</tr>
</tbody>
</table>

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Flow control in Half-duplex mode

In Half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Table 568 describes the flow control in the Tx path based on the setting of the following bits:

- TFE bit of *Tx Queue flow control register (ETH_MACQTXFCR)*
- DM bit of *Operating mode configuration register (ETH_MACCR)*

Flow control is similar for all queues.
Transmit flow control

The transmit flow control is enabled when TFE bit is set in Tx Queue flow control register (ETH_MACQTXFCR).

Flow control trigger

The application can request the MAC to send a Pause packet or initiate back-pressure by setting the FCB bit in the corresponding Tx Queue flow control register (ETH_MACQTXFCR).

Receive flow control

In the Receive path, the flow control is functional only in Full-duplex mode. If any Pause packet is received in Half-duplex mode, the packet is considered as a normal control packet.

Description of receive flow control

Table 569 describes the flow control in the Rx path based on the setting of the following bits:
- RFE bit of Rx flow control register (ETH_MACRXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

<table>
<thead>
<tr>
<th>RFE</th>

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.</td>
</tr>
</tbody>
</table>

The following sequence describes the Rx flow control:
1. The MAC checks the destination address (DA) of the received Pause packet for either of the following:
   - Multicast destination address: the DA matches the unique multicast address specified for the control packet (0x0180 C200 0001).
   - Unicast destination address: the DA matches the content of the MAC Address 0 registers (MAC Address 0 high register (ETH_MACA0HR) and MAC Address x)
low register (ETH_MACAxLR)) and the UP bit of Rx flow control register (ETH_MACRXFCR) is set.

If the UP bit is set, the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.

2. The MAC decodes the following fields of the received packet:
   - Type field: this field is checked for 0x8808.
   - Opcode field: this field is checked for 0x0001 (Pause packet).
   - Pause time: the Pause time (for Pause packet) is captured to determine the time for which the transmitter needs to be blocked.

3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).

If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

**Enabling receive flow control**

Set the RFE bit in the Rx flow control register (ETH_MACRXFCR) to enable the Pause flow control.
63.5.10 MAC management counters

The peripheral supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC management counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the AHB slave interface in the same way the CSR registers are accessed. The organization of these registers is shown in Section 63.11.4: Ethernet MAC and MMC registers.

The MMC counters are free running. There is no separate enable for the counters to start. A particular MMC counter starts counting when corresponding packet is received or transmitted.

The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set bit 0 in the Packet filtering control register (ETH_MACPFR). The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

In addition to control registers, two sets of registers are implemented:

- 6 registers used for collision, error and good packets counters:
  - Tx single collision good packets register (Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS))
  - Tx multiple collision good packets register (Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS))
  - Tx packet count good register (Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD))
  - Rx CRC error packets register (Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS))
  - Rx alignment error packets register (Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS))
  - Rx unicast packets good register (Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD))

- 4 registers to record LPI mode transition:
  - Tx LPI microsecond timer register (Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR))
  - Tx LPI transition counter register (Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR))
  - Rx LPI microsecond counter register (Rx LPI microsecond counter register (ETH_RX_LPI_USEC_CNTR))
  - Rx LPI transition counter register (Rx LPI transition counter register (ETH_RX_LPI_TRAN_CNTR))
Definitions

The following terminology is used in MMC register descriptions:

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber timeout
  - No carrier or loss of carrier
  - Late collision
  - Packet underflow
  - Excessive deferral
  - Excessive collision

- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of range (non-Type packet only, longer than 1518 bytes)

- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN frame maxsize = 1,522
  - Jumbo frame maxsize = 9,018
  - JumboVLAN frame maxsize = 9,022

- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the Table 570.

63.5.11 Interrupts generated by the MAC

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA on the eth_sbd_intr_it signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The interrupt status register (ETH_MACISR) describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the eth_sbd_intr_it signals by setting the corresponding mask bits in the interrupt enable register (ETH_MACIER).

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

63.5.12 MAC and MMC register descriptions

Refer to Section 63.11.4: Ethernet MAC and MMC registers.
63.6 Ethernet functional description: PHY interfaces

The Ethernet peripheral support several PHY interfaces. The root interface is the MII one. All other interfaces are derived from it as shown in Figure 823.

Figure 823. Supported PHY interfaces

This section describes the SMA module used for PHY control and different PHY interfaces. It contains the following sections:

- Station management agent (SMA)
- Media independent interface (MII)
- Reduced media independent interface (RMII)

63.6.1 Station management agent (SMA)

The application can access the PHY registers through the station management agent (SMA) module. The SMA includes a two-wire station management interface (MIM).

The SMA module supports accessing up to 32 PHYs. The application can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in Figure 824.

Figure 824. SMA Interface block
SMA functional overview

The MAC initiates the management write or read operation with respect to the MDC clock. The MDC clock is derived from the CSR clock (eth_hclk). The maximum operating frequency of the ETH_MDC pin is 2.5 MHz, as specified in IEEE 802.3 specifications. However, a different divider can be selected if the system supports higher clock frequencies. The division factor depends on the clock range setting through CR[3:0] in the MDIO address register (ETH_MACMDIOAR) register. The MDC clock is selected as follows:

<table>
<thead>
<tr>

The data exchange between the MAC and the PHY is performed through a three-state buffer and brought out as ETH_MDIO line connected to the PHY.

Figure 825 shows the structure of a Clause 45 MDIO packet, while Table 572 provides a detailed description of the packet fields.

</tr>
</tbody>
</table>

The frame structure for Clause 22 frames is also supported. The C45E bit in MDIO address register (ETH_MACMDIOAR) can be programmed to enable Clause 22 or Clause 45 mode of operation. Figure 826 shows the structure of a Clause 22 MDIO packet, while Table 573 provides a detailed description of the packet fields.

Figure 826. MDIO packet structure (Clause 22)
In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

**MII management write operations**

After the station management agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

*Figure 827* illustrates the flow for a write operation from the SMA module to the PHY registers.

<table>

<tr>
<td>DATA</td>
<td>Any 16-bit value. In a Write operation, the MAC drives ETH_MDIO. In a Read operation, the PHY drives it.</td>
</tr>
</tbody>
</table>
When bits[3:2] are set to 01 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MDIO data register (ETH_MACMDIODR)) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII management Interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MDIO address register (ETH_MACMDIOAR) or the MDIO data register.
(ETH_MACMDIODR) during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit. The packet format for the Write operation is as follows:

**Figure 828. Write data packet**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**MII management read operation**

When bits [3:2] are set to 11 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII management interface using the management packet format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MDIO address register (ETH_MACMDIOAR) or MDIO data register (ETH_MACMDIODR) during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface. When the Read operation is complete, the SMA indicates this to the CSR. The CSR resets the Busy bit and updates the MDIO data register (ETH_MACMDIODR) with the data read from the PHY. The MAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

**Figure 829. Read data packet**

</tbody>
</table>
Preamble suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The peripheral provides controls to support preamble suppression. It transmits MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting the PSE bit in MDIO address register (ETH_MACMDIOAR).

Trailing clocks and back-to-back transactions

The peripheral drives the ETH_MDC clock for the duration of the MDIO frame. There is no clock driven during the idle period. The trailing clock feature can be used if the PHY needs the ETH_MDC clock to be active for some cycles after the MDIO frame. The NTC[2:0] bitfield in MDIO address register (ETH_MACMDIOAR) allows the programming of trailing clocks from 0 to 7.

The peripheral supports back-to-back transactions which allow starting the next MDIO frame even before the trailing clocks are complete for previous MDIO frame. This feature can be enabled by setting BTB bit in MDIO address register (ETH_MACMDIOAR) when the trailing clock feature is also enabled. When back-to-back transactions are enabled, the GMII busy bit (GB) is cleared immediately after MDIO frame completion. This allows the software to issue the next command, which is executed by the peripheral while trailing clocks are still on for the previous MDIO frame. When (GB) transactions are not enabled, the GMII busy bit is cleared after the trailing clocks are complete for the MDIO frame.

Interrupt for MDIO transaction completion

The peripheral can generate an interrupt on completion of MDIO read or write transactions. Therefore, the application need not poll the GMII busy bit of the MDIO address register (ETH_MACMDIOAR) to know the completion of MDIO commands.
63.6.2 Media independent interface (MII)

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

MII signals are given in Figure 830: Media independent interface (MII) signals.

Figure 830. Media independent interface (MII) signals

- TX_CLK: continuous clock that provides the timing reference for Tx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s and 25 MHz at 100 Mbit/s.
- TXD[3:0]: transmit data. TXD is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the TX_EN signal. TXD[0] is the least significant bit, TXD[3] is the most significant bit. While TX_EN is deasserted, the transmit data must have no effect upon the PHY.
- TX_EN: transmission enable signal indicating that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (TX_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- TX_ER (optional): required only for Energy Efficient Ethernet (EEE). The transmit error is indicated by inverting the CRC. The remote station can detect the Transmit error through incorrect CRC.
- RX_CLK: continuous clock that provides the timing reference for Rx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s, 25 MHz at 100 Mbit/s.
- RXD[3:0]: receive data RXD is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the RX_DV signal. RXD[0] is the least significant bit, RXD[3] is
the most significant bit. While RX_EN is deasserted and RX_ER is asserted, a specific RXD[3:0] value is used to transfer specific information from the PHY.

- RX_DV: receive data valid
  This signal indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (RX_CLK) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the RX_DV signal must encompass the frame, starting no later than the SFD field.

- RX_ER: receive error
  This signal must be asserted for one or more clock periods (RX_CLK) to indicate to the MAC sublayer that an error was detected somewhere in the frame. This error condition must be qualified by RX_DV assertion.

- CRS: carrier sense.
  This signal is asserted by the PHY when either the transmit or receive medium is non idle. It shall be deasserted by the PHY when both transmit and receive media are idle. The PHY must ensure that the CS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode the state of this signal is don’t care for the MAC sublayer.

- COL: collision detection signal
  This signal must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In Full-duplex mode, the state of this signal is don’t care for the MAC sublayer.

63.6.3 Reduced media independent interface (RMII)

The reduced media independent interface (RMII) specification reduces the pin count between Ethernet PHYs and STM32 MCU. According to the IEEE 802.3u, an MII contains 16 pins for data and control. RMII specification reduces the pin count to 7.

Part of the Ethernet peripheral, the RMII module is instantiated at the MAC output. This helps in translating the MII of the MAC into the RMII. The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock references externally.
**RMII block diagram**

*Figure 831: RMII block diagram* shows the position of the RMII block relative to the MAC and RMII PHY. The RMII block is placed in front of the MAC to translate the MII signals to RMII signals.

**Figure 831. RMII block diagram**

- RMII_REF_CLK: continuous 50 MHz reference clock input
- TXD[1:0]: transmit data
- TX_EN: transmit data enable. When high, this bit indicates that valid data are being transmitted on TXD[1:0].
- RXD[1:0]: receive data
- CRS_DV: carrier Sense (CRS) and RX_Data Valid (RX_DV) multiplexed on alternate clock cycles. In 10 Mbit/s mode, it alternates every 10 clock cycles.
Transmit bit order

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in Figure 832: Transmission bit order. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

**Figure 832. Transmission bit order**
Receive bit order

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in Figure 833: Receive bit order. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 833. Receive bit order
63.7 Ethernet low-power modes

63.7.1 Low-power management

The Ethernet peripheral supports the following techniques to save power:

- Magic packet
- Remote wakeup

The magic packet and remove wakeup techniques are used to save power in the host system when it is idle (Sleep mode) and has to be woken up only at the reception of specific packets from the Ethernet network. In Sleep mode, the power to the host logic along with the majority of the peripheral (except the MAC receiver logic), can be shut down. On receiving the specific packets from the network, the MAC provides the trigger to restore the power to the host system and come back to normal state.

The Energy Efficient Ethernet (EEE) mode is compliant with the IEEE 802.3az-2010 standard. It is primarily targeted to save power in the Ethernet port when there is no traffic on the line. In this mode, the host indicates to the far-end that it does not have any packets to transmit in the near future and puts the transmitter port (MAC controller, PCS and PHY layers) in low-power mode. Similarly, the receiver port can also be put in low-power mode when the far-end host indicates that it does not have any traffic to transfer. This allows significant saving of power in the Ethernet port (mainly in the PHY) with intermittent and bursty traffic profile. The triggering of entry and exit out of the EEE mode is controlled by the MAC and is supported within the peripheral.

Simultaneous operation of the EEE mode along with any or both the other power saving modes is also supported.

Description of magic packet mode

This section describes how to save power through magic packet detection.

