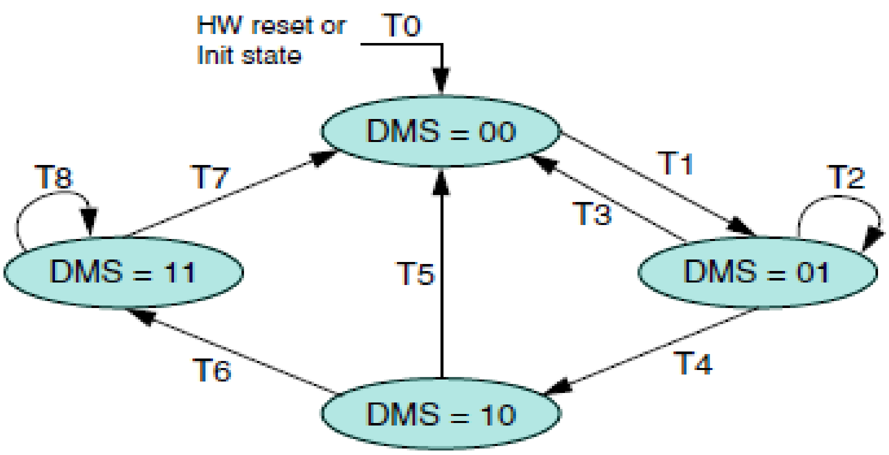
Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

46.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S.DMS.

Figure 580. Debug Message Handling State Machine



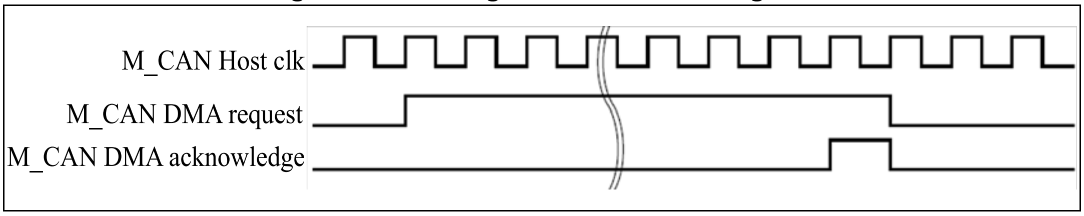
T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C
T1: reception of debug message A
T2: reception of debug message A
T3: reception of debug message C
T4: reception of debug message B
T5: reception of debug messages A, B
T6: reception of debug message C
T7: DMA transfer completed
T8: reception of debug message A,B,C (message rejected)

46.3.12.3 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message handling state machine enters idle state (DMS = ‘00’) and waits for reception of the next debug messages.

Figure 581. Timing of DMA interface signals



Note: If the DMA unit activates input M_CAN DMA acknowledge signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

46.3.13 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indexes, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in the Note: on page 1017.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

46.3.13.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU’s CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If for example CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR.TXP = ‘0’).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

46.3.13.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 643*). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

Table 643. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

46.3.13.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to ‘0’. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = ‘1’) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a ‘1’ to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (refer to *Table 643*). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

46.3.13.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to ‘1’. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = ‘1’), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

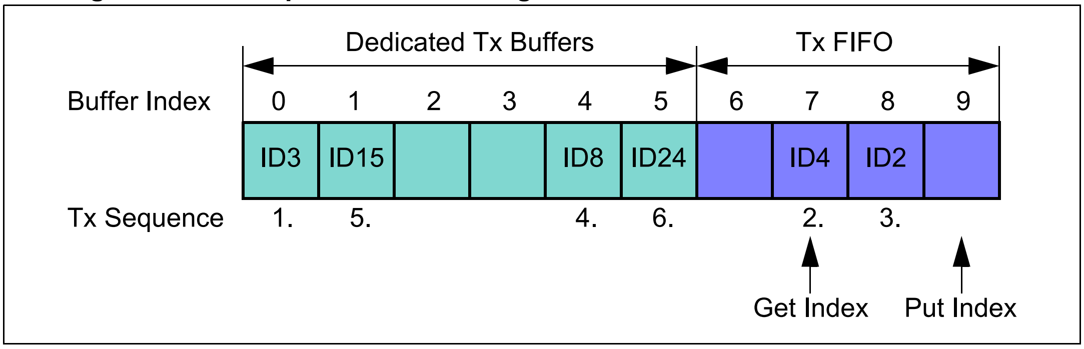
The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 643*). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

46.3.13.5 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 582. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO



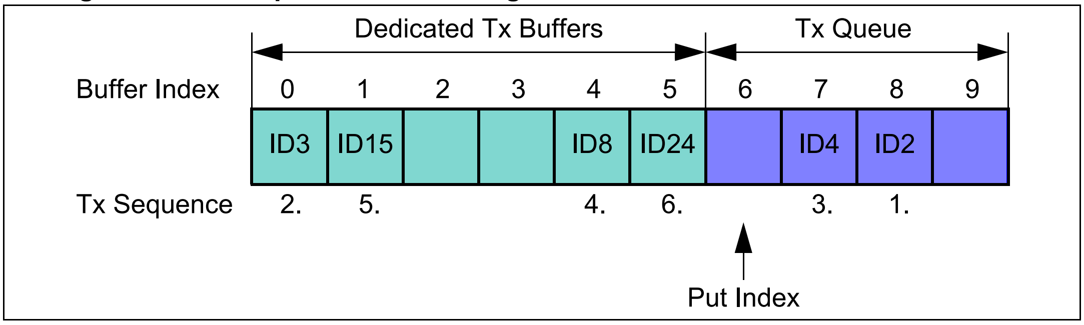
Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

46.3.13.6 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 583. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue



Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

46.3.13.7 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a ‘1’ to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to ‘1’.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

46.3.13.8 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in the *Note: on page 1019*. When a Tx Event FIFO full condition is signaled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

46.3.14 FIFO acknowledge handling

The Get Indexes of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (refer to *Section 46.3.5.2.28: Rx FIFO 0 Acknowledge Register (RXF0A)* and *Section 46.3.5.2.46: Tx Event FIFO Acknowledge Register (TXEFA)*). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN’s Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

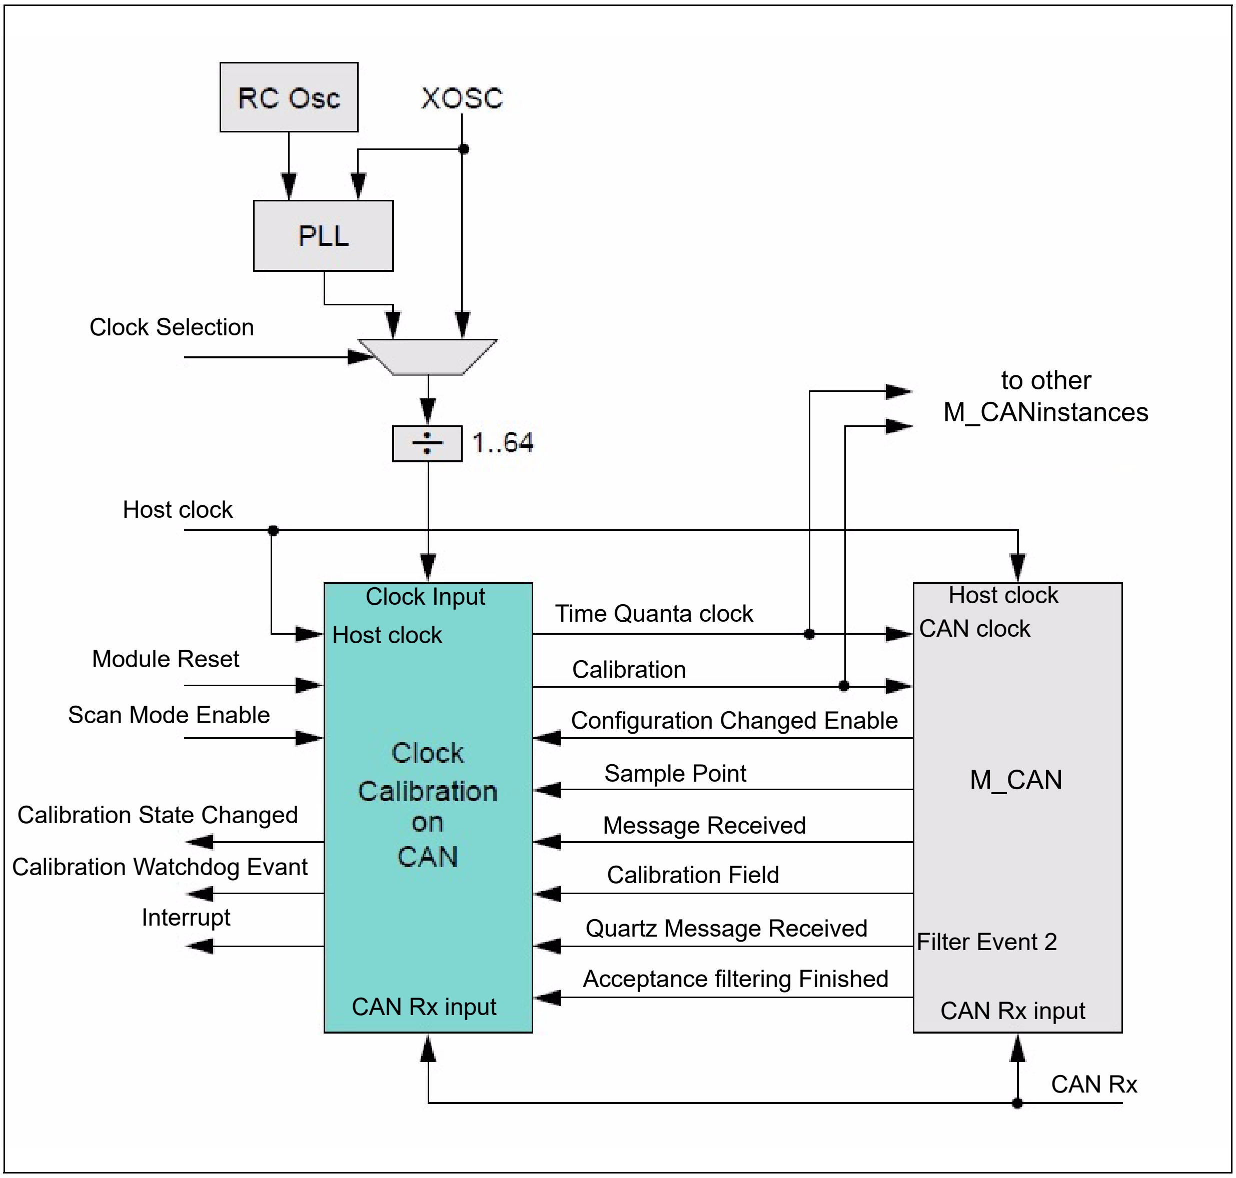
46.3.15 Clock Calibration on CAN Unit (CCCU)