**Note:** The magic packet feature is based on the magic packet technology white paper from Advanced Micro Device (AMD).

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the magic-packet-based power saving mode, the reception of a valid magic packet by the MAC receiver triggers an exit from low-power mode. The MAC enters power saving mode when PWRDWN bit of PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the magic-packet-based power saving mode is enabled by setting the MGPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The magic packet contains a unique pattern at any offset after the Destination address, Source address, and Length/Type fields. In addition to the unique pattern matching, the MAC receiver also checks for the following, to detect the received packet as a valid magic packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
- The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

**Magic packet data format**

The content of the unique pattern in magic packets is described as follows:

- Six bytes of all-ones (0xFF FF FF FF FF FF) called synchronization stream. There can be more than six bytes of 0xFF, but only the last six are considered.
- The synchronization stream is immediately followed by 16 repetitions of the Destination address field of the packet (MAC Address 0 high register (ETH_MACA0HR) and the MAC Address 0 low register (ETH_MACA0LR)) or multicast/broadcast address.
- No break or interruption between synchronization stream and first repetition of Destination address field or within its 16 repetitions.

If the MAC address of a node is 0x00 11 22 33 44 55, the MAC scans for the following data sequence:

```
Destination Address Source Address Length/Type .................. FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
...CRC
```

**Description of remote wakeup packet mode**

This section describes the power saving mode based on remote wakeup packet.

*Note:* The remote wakeup packet feature implementation is based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit in Operating mode configuration register (ETH_MACCR) and PWE bit in Watchdog timeout register (ETH_MACWTR).

In the remote-wakeup-magic-packet-based power saving mode, the reception of expected remote wakeup packet by the MAC receiver triggers the exit from low-power mode. The MAC enters power saving mode when PWRDWN bit in PMT control status register (ETH_MACPCSR) is programmed to 1. Exit from the remote-wakeup-magic-packet-based power saving mode is enabled by programming RWKPKTEN bit of PMT control status register (ETH_MACPCSR) to 1.

The MAC implements a filter lookup table (programmed through Remote wakeup packet filter register (ETH_MACRWPFR) in which CRC, offset, and byte mask of the pattern embedded in remote wakeup packet and the filter operation commands are programmed.

The pattern embedded in the remote wakeup packet is located at any offset after the Destination address and Source address fields. In addition to the CRC match for the pattern, the MAC receiver also checks the following, to detect the received packet as a valid remote wakeup packet:

- The packet must be addressed to it (Destination Address of the received packet should perfect match the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register (ETH_MACA0LR)) or with multicast/broadcast address.
- The packet must not have any length error, FCS error, dribble bit error, GMII error, and collision.
The packet must not be runt (length including Ethernet header and FCS is at least 64 bytes).

When a valid remote wakeup packet is received, the MAC receiver sets the RWKPRCVD bit in PMT control status register (ETH_MACPCSR) and triggers the interrupt on pmt_intr_o output port. The PMTIS bit in Interrupt status register (ETH_MACISR) is set when power-gating is not enabled in low-power mode. An interrupt is triggered to the application on the sbd_intr_o output port when interrupt is enabled (PMTIE bit in Interrupt enable register (ETH_MACIER) is set) and CSR clock is not gated off in low-power mode.

Remote wakeup packet filters

When the remote-wakeup-based power saving mode is enabled, four remote wakeup filters can be selected. The structure of the remote wakeup filters is shown in Table 574: Remote wakeup packet filter register.

Table 575. Description of the remote wakeup filter fields

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
</table>
| Filter i Byte mask| The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 or 3) to determine whether or not a packet is a wakeup packet.  
    − The MSB (31st bit) must be zero.  
    − Bit [30:0] is the byte mask.  
    − If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.                                                                                                                                                                                                                           |
| Filter i Command  | The 4-bit filter i command controls the filter i operation.  
    − Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.  
    − Bit 2 (Inverse mode), when set, reverses the logic of the CRC16 Hash function signal, to reject a packet with matching CRC_16 value.  
    − Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wakeup packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".  
    − Bit 1 (And_Previous) implements the Boolean logic(1). When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.  
    − Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.                                                                                                                                                                                                                                     |
| Filter i Offset   | This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.  
    − This 8-bit pattern-offset is the offset for the filter i first byte to be examined.  
    − The minimum allowed offset is 12, which refers to the 13th byte of the packet.  
    − The offset value 0 refers to the first byte of the packet.                                                                                                                                                                                                                                                                                       |
| Filter i CRC-16   | This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wakeup filter register block.  
    − The 16-bit CRC calculation uses the following polynomial:  
    \[ G(x) = x^{16} + x^{15} + x^2 + 1 \]  
    Each mask, used in the Hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:  
    − 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.  
    − 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.                                                                                                                                                                      |

1. The And_Previous bit setting is applicable within a set of four filters. Setting And_Previous bit of a filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of four filters has no effect. For example, setting And_Previous bit of Filter 0 has no effect.  
   If And_Previous bit is set for a given filter to form an AND chained filter, the AND chain breaks when it finds a disabled filter. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting Filter 2 And_Previous bit has no effect, only Filter 1 result ORed with Filter 3 result is considered.  
   If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, then a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address types.
The remote wakeup filter registers are implemented as eight indirect access registers (wkuppktfilter_reg#i) for four remote wakeup filters, and accessed by the application through Remote wakeup packet filter register (ETH_MACRWKPFR). The entire set of wkuppktfilter_reg registers must be written to program the remote wakeup filters. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in Remote wakeup packet filter register (ETH_MACRWKPFR) for wkuppktfilter_reg0 to wkuppktfilter_reg3, respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of PMT control status register (ETH_MACPCSR).

**Note:** If the Remote wakeup packet filter register (ETH_MACRWKPFR) is accessed in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when the CPU accesses Lane 3.

When Remote wakeup packet filter register (ETH_MACRWKPFR) is written, the content is transferred from CSR clock domain to PHY receive clock domain after the write operation. There should not be any further write to the Remote wakeup packet filter register (ETH_MACRWKPFR) until the first write is updated in PHY receive clock domain. Otherwise, the second write operation does not get updated to the PHY receive clock domain. Therefore, the delay between two write operations to the Remote wakeup packet filter register (ETH_MACRWKPFR) should be at least 4 cycles of the PHY receive clock.

### PMT interrupt

The PMT interrupt signal is asserted when a valid remote wakeup packet is received. Table 576 lists the remote wakeup scenarios in which PMT interrupt is generated.

1. In all other combinations, the Remote Wakeup packet is not detected and PMT interrupt is not generated.

In addition to sbd_intr_o signal, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the power-down mode. It is ORed with lpi_intr_o signal (see Section : LPI interrupt) and tied to the EXTI peripheral (line 86).

As the pmt_intr_o signal is generated in the PHY Rx clock domain, it is not cleared immediately when the PMT control status register (ETH_MACPCSR) is read. This is
because the resultant clear signal has to cross to the PHY Rx clock domain, and then clear
the interrupt source. This delay is at least 4 clock cycles of Rx clock and can be significant
when the peripheral is operating in the 10 Mbps mode. When the application clears the
PWRDWN bit in Remote wakeup packet filter register (ETH_MACRWKPFR), the MAC
comes out of the power-down mode, but this event does not generate the PMT interrupt.

Power-down sequence

The software must perform the following tasks to initiate the power-down sequence:

- Disable the Transmit DMA (if applicable) by clearing the ST bit of the Channel transmit
  control register (ETH_DMACTXCR).
- Wait for any previous frame transmissions to complete. You can check this by reading
  TFCSTS[1:0] and TPESTS bits in Debug register (ETH_MACDR) and TXQSTS bit in
  Tx queue debug Register (ETH_MTLTXQDR) of all MTL Tx Queues.
- Disable the MAC transmitter and MAC receiver by clearing TE and RE bits in Operating
  mode configuration register (ETH_MACCR).
- Wait till the Receive DMA empties all frames from the Rx FIFO. You can check this by
  reading PRXQ[13:0] in Rx queue debug register (ETH_MTLRXQDR) of all Rx Queues.
  If these bits are zero, it indicates that the Rx FIFO is empty.
- Configure the magic packet (MGKPKTEN) and/or remote wake-up (RWKPKTEN)
  detection in the PMT control status register (ETH_MACPCSR).
- Set bit 31 (ARPEN) in the Operating mode configuration register (ETH_MACCR).
- Enable the MAC Receiver by setting RE bit and then set PWRDWN bit in the PMT
  control status register (ETH_MACPCSR) to initiate the power-down sequence in MAC.

Note: If the feature is enabled and the MAC Transmitter is in the LPI mode when it is put into the
power-down mode, then the MII interface gets clamped to assert the LPI pattern. If the MAC
Transmitter is not in the LPI mode when it is put into the power-down mode, the GMII or MII
interface gets clamped to all-zero.

Power-up sequence

The MAC wakes up on receiving the magic packet or remote wake-up frame. The power-up
sequence is as follows:

- The MAC asserts pmt_intr_o. When only clock-gating is employed in low-power mode,
  the pmt_intr_o signal can be used to start the clocks that were gated-off after entering
  low-power mode.
- The software performs the following tasks:
  - De-assert the pmt_intr_o by reading the PMT control status register
    (ETH_MACPCSR).
  - Perform a write operation (with reset values) to the PMT control status register
    (ETH_MACPCSR) and the Remote wakeup packet filter register
    (ETH_MACRWKPFR) so that the corresponding values in the always-on block
    gets synchronized. Otherwise, the values of these registers are different.
  - Perform write operations to the Operating mode configuration register
    (ETH_MACCR), MAC Address 0 high register (ETH_MACA0HR) and MAC
    Address 0 low register (ETH_MACA0LR) to synchronize the values in the CSR
    module and the respective bits in the always-on block. Otherwise, the MAC
    receiver is on even though the Receive Enable bit is set to 0.
After completing these steps, the software must initialize all registers, enable the transmitter, and program the DMA (in DMA configurations) to resume the normal operation.

63.7.2 Energy Efficient Ethernet (EEE)

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The peripheral supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows saving power by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Transmit path functions

The transmit path functions include tasks that the MAC must perform to make the PHY enter the LPI state.

In the transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER LST[9:0] bitfield of LPI timers control register (ETH_MACLTCR). The PHY Link Status PLS bit of the LPI control and status register (ETH_MACLCSR) indicates the link status of the PHY.

Note: The EEE feature is not supported when the MAC is configured to use the RMII.

According to the standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps)
4. Updates the status (TLPIEN bit of LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
To bring the PHY out of the LPI state, that is when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER:
   - The MAC cannot start the transmission until the wakeup time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the LPI timers control register (ETH_MACLTCR).
3. Updates the LPI exit status (TLPIEX bit of the LPI control and status register (ETH_MACLCSR)) and generates an interrupt.

Figure 834 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

**Note:** The MAC does not stop the TX_CLK clock. The application can stop this clock (as shown in Figure 834) if the PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after nine Tx Clock Cycles, one Pulse Synchronizer delay, and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal depends on the LPITCSE bit of the LPI control and status register (ETH_MACLCSR) and can be done automatically as shown on Figure 835.

If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern and so the Tx Clock cannot be gated.

If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.

If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

**Figure 834. LPI transitions (Transmit, 100 Mbds)**
Automated entry/exit from LPI mode in transmit path

The MAC transmitter can be programmed to enter and exit LPI Idle mode automatically based on whether it is Idle for a specific period of time or has a packet to transfer. These modes are enabled and controlled by the *LPI control and status register (ETH_MACLCSR)*.

When LPITXA and LPIEN of *LPI control and status register (ETH_MACLCSR)* are set, the MAC transmitter enters LPI Idle state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI Idle state and clears the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when LPITE is also set, the MAC transmitter enters LPI Idle state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in *LPI entry timer register (ETH_MACLETR)*. In this mode also, the MAC transmitter exits the LPI Idle state as soon as any of the functions becomes non-idle. However, the LPIEN bit is not cleared but remains active so that reentry to LPI Idle state is possible without any software intervention when the MAC becomes idle again.

When both LPITE and LPITXA bits are cleared, the application can directly control the entry and exit of LPI Idle state by programming the LPIEN bit.

Receive path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[3:0] to 0x1 (for 100 Mbps).
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the *LPI control and status register (ETH_MACLCSR)* and immediately generates an interrupt.
Note: The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.

If the duration between the end of the current Rx LPI pattern and the start of the next Rx LPI pattern is very short (that is, less than two Rx clock cycles), then the MAC exits and enters again the Rx LPI mode. The MAC does not trigger the Rx LPI Exit and Entry interrupts.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the LPI control and status register (ETH_MACLCSR) and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 836 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

![Figure 836. LPI transitions (receive, 100 Mbps)](image)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in Figure 836.

If the MAC is in LPI mode and the application issues a soft reset or hard reset, the MAC receiver exits from LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver enters again the LPI state.

If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.

When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.
LPI timers
The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

The following LPI timers are loaded with the respective values from the LPI timers control register (ETH_MACLTCR) and LPI entry timer register (ETH_MACLETR):

- **LPI LS TIMER**
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in the LST[9:0] bitfield in the LPI timers control register (ETH_MACLTCR). The LPI LS TIMER is 10-bit wide. The software can program up to 1023 milliseconds.

- **LPI TW TIMER**
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[15:0] of LPI timers control register (ETH_MACLTCR). The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.
  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 micro seconds.

- **LPI AUTO ENTRY TIMER**
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in LPI control and status register (ETH_MACLCSR) is set.

LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt sbd_inr_o is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the LPI control and status register (ETH_MACLCSR).

When the MAC exits the Rx LPI state, then in addition to the sbd_inr_o, the sideband signal lpi_inr_o (synchronous to Rx clock) is asserted. The lpi_inr_o signal can be used to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_inr_o signal, synchronous to the Rx clock domain, is provided so that the application clock can be stopped by software when the MAC is in the LPI state. It is ORed with pmt_inr_o signal (see Section : PMT interrupt) and tied to the EXTI peripheral (line 86).

The lpi_inr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the LPI control and status register (ETH_MACLCSR) is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the peripheral is operating in the 10 Mbps mode.
Programming guidelines for Energy Efficient Ethernet

For detailed guidelines on the programming guidelines, see Section 63.9.11: Programming guidelines for Energy Efficient Ethernet (EEE).
63.8 Ethernet interrupts

The Ethernet peripheral generates a single interrupt signal (eth_sbd_intr_it). This signal can be raised as a result of various events. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the *Interrupt status register (ETH_DMAISR)* register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- ETH_DMACSR: Channel Status (see *Channel status register (ETH_DMACSR)*)
- ETH_MTLISR: Interrupt Status (see *Interrupt status Register (ETH_MTLISR)*)
- ETH_MACISR: Interrupt Status (see *Interrupt status register (ETH_MACISR)*)

63.8.1 DMA interrupts

**Interrupt registers description**

The ETH_DMACSR: Channel Status register (see *Channel status register (ETH_DMACSR)*) captures all the interrupt events of that TxDMA and RxDMA channel. The ETH_DMACIER: Channel Interrupt Enable register (see *Channel interrupt enable register (ETH_DMACIER)*) contains the corresponding enable bits for each of the interrupt event.

There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of ETH_DMACSR register respectively. The normal group is for events that happen during the normal transfer of packets (TI: transmit interrupt, RI: receive interrupt, TBU: Transmit buffer unavailable) while the abnormal interrupt events are for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. An interrupt is generated only once for multiple events. The driver must scan the *Interrupt status register (ETH_DMAISR)* for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of *Interrupt status register (ETH_DMAISR)* are cleared.

**Periodic scheduling of Transmit and Receive Interrupt**

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet peripheral gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31] in *Table 580: TDES2 normal descriptor (read format)*) once for every “required” number of packets to be transmitted.
2. Similarly, set the IOC (RDES3[30] in *Table 593: RDES3 normal descriptor (read format)*) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.
In addition to above, an interrupt timer (ETH_DMACRXIWTR: Channel Rx Interrupt Watchdog Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30] in Table 593: RDES3 normal descriptor (read format)) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

**Channel transfer complete interrupt**

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in the Channel Status register (Channel status register (ETH_DMACSR)). The TI bit is set whenever the Tx DMA channel closes the descriptor in which the IOC bit is set (Interrupt On Completion - TDES2[31]). Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with the LD bit set and, in any of the descriptors used for transferring that packet, IOC bit is set (Interrupt Enable on completion - RDES3[30]).

The interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in the channel interrupt enable register (Channel interrupt enable register (ETH_DMACIER)).

The behavior of the RI/TI interrupts changes depending on the settings of INTM field (bits[17:16]) in the ETH_DMAMR register (DMA mode register (ETH_DMAMR)). Table 577 explains the behavior of the Transfer Complete interrupt.

**Table 577. Transfer complete interrupt behavior**

<table>
<thead>
<tr>
<th>Interrupt Mode</th>
<th>Behavior of TI/RI and interrupt signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTM=0</td>
<td>The TI/RI status signals are set whenever the Transfer complete event is detected. These bits are cleared whenever the software driver writes 1 to these bits. The interrupt signal is asserted whenever the corresponding interrupts are also enabled in ETH_DMACIER register.</td>
</tr>
<tr>
<td>INTM=1</td>
<td>The TI/RI is set as explained above. However, the interrupt is not asserted for any RI/TI event.</td>
</tr>
<tr>
<td>INTM=2</td>
<td>The RI/TI status bits are set whenever the Transfer Complete event is detected and are reset whenever software driver clears them by writing 1. However, if another Transfer complete event is detected before it is cleared (serviced) by the software, then these status bits are automatically set again. However, the interrupt is not generated based on TI/RI.</td>
</tr>
</tbody>
</table>
63.8.2 MTL interrupts

MTL interrupt events are combined with the events in the DMA to generate the interrupt signal.

The register *Interrupt status Register (ETH_MTLISR)* report the queue number responsible for the event. ETH_MTLQICS: Queue Interrupt Control Status shall be read for event description.

The MTL interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the *Interrupt status Register (ETH_MTLISR)* register.

MTL interrupt signal is driven by one of these events:
- Receive Queue Overflow Interrupt
- Transmit Queue Underflow

63.8.3 MAC Interrupts

MAC interrupt events are combined with the events in the DMA to generate the interrupt signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The *Interrupt status register (ETH_MACISR)* describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the *Interrupt status register (ETH_MACISR)*.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

MAC interrupt signal is driven by one of these events:
- Receive Status Interrupt
- Transmit Status Interrupt
- Timestamp Interrupt Status
- MMC Interrupt Status
  - MMC Receive Checksum Offload Interrupt Status
  - MMC Transmit Interrupt Status
  - MMC Receive Interrupt Status
- LPI Interrupt Status
- PMT Interrupt Status
- PHY Interrupt

*Note:* Two sidebands signals are generated together with LPI and PMT interrupts: lpi_intr_o and pmt_intr_o. They are used for wakeup event detection at EXTI level.
63.9 Ethernet programming model

This chapter provides the instructions for initializing the DMA or MAC registers in the proper sequence. It contains the following sections:

- DMA initialization (see Section 63.9.1)
- MTL initialization (see Section 63.9.2)
- MAC initialization (see Section 63.9.3)
- Performing Normal Receive and Transmit Operation (see Section 63.9.4)
- Stopping and Starting Transmission (see Section 63.9.5)
- Programming Guidelines for MII Link State Transitions (see Section 63.9.8)
- Programming Guidelines for IEEE 1588 Timestamping (see Section 63.9.9)
- Programming Guidelines for Energy Efficient Ethernet (see Section 63.9.11)
- Programming Guidelines for flexible pulse-per-second (PPS) output (see Section 63.9.12)
- Programming Guidelines for VLAN filtering on Receive (see Section 63.9.14)
- Programming Guidelines for TSO (see Section 63.9.13)

63.9.1 DMA initialization

Complete the following steps to initialize the DMA:

1. Provide a software reset to reset all MAC internal registers and logic (bit 0 of DMA mode register (ETH_DMAMR)).
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register (ETH_DMAMR), which is cleared when the reset operation is completed).
3. Program the following fields to initialize the System bus mode register (ETH_DMASBMR):
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface.
4. Create a transmit and a receive descriptor list. In addition, ensure that the receive descriptors are owned by the DMA (set bit 31 of TDES3/RDES3 descriptor). For more information on descriptors, refer to Section 63.10: Descriptors.
5. Program ETH_DMACTXRLR and ETH_DMACRXRLR registers (see Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR)). The programmed ring length must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor (Channel Tx descriptor list address register (ETH_DMACTXDLAR), Channel Rx descriptor list address register (ETH_DMACRXDLAR)). In addition, program the transmit and receive tail pointer registers that inform the DMA about the available descriptors (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) and Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).
7. Program ETH_DMACCR, ETH_DMACTXCR and ETH_DMACRXCR registers (see Channel control register (ETH_DMACCR), Channel transmit control register (ETH_DMACTXCR) and Channel receive control register (ETH_DMACRXCR)) to

Note: Descriptor address from start to end of the ring should not cross the 4GB boundary.
configure the parameters such as the maximum burst-length (PBL) initiated by the DMA, descriptor skip lengths, OSP for TxDMA, RBSZ[13:0] for RxDMA, and so on.

8. Enable the interrupts by programming the ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)).

9. Start the Receive and Transmit DMAs by setting SR (bit 0) of Channel receive control register (ETH_DMACRXCR) and ST (bit 0) of the ETH_DMACTXCR (see Channel transmit control register (ETH_DMACTXCR)).

### 63.9.2 MTL initialization

Complete the following steps to initialize the MTL registers:

1. Program the following fields to initialize the operating mode in Tx queue operating mode Register (ETH_MTLTXQOMR).
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) if the Threshold mode is used.
   b) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue 0.
   c) Transmit Queue Size (TQS).

2. Program the following fields to initialize the operating mode in the ETH_MTLRXQOMR register (see Rx queue operating mode register (ETH_MTLRXQOMR)):
   a) Receive Store and Forward (RSF) or RTC if Threshold mode is used.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP).
   d) Receive Queue Size (RQS).

### 63.9.3 MAC initialization

The MAC configuration registers establish the operating mode of the MAC. If possible, these registers must be initialized before initializing the DMA. The following MAC Initialization operations can also be performed after DMA initialization. If the MAC initialization is complete before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC Address x low register (ETH_MACAxLR), MAC Address 0 high register (ETH_MACA0HR) and MAC Address x high register (ETH_MACAxHR).

2. Program the following fields to set the appropriate filters for the incoming frames in the Packet filtering control register (ETH_MACPFR):
   a) Receive All.
   b) Promiscuous mode.
   c) Hash or Perfect Filter.
   d) Unicast, multicast, broadcast, and control frames filter settings.

3. Program the following fields for proper flow control in the Tx Queue flow control register (ETH_MACQTXFCR):
   a) Pause time and other Pause frame control bits.
   b) Transmit Flow control bits.
   c) Flow Control Busy.
4. Program the Interrupt enable register (ETH_MACIER) as required, if it is applicable for your configuration.

5. Program the appropriate fields in the Operating mode configuration register (ETH_MACCR) register. For example, Inter-packet gap while transmission and jabber disable.

6. Set bit 0 and 1 in Operating mode configuration register (ETH_MACCR) register to start the MAC transmitter and receiver.

To support Jumbo Transmit/Receive packets, follow these steps:
- In the Operating mode configuration register (ETH_MACCR)
  a) Set JE bit to 1.
  b) Set JD and WD bits to 0 to avoid giant packet error reporting.
  c) Set GPSLCE bit to 1
  d) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to a value > 9026

To support Transmit/Receive packets, up to 16K, follow these steps:
- In the Operating mode configuration register (ETH_MACCR)
  a) Set JD and WD bits to 1 to avoid giant packet error reporting.
  b) Set GPSLCE bit to 1.
  c) Set GPSL bitfield of the Extended operating mode configuration register (ETH_MACECR) to 16383.

63.9.4 Performing normal receive and transmit operation

For normal operation, complete the following steps:
1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptor by reading the status of the descriptor owned by the Host (either transmit or receive).

2. Set the descriptors to appropriate values. Make sure that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.

3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into Suspend state. The transmission or reception can be resumed by freeing the descriptors and writing the ETH_DMACTXDTPR (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR)) and ETH_DMACRXDTPR (see Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).

4. In debug mode, the values of the current host transmitter or receiver descriptor address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).

5. In debug mode, the values of the current host transmit buffer address pointer and receive buffer address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).
63.9.5 Stopping and starting transmission

Complete the following steps to pause the transmission for some time:

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)).
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug Register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01 and TXQSTS = 0).
3. Disable the MAC transmitter and MAC receiver by clearing RE and TE bits of the Operating mode configuration register (ETH_MACCR) Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of Tx queue debug Register (ETH_MTLTXQDR), PRXQ=0 and RXQSTS[1:0] = 00).
5. Make sure that both Tx queue and Rx queue are empty (TXQSTS is 0 in Tx queue debug Register (ETH_MTLTXQDR) and RXQSTS[1:0] is set to 00).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active. Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

63.9.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in Suspend state, as explained below:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to Suspend state due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames are lost because of an RxFIFO overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into Stop state.

63.9.7 Programming guidelines for switching the AHB clock frequency

To dynamically change the AHB clock frequency (without applying soft reset or hard reset), follow these steps:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. When the frame transmissions is complete, the Tx FIFO becomes empty and the Tx DMA enters Stop state. The Tx FIFO status is given in the Tx queue debug
Register (ETH_MTLTXQDR) and the status of DMA is given in Debug status register (ETH_DMADSR).

2. Disable the MAC transmitter and the MAC receiver by clearing the appropriate bits in Operating mode configuration register (ETH_MACCR).

3. Disable the Receive DMA (if applicable) after making sure that the data in the Rx FIFO is transferred to the system memory. The Rx FIFO empty status is given in Rx queue debug register (ETH_MTLRXQDR).

4. Ensure that the application does not perform any register read or write operation.

5. Change the frequency of the AHB clock.

6. Enable the MAC Transmitter or the MAC Receiver and the Transmit or Receive DMA. These steps ensure that no valid data is present in the Tx FIFO or Rx FIFO at the time of clock frequency switching and prevent any data corruption.