This section describes an add-on for the M_CAN modules that generates a calibrated CAN Time Quanta Clock from an on-chip RC-oscillator clock by evaluating CAN messages received by the attached M_CAN. Calibration on CAN is only possible when the M_CAN is operated in standard CAN mode.

Note: If calibration unit is intended to generate the protocol clock, then it is mandatory to configure calibration unit and MCAN1 before use the other CAN controller like MCAN2 and MCAN3, because the calibrated clock is generated through MCAN1.

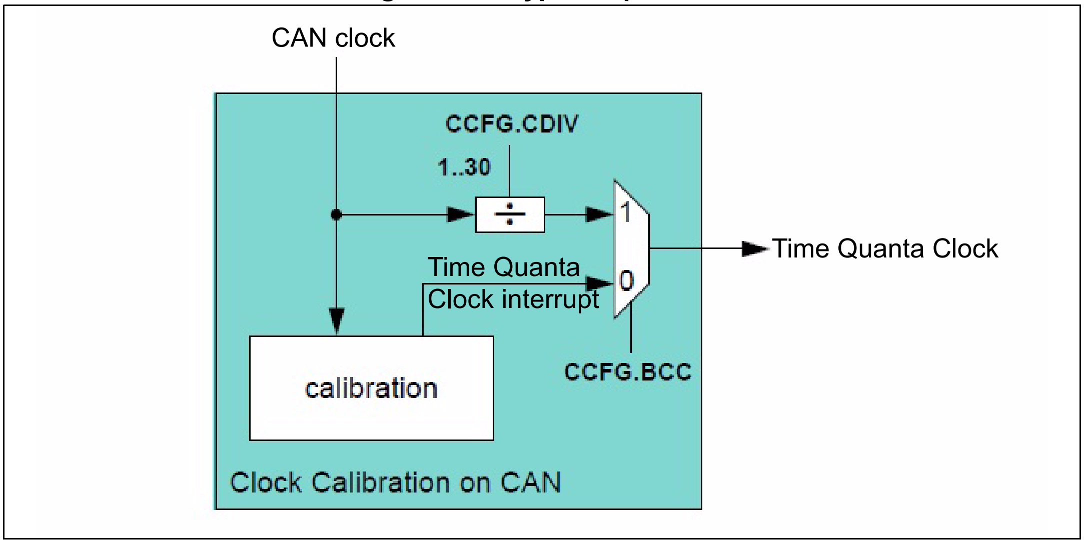
Figure 584 shows the interface of the Clock Calibration on CAN Unit. The clock multiplexer controlled by clock input from Clock Select multiplexer controls whether the clock from the PLL or XOSC is routed to Clock Select multiplexer input. The calibrated Time Quanta Clock is routed to all CAN instances. In case of a successful calibration this is signaled via Calibration.

Figure 584. Connection of Clock Calibration on CAN Unit to M_CAN



CPU accesses to the Clock Calibration on CAN Unit use the Host clock connected to Host clock input from Clock Select Multiplexer. Clock calibration is bypassed when CCFG.BCC = ‘1’. In this case, the clock from Clock Select multiplexer is routed through a clock divider to Time Quanta Clock output (refer to *Figure 585*).

Figure 585. Bypass operation



46.3.15.1 Operating Conditions

The Clock Calibration on CAN Unit is designed to operate under the following conditions:

- Clock input from PLL (clock input from Clock Select multiplexer) between 80 MHz and 500 MHz
- M_CAN bit rates between 125 kbit/s and 1 Mbit/s
- Clock for Host accesses (Host clock) is 40/50 MHz

The Clock Calibration on CAN Unit generates a calibrated Time Quanta clock in the range from 0.5 MHz to 25 MHz.

Note: The M_CAN requires that the CAN clock is always below or equal to the Host clock (CAN clock ≤ Host clock). This has to be considered when the Clock Calibration on CAN Unit is bypassed (CCFG.BCC = '1').

46.3.15.2 Calibration Accuracy

The calibration accuracy in state Precision_Calibrated depends on:

- The dynamic clock tolerance at the clock input from clock select multiplexer
- The measurement error. For each bit sequence used for calibration measurement, there is a maximum error of one clock input from Clock Select multiplexer period. The number of bits used for measurement of the bit time is 32 or 64-bit, depending on configuration of CCFG.CFL.
- Tolerable error in calibration mechanism

The distance between two calibration messages has to be chosen to fit the clock tolerance requirements of the attached M_CANs.

Note: Dynamic clock tolerance is the clock frequency variation between two calibration messages, such as, caused by change of temperature or operating voltage.

46.3.15.3 Memory map and register description

46.3.15.3.1 Hardware Reset Description

After hardware reset, the registers of the Clock Calibration on CAN Unit hold the reset values listed in *Table 644*.

The Clock Calibration on CAN Unit allocates an address space of 16 bytes. All registers are organized as 32-bit registers. The Clock Calibration on CAN Unit is accessible by the Host CPU using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access). Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when Configuration Change Enable input = ‘1’. Configuration Change Enable signal is activated when the M_CAN control bits CCCR.CCE = ’1’ AND CCCR.INIT = ‘1’.

Table 647. CCFG field descriptions

Field	Description
0 SWR	Software Reset Writing a ‘1’ to this bit will reset the calibration FSM to state Not_Calibrated (CSTAT.CALS = ‘00’). The Calibration Watchdog value CWD.WDV is also reset. Registers CCFG, CSTAT and the Calibration Watchdog configuration CWD.WDC are unchanged. The bit remains set until reset has completed.
12:15 CDIV	Clock Divider The clock divider has to be configured when the clock calibration is bypassed (BCC = ‘1’) to assure that the M_CAN requirement CAN clock <= Host clock is fulfilled. 0000 Divide by 1 0001 Divide by 2 0010 Divide by 4 0011 Divide by 6 0100 Divide by 8 0101 Divide by 10 0110 Divide by 12 0111 Divide by 14 1000 Divide by 16 1001 Divide by 18 1010 Divide by 20 1011 Divide by 22 1100 Divide by 24 1101 Divide by 26 1110 Divide by 28 1111 Divide by 30
16:23 OCPM	Oscillator Clock Periods Minimum (0x00–0xFF) Configures the minimum number of clock input from Clock Select multiplexer periods in two CAN bit times. OCPM is used in Basic Calibration to avoid false measurements in case of glitches on the bus line. The configured number of clock input from Clock Select multiplexer periods is OCPM $\times$ 32. The configuration depends on the clock input from Clock Select multiplexer frequency (80 MHz to 500 MHz) and the bit rate configured in the attached M_CANs (125 kbit/s to 1 Mbit/s). It is recommended to configure a value slightly below two CAN bit times. The reset value is 1.6 bit times at 80 MHz clock input from Clock Select multiplexer and 1 Mbit/s CAN bit rate.
24 CFL	Calibration Field Length 0 Calibragation field length is 32 bits. 1 Calibragation field length is 64 bits.