63.9.8 Programming guidelines for MII link state transitions

Transmit and Receive clocks are running when the link is down

Complete the following steps when the link is down while the Transmit and Receive clocks are running:

1. Disable the Transmit DMA (if applicable) by clearing bit 0 (ST) of Channel control register (ETH_DMACCR).

2. Disable the MAC receiver by clearing RE bit of Operating mode configuration register (ETH_MACCR).

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug Register (ETH_MTLTXQDR) (TRCSTS[1:0] is not 01).

   or

   Flush the Tx FIFO for faster empty operation.

4. Disable the MAC transmitter by clearing TE bit of the Operating mode configuration register (ETH_MACCR) Register.

5. Make sure that both Tx and Rx queues are empty (TXQSTS is set to 0 in Tx queue debug Register (ETH_MTLTXQDR) and RXQSTS[1:0] to 00 in Rx queue debug register (ETH_MTLRXQDR)).

6. After the link is up, read the PHY registers to identify the latest configuration and program the MAC registers accordingly.

7. Restart the operation by starting the Tx DMA. Then enable the MAC Transmitter and Receiver.

   The Rx DMA does not need to be enabled: since the Receiver is disabled, there are no data in the Rx FIFO.
Transmit and Receive clocks are stopped when the link is down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing RE and TE bits in the Operating mode configuration register (ETH_MACCR). This will not take immediate effect as the clocks are absent.

2. Wait till the link is up and the clocks are restored.

3. Wait until the transfer of any partial frame is complete if any was ongoing when the Transmit/Receive clock is stopped. This can be checked by reading the Debug register (ETH_MACDR) (all bits should be set to 0). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.

4. Read the PHY registers to identify the latest operating mode and program the MAC registers accordingly.

5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

63.9.9 Programming guidelines for IEEE 1588 timestamping

Initializing the System time generation

The timestamp feature can be enabled by setting bit 0 of the Timestamp control Register (ETH_MACTSCR). However, it is essential that the timestamp counter is initialized after this bit is set. Complete the following steps to perform the peripheral initialization:

1. Mask the Timestamp Trigger interrupt by clearing bit 12 of Interrupt enable register (ETH_MACIER).

2. Set bit 0 of Timestamp control Register (ETH_MACTSCR) to enable timestamping.

3. Program Subsecond increment register (ETH_MACSSIR) based on the PTP clock frequency.

4. If you use the Fine Correction method, program Timestamp addend register (ETH_MACTSAR) and set bit 5 of Timestamp control Register (ETH_MACTSCR).

5. Poll the Timestamp control Register (ETH_MACTSCR) until bit 5 is cleared.

6. Program bit 1 of Timestamp control Register (ETH_MACTSCR) to select the Fine Update method (if required).

7. Program System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR) with the appropriate time value.

8. Set bit 2 in Timestamp control Register (ETH_MACTSCR).

The timestamp counter starts as soon as it is initialized with the value written in the timestamp update registers. If one-step timestamping is required:

a) Enable one-step timestamping by programming bit 27 of the TDES3 Context Descriptor.

b) Program Timestamp Ingress asymmetric correction register (ETH_MACTSIACR) to update the correction field in PDelay_Req PTP messages.

9. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing bit 0 of Timestamp control Register (ETH_MACTSCR), repeat all these steps to restart the timestamp operation.
System time correction

To synchronize or update the system time in one shot (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR)).

2. Set bit 3 (TSUPDT) of the Timestamp control Register (ETH_MACTSCR).

   The value in the timestamp update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm described in Section : System time register module, calculate at which rate you intend to increment or decrement the system time.

2. Update the Timestamp addend register (ETH_MACTSAR) with the new value and set bit 5 of the Timestamp control Register (ETH_MACTSCR) Register.

3. Wait for the time during which you want the new value of the Addend register to be active. This can be done by enabling the Timestamp Trigger interrupt after the system time reaches the target value.

4. Program the required target time in PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).

5. Enable the Timestamp interrupt in bit 12 of Interrupt enable register (ETH_MACIER).

6. Set bit 4 in Register Timestamp control Register (ETH_MACTSCR).

7. When this trigger generates an interrupt, read Interrupt status register (ETH_MACISR).

8. Reprogram Timestamp addend register (ETH_MACTSAR) with the old value and set bit 5 again.

63.9.10 Programming guidelines for PTP offload feature

Programming guidelines to enable automatic periodic generation of PTP sync messages

Follow these steps to enable automatic periodic generation of PTP sync messages:

1. Program SNAPTYPSEL, TSMSTRENA, and TSEVTENENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively, to configure the node as Ordinary or Boundary Master (1, 1, and 1 for Transparent Master).

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Sync message.

3. Program the ASYNCECN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Sync messages.

4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP
Source port identity 2 register (ETH_MACSPI2R) to send in egress PTP Sync message.

5. Program the LSI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Sync messages.
   For example, a value of 1 corresponds to $2^1$ which translates to PTP Sync message every 2 seconds, and a value of 0xFF (twos complement of -1) corresponds to $2^{-1}$ which translates to PTP Sync message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable periodic generation of PTP Pdelay_Req messages

Follow these steps to enable automatic periodic generation of PTP Pdelay_Req messages

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively to configure the node as Transparent Slave (1, 1, and 1 for Transparent Master OR 3, X, and X for Peer-to-Peer Transparent).

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to send in egress PTP Pdelay_Req message.

3. Program the APDREQEN bit of PTP Offload control register (ETH_MACPOCR) to enable periodic generation of PTP Pdelay_Req messages.

4. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to send in egress PTP Pdelay_Req message.

5. Program the LMPDRI field of Log message interval register (ETH_MACLMIR) to program the periodicity of the PTP Pdelay_Req messages.
   For example, a value of 1 corresponds to $2^1$ which translates to PTP Pdelay_Req message every 2 seconds, and a value of 0xFF (twos complement of -1) corresponds to $2^{-1}$ which translates to PTP Pdelay_Req message every 0.536 seconds.

6. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

7. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Master mode

Follow these steps to enable the generation of PTP response messages for Ordinary or Boundary Master mode (Periodic PTP Sync messages generated and PTP Delay_Resp message generated in response to PTP Delay_Req message):
1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 1, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req message and send in egress PTP Delay_Resp message.
4. Program the DRSYNCR and LSI fields in Log message interval register (ETH_MACLMIR). The sum of both fields is updated in logMinDelayReqInterval field of PTP Delay_Resp message.

Programming guidelines to enable the generation of PTP response messages for Ordinary or Boundary Slave mode

Follow these steps to enable generation of PTP response messages for Ordinary or Boundary Slave mode (PTP Delay_Req message generated in response to PTP Sync message):

1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 0, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync message and send in egress PTP Delay_Req message.
4. Program the DRSYNCR field in Log message interval register (ETH_MACLMIR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Slave mode

Follow these steps to enable generation of PTP response messages for Transparent Slave mode (PTP Delay_Req message generated in response to PTP Sync message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated)

1. Program SNAPTYPESEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 0, and 1 respectively.
2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Sync or Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.
3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Sync or
Pdelay_Req message and send in egress PTP Delay_Req or Pdelay_Resp or Pdelay_Req message.

4. Program the DRSYNCR and LMPDRI fields in Log message interval register (ETH_MACLMIR) to indicate one PTP Delay_Req message is generated in response to how many received PTP Sync messages and periodicity of the PTP Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Transparent Master mode

Follow these steps to enable generation of PTP response messages for Transparent Master mode (PTP Delay_Resp message generated in response to PTP Delay_Req message, PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req or Sync messages generated):

1. Program SNAPTYPSEL, TSMSTRENA and TSEVNTENA fields of Timestamp control Register (ETH_MACTSCR) to 1, 1, and 1 respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain number to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Delay_Req or Pdelay_Req message and send in egress PTP Delay_Resp or Pdelay_Resp or Pdelay_Req or Sync message.

4. Program the DRSYNCR, LSI and LMPDRI fields in Log message interval register (ETH_MACLMIR), the sum of DRSYNCR and LSI is updated in logMinDelayReqInterval field of PTP Delay_Resp message and periodicity of the PTP Sync or Pdelay_Req messages.

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt.

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Sync, Pdelay_Req and Pdelay_Resp messages.

Programming guidelines to enable the generation of PTP response messages for Peer-to-Peer Transparent mode

Follow these steps to enable generation of PTP response messages for Peer-to-Peer Transparent mode (PTP Pdelay_Resp message generated in response to PTP Pdelay_Req message and Periodic PTP Pdelay_Req messages generated):
1. Program the SNAPTyPSEL, TSMSTREN and TSEVNTEN fields of Timestamp control Register (ETH_MACTSCR) to 3, X, and X respectively.

2. Program the PTOEN bit and DN field of PTP Offload control register (ETH_MACPOCR) to enable PTP Offload feature and domain Number to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

3. Program the 80-bit Source Port Identity in PTP Source Port Identity 0 Register (ETH_MACSPI0R), PTP Source port identity 1 register (ETH_MACSPI1R) and PTP Source port identity 2 register (ETH_MACSPI2R) to match with ingress PTP Pdelay_Req message and send in egress PTP Pdelay_Resp message.

4. Program the LMPDRI field in Log message interval register (ETH_MACLMIR) to indicate periodicity of the PTP Pdelay_Req messages

5. Program the TSIE bit of Interrupt enable register (ETH_MACIER) to enable generation of Timestamp interrupt

6. Wait for sbd_intr_o interrupt generated by setting TXTSSIS bit in Timestamp status register (ETH_MACTSSR). It indicates that the timestamp for PTP Sync message is captured in Tx timestamp status seconds register (ETH_MACTXTSSSR) and Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) for egress PTP Pdelay_Req and Pdelay_Resp messages.

63.9.11 Programming guidelines for Energy Efficient Ethernet (EEE)

Entering and exiting Tx LPI mode

EEE enables the IEEE 802.3 Media Access Control (MAC) sublayer along with a family of physical layers to operate in the Low-power idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the LPI control and status register (ETH_MACLCSR) to indicate to the MAC to stop transmission and initiate the LPI protocol.

Complete the following steps during MAC initialization:

1. Read the PHY register through the MDIO interface and check if the remote end has the EEE capability. Then negotiate the timer values.

2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode or not).

3. Program bits 25 to 16 and bits 15 to 0 in LPI timers control register (ETH_MACLTCR).

4. Read the PHY link status by using the MDIO interface and update bit 17 of LPI control and status register (ETH_MACLCSR).

Update LPI control and status register (ETH_MACLCSR) accordingly. This update should be done whenever the link status in the PHY chip changes.

5. Program One-microsecond-tick counter register (ETH_MAC1USTCR) as per the frequency of the clock used for accessing the CSR slave port.

6. Program the LPIET bit in the LPI entry timer register (ETH_MACLETR) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bits 20 to 19) of **LPI control and status register (ETH_MACLCSR)** to enable LPI auto-entry and MAC auto-exit from LPI state.

8. Set bit 16 of **LPI control and status register (ETH_MACLCSR)** to put the MAC transmitter in LPI state.

   The MAC enters the LPI state when all scheduled packets are completed. It remains IDLE for the time indicated by LPIET bits. It sets the TLPIEN (bit 0) after entering LPI state.

9. When a packet transmission is scheduled (when the TxDMA exits IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter automatically exits LPI state. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. The MAC Transmitter enters again LPI state if it remains IDLE for LPIET time. It then sets the TLPIEN bit and the entry-exit cycle continues.

11. Reset LPIEN bit if the application needs to override the auto-entry/exit modes and directly exit the MAC Transmitter from LPI state.

**Note:** To make sure the MAC enters the LPI state only after the transmission of all the queued frames in the Tx FIFO is complete, set LPITXA bit in **LPI control and status register (ETH_MACLCSR)**.

To switch off the CSR clock or power to the rest of the system during the LPI state, wait for the TLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)** to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

**Gating Off the CSR Clock in the LPI mode**

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

**Gating off the CSR clock in the Rx LPI mode**

The following operations are performed when the MAC receives the LPI pattern from the PHY:

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status (RLPIEN interrupt of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.

After the sbd_intr_o interrupt is asserted and the MAC Tx is also in the LPI mode, the CSR clock can be gated off. If the MAC TX is not in LPI mode when the CSR clock is gated off, the events on the MAC transmitter do not get reported or updated in the CSR. To restore the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when **LPI control and status register (ETH_MACLCSR)** is read.

**Gating off the CSR clock in the Tx LPI mode**

The following operations are performed when bit 16 (LPIEN) of **LPI control and status register (ETH_MACLCSR)** is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of **LPI control and status register (ETH_MACLCSR)**) is set.

2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the **LPI control and status register (ETH_MACLCSR)**.
After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, the CSR clock can be gated off. If the MAC RX is not in LPI mode when the CSR clock is gated off, the events on the MAC receiver do not get reported or updated in the CSR. To restore the CSR clock, switch on the CSR clock when the MAC has exited TX LPI mode. After the CSR clock is resumed, reset bit 16 (LPIEN) of LPI control and status register (ETH_MACLCSR) to exit the MAC from LPI mode.

63.9.12 Programming guidelines for flexible pulse-per-second (PPS) output

Generating a single pulse on PPS

To generate a single pulse on PPS:
1. Program TRGTMODSEL[1:0] bit to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) as start time of PPS signal output.
2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).
3. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR) Register.
4. Program PPSCMD[3:0] of PPS control register (ETH_MACPPSCR) to 0001. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers.

Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time has elapsed. You can also program the behavior of the next pulse in advance. To program the next pulse:
1. Program the start time for the next pulse in the Target Time registers. This time should be higher than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in PPS width register (ETH_MACPPSWR).
3. Program PPSCMD[3:0] bits of PPS control register (ETH_MACPPSCR) to generate a single pulse after the previous pulse is deasserted. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in Target Time registers.
   If this command is given before the previous pulse becomes low, then the new command overwrites the previous command and the peripheral may generate only 1 extended pulse.

Generating a pulse train on PPS

To generate a pulse train on PPS:
1. Program TRGTMODSEL[1:0] bits to 11 or 10 (for interrupt) in PPS control register (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (PPS
target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) for start time of the PPS signal output.

2. Program the start time value in the Target Time registers (register PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)).

3. Program the interval value between the train of pulses on the PPS signal output in PPS interval register (ETH_MACPPSIR).

4. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR).

5. Program PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0010. This instructs the MAC to generate a train of pulses on the PPS signal output at the start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless it is stopped by issuing a ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in PPS target time nanoseconds register (ETH_MACPPSTTNR) is reset before programming the Target Time registers again.

7. Program the PPSCMD[3:0] bits in PPS control register (ETH_MACPPSCR) to 0100 to stop the train of pulses on PPS signal output after the programmed stop time specified at step 6 has elapsed.

The pulse train can be stopped at any time by programming 0101 in the PPSCMD[3:0] field.

Similarly, the Stop Pulse train command (given in Step 7) can be canceled by programming PPSCMD[3:0] bits to 0110 before the time (programmed at step 6) has elapsed.

The pulse train generation can be stopped by programming PPSCMD[3:0] to 0011 before the start time programmed at step 2) has elapsed.

**Generating an interrupt without affecting the PPS**

TRGTMODSEL[1:0] bits in PPS control register (ETH_MACPPSCR) enable you to program the Target Time registers (PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR)) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt event:

1. Program TRGTMODSEL[1:0] bits of PPS control register (ETH_MACPPSCR) to 00 (for interrupt). This instructs the MAC to use the Target Time registers for target time interrupt.

2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If TRGTMODSEL[1:0] bits are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

*Note:* The TSTRGTERR0 bit in Timestamp status register (ETH_MACTSSR) is set when the programmed target time is smaller (that is corresponds to a time in the past) compared to
the system time in the System time seconds register (ETH_MACSTSR) and System time nanoseconds register (ETH_MACSTNR).

An interrupt is generated (sbd_intr_o) if the TSIE bit in the Interrupt enable register (ETH_MACIER) is set.

Therefore, to avoid unwanted interrupt, the correct writing order is as follow:
1. PPS target time nanoseconds register (ETH_MACPPSTTNR).
2. PPS target time seconds register (ETH_MACPPSTTSR).
3. PPS interval register (ETH_MACPPSIR).
4. PPS width register (ETH_MACPPSWR).
5. PPSCTRL[3:0] and PPSCTRL[3:0] and PPSEN0 bitfields of PPS control register (ETH_MACPPSCR).

### 63.9.13 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.

Follow the steps below to program TSO:
1. Program TSE bit of the corresponding Channel transmit control register (ETH_DMACTXCR) to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a) Enable TSE of TDES3 (bit 18).
   b) Program the length of the unsegmented TCP/IP packet payload in bits 17 to 0 of TDES3, and the TCP header in bits 22 to 19 of TDES3.
   c) Program the maximum size of the segment in:
      – MSS[13:0] of Channel control register (ETH_DMACCR)
      – or MSS in the context descriptor
         If MSS[13:0] field is programmed in both Channel control register (ETH_DMACCR) and in the context descriptor, the latest software programmed sequence is considered.
3. The unsegmented TCP/IP packet header should be stored in Buffer 1 of the first descriptor. This buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

**Caution:** If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.
63.9.14 **Programming guidelines to perform VLAN filtering on the receive**

Follow the sequence below to perform VLAN filtering on the receiver:

1. Program **VLAN tag register (ETH_MACVTR)** for the following bit to select the filtering method:
   - ETV: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   - VTHM: VLAN Tag Hash Table Match Enable.
   - ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   - ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   - DOVLTC: Ignores VLAN Type for Tag Match
   - VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program **VL bit in VLAN tag register (ETH_MACVTR)** for the 12-bit or 16-bit VLAN tag.

3. If VLAN tag Hash filtering is enabled, program **VLAN Hash table register (ETH_MACVHTR)**:
   - When the ETV bit is reset, the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and used to index the content of the **VLAN Hash table register (ETH_MACVHTR)**.
   - When ETV bit is set, the upper 4 bits of the calculated CRC-32 of VLAN tag are used to index the content of **VLAN Hash table register (ETH_MACVHTR)**.

For example, when ETV bit is set, a hash value of 0b1000 selects bit 8 of the VLAN Hash table. When ETV bit is reset, a hash value of 0b1000 selects bit 7 of the VLAN Hash table.

63.10 **Descriptors**

63.10.1 **Descriptor overview**

In the Ethernet peripheral, the DMA transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory (SRAM). The following two types of descriptors are supported:

- **Normal descriptors**
  - The normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.

- **Context descriptors**
  - The context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

There is no limit to the number of descriptors that can be used for a single packet.
### 63.10.2 Descriptor structure

The Ethernet peripheral supports the ring structure for DMA descriptors.

In a ring structure, descriptors are separated by the 32-bit word number programmed in the DSL field of the Channel control register (ETH_DMACCR)). The application needs to program the total ring length, that is the total number of descriptors in ring span, in the following registers of a DMA channel:

- **Channel Tx descriptor ring length register (ETH_DMACTXRLR)**
- **Channel Rx descriptor ring length register (ETH_DMACRXRLR)**

The Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) or Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR) contains the pointer to the descriptor address (\(N\)). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (\(N - 1\)) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA enters the Suspend state when this condition occurs. The application must perform a write operation to the Descriptor tail pointer register and update the tail pointer so that the following condition is met:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```
The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 838: DMA descriptor ring.

Figure 838. DMA descriptor ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0.

For descriptors owned by the DMA, the OWN bit is set to 1.

At the beginning, if the application has only one descriptor, it sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA then processes the first descriptor and waits for the application to increment the tail pointer.
63.10.3 Transmit descriptor

The Ethernet peripheral DMA requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor features control fields which can be used to manage the MAC operation on per-transmit packet basis. The Transmit normal descriptor has the following two formats: Read format and Write-back format.

Transmit normal descriptor (read format)

Figure 839 shows the Read format for Transmit normal descriptor. Table 578 to Table 581 provide a detailed description of all Transmit normal descriptors (read format).

</tr>
</tbody>
</table>
This field controls the CRC and Pad Insertion for Tx packet. It is valid only when the first descriptor bit (TDES3[29]) is set. The values of bits[27:26] are the following:

- 00: CRC and Pad Insertion
- 01: CRC Insertion (Disable Pad Insertion)
- 10: Disable CRC Insertion
- 11: CRC Replacement

When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.

These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must appropriately set the CRC Pad Control bits when SA Insertion Control is enabled for the packet.

- 00: Do not include the source address
- 01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.
- 10: Replace the source address. For reliable transmission, the application must provide frames with source addresses.
- 11: Reserved

These bits are valid when the First Segment control bit (TDES3 [29]) is set.

If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. THL value must be equal to 2 for UDP header. This field is valid only for the first descriptor.

When this bit is set, the DMA performs the TCP/UDP segmentation for a packet. This bit is valid only if the FD bit is set.

Transmit normal descriptor (write-back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

*Figure 840* shows the write-back format for Transmit normal descriptors. *Table 582* to *Table 585* provide a detailed description of all Transmit Normal descriptors (Write-Back Format).

Table 585. TDES3 normal descriptor (write-back format)\(^{(1)}\) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 14  | JT   | Jabber Timeout  
This bit indicates that the MAC transmitter has experienced a jabber timeout. This bit is set only when the JD bit of the Operating mode configuration register (ETH_MACCR) is not set. |
| 13  | FF   | Packet Flushed  
This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU. |
| 12  | PCE  | Payload Checksum Error  
This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either caused by insufficient bytes, as indicated by the Payload Length field of the IP Header, or by the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when a Bus error is detected during packet transfer. |
| 11  | LoC  | Loss of Carrier  
This bit indicates that Loss of Carrier occurred during packet transmission (that is, the ETH_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the Half-duplex mode. |
| 10  | NC   | No Carrier  
This bit indicates that the carrier sense signal form the PHY was not asserted during transmission. |
| 9   | LC   | Late Collision  
This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode ). This bit is not valid if Underflow Error is set. |
| 8   | EC   | Excessive Collision  
This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after first collision and the transmission of the packet is aborted. |
| 7:4 | CC   | Collision Count  
This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set. |
| 3   | ED   | Excessive Deferral  
This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times if DC bit is set in the Operating mode configuration register (ETH_MACCR). |
Transmit context descriptor

The Transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, and VLAN Tag ID for VLAN insertion feature. Write-back is only done on a context descriptor to reset the OWN bit.

Note: The VLAN tag IDs and MSS values, which are provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.

When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 841 shows the format for Transmit context descriptors. Table 586 to Table 589 provide a detailed description of all Transmit context descriptors.

---

Table 585. TDES3 normal descriptor (write-back format) (1) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2   | UF   | Underflow Error  
|     |      | This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:  
|     |      | The DMA encountered an empty Transmit Buffer while transmitting the packet  
|     |      | The application filled the MTL Tx FIFO slower than the MAC transmit rate  
|     |      | The transmission process enters the Suspend state and sets the underflow bit corresponding to a queue in the ETH_MTLISR register. |
| 1   | DB   | Deferred Bit  
|     |      | This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the Half-duplex mode. |
| 0   | IHE  | IP Header Error  
|     |      | When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. |

1. This format is only applicable to the last descriptor of a packet.

### Context Descriptor Error

When this bit is set, it indicates that the context descriptor is incorrect. The DMA sets this bit during write-back while closing the context descriptor.

The Context Descriptor errors can be:

- Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet.
- All 1s.
- CD, LD, and FD bits set to 1.

**Note:** When a Context Descriptor error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA sets the TI bit in the Channel status register (ETH_DMACSR).

Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent. This error is categorized as an abnormal event; recovery is only by issuing a software reset (DMA stopping-reconfiguring-restarting recovery mechanism is not supported).

### Inner VLAN Tag Insert or Replace

When these bits are set, they request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes.

This bitfield has the following values:

00: Do not add the inner VLAN tag.
01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames.
10: Insert an inner VLAN tag with the tag value programmed in the **Inner VLAN inclusion register (ETH_MACIVIR)** or context descriptor.
11: Replace the inner VLAN tag in packets with the tag value programmed in the **Inner VLAN inclusion register (ETH_MACIVIR)** or context descriptor. This option should be used only with the VLAN frames.

### Inner VLAN Tag Valid

When this bit is set, it indicates that the IVT field of TDES2 is valid.

### VLAN Tag Valid

When this bit is set, it indicates that the VT field of TDES3 is valid.

### VLAN Tag

This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the **VLAN inclusion register (ETH_MACVIR)** is reset.
63.10.4 Receive descriptor

The DMA in the Ethernet peripheral attempts to read a descriptor only if the Tail pointer is different from the Base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC; otherwise, the performance of the DMA is greatly impacted because of the unavailability of the descriptors. In such a situation, the MTL RxFIFO becomes full and starts dropping packets.

The following Receive descriptors are present:
- Normal descriptors with read and write-back formats
- Context descriptors

All received descriptors are prepared by the software and given to the DMA as “normal” descriptors (see Figure 842: Receive normal descriptor (read format) for a description of their content). The DMA reads this descriptor and, after transferring a received packet (or part of it) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The status format is given in Figure 843: Receive normal descriptor (write-back format).

For some packets, the normal descriptor bits are not sufficient to write the complete status. For such packets, the Rx DMA will write the extended status to the next descriptor (without processing or using the Buffers pointers embedded in that descriptor). The format and content of this write-back descriptor is described in Figure 844: Receive context descriptor.

Receive normal descriptor (read format)

Figure 842 shows the read format for Receive normal descriptors. Table 590 to Table 593 provide a detailed description of all Receive normal descriptors (read format).