Table 647. CCFG field descriptions (continued)

Field	Description
25 BCC	Bypass Clock Calibration If this bit is set, the clock input clock input from Clock Select multiplexer is routed to the Time Quanta clock output through a clock divider configurable via CDIV, Calibration is always ‘1’. In this case the baud rate prescaler of the connected M_CANs has to be configured to generate the M_CAN internal time quanta clock. 0 Clock calibration unit generates Time Quanta clock 1 Clock calibration unit bypassed **Note:** As long as clock input from Clock Select multiplexer is equal or above 80 MHz the Clock Calibration on CAN Unit is functional, even when BCC = ‘1’. The calibration state can be read from register CSTAT.
27:31 TQBT	Time Quanta per Bit Time (0x04–0x19) Configures the number of time quanta per bit time. Same value as configured in the attached M_CANs. The range of the resulting Time Quanta clock is from 0,5 MHz (bit rate of 125 kbit/s with 4 tq per bit time) to 25 MHz (bit rate of 1 Mbit/s with 25 tq per bit time). Valid values are 4 to 25. Configured values below 4 are interpreted as 4, values above 25 are interpreted as 25.

46.3.15.3.5 Calibration Watchdog Register (CWD)

The calibration watchdog is started after the first falling edge when the calibration FSM is in state Not_Calibrated (CSTAT.CALS = ‘00’). In this state the calibration watchdog monitors the Message Received input. In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM stays in state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When in state Basic_Calibrated (CSTAT.CALS = ‘01’), the calibration watchdog is restarted with each Message Received = ‘1’). In case no message was received until the calibration watchdog has counted down to zero, the calibration FSM returns to state Not_Calibrated (CSTAT.CALS = ‘00’), the counter is reloaded with RWD.WDC and basic calibration is restarted after the next falling edge.

When a quartz message was received, state Precision_Calibrated (CSTAT.CALS = ‘10’) is entered and the calibration watchdog is restarted. In this state the calibration watchdog monitors the Quartz Message Received input. In case no message from a quartz controlled node was received by the attached M_CAN until the calibration watchdog has counted down to zero, the calibration FSM transits back to state Basic_Calibrated (CSTAT.CALS = ‘01’).

The Calibration Watchdog Counter is clocked by the Sample Point input. The duration of a cu_spt pulse is one Time Quanta clock period. The signal is active when the CAN protocol engine on the attached M_CAN is started, that is when the INIT bit is reset.

A calibration watchdog event is signaled by Calibration Watchdog Event output. The duration of aCalibration Watchdog Event pulse is one Host clock period.

A calibration watchdog event also sets interrupt flag **CUIR.CWE**. If enabled by **CUIE.CWEE**, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag **CUIR.CWE** is reset.

46.3.15.3.6 CU Interrupt Register (CUIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ’0’ has no effect. A hard reset will clear the register. The configuration of CUIE controls whether an interrupt is generated.

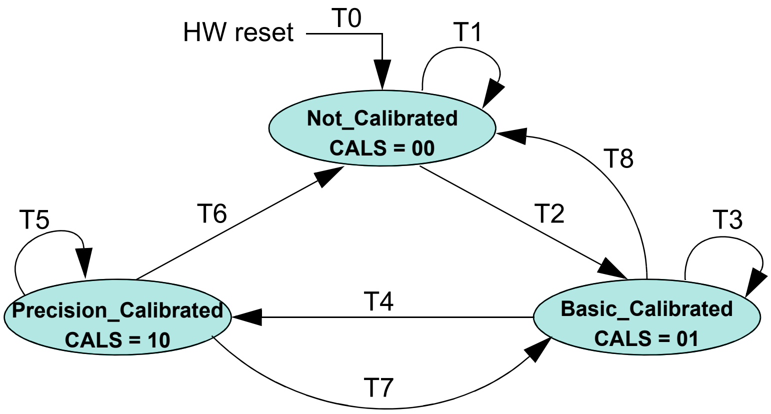
46.3.15.4 Functional Description

Calibration of the Time Quanta clock via CAN messages is performed by adapting a clock divider that generates the CAN protocol time quantum tq from the clock input from Clock Select multiplexer .

- First step: Basic Calibration–The minimum distance between two edges from recessive to dominant is measured, this time to be assumed two CAN bit times, counted in PLL clock periods. The clock divider is updated each time a new measurement finds a smaller distance between edges. Basic calibration is achieved when the CAN protocol controller detects a valid CAN message. This is signaled to the Calibration on CAN unit by Message Received input signal.

- Second step: Precision Calibration – The calibration state machine measures the length of a longer bit sequence inside a CAN frame by counting the number of clock input from Clock Select multiplexer periods. The length of this bit sequence can be configured to 32 or 64 bits via CCFG.CLF. For a calibration field length of 32/64 bit a calibration message with at least 2/6 byte data field is required. The counter is controlled by Calibration Field and Sample Point input signals. The counter is enabled when Calibration Field is set and stops after the configured number of bits has been received. Received bits are signaled by the M_CAN by Sample Point signal. Precision calibration is based on the new clock divider value calculated from the measurement of the longer bit sequence.

Figure 592. Calibration FSM



T0: HW reset

T1: check for minimum

T2: Message Received = ‘1’

T3: evaluate messages

T4: Quartz Message Received = ‘1’

T5: evaluate quartz messages

T6: Configuration Change Enabled = ‘1’

T7: watchdog event: no quartz message received

T8: watchdog event: no message received
or Configuration Change Enabled = ‘1’

A change in the calibration state is signaled via by Calibration State Changed output. The duration of a Calibration State Changed output pulse is one Host clock period.

A change in the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

Until precision calibration is achieved (Calibration=‘1’), the attached M_CANs operate in a restricted mode (no frame transmission, no error or overload flag transmission, no error counting). In case calibration of the PLL is done by software by evaluating the calibration status from register CSTAT, the attached M_CANs have to be set to restricted operation mode (CCCR.ASM = ‘1’) until the Calibration on CAN unit is in state Precision_Calibrated (refer to *Section 46.3.15.4.3: Software Calibration*).

Precision calibration may be performed only on valid CAN frames transmitted by a node with a stable, quartz-controlled clock. Calibration frames are detected by the M_CAN’s acceptance filtering and are signaled to the Clock Calibration on CAN Unit by Quartz Message Received, to be connected to one of the M_CAN’s Filter Event outputs, signal. A filter element and an Rx Buffer have to be configured in the attached M_CAN to identify and store calibration messages. After reception of a calibration message the Rx Buffer’s new data flag has to be reset to enable signaling of the next calibration message.

In case there is only one CAN transmitter with a quartz clock in the network, this node has to transmit its first message after startup with at least one ‘1010’ sequence in the data field or in the identifier. This assures that the non-quartz nodes can enter state Basic_Calibrated and then acknowledge the quartz node’s messages.

Precision calibration must be repeated in predefined maximum intervals supervised by the calibration watchdog.

Note: When the Clock Calibration on CAN Unit transits from state Precision_Calibrated back to Basic_Calibrated, the calibration OK signal is deasserted, the attached M_CANs complete ongoing transmissions, and then enter restricted operation (no frame transmission, no error or overload flag transmission, no error counting).

46.3.15.4.1 Configuration

The Clock Calibration on CAN Unit is configured via register CCFG. The register is only writeable while Configuration Change Enable = ‘1’, that is when the attached M_CAN has CCCR.CCE and CCCR.INIT set.

For basic calibration the minimum number of oscillator periods between two consecutive falling edges at CAN receive input pin is measured. The number of clock periods depends on the clock frequency applied at clock input from clock select multiplexer. In case the measured number of clock periods is below the minimum configured by CCFG.OCPM, for example due to a glitch on CAN receive input, the value is discarded and measurement continues.

It is recommended to configure CCFG.OCPM slightly below two CAN bit times:

CCFG.OCPM < ((2 x CAN bit time) / Clock input from Clock Select multiplexer period) / 32

The length of the bit field used for precision calibration can be configured to 32 or 64 bits via CCFG.CFL. The number of bits used for precision calibration has an impact on calibration accuracy and the maximum distance between two calibration messages. The reception of the bits is signaled by the attached M_CAN by Sample Point input.

The number of time quanta per bit time configured by CCFG.TQBT is used together with the measured number of oscillator clock periods CSTAT.OCPC to define the number of oscillator clocks per bit time.

When the clock calibration is bypassed by configuring CCFG.BCC = ‘1’, the internal clock divider has to be configured via CCFG.CDIV to fulfill the condition CAN clock ≤ Host clock.

Note: When clock calibration on CAN is active (CCFG.BCC = ‘0’), the baud rate prescaler of the attached M_CANs has to be configured to inactive.

46.3.15.4.2 Status signaling

The status of the Clock Calibration on CAN Unit can be monitored by reading register CSTAT. When in state Precision_Calibrated the oscillator clock period counter CSTAT.OCPC signals the number of oscillator clock periods in the calibration field while CSTAT.TQC signals the number of time quanta in the calibration field.

The calibration state is monitored by CSTAT.CALS. A change in the calibration state is signalled at the module interface by Calibration State Changed. The duration of a Calibration State Changed pulse is one Host clock period. A change in the calibration state also sets interrupt flag CUIR.CSC. If enabled by CUIE.CSCE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CSC is reset.

A calibration watchdog event is signalled by Calibration Watchdog Event output. The duration of a Calibration Watchdog Event output pulse is one Host clock period. A calibration watchdog event also sets interrupt flag CUIR.CWE. If enabled by CUIE.CWEE, Interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CUIR.CWE is reset

46.3.15.4.3 Software Calibration

The Clock Calibration on CAN Unit also supports software calibration of the clock generated from an adjustable PLL, connected to the clock input, from Clock Select multiplexer. For this purpose the clock from Clock Select multiplexer has to be routed to Time Quanta clock output by programming CCFG.BCC = ‘1’. The Clock Calibration on CAN Unit’s internal clock divider has to be configured via CCFG.CDIV to meet the clock requirements of the attached M_CANs. All other configuration parameters have to be set via CCFG as if the Clock Calibration on CAN Unit is generating Time Quanta clock.

For startup the M_CANs attached to the Clock Calibration on CAN Unit have to be configured for Restricted Operation (CCCR.ASM = ‘1’). The PLL clock has to be adjusted until the Clock Calibration on CAN Unit has reached state Precision_Calibrated. Now the software has to reset CCCR.ASM and the M_CANs can start normal operation.

During operation the software has to check regularly whether the Clock Calibration on CAN Unit is still in state Precision_Calibrated. In case the Clock Calibration on CAN Unit has left state Precision_Calibrated due to drift of the PLL clock, the attached M_CANs have to be set into Restricted Operation Mode by programming CCCR.INIT, CCCR.CCE, and CCCR.ASM to ‘1’.

After the PLL clock has been adjusted successfully (Clock Calibration on CAN Unit is in state Precision_Calibrated), the M_CANs can be set to normal operation again.

46.4 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note: From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

46.4.1 Features

- Active low asynchronous reset
- 1–CPU + up to 5–CAN arbiter
- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth
- Time slot is defined as one peripheral clock cycle

46.4.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
  – CPU obtains every 2nd slot
  – CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
  – CPU obtains no time slots
  – CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
  – CPU obtains every 2nd time slot
  – Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):
  – CPU obtains no time slots
  – Active CAN 1/2 obtains every 2nd time slot

46.5 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are detailed in *Section 46.7: Shared memory map*.

46.5.1 ECC controller

The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access.

The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2 bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors displays the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

46.5.1.1 Features

The ECC module supports the following:

- ecc_error = ‘00’ No error is detected in the read data from memory
- ecc_error = ‘01’ This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.
- ecc_error = ‘10’ This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- ecc_error = ‘11’ This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

46.6 External signal description

The CAN subsystem has the following external pins.

- M_CAN_x_RX: M_CAN x receive input
- M_CAN_x_TX: M_CAN x transmit output
- M_CAN_x_RXFD: M_CAN_x Receive Fast Data control signal
- M_CAN_x_TXFD: M_CAN_x Transmit Fast Data control signal

46.7 Shared memory map

Table 652 shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 652. Shared memory map versus CAN transmit, receive and filters elements

</table>

Note: There is no write access protection from a CAN module to the message memory space.

The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters and the Tx/Rx buffers used, it is mandatory for the user to configure the start address registers, specified in Table 653, in order to fit the memory mapping specified in Table 652.

The CPU uses the peripheral interface to access the memory locations. It must be noted that there is no transfer error reported to the CPU in case of access to reserved memory locations.

47 Ethernet

47.1 Overview

The Ethernet module enables a host to transmit and receive data over the Ethernet in compliance with the IEEE 802.3-2008. *Figure 593* shows a system-level block diagram of the Ethernet module.

As shown in *Figure 593*, the Ethernet module uses a 64-bit AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through AHB master interface. One AHB master interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all the paths (Transmit and Receive) in all channels.

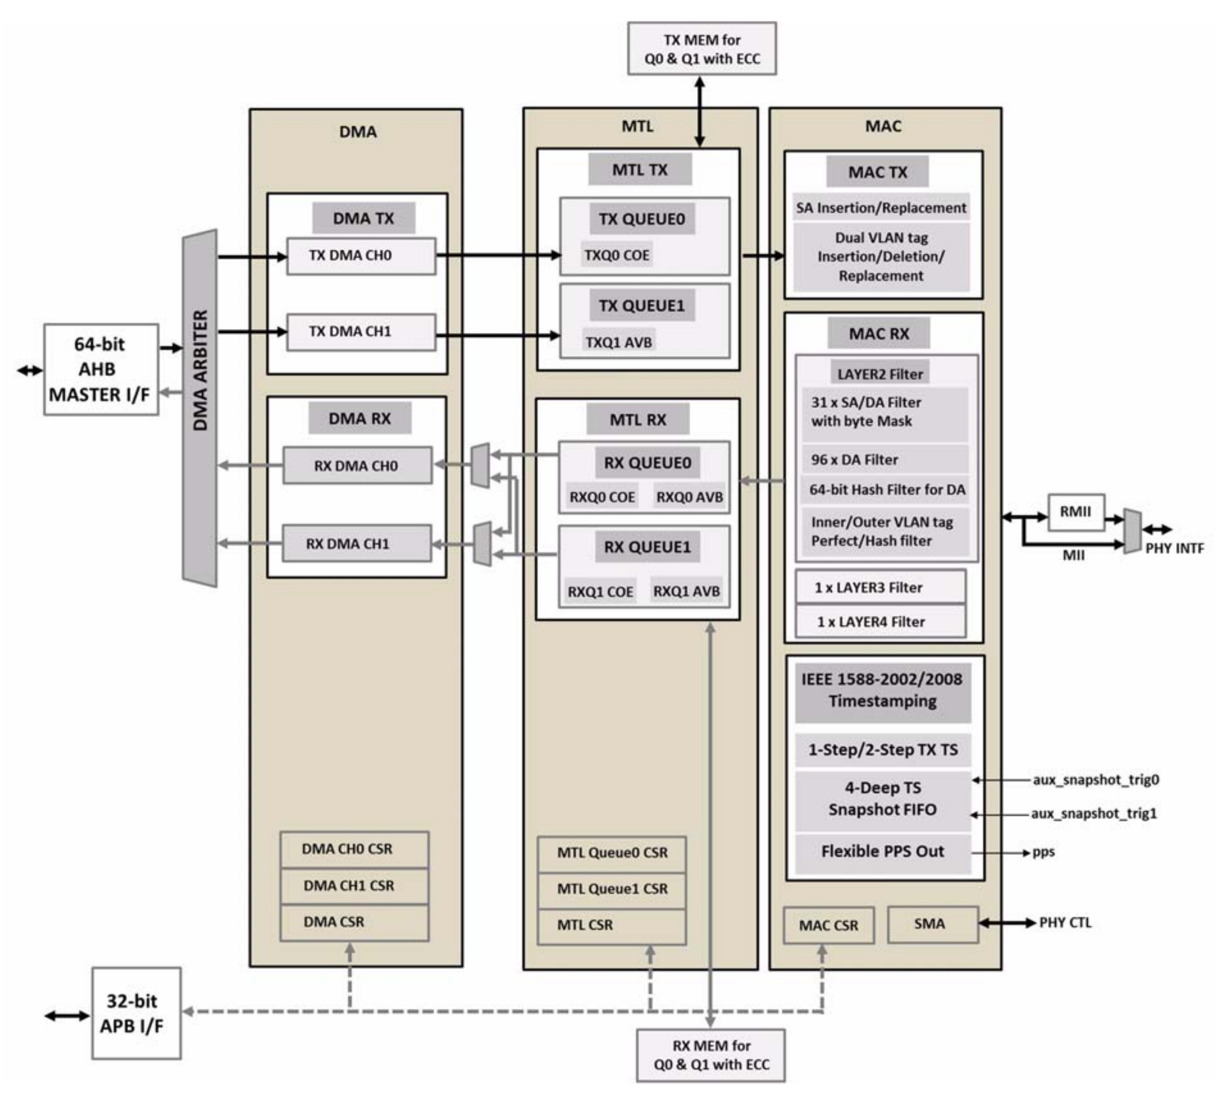
As shown in *Figure 593*, the Ethernet module uses a 32-bit APB interface to program the Control and Status registers (CSR). Each channel has a separate set of Control and Status registers (CSR) for managing the Transmit and Receive functions, descriptor handling, and interrupt handling.