![Receive normal descriptor (read format)](image)

Note: In the Receive descriptor (read format), if the Buffer Address field contains only 0s, the MAC does not transfer data to this buffer and skips to the next buffer or next descriptor.
• RDES0 normal descriptor (read format)

**Table 590. RDES0 normal descriptor (read format)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:0| BUF1AP    | Buffer 1 Address Pointer  
      |            | These bits indicate the physical address of Buffer 1.  
      |            | The application can program a byte-aligned address for this buffer, which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a write operation with RDES2[1:0]=0 in case of 64-/128-bit configuration) as zero. However, the packet data is shifted by the actual offset as given in the buffer address pointer.  
      |            | If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width. |

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 6   | IPCB | IP Checksum Bypassed  
This bit indicates that the checksum offload engine is bypassed. |
| 5   | IPV6 | IPv6 header Present  
This bit indicates that an IPV6 header is detected. |
| 4   | IPV4 | IPv4 Header Present  
This bit indicates that an IPV4 header is detected. |
| 3   | IPHE | IP Header Error  
– When this bit is set, it indicates either of the following:  
  – The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes.  
  – The IP datagram version is not consistent with the Ethernet Type value.  
  – Ethernet packet does not have the expected number of IP header bytes.  
This bit is valid when either bit 5 or bit 4 is set. |
| 2:0 | PT   | Payload Type  
These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE):  
000: Unknown type or IP/AV payload not processed  
001: UDP  
010: TCP  
011: ICMP  
100: IGMP if IPV4 Header Present bit is set  
Others: reserved.  
If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000. |

1. The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

– 010: Filter 2  
– 011: Filter 3  
– 100: Filter 4  
– 101: Filter 5  
– 110: Filter 6  
– 111: Filter 7  
This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. |
| 28    | L4FM | **Layer 4 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:  
– Layer 3 fields are not enabled and all enabled Layer 4 fields match  
– All enabled Layer 3 and Layer 4 filter fields match  
When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29]. |
| 27    | L3FM | **Layer 3 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true:  
– All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed  
– All enabled filter fields match  
When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. |
| 26:19 | MADRM | **MAC Address Match or Hash Value**  
When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.  
When the HF bit is set, this field contains the Hash value computed by the MAC. A packet passes the Hash filter when the bit corresponding to the Hash value is set in the Hash filter register. |
| 18    | HF   | **Hash Filter Status**  
When this bit is set, it indicates that the packet passed the MAC address Hash filter. Its[26:19] indicate the Hash value. |
| 17    | DAF  | **Destination Address Filter Fail**  
When this bit is set, it indicates that the packet failed the DA Filter in the MAC. |
| 16    | SAF  | **SA Address Filter Fail**  
When this bit is set, it indicates that the packet failed the SA Filter in the MAC. |
Table 596. RDES2 normal descriptor (write-back format) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 15  | VF   | VLAN Filter Status  
When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter. |
| 14:11 | Reserved |  |
| 10  | ARPNR | ARP Reply Not Generated  
When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). |
| 9:0 | Reserved |  |

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31  | OWN | Own bit  
1: The DMA owns the descriptor.  
0: The application owns the descriptor.  
The DMA clears this bit when either of the following conditions is true:  
The DMA completes the packet reception  
The buffers associated with the descriptor are full |
| 30  | CTXT | Receive Context Descriptor  
When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0 to this bit for normal receive descriptor.  
When CTXT and FD bits are used together, (CTXT, FD) possible values are:  
00: Intermediate Descriptor  
01: First Descriptor  
10: Reserved  
11: Descriptor error (due to all 1s)  
Note: When a Descriptor error occurs, the Receive DMA closes the receive descriptor indicating a Descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. The receive DMA sets the CDE field of the Channel status register (ETH_DMACSR) but does not set the RI field, even when IOC field is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data. |

### Table 597. RDES3 normal descriptor (write-back format) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>FD</td>
<td><strong>First Descriptor</strong>&lt;br&gt;When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. Refer to the CTXT bit description for details on how to use the CTXT bit and FD bit together.</td>
</tr>
<tr>
<td>28</td>
<td>LD</td>
<td><strong>Last Descriptor</strong>&lt;br&gt;When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.</td>
</tr>
<tr>
<td>27</td>
<td>RS2V</td>
<td><strong>Receive Status RDES2 Valid</strong>&lt;br&gt;When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.</td>
</tr>
<tr>
<td>26</td>
<td>RS1V</td>
<td><strong>Receive Status RDES1 Valid</strong>&lt;br&gt;When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.</td>
</tr>
<tr>
<td>25</td>
<td>RS0V</td>
<td><strong>Receive Status RDES0 Valid</strong>&lt;br&gt;When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.</td>
</tr>
<tr>
<td>24</td>
<td>CE</td>
<td><strong>CRC Error</strong>&lt;br&gt;When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.</td>
</tr>
<tr>
<td>23</td>
<td>GP</td>
<td><strong>Giant Packet</strong>&lt;br&gt;When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set).&lt;br&gt;Giant packet indicates only the packet length. It does not cause any packet truncation.</td>
</tr>
<tr>
<td>22</td>
<td>RWT</td>
<td><strong>Receive Watchdog Timeout</strong>&lt;br&gt;When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.</td>
</tr>
<tr>
<td>21</td>
<td>OE</td>
<td><strong>Overflow Error</strong>&lt;br&gt;When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO.&lt;br&gt;This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.</td>
</tr>
<tr>
<td>20</td>
<td>RE</td>
<td><strong>Receive Error</strong>&lt;br&gt;When this bit is set, it indicates that the ETH_RX_ER signal is asserted while the ETH_RX_DV signal is asserted during packet reception.</td>
</tr>
</tbody>
</table>
Table 597. RDES3 normal descriptor (write-back format) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 19   | DE   | Dribble Bit Error  
When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. |
| 18:16 | LT   | Length/Type Field  
This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows:  
000: The packet is a length packet  
001: The packet is a type packet.  
011: The packet is a ARP Request packet type  
100: The packet is a type packet with VLAN Tag  
101: The packet is a type packet with Double VLAN tag  
110: The packet is a MAC Control packet type  
111: The packet is a OAM packet type  
010: Reserved |
| 15   | ES   | Error Summary  
When this bit is set, it indicates the logical OR of the following bits:  
RDES3[19]: Dribble Error  
RDES3[20]: Receive Error  
RDES3[21]: Overflow Error  
RDES3[22]: Watchdog Timeout  
RDES3[23]: Giant Packet  
RDES3[24]: CRC Error  
This field is valid only when the LD bit of RDES3 is set. |
| 14:0 | PL   | Packet Length  
These bits indicate the byte length of the received packet that was transferred to system memory (including CRC).  
This field is valid when both the LD bit of RDES3 is set and the Overflow Error bit is reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.  
When LD bit of RDES3 is reset, this field contains the accumulated number of bytes (partial) that have been transferred for the current packet. |
Receive context descriptor

This descriptor is read-only for the application. This descriptor can be written only by the DMA.

The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor. 

*Figure 844* shows the format for Receive context descriptors. *Table 598* to *Table 601* provide a detailed description of all Receive context descriptors.

63.11 Ethernet registers

63.11.1 Ethernet registers maps

This section provides the following register maps:

- DMA registers (see Section 63.11.2: Ethernet DMA registers)
- MTL registers (see Section 63.11.3: Ethernet MTL registers)
- MAC registers including MMC register (see Section 63.11.4: Ethernet MAC and MMC registers)

63.11.2 Ethernet DMA registers

DMA mode register (ETH_DMAMR)

Address offset: 0x1000
Reset value: 0x0000 0000

The DMA mode register establishes the bus operating modes for the DMA.

</tbody>
</table>

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **INTM[1:0]: Interrupt Mode**

This field defines the interrupt mode of the Ethernet peripheral.

The behavior of the interrupt signal and of the RI/TI bits in the ETH_DMACSR register changes depending on the INTM value (refer to Table 577: Transfer complete interrupt behavior).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PR[2:0]: Priority ratio**

These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set.

- 000: The priority ratio is 1:1
- 001: The priority ratio is 2:1
- 010: The priority ratio is 3:1
- 011: The priority ratio is 4:1
- 100: The priority ratio is 5:1
- 101: The priority ratio is 6:1
- 110: The priority ratio is 7:1
- 111: The priority ratio is 8:1

Bit 11 **TXPR: Transmit priority**

When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.
Bits 10:2  Reserved, must be kept at reset value.

Bit 1  **DA**: DMA Tx or Rx Arbitration Scheme
This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels:
0: Weighted Round-Robin with Rx:Tx or Tx:Rx
The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit.
1: Fixed priority
The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.

Bit 0  **SWR**: Software Reset
When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all clock domains. Before reprogramming any register, a value of zero should be read in this bit.

**Note**: The reset operation is complete only when all resets in all active clock domains are deasserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock.
System bus mode register (ETH_DMASBMR)

Address offset: 0x1004
Reset value: 0x0000 0000

The System bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  RB: Rebuild INCRx Burst
When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.

Bit 14  MB: Mixed Burst
When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).

Bit 13  Reserved, must be kept at reset value.

Bit 12  AAL: Address-Aligned Beats
When this bit is set to 1, the master performs address-aligned burst transfers on Read and Write channels.

Bits 11:1  Reserved, must be kept at reset value.

Bit 0  FB: Fixed Burst Length
When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE).
When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.
Interrupt status register (ETH_DMAISR)

Address offset: 0x1008
Reset value: 0x0000 0000

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 MACIS: MAC Interrupt Status
This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.

Bit 16 MTLIS: MTL Interrupt Status
This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 DCONIS: DMA Channel Interrupt Status
This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source.

Debug status register (ETH_DMADSR)

Address offset: 0x100C
Reset value: 0x0000 0000

The Debug status register gives the Receive and Transmit process status for DMA Channel for debugging purpose.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **TPS0[3:0]: DMA Channel Transmit Process State**
This field indicates the Tx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Transmit Command issued)
- 001: Running (Fetching Tx Transfer Descriptor)
- 010: Running (Waiting for status)
- 011: Running (Reading Data from system memory buffer and queuing it to the Tx buffer (Tx FIFO))
- 100: Timestamp write state
- 101: Reserved for future use
- 110: Suspended (Tx Descriptor Unavailable or Tx Buffer Underflow)
- 111: Running (Closing Tx Descriptor)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 11:8  **RPS0[3:0]: DMA Channel Receive Process State**
This field indicates the Rx DMA FSM state for Channel:
- 000: Stopped (Reset or Stop Receive Command issued)
- 001: Running (Fetching Rx Transfer Descriptor)
- 010: Reserved for future use
- 011: Running (Waiting for Rx packet)
- 100: Suspended (Rx Descriptor Unavailable)
- 101: Running (Closing the Rx Descriptor)
- 110: Timestamp write state
- 111: Running (Transferring the received packet data from the Rx buffer to the system memory)
The MSB of this field always returns 0. This field does not generate an interrupt.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0  **AXWHSTS: AHB Master Write Channel**
When high, this bit indicates that the write channel of the AHB master FMSs are in non-idle state.

**Channel control register (ETH_DMACCR)**

Address offset: 0x1100
Reset value: 0x0000 0000

The DMA Channel control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:18  **DSL[2:0]: Descriptor Skip Length**
This bit specifies the 32-bit word number to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor.
When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.

Bit 17  Reserved, must be kept at reset value.

Bit 16  **PBLX8: 8xPBL mode**
When this bit is set, the PBL value programmed in Bits[21:16] in *Channel transmit control register (ETH_DMACTXCR)* is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:0  **MSS[13:0]: Maximum Segment Size**
This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of *Channel transmit control register (ETH_DMACTXCR)* is set.
The value programmed in this field must be more than the configured Data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

---

**Channel transmit control register (ETH_DMACTXCR)**

Address offset: 0x1104

Reset value: 0x0000 0000

The DMA Channel Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

ST
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:16  **TXPBL[5:0]: Transmit Programmable Burst Length**

These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a) Set the PBLx8 mode in ETH_DMACCR.

b) Set the TXPBL[5:0].

Note: The maximum value of TXPBL must be less than or equal to half the Tx Queue size (TQS field of *Tx queue operating mode Register (ETH_MTLTXQOMR)*) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. The total locations in Tx Queue of size 2048 bytes is 512, TXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **TSE: TCP Segmentation Enabled**

When this bit is set, the DMA performs the TCP segmentation for packets in Channel i. The TCP segmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TXPBL value must be greater than or equal to 4.

Bits 11:5  Reserved, must be kept at reset value.

Bit 4  **OSF: Operate on Second Packet**

When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **ST: Start or Stop Transmission Command**

When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the base address of the Transmit list set by the ETH_DMACTXDLAR register.
- The position at which the transmission was previously stopped

If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the ETH_DMACSR is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the ETH_DMACTXDLAR register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program ETH_DMACTXDLAR register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.
**Channel receive control register (ETH_DMACRXCR)**

Address offset: 0x1108

Reset value: 0x0000 0000

The DMA Channel Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

**Bit 31**: **RPF**: DMA Rx Channel Packet Flush

When this bit is set to 1, the Ethernet peripheral will automatically flush the packet from the Rx queue destined to DMA Rx Channel when the DMA Rx Channel is stopped after a system bus error has occurred. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx queue. When this bit is set to 0 the Ethernet peripheral does not flush the packet in the Rx queue destined to DMA Rx Channel after the DMA is stopped due to a system bus error. This might cause head-of-line blocking in the corresponding RxQueue.

**Note**: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in ETH_DMACRXCR register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel.