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the Ethernet module. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are one-ported RAM of 68-bit width for 64 data bus widths. The extra bits are used for storing the byte-enable information.

For multiple queues, all Tx queue share the Tx FIFO memory and all Rx queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue. The Ethernet module provides a direct read or write access to the FIFO memories in Debug mode.

The Ethernet module can be programed to use either of MII or RMII PHY interfaces.

Figure 593. System Level block diagram



47.1.1 Ethernet module Features

47.1.1.1 Standard Compliance

The Ethernet module is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC, Media Independent Interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization
- IEEE 802.1AS-2011 and 802.1-Qav-2009 for Audio Video (AV) traffic
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and APB slave ports
- RMII specification version 1.2 from RMII consortium

47.1.1.2 MAC

The MAC supports the following features:

- MAC Tx and Rx features
- MAC Tx features
- MAC Rx features

47.1.1.2.1 MAC Tx and Rx features

Following is the list of MAC Tx and Rx features:

- Separate transmission, reception, and control interfaces to the application
- 10 and 100, Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using backpressure support
  - Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs.
- 64-bit data transfer interface on the application side
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- Network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Support for Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in TX direction
- Flexibility to control the Pulse-Per-Second (PPS) output signal
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management

47.1.1.2.2 MAC Tx features

Following is the list of MAC Tx features:

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 16 KB of size
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Source Address field insertion or replacement, and VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement, or deletion of up to two VLAN tags
- Option to transmit packets with reduced preamble size in full-duplex mode

47.1.1.2.3 MAC Rx features

Following is the list of MAC Rx features:

- Automatic Pad and CRC Stripping options
- Option to disable Automatic CRC checking
- Preamble and SFD deletion
- Separate 112-bit or 128-bit status
- Programmable watchdog timeout limit
- Flexible address filtering modes:
  - 128 MAC addresses for unicast 48-bit perfect filtering
    - 31 filters for destination address (DA) or source address (SA) comparison with masks for each byte
    - 97 filters for destination address (DA) that can be selected in blocks of 32 and 64 registers
  - 64 bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multicast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- module to detect remote wake-up packets and AMD magic packets
- forwarding of received Pause packets to the application (in full-duplex mode)
- Receive module for Layer 3/Layer 4 checksum offload for received packets
- Stripping of up to two VLAN Tags and providing the tags in the status

47.1.1.3 MAC Transaction Layer (MTL)

The MTL block consists of the following FIFOs: Tx FIFO and Rx FIFO. The FIFO space is shared by multiple queues. The buffer size is configured for each queue in multiples of 256 bytes.

47.1.1.3.1 MTL Tx and Rx features

Following is the list of MTL Tx and Rx features:

- 64-bit Transaction Layer block (bridges the application and the MAC)
- Data transfers executed using simple FIFO protocol
- Synchronization for all clocks in the design (Transmit, Receive, and Application clocks)
- Optimization for packet-oriented transfers with packets delimiters
- Programmable threshold capability for each queue (default of 64 bytes)
- Debug and slave mode operation on Queue 0 (default queue)

47.1.1.3.2 MTL Tx features

Following is the list of MTL Tx features:

- Two single-port RAM-based (SPRAM) synchronous FIFO controllers
- 4 KB TX FIFO size
- Dual queues on the Transmit path with a common memory for both Tx queues
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable queue size. Each queue size can be programed in terms of 256 bytes
- Automatic retransmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Disabling of Data Memory RAM chip-select when inactive to reduce power consumption
- Checksum offload engine calculates and inserts IPv4 header checksum and TCP, UDP, or ICMP checksum
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Programmable interrupt options for different operational conditions
- Option to support dropping of Tx Status to improve the Transmit throughput
- Packet-level control for:
  - VLAN tag insertion or replacement
  - Ethernet source address insertion
  - Layer3/Layer4 Checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
- Following scheduling algorithms in configurations with multiple queues:
  - Weighted Round Robin (WRR)
  - Strict Priority (SP)
  - Credit-based Shaper (CBS) for AVB
- Statistics related to bandwidth consumption by each queue of up to 16 blocks over a 125 µs period

47.1.1.3.3 MTL Rx features

Following is the list of MTL Rx features:

- 8 KB Rx FIFO size
- Dual queues on the Receive path with a common memory for all Rx queues
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)

47.1.1.4 DMA block

The DMA block exchanges data between the MTL block and system memory. The well-defined descriptors structure acts as a software and hardware interface. The application can use a set of registers (DMA CSR) to control the DMA operations. The DMA block supports the following features:

- 64-bit data transfers
- 2-channel Transmit and 2-channel Receive engines
- Separate DMA channel in the Transmit path for each queue in MTL
- 2-DMA channels for queues in MTL Receive path
- Fully synchronous design operating on a single application clock except for CSR module
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 KB of data)
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions

- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host CSR access and host data interface
- Routing of received packets to the RX DMA channels based on the DA or VLAN Priority in multi-channel DMA configurations
- Time-sensitive conditional packet transmission by comparing the Slot Time information provided in the descriptor (useful for AV applications)

47.1.1.5 AMBA AHB Master Interface

The AHB master interface supports the following features:

- Interfaces with the application through 64-bit AHB
- Option to select address-aligned bursts from AHB master port
- Split, Retry, and Error AHB responses
- AHB 1 K boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)

The AHB master interface does not generate the following:

- Wrap burst
- Locked or Protected transfers

47.1.1.6 AMBA APB Slave Interface

The Ethernet module supports the 32-bit APB slave interface without any byte-enable to program the CSR registers.

47.1.1.7 Audio Video Support

The Ethernet module supports the following Audio Video (AV) features:

- Separate channels or queues for AV data transfer in 100 Mbps modes
- Up to 2-queues on the Receive paths for AV traffic and 1-queue on the Transmit path for AV traffic
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for Transmit channels
- Single Tx FIFO and Rx FIFO (MTL) for all selected queues (system-side interface [AHB] remains the same)

47.1.1.8 Monitoring, Testing, and Debugging Support

The Ethernet module supports the following features for monitoring, testing, and debugging:

- Internal loopback from Tx to Rx on the MII for debugging
- DMA states (Tx and Rx) as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data paths and FIFO fill-levels
- Application Abort status bits
- MMC (RMON) module
- Current Tx or Rx Buffer pointer as status registers
- Current Tx or Rx Descriptor pointer as status registers
- Statistical counters to calculate the bandwidth served by each Transmit channel when AV support is enabled
- Tx or Rx Queues memory accessible through Slave port for debug

47.2 Memory map and register description

This section provides a detailed description of all registers accessible in this module.

Table 654. Ethernet memory map

Address offset (hex)	Register	Location
0x0000	MAC Configuration register (MAC_CONFIGURATION)	*Section 47.2.1*
0x0004	MAC Extended Configuration register (MAC_EXT_CONFIGURATION)	*Section 47.2.2*
0x0008	MAC Packet Filter register (MAC_PACKET_FILTER)	*Section 47.2.3*
0x000C	Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)	*Section 47.2.4*
0x0010	Hash Table register 0 (MAC_HASH_TABLE_REG0)	*Section 47.2.5*
0x0014	Hash Table register 1 (MAC_HASH_TABLE_REG1)	*Section 47.2.6*
0x0018–0x004F	Reserved	
0x0050	VLAN Tag register (MAC_VLAN_TAG)	*Section 47.2.7*
0x0054–0x0057	Reserved	
0x0058	VLAN Hash Table register (MAC_VLAN_HASH_TABLE)	*Section 47.2.8*
0x005C–0x005F	Reserved	
0x0060	VLAN Tag Inclusion register (MAC_VLAN_INCL)	*Section 47.2.9*
0x0064	Inner VLAN Tag Inclusion register (MAC_INNER_VLAN_INCL)	*Section 47.2.10*
0x0068–0x006F	Reserved	
0x0070	MAC Q0 Flow Control register (MAC_Q0_TX_FLOW_CTRL)	*Section 47.2.11*
0x0074	MAC Q1 Flow Control register (MAC_Q1_TX_FLOW_CTRL)	*Section 47.2.12*
0x0078–0x008F	Reserved	
0x0090	MAC Receive Flow Control register (MAC_RX_FLOW_CTRL)	*Section 47.2.13*
0x0094–0x0097	Reserved	

Table 654. Ethernet memory map (continued)

Address offset (hex)	Register	Location

Figure 594. MAC Configuration Register (MAC_CONFIGURATION)

Table 655. MAC_CONFIGURATION field descriptions

Field	Description
0 ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It will forward the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.
1:3 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 1 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[2:3]: 0x If TDES3[SAIC] = 3'b000 then the application provides the correct SA field else insertion logic will work according to the setting of TDES3[SAIC]. 10 If Bit 1 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 11 If Bit 1 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. **Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. These bits are reserved and RO when the Enable SA and VLAN Insertion on Tx feature is not selected while configuring the core.
4 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.
5:7 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. 000 96 bit times 001 88 bit times 010 80 bit times ... 111 40 bit times This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register.

Table 655. MAC_CONFIGURATION field descriptions (continued)

Field	Description
8 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programed giant packet limit should be less than the watchdog limit to get the giant packet status.
9 S2KP	IEEE 802.3 as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, refer to Giant Packet Status based on S2KP and JE Bits. **Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.
10 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. This function is valid when Type 2 Checksum Offload Engine is enabled. **Note:** For information about how the settings of the ACS bit and this bit impact the packet length, refer to *Table 656*.
11 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. For more details, refer to *Table 656* **Note:** For information about how the settings of CST bit and this bit impact the packet length, refer to *Table 656*.
12 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Table 655. MAC_CONFIGURATION field descriptions (continued)

Field	Description
14 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.
15 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
16 PS	Port Select 1 For 10 or 100 Mbps operations
17 FES	Speed This bit selects the speed in the 10/100 Mbps mode: 0 10 Mbps 1 100 Mbps
18 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously.
19 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.
20 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal.
21 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the MII_TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode.
22 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.
23 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode.

Table 655. MAC_CONFIGURATION field descriptions (continued)

Field	Description
25:26 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. 00 k = min (n, 10) 01 k = min (n, 8) 10 k = min (n, 4) 11 k = min (n, 1) where - = retransmission attempt The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode.
27 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.
28:29 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 7 bytes of preamble 01 5 bytes of preamble 10 3 bytes of preamble 11 Reserved
30 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.
31 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

Table 656. Packet length based on the CST and ACS bits

Receive checksum offload engine	Receive packet length	CST	ACS	FCS stripping done
IPCKSUM_EN = 0 and IPC_FULL_OFFLOAD = 0 or IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 1	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	0	x	No
		1	x	Yes (for Type packets)
IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 0	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	x	x	No

47.2.2 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Offset 0x0004 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 595. MAC_Ext_Configuration Register (MAC_EXT_CONFIGURATION)

Table 657. MAC_EXT_CONFIGURATION field descriptions

Field	Description
2:6 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------------------- 8'hFF - 2144 bit times
7 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. **Note:** The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode.
13 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
14 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.
15 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.
18:31 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programed in this field must be greater than or equal to 1,518 bytes. Any other programed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

47.2.3 MAC Packet Filter Register (MAC_PACKET_FILTER)

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Figure 596. MAC Packet Filter Register (MAC_PACKET_FILTER)

Table 658. MAC_PACKET_FILTER field descriptions

Field	Description
0 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.
10 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
11 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.
15 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.
21 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Table 658. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
22 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. **Note:** According to the IEEE specification, Bit 47 of the SA is reserved. However, in the Ethernet module, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.
23 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programed in the SA registers, it is marked as failing the SA Address filter.
24:25 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 The MAC filters all control packets from reaching the application. 01 The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 10 The MAC forwards all control packets to the application even if they fail the Address filter. 11 The MAC forwards the control packets that pass the Address filter.
26 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets.
27 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
28 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
29 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programed in DA registers.

Table 658. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
30 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programed in DA registers.
31 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

47.2.4 Watchdog Timeout Register (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

Offset 0x000C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 597. MAC Watchdog Timeout Register (MAC_WATCHDOG_TIMEOUT)

Table 659. MAC_WATCHDOG_TIMEOUT field descriptions

Field	Description
23 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register.
28:31 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Encoding is as follows: 0x0 2 KB 0x1 3 KB 0x2 4 KB 0x3 5 KB ... 0xC 14 KB 0xD 15 KB 0xE 16383 Bytes 0xF Reserved **Note:** When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

47.2.5 Hash Table Register 0 (MAC_HASH_TABLE_REG0)

The Hash Table Register 0 contains the first 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bit determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (Refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Field	Description
0:31 HT31T0	This field contains the first 32 Bits [0:31] of the Hash table.

47.2.6 Hash Table Register 1 (MAC_HASH_TABLE_REG1)

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determine the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 600. VLAN Tag Register (MAC_VLAN_TAG)

Table 662. MAC_VLAN_TAG field descriptions

Field	Description
0 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.
2:3 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
4 ERIVLT	Enable Inner VLAN Tag When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
5 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).
6 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed.
7 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.
9:10 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
11 DOVLTC	Disable VLAN Type Check When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Table 662. MAC_VLAN_TAG field descriptions (continued)

Field	Description
12 ERSVLM	Enable Receive S-VLAN Match When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching.
13 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.
14 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.
15 ETV	Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[20:31] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN hash filtering.
16:31 VL	VLAN Tag Identifier for Receive Packets This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: – Bits[16:18]: User Priority – Bit 19: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31]: VLAN Identifier (VID) field of VLAN tag When the ETV bit is set, only the VID is used for comparison. If this field ([20:31] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.

47.2.8 VLAN Hash Table Register (MAC_VLAN_HASH_TABLE)

When the ERSVLM bit of MAC_Hash_Table_Reg1 register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, refer to Section 3.2.8 of IEEE 802.3 - 2008).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 602. VLAN Tag Inclusion Register (MAC_VLAN_INCL)

Table 664. MAC_VLAN_INCL field descriptions

Field	Description
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
13 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.
14:15 VLC	VLAN Tag Control in Transmit Packets 00 No VLAN tag deletion, insertion, or replacement 01 VLAN tag deletion, The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. 10 VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11 VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

47.2.11 MAC Q0 Flow Control Register (MAC_Q0_TX_FLOW_CTRL)

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

Name	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.

Table 666. MAC_Q0_TX_FLOW_CTRL field descriptions (continued)

Name	Description
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.
30 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.
31 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.12 MAC Q1 Flow Control Register (MAC_Q1_TX_FLOW_CTRL)

This register controls the generation of PFC Control packets of priorities mapped as per the PSRQ*i* field in the MAC_RxQ_Ctrl2 registers. This register is present only when the Enable Data Center Bridging feature is selected during configuration.

Figure 605. MAC Q1 Flow Control Register (MAC_Q1_TX_FLOW_CTRL)

Table 667. MAC_Q1_TX_FLOW_CTRL field descriptions

Name	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Table 667. MAC_Q1_TX_FLOW_CTRL field descriptions (continued)

Name	Description
30 TFE	When this bit is set in full-duplex mode, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.
31 FCB_BPA	This bit initiates a PFC packet if the TFE bit is set. To initiate a PFC packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When PFC packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.13 MAC Receive Flow Control Register (MAC_RX_FLOW_CTRL)

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Figure 606. MAC Receive Flow Control Register (MAC_RX_FLOW_CTRL)

Table 668. MAC_RX_FLOW_CTRL field descriptions

Field	Description
30 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. **Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.
31 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

47.2.14 Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)

The Transmit Queue Priority Mapping 0 register contains the priority values assigned to Tx Queue 0 and Tx Queue1.