**Bits 30:22**: Reserved, must be kept at reset value.

**Bits 21:16**: **RXPBL[5:0]**: Receive Programmable Burst Length

These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:

a) Set the PBLx8 mode in the ETH_DMACCGR.

b) Set the RXPBL[5:0].

**Note**: The maximum value of RXPBL must be less than or equal to half the Rx Queue size (RQS field of Rx queue operating mode register (ETH_MTLRXQOMR)) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the MTL Rx Queue Controller is transferring data to MAC. The total locations in Rx Queue of size 2048 bytes is 512, RXPBL and 8xPBL needs to be programmed to less than or equal to 512/2.
Bit 15  Reserved, must be kept at reset value.

Bits 14:1  **RBSZ[13:0]:** Receive Buffer size
This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes.

**Note:** The buffer size must be a multiple of 4. This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, it may result into an undefined behavior.

The LSB bits (1:0) are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).

Bit 0  **SR:** Start or Stop Receive
When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets.
The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the address set by the Channel Rx descriptor list address register (ETH_DMACRXDLAR).
- The position at which the Rx process was previously stopped

If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the ETH_DMACSR is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the Channel Rx descriptor list address register (ETH_DMACRXDLAR), the DMA behavior is unpredictable.

When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.
Channel Tx descriptor list address register (ETH_DMACTXDLAR)

Address offset: 0x1114
Reset value: 0x0000 0000

Channel Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in ETH_DMACiTXCR register. When stopped, this register can be written with a new descriptor list address. When you set ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Bits 31:0 **TDESLA[31:0]**: Start of Transmit List

This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).
Channel Rx descriptor list address register (ETH_DMACRXDLAR)

Address offset: 0x111C
Reset value: 0x0000 0000

The Channel Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in ETH_DMACRXCR register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **ARBS[7:0]: Alternate Receive Buffer Size**
Indicates size in bytes for Buffer 1 when ARBS[7:0] is programmed to a non-zero value.
When ARBS[7:0] = 0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ[13:0] field of Channel receive control register (ETH_DMACRXCR).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **RDRL[9:0]: Receive Descriptor Ring Length**
This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors.
For example, you can program any value up to 0x3FF in this field. This field is 10-bit wide. If you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

Channel interrupt enable register (ETH_DMACIER)

Address offset: 0x1134
Reset value: 0x0000 0000

The Channel Interrupt Enable register enables the interrupts reported by the Status register.

RM0468 Rev 3 2975/3357
Bits 31:16  Reserved, must be kept at reset value.

Bit 15 **NIE**: Normal Interrupt Summary Enable
When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
When this bit is reset, the normal interrupt summary is disabled.

Bit 14 **AIE**: Abnormal Interrupt Summary Enable
When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the Channel status register (ETH_DMACSR):
- Bit 1: Transmit Process Stopped
- Bit 7: Rx Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 9: Receive Watchdog Timeout
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
When this bit is reset, the abnormal interrupt summary is disabled.

Bit 13 **CDEE**: Context Descriptor Error Enable
When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.

Bit 12 **FBEE**: Fatal Bus Error Enable
When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Bit 11 **ERIE**: Early Receive Interrupt Enable
When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Bit 10 **ETIE**: Early Transmit Interrupt Enable
When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.

Bit 9 **RWTE**: Receive Watchdog Timeout Enable
When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.

Bit 8 **RSE**: Receive Stopped Enable
When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.

Bit 7 **RBUUE**: Receive Buffer Unavailable Enable
When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.

Bit 6 **RIE**: Receive Interrupt Enable
When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Bits 5:3  Reserved, must be kept at reset value.
Bit 2 **TBUE**: Transmit Buffer Unavailable Enable
When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.

Bit 1 **TXSE**: Transmit Stopped Enable
When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.

Bit 0 **TIE**: Transmit Interrupt Enable
When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.
Figure 845. Generation of ETH_DMAISR flags
Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR)

Address offset: 0x1138  
Reset value: 0x0000 0000

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the Channel status register (ETH_DMACSR).

Channel current application transmit descriptor register (ETH_DMACCATXDR)

Address offset: 0x1144
Reset value: 0x0000 0000

The Channel Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Channel current application receive descriptor register (ETH_DMACCARXDR)

Address offset: 0x114C
Reset value: 0x0000 0000

The Channel Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.
Channel current application transmit buffer register (ETH_DMACCATXBR)

Address offset: 0x1154
Reset value: 0x0000 0000

The Channel Current Application Transmit Buffer Address register points to the current Tx buffer address read by the DMA.

</table>

Channel status register (ETH_DMACSR)

Address offset: 0x1160
Reset value: 0x0000 0000

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.
Bits 31:22 Reserved, must be kept at reset value.

Bits 21:19 \textbf{REB[2:0]}: Rx DMA Error Bits
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
- Bit [2]: Error during data transfer by Rx DMA when 1, no Error during data transfer by Rx DMA when 0.
- Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0
- Bit[0]: Error during read transfer when 1, Error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bits 18:16 \textbf{TEB[2:0]}: Tx DMA Error Bits
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
- Bit[2]: Error during data transfer by Tx DMA when 1, no Error during data transfer by Tx DMA when 0
- Bit[1]: Error during descriptor access when 1, Error during data buffer access when 0
- Bit[0]: Error during read transfer when 1, Error during write transfer when 0
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bit 15 \textbf{NIS}: Normal Interrupt Summary
Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
Only unmasked bits (interrupts for which interrupt enable is set in ETH_DMACIER register) affect the Normal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared.

Bit 14 \textbf{AIS}: Abnormal Interrupt Summary
Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
- Bit 1: Transmit Process Stopped
- Bit 7: Receive Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
- Bit 13: Context Descriptor Error
Only unmasked bits affect the Abnormal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared.

Bit 13 \textbf{CDE}: Context Descriptor Error
This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one’s descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid.

Bit 12 \textbf{FBE}: Fatal Bus Error
This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses.
Bit 11  **ERI**: Early Receive Interrupt
This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit.

Bit 10  **ETI**: Early Transmit Interrupt
This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO.

Bit 9  **RWT**: Receive Watchdog Timeout
This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.

Bit 8  **RPS**: Receive Process Stopped
This bit is asserted when the Rx process enters the Stopped state.

Bit 7  **RBU**: Receive Buffer Unavailable
This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor.

Bit 6  **RI**: Receive Interrupt
This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state.

Bits 5:3  Reserved, must be kept at reset value.

Bit 2  **TBU**: Transmit Buffer Unavailable
This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPSi field of the Debug status register (ETH_DMADSR) register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following:
1. Change the ownership of the descriptor by setting Bit 31 of TDES3.
2. Issue a Transmit Poll Demand command.
For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel.

Bit 1  **TPS**: Transmit Process Stopped
This bit is set when the transmission is stopped.

Bit 0  **TI**: Transmit Interrupt
This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.
Channel missed frame count register (ETH_DMACMFCR)

Address offset: 0x116C
Reset value: 0x0000 0000

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in Channel receive control register (ETH_DMACRXCR) register.

Table 603. ETH_DMA_CH register map and reset values (continued)
63.11.3 Ethernet MTL registers

Operating mode Register (ETH_MTLOMR)

Address offset: 0x0C00
Reset value: 0x0000 0000

The Operating Mode register establishes the Transmit and Receive operating modes and commands.

| Bit 31:10 Reserved, must be kept at reset value. |
| Bit 9 CNTCLR: Counters Reset |
| WHEN THIS BIT IS SET, ALL COUNTERS ARE RESET. THIS BIT IS CLEARED AUTOMATICALLY AFTER 1 CLOCK CYCLE. IF THIS BIT IS SET ALONG WITH CNTPRST BIT, CNTPRST HAS PRECEDENCE. |
| Bit 8 CNTPRST: Counters Preset |
| WHEN THIS BIT IS SET: |
| Tx queue underflow register (ETH_MTLTXQUR) is initialized/preset to 0x7F0. |
| Missed Packet and Overflow Packet counters in Rx queue missed packet and overflow counter register (ETH_MTLRXXMPOCR) is initialized/preset to 0x7F0 |
| This bit is cleared automatically. |
| Bit 7 Reserved, must be kept at reset value. |
| Bits 6:2 Reserved, must be kept at reset value. |
| Bit 1 DTXSTS: Drop Transmit Status |
| WHEN THIS BIT IS SET, THE Tx packet status received from the MAC is dropped in the MTL. |
| WHEN THIS BIT IS RESET, THE Tx packet status received from the MAC is forwarded to the application. |
| Bit 0 Reserved, must be kept at reset value. |
## Interrupt status Register (ETH_MTLISR)

Address offset: 0x0C20  
Reset value: 0x0000 0000

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

**Bits 31:1** Reserved, must be kept at reset value.

**Bit 0** **Q0IS**: Queue interrupt status  
This bit indicates that an interrupt has been generated by Queue. To reset this bit, read ETH_MTLQICSR register to identify the interrupt cause and clear the source.

## Tx queue operating mode Register (ETH_MTLTXQOMR)

Address offset: 0x0D00  
Reset value: 0x0007 0008

The Queue Transmit Operating Mode register establishes the Transmit queue operating modes and commands.

**Bits 31:19** Reserved, must be kept at reset value.

**Bits 18:16** **TQS[2:0]**: Transmit queue size  
This field indicates the size of the allocated transmit queues in blocks of 256 bytes. Queue size range from 256 bytes (TQS=0b000) to 2048 bytes (TQS=0b111).

**Bits 15:7** Reserved, must be kept at reset value.
Bits 6:4 **TTC[2:0]**: Transmit Threshold Control

These bits control the threshold level of the MTL Tx queue. The transmission starts when the packet size within the MTL Tx queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset.

Bits 3:2 **TXQEN[1:0]**: Transmit Queue Enable

This field is used to enable/disable the transmit queue.

- 00: Not enabled
- 10: Enabled
- Others: Reserved, must not be used.

*Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field.*

Bit 1 **TSF**: Transmit Store and Forward

When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped.

Bit 0 **FTQ**: Flush Transmit Queue

When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the ETH_MTLTXQOMR register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.

*Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (eth_mii_tx_clk) should be active.*

**Tx queue underflow register (ETH_MTLTXQUR)**

Address offset: 0x0D04

Reset value: 0x0000 0000

The Queue Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.
Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **UFNTOVF**: Overflow Bit for Underflow Packet Counter
This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.

Bits 10:0 **UFFRMCNT[10:0]**: Underflow Packet Counter
This field indicates the number of packets aborted by the controller because of Tx queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read.

**Tx queue debug Register (ETH_MTLTXQDR)**
Address offset: 0x0D08
Reset value: 0x0000 0000

The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **STXSTSF[2:0]**: Number of Status Words in Tx Status FIFO of Queue
This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **PTXQ[2:0]**: Number of Packets in the Transmit Queue
This field indicates the current number of packets in the Tx queue. When the DTXSTS bit of **Operating mode Register (ETH_MTLOMR)** register is set to 1, this field does not reflect the number of packets in the Transmit queue.

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **TXSTSFSTS**: MTL Tx Status FIFO Full Status
When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.

Bit 4 **TXQSTS**: MTL Tx Queue Not Empty Status
When this bit is high, it indicates that the MTL Tx queue is not empty and some data is left for transmission.
Bit 3  **TWCSTS**: MTL Tx Queue Write Controller Status
When high, this bit indicates that the MTL Tx queue Write Controller is active, and it is transferring the data to the Tx queue.

Bits 2:1  **TRCSTS[1:0]**: MTL Tx Queue Read Controller Status
This field indicates the state of the Tx Queue Read Controller:
00: Idle state
01: Read state (transferring data to the MAC transmitter)
10: Waiting for pending Tx Status from the MAC transmitter
11: Flushing the Tx queue because of the Packet Abort request from the MAC

Bit 0  **TXQPAUSED**: Transmit Queue in Pause
When this bit is high and the Rx flow control is enabled, it indicates that the Tx queue is in the Pause condition (in the Full-duplex only mode) because of the following:
- Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled
- Reception of 802.3x Pause packet when PFC is disabled

Queue interrupt control status Register (ETH_MTLQICSR)

Address offset: 0x0D2C
Reset value: 0x0000 0000

This register contains the interrupt enable and status bits for the queue interrupts.

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **RXOIE**: Receive Queue Overflow Interrupt Enable
When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.

Bits 23:17  Reserved, must be kept at reset value.

Bit 16  **RXOVFIS**: Receive Queue Overflow Interrupt Status
This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit.

Bits 15:9  Reserved, must be kept at reset value.
Bit 8 **TXUIE**: Transmit Queue Underflow Interrupt Enable
   When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0 **TXUNFIS**: Transmit Queue Underflow Interrupt Status
   This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit.
Rx queue operating mode register (ETH_MTLRXQOMR)

Address offset: 0x0D30
Reset value: 0x0070 0000

The Queue Receive operating Mode register establishes the Receive queue operating modes and command.

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:20  **RQS[2:0]: Receive Queue Size**

This field is read-only and the configured Rx FIFO size in blocks of 256 bytes is reflected in the reset value. The size of the Queue is (RQS + 1) * 256 bytes.

Bits 19:7  Reserved, must be kept at reset value.