Offset 0x0098 Access: User Read/Write

Figure 607. Transmit Queue Priority Mapping 0 Register (MAC_TXQ_PRTY_MAP0)

Table 669. MAC_TXQ_PRTY_MAP0 field descriptions

Field	Description
16:23 PSTQ1	Priorities Selected in Transmit Queue 1 This bit is similar to the PSTQ0 bit.
24:31 PSTQ0	Priorities Selected in Transmit Queue 0 This field holds the priorities assigned to Tx Queue 0 by the software. This field determines if Tx Queue 0 should be blocked from transmitting specified pause time when a PFC packet is received with priorities matching the priorities programed in this field. If the content of this field is not mutually exclusive to corresponding fields of other Transmit queues, that is, same priority is mapped to multiple Tx queues, the MAC blocks all queues with matching priority for specified time.

47.2.15 Receive Queue Control 0 Register (MAC_RXQ_CTRL0)

The Receive Queue Control 0 register controls the queue management in the MAC Receiver.

Table 672. MAC_RXQ_CTRL2 field descriptions

Name	Description
16:23 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
24:31 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. Value After Reset: 0x0

47.2.18 Interrupt Status Register (MAC_INTERRUPT_STATUS)

The Interrupt Status register contains the status of interrupts.

Offset 0x00B0 Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 611. Interrupt Status Register (MAC_INTERRUPT_STATUS)

Table 673. MAC_INTERRUPT_STATUS field descriptions

Field	Description
17 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read in the MAC_Rx_Tx_Status register.
18 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: – Excessive Collision (EXCOL) – Late Collision (LCOL) – Excessive Deferral (EXDEF) – Loss of Carrier (LCARR) – No Carrier (NCARR) – Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read in the MAC_Rx_Tx_Status register.
19 TSIS	Timestamp Interrupt Status This bit is set when any of the following conditions is true: – The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. – There is an overflow in the Seconds register. – The Target Time Error occurred, that is, programed target time already elapsed. – When the auxiliary snapshot trigger is asserted. – When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read in the MAC_Timestamp_Status register.
20 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
21 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
22 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
23 MMCIS	MMC Interrupt Status This bit is set high when Bit 20, Bit 21, or Bit 22 is set high. This bit is cleared only when all these bits are low.

Table 673. MAC_INTERRUPT_STATUS field descriptions (continued)

Field	Description
26 LPIIS	LPI Interrupt Status This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of MAC_LPI_Control_Status register is read.
27 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when Bits[25:26] are cleared because of a Read operation to the MAC_PMT_Control_Status register.

47.2.19 Interrupt Enable Register (MAC_INTERRUPT_ENABLE)

The Interrupt Enable register contains the masks for generating the interrupts.

Offset 0x00B4 Access: User Read

Figure 613. Receive Transmit Status Register (MAC_RX_TX_STATUS)

Table 675. MAC_RX_TX_STATUS field descriptions

Field	Description
23 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 675. MAC_RX_TX_STATUS field descriptions (continued)

Field	Description
27 LCOL	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled). Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 LCARR	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 NCARR	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.21 PMT Control and Status Register (MAC_PMT_CONTROL_STATUS)

This register captures the remote wakeup control and status.

Offset 0x00C0 Access: User Read/Write

Figure 614. PMT Control and Status Register (MAC_PMT_CONTROL_STATUS)

Table 676. MAC_PMT_CONTROL_STATUS field descriptions

Field	Description
0 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
5:7 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
21 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. **Note:** If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
22 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.

Table 676. MAC_PMT_CONTROL_STATUS field descriptions (continued)

Field	Description
25 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.
30 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet.
31 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. **Note:** You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.22 Wake-up Packet Filter Registers

The wkuppktfilter_reg register at address 0x00C4 loads the Wake-up Packet Filter register.

To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight register values in address (0x00C4) for wkuppktfilter_reg0, wkuppktfilter_reg1, …, wkuppktfilter_reg7, respectively. The wkuppktfilter_reg register is read in a similar way.

The Ethernet module updates the wkuppktfilter_reg register current pointer value in Bits[5:7] of MAC_PMT_Control_Status register.

- Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3) to determine whether or not a packet is a wake-up packet.
  - The MSB (bit 0) must be zero.
  - Bit j[1:31] is the byte mask.
  - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.
- Filter i Command: The 4-bit filter i command controls the filter i operation.
  - Bit 28 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.
  - Bit 29 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.
  - Bit 29, along with Bit 30, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".
  - Bit 30 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.
  - Bit 31 is the enable for filter i. If Bit 31 is not set, filter i is disabled.
- Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.
  - This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
  - The minimum allowed offset is 12, which refers to the 13th byte of the packet.
  - The offset value 0 refers to the first byte of the packet.
- Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programed to the wake-up filter register block.
  - The 16-bit CRC calculation uses the following polynomial:
    $G(x) = x^{16} + x^{15} + x^2 + 1$
    Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  - 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.
  - 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.

The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.

Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).

When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should *be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).*

Table 677. Remote Wake-Up Packet Filter Register

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 623. LPI Control and Status Register (MAC_LPI_CONTROL_STATUS)

Table 686. MAC_LPI_CONTROL_STATUS field descriptions

Field	Description
10 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode.
11 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions.
12 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of the MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.
14 PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit
15 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.
22 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.
23 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Table 686. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
28 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
29 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
30 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register.
31 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register.

47.2.24 LPI Timers Control Register (MAC_LPI_TIMERS_CONTROL)

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Figure 624. LPI Timers Control Register (MAC_LPI_TIMERS_CONTROL)

Table 687. MAC_LPI_TIMERS_CONTROL field descriptions

Field	Description
6:15 LST	LPI LS TIMER This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
16:31 TWT	LPI TW TIMER This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

47.2.25 LPI Entry Timer Register (MAC_LPI_ENTRY_TIMER)

This register controls the Tx LPI entry timer. This counter is enabled only when bit[11](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Figure 626. 1US Tic Counter Register (MAC_1US_TIC_COUNTER)

Table 689. MAC_1US_TIC_COUNTER field descriptions

Field	Description
20:31 TIC_1US_CNTR	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100MHz then this field needs to be programed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

47.2.27 Version Register (MAC_VERSION)

The version register identifies the version of the Ethernet module.

Figure 632. MDIO Address Register (MAC_MDIO_ADDRESS)

Table 695. MAC_MDIO_ADDRESS field description

Field	Description
4 PSE	Preamble Suppression Enable When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.
5 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0.
6:10 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

Table 695. MAC_MDIO_ADDRESS field description (continued)

Field	Description
11:15 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
17:19 NTC	Number of Training Clocks This field controls the number of trailing clock cycles generated on sma_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
20:23 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0000 CSR clock = 60-100 MHz; MDC clock = CSR clock/42 0001 CSR clock = 100-150 MHz; MDC clock = CSR clock/62 0010 CSR clock = 20-35 MHz; MDC clock = CSR clock/16 0011 CSR clock = 35-60 MHz; MDC clock = CSR clock/26 0100 CSR clock = 150-250 MHz; MDC clock = CSR clock/102 0101 CSR clock = 250-300 MHz; MDC clock = CSR clock/124 0110 Reserved 0111 Reserved The suggested range of CSR clock frequency applicable for each value (when Bit 20 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 20 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000 CSR clock/4 1001 CSR clock/6 1010 CSR clock/8 1011 CSR clock/10 1100 CSR clock/12 1101 CSR clock/14 1110 CSR clock/16 1111 CSR clock/18
27 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
28:29 GOC	PHY SMA interface Operation Command This field indicates the operation command to the PHY: 00 Reserved 01 Write 10 Post Read Increment Address for Clause 45 PHY 11 Read When Clause 22 PHY is enabled, only Write (01) and Read (11) commands are valid.

Table 695. MAC_MDIO_ADDRESS field description (continued)

Field	Description
30 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
31 GB	PHY SMA interface Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. **Note:** Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

47.2.33 MDIO Data Register (MAC_MDIO_DATA)

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Table 697. MAC_ARP_ADDRESS field descriptions

Name	Description
0:31 ARPPA	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

47.2.35 Address0 High Register (MAC_ADDRESS0_HIGH)

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [24:31]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [0:47] is compared with 0x665544332211.

Figure 637. MAC Address High register 1 to 31 (MAC_ADDRESS*n*_HIGH31_1)

Table 700. MAC_ADDRESS*n*_HIGH31_1 field descriptions

Field	Description
0 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.
1 SA	Source Address When this bit is set, the MAC Address1[0:47] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[0:47] is used to compare with the DA fields of the received packet.
2:7 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: Bit 2: Register 194[16:23] Bit 3: Register 194[24:31] Bit 4: Register 195[0:7] … Bit 7: Register 195[24:31] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
15 DCS	DMA Channel Select This field contains the DMA Channel number to which the Rx packet whose DA matches the MAC Address1 content is routed. 0 Route RX packet to DMA channel0 1 Route RX packet to DMA channel1
16:31 ADDRHI	MAC Address1 [0:15] This field contains the upper 16 bits[0:15] of the second 6-byte MAC address.

47.2.38 MAC Address Low register 1 to 31 (MAC_ADDRESSn_LOW31_1)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 643. MMC Control Register (MMC_CONTROL)

Table 706. MMC_CONTROL field descriptions

Field	Description
23 UCDBC	Update MMC Counters for Dropped Broadcast Packets When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets.
26 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16).

Table 706. MMC_CONTROL field descriptions (continued)

Field	Description
27 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.
28 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
29 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[0:7]) is read.
30 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value.
31 CNTRST	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

47.2.44 MMC Receive Interrupt Register (MMC_RX_INTERRUPT)

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values, that is 0x8000_0000.
- Receive statistic counters cross their maximum values, that is 0xFFFF_FFFF.
- When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

7 RXRCVERRPIS	MMC Receive Error Packet Counter Interrupt Status This bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
8 RXWDOGPIS	MMC Receive Watchdog Error Packet Counter Interrupt Status This bit is set when the rxwatchdog error counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
9 RXVLANGBPIS	MMC Receive VLAN Good Bad Packet Counter Interrupt Status This bit is set when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
10 RXFOVPIS	MMC Receive FIFO Overflow Packet Counter Interrupt Status This bit is set when the rxfifooverflow counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
11 RXPAUSPIS	MMC Receive Pause Packet Counter Interrupt Status This bit is set when the rxpausepackets counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
12 RXORANGEPIS	MMC Receive Out Of Range Error Packet Counter Interrupt Status. This bit is set when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
13 RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
14 RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15 RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 707. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
16 RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
17 RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
18 RX128T255OCTGBPIS	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
19 RX65T127OCTGBPIS	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 RX64OCTGBPIS	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21 RXOSIZEGPIS	MMC Receive Oversize Good Packet Counter Interrupt Status This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
22 RXUSIZEGPIS	MMC Receive Undersize Good Packet Counter Interrupt Status This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
23 RXJABERPIS	MMC Receive Jabber Error Packet Counter Interrupt Status This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 707. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
24 RXRUNTPIS	MMC Receive Runt Packet Counter Interrupt Status This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
25 RXALGNERPIS	MMC Receive Alignment Error Packet Counter Interrupt Status This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 RXCRCERPIS	MMC Receive CRC Error Packet Counter Interrupt Status This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
27 RXMCGPIS	MMC Receive Multicast Good Packet Counter Interrupt Status This bit is set when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 RXBCGPIS	MMC Receive Broadcast Good Packet Counter Interrupt Status This bit is set when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 RXGOCTIS	MMC Receive Good Octet Counter Interrupt Status This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

47.2.45 MMC Tx Interrupt Register (MMC_TX_INTERRUPT)

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values, that is 0x8000_0000, and when they cross their maximum values, that is 0xFFFF_FFFF. When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Field	Description
4 RXLPITRCIM	MMC Receive LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 RXLPIUSCIM	MMC Receive LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.
6 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value.
7 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.

Table 709. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
8 RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value.
9 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value.
10 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxfifooverflow counter reaches half of the maximum value or the maximum value.
11 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpausepackets counter reaches half of the maximum value or the maximum value.
12 RXORANGEPIM	MMC Receive Out Of Range Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value.
13 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value.
14 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.
15 RX1024TMAXOCTGBPIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask. Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
16 RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value.
17 RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value.
18 RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value.
19 RX65T127OCTGBPIM	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value.
20 RX64OCTGBPIM	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value.

Table 709. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
21 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value.
22 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value.
23 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value.
24 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value.
25 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value.
26 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value.
27 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value.
28 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
29 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value.
30 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value.
31 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value.

47.2.47 MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Transmit statistics counters.

Figure 647. MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)

Table 710. MMC_TX_INTERRUPT_MASK field descriptions

Field	Description
4 TXLPITRCIM	MMC Transmit LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when TX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 TXLPIUSCIM	MMC Transmit LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when TX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.
6 TXOSIZEGPIM	MMC Transmit Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
7 TXVLANGPIM	MMC Transmit VLAN Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txvlanpackets_g counter reaches half of the maximum value or the maximum value.
8 TXPAUSPIM	MMC Transmit Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpausepackets counter reaches half of the maximum value or the maximum value.
9 TXEXDEFPIM	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value.
10 TXGPKTIM	MMC Transmit Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_g counter reaches half of the maximum value or the maximum value.

Table 710. MMC_TX_INTERRUPT_MASK field descriptions (continued)

Field	Description
11 TXGOCTIM	MMC Transmit Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value.
12 TXCARERPIM	MMC Transmit Carrier Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value.
13 TXEXCOLPIM	MMC Transmit Excessive Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value.
14 TXLATCOLPIM	MMC Transmit Late Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value.
15 TXDEFPIM	MMC Transmit Deferred Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value.
16 TXMCOLGPIM	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value.
17 TXSCOLGPIM	MMC Transmit Single Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value.
18 TXUFLOWERPIM	MMC Transmit Underflow Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value.
19 TXBCGBPIM	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value.
20 TXMCGBPIM	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value.
21 TXUCGBPIM	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value.
22 TX1024TMAXOCTGBPIM	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
23 TX512T1023OCTGBPIM	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value.

Table 710. MMC_TX_INTERRUPT_MASK field descriptions (continued)

Field	Description
24 TX256T511OCTGBPIM	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value.
25 TX128T255OCTGBPIM	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value.
26 TX65T127OCTGBPIM	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value.
27 TX64OCTGBPIM	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value.
28 TXMCGPIM	MMC Transmit Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value.
29 TXBCGPIM	MMC Transmit Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
30 TXGBPKTIM	MMC Transmit Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_gb counter reaches half of the maximum value or the maximum value.
31 TXGBOCTIM	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value.

47.2.48 Transmit Octet Count Good Bad Register (TX_OCTET_COUNT_GOOD_BAD)

This register provides the number of bytes transmitted by the Ethernet module, exclusive of preamble and retried bytes, in good and bad packets.

Offset 0x0714																Access: User Read

Figure 662. Transmit Single Collision Good Packets Register (TX_SINGLE_COLLISION_GOOD_PACKETS)

Table 725. TX_SINGLE_COLLISION_GOOD_PACKETS field descriptions

Field	Description
0:31 TXSNGLCOLG	This field indicates the number of successfully transmitted packets after a single collision in the half-duplex mode.

47.2.63 Transmit Multiple Collision Good Packets Register (TX_MULTIPLE_COLLISION_GOOD_PACKETS)

This register provides the number of successfully transmitted packets by the Ethernet module after multiple collisions in the half-duplex mode.

Offset 0x0750 Access: User Read

Field	Description
0:31 TXDEFRD	This field indicates the number of successfully transmitted after a deferral in the half-duplex mode.

47.2.65 Transmit Late Collision Packets Register (TX_LATE_COLLISION_PACKETS)

This register provides the number of packets aborted by the Ethernet module because of late collision error.

Offset 0x0758 Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 TXLATECOL	This field indicates the number of packets aborted because of late collision error.

47.2.66 Transmit Excessive Collision Packets Register (TX_EXCESSIVE_COLLISION_PACKETS)

This register provides the number of packets aborted by the Ethernet module because of excessive (16) collision errors.

Offset 0x075C Access: User Read

Field	Description
0:31 TXEXSCOL	This field indicates the number of packets aborted because of excessive (16) collision errors.

47.2.67 Transmit Carrier Error Packets Register (TX_CARRIER_ERROR_PACKETS)

This register provides the number of packets aborted by the Ethernet module because of carrier sense error (no carrier or loss of carrier).

Offset 0x0760 Access: User Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0:31 TXPKTG	This field indicates the number of good packets transmitted.

47.2.70 Transmit Excessive Deferral Error Register (TX_EXCESSIVE_DEFERRAL_ERROR)

This register provides the number of packets aborted by the Ethernet module because of excessive deferral error (deferred for more than two max-sized packet times).

Offset 0x076C Access: User Read

Field	Description
0:31 TXVLANG	This field provides the number of good VLAN packets transmitted.

47.2.73 Transmit OSize Packets Good Register (TX_OSIZE_PACKETS_GOOD)

This register provides the number of packets transmitted by the Ethernet module without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register).

Offset 0x0778 Access: User Read