Bit 6  **DIS_TCP_EF: Disable Dropping of TCP/IP Checksum Error Packets**

When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

When this bit is reset, all error packets are dropped if the FEP bit is reset.

Bit 5  **RSF: Receive Queue Store and Forward**

When this bit is set, the Ethernet peripheral reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Bit 4  **FEP: Forward Error Packets**

When this bit is reset, the Rx queue drops packets with error status (CRC error, receive error, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped.

When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
Bit 3 **FUP**: Forward Undersized Good Packets
When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **RTC[1:0]**: Receive Queue Threshold Control
These bits control the threshold level of the MTL Rx queue (in bytes):
00: 64
01: 32
10: 96
11: 128

The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred.

This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
**Rx queue missed packet and overflow counter register**  
*(ETH_MTLRXQMPOCR)*

Address offset: 0x0D34  
Reset value: 0x0000 0000

The Queue missed packet and overflow counter registers contain the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **MISCNTOVF**: Missed Packet Counter Overflow Bit  
When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit.

Bits 26:16  **MISPKTCNT[10:0]**: Missed Packet Counter  
This field indicates the number of packets missed by the Ethernet peripheral because the application requested to flush the packets for this queue. This counter is reset when this register is read.  
This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.

Bits 15:12  Reserved, must be kept at reset value.

Bit 11  **OVFCNTOVF**: Overflow Counter Overflow Bit  
When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit.

Bits 10:0  **OVFPKTCNT[10:0]**: Overflow Packet Counter  
This field indicates the number of packets discarded by the Ethernet peripheral because of Receive queue overflow. This counter is incremented each time the Ethernet peripheral discards an incoming packet because of overflow. This counter is reset when this register is read.
Rx queue debug register (ETH_MTLRXQDR)

Address offset: 0x0D38
Reset value: 0x0000 0000

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

| Bit 31-30 | Reserved, must be kept at reset value. |
| Bit 29-16 | PRXQ[13:0]: Number of Packets in Receive Queue |
|           | This field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256Kbyte/16bytes = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size. |
| Bit 15-6  | Reserved, must be kept at reset value. |
| Bit 5-4   | RXQSTS[1:0]: MTL Rx Queue Fill-Level Status |
|           | This field gives the status of the fill-level of the Rx queue: |
|           | 00: Rx queue empty |
|           | 01: Rx queue fill-level below flow-control deactivate threshold |
|           | 10: Rx queue fill-level above flow-control activate threshold |
|           | 11: Rx queue full |
| Bit 3     | Reserved, must be kept at reset value. |
| Bit 2:1   | RRCSTS[1:0]: MTL Rx Queue Read Controller State |
|           | This field gives the state of the Rx queue Read controller: |
|           | 00: Idle state |
|           | 01: Reading packet data |
|           | 10: Reading packet status (or timestamp) |
|           | 11: Flushing the packet data and status |
| Bit 0     | RWCSTS: MTL Rx Queue Write Controller Active Status |
|           | When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue. |
## Ethernet MTL register map and reset values

</tr>
</tbody>
</table>
Bit 27  **IPC**: Checksum Offload

When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.

The Layer 3 and Layer 4 Packet Filter feature automatically selects the IPC Full Checksum Offload Engine on the Receive side. When this feature is enabled, you must set the IPC bit.

Bits 26:24  **IPG[2:0]**: Inter-Packet Gap

These bits control the minimum IPG between packets during transmission.

000: 96 bit times
001: 88 bit times
010: 80 bit times
...
111: 40 bit times

This range of minimum IPG is valid in Full-duplex mode.

In the Half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.

When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.

The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in ETH_MACECR register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in ETH_MACECR register.

Bit 23  **GPSLCE**: Giant Packet Size Limit Control Enable

When this bit is set, the MAC considers the value in GPSL field in ETH_MACECR register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit.

When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).

The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.

Bit 22  **S2KP**: IEEE 802.3as Support for 2K Packets

When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets.

When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the giant packet status, see Table 605: Giant Packet Status based on S2KP and JE Bits.

**Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.

Bit 21  **CST**: CRC stripping for Type packets

When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.

This function is valid when Type 2 Checksum Offload Engine is enabled.

**Note:** For information about how the settings of the ACS bit and this bit impact the packet length, see Table 606: Packet Length based on the CST and ACS bits.
Bit 20 **ACS**: Automatic Pad or CRC Stripping

When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.

When this bit is reset, the MAC passes all incoming packets to the application, without any modification.

*Note: For information about how the settings of CST bit and this bit impact the packet length, see Table 606: Packet Length based on the CST and ACS bits.*

Bit 19 **WD**: Watchdog Disable

When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes.

When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **JD**: Jabber Disable

When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes.

When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.

Bit 16 **JE**: Jumbo Packet Enable

When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.

For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Table 605: Giant Packet Status based on S2KP and JE Bits.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **FES**: MAC Speed

This bit selects the speed in the 10/100 Mbps mode:

- 0: 10 Mbps
- 1: 100 Mbps

Bit 13 **DM**: Duplex Mode

When this bit is set, the MAC operates in the Full-duplex mode in which it can transmit and receive simultaneously.

Bit 12 **LM**: Loopback Mode

When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (eth_mii_rx_clk) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Bit 11 **ECRSFD**: Enable Carrier Sense Before Transmission in Full-duplex mode

When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the Full-duplex mode. The MAC starts the transmission only when the CRS signal is low.

When this bit is reset, the MAC transmitter ignores the status of the CRS signal.

Bit 10 **DO**: Disable Receive Own

When this bit is set, the MAC disables the reception of packets when the ETH_TX_EN is asserted in the Half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY.

This bit is not applicable in the Full-duplex mode. This bit is reserved and read-only (RO) with default value in the full-duplex-only configurations.
Bit 9  **DCRS**: Disable Carrier Sense During Transmission
When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the Half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission.
When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.

Bit 8  **DR**: Disable Retry
When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status.
When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the Half-duplex mode.

Bit 7  Reserved, must be kept at reset value.

Bits 6:5  **BL[1:0]**: Back-Off Limit
The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision:
00: k = min (n, 10)
01: k = min (n, 8)
10: k = min (n, 4)
11: k = min (n, 1)
where n = retransmission attempt
The random integer r takes the value in the range 0 ≤ r < 2^k.
This bit is applicable only in the Half-duplex mode.

Bit 4  **DC**: Deferral Check
When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode.
Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII.
The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted.
When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive.
This bit is applicable only in the Half-duplex mode.

Bits 3:2  **PRELEN[1:0]**: Preamble Length for Transmit packets
These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the Full-duplex mode.
00: 7 bytes of preamble
01: 5 bytes of preamble
10: 3 bytes of preamble
11: Reserved, must not be used
Bit 1 **TE**: Transmitter Enable
When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Bit 0 **RE**: Receiver Enable
When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

*Table 605* shows how the settings of S2KP and JE bits of the ETH_MACCR register impact the giant packet status.

<td></td>
</tr>
</tbody>
</table>

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **EIPG[4:0]**: Extended Inter-Packet Gap

The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits) along with IPG field in Operating mode configuration register (ETH_MACCR), gives the minimum IPG greater than 96 bit times in steps of 8 bit times. For example:
- EIPG = 0 and IPG = 0 give 104 bit times
- EIPG = 0 and IPG = 1 give 112 bit times
- EIPG = 0 and IPG = 2 give 120 bit times
- ...
- EIPG = 7 and IPG = 31 give 2144 bit times

Bit 24  **EIPGEN**: Extended Inter-Packet Gap Enable

When this bit is set, the MAC interprets EIPG field and IPG field in Operating mode configuration register (ETH_MACCR) together as minimum IPG greater than 96 bit times in steps of 8 bit times.

When this bit is reset, the MAC ignores EIPG field and interprets IPG field in Operating mode configuration register (ETH_MACCR) as minimum IPG less than or equal to 96 bit times in steps of 8 bit times.

**Note**: The extended Inter-Packet Gap feature must be enabled when operating in Full-duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-duplex mode.

Bits 23:19  Reserved, must be kept at reset value.

Bit 18  **USP**: Unicast Slow Protocol Packet Detect

When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR). The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02).

When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
Bit 17 **SPEN**: Slow Protocol Detection Enable
When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid subtypes. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.

Bit 16 **DCRCC**: Disable CRC Checking for Received Packets
When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **GPSL[13:0]**: Giant Packet Size Limit
If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes.

For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. For double VLAN tagged packets, the MAC adds 8 bytes to the programmed value. The value in this field is applicable when the GPSLCE bit is set in ETH_MACCR register.

**Packet filtering control register (ETH_MACPFR)**
Address offset: 0x0008
Reset value: 0x0000 0000

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>RA: Receive All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ra</td>
<td>Receive All</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.

Bits 30:22 Reserved, must be kept at reset value.

Bit 21 **DNTU**: Drop Non-TCP/UDP over IP Packets
When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forwards only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
Bit 20 **IPFE**: Layer 3 and Layer 4 Filter Enable
When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect.
When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **VTFE**: VLAN Tag Filter Enable
When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **HPF**: Hash or Perfect Filter
When this bit is set, the address filter passes a packet if it matches either the perfect filtering or Hash filtering as set by the HMC or HUC bit.
When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Bit 9 **SAF**: Source Address Filter Enable
When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet.
When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison.

*Note:* According to the IEEE specification, Bit 47 of the SA is reserved. However, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.

Bit 8 **SAIF**: SA Inverse Filtering
When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter.
When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.

Bits 7:6 **PCF[1:0]**: Pass Control Packets
These bits control the forwarding of all control packets (including unicast and multicast Pause packets).
00: The MAC filters all control packets from reaching the application.
01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter.
10: The MAC forwards all control packets to the application even if they fail the Address filter.
11: The MAC forwards the control packets that pass the Address filter.

Bit 5 **DBF**: Disable Broadcast Packets
When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings.
When this bit is reset, the AFM module passes all received broadcast packets.

Bit 4 **PM**: Pass All Multicast
When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is ‘1’) are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
Bit 3 **DAIF**: DA Inverse Filtering  
When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.

Bit 2 **HMC**: Hash Multicast  
When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the Hash table.  
When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 1 **HUC**: Hash Unicast  
When this bit is set, the MAC performs the destination address filtering of unicast packets according to the Hash table.  
When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.

Bit 0 **PR**: Promiscuous Mode  
When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

**Watchdog timeout register (ETH_MACWTR)**

Address offset: 0x000C  
Reset value: 0x0000 0000  
The Watchdog Timeout register controls the watchdog timeout for received packets.

3008/3357  
RM0468 Rev 3
Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **PWE**: Programmable Watchdog Enable
When this bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in Operating mode configuration register (ETH_MACCR) register.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **WTO[3:0]**: Watchdog Timeout
When the PWE bit is set and the WD bit of the Operating mode configuration register (ETH_MACCR) register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.

Encoding is as follows:
- 0x0: 2 Kbytes
- 0x1: 3 Kbytes
- 0x2: 4 Kbytes
- 0x3: 5 Kbytes
- ... 0xC: 14 Kbytes
- 0xD: 15 Kbytes
- 0xE: 16383 Bytes
- 0xF: Reserved, must not be used

*Note*: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

### Hash Table 0 register (ETH_MACHT0R)

Address offset: 0x0010
Reset value: 0x0000 0000

The Hash Table Register 0 contains the first lower 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 0b10000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.
Hash Table 1 register (ETH_MACHT1R)

Address offset: 0x0014
Reset value: 0x0000 0000

The Hash Table 1 register contains the upper 32 bits of the Hash table (64 bits).

The Hash table is used for group address filtering.

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1) and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 selects Bit 0 of the Hash Table Register 1.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.
VLAN tag register (ETH_MACVTR)

Address offset: 0x0050

Reset value: 0x0000 0000

The VLAN Tag register identifies the IEEE 802.1Q VLAN type packets.

<tbody>
<tr>
<td></td>
<td>When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.</td>
</tr>
</tbody>
</table>

| Bit 23 | Reserved, must be kept at reset value. |
Bits 22:21 **EVLS[1:0]**: Enable VLAN Tag Stripping on Receive
   This field indicates the stripping operation on the outer VLAN Tag in received packet:
   00: Do not strip
   01: Strip if VLAN filter passes
   10: Strip if VLAN filter fails
   11: Always strip

Bit 20 **DOVLTC**: Disable VLAN Type Check
   When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.
   When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Bit 19 **ERSVLM**: Enable Receive S-VLAN Match
   When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
   The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

Bit 18 **ESVL**: Enable S-VLAN
   When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.

Bit 17 **VTIM**: VLAN Tag Inverse Match Enable
   When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Bit 16 **ETV**: Enable 12-Bit VLAN Tag Comparison
   When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for Hash-based VLAN filtering.
   When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN Hash filtering.

Bits 15:0 **VL[15:0]**: VLAN Tag Identifier for Receive Packets
   This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:
   Bits[15:13]: User Priority
   Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
   Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
   When the ETV bit is set, only the VID is used for comparison.
   If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.
VLAN Hash table register (ETH_MACVHTR)

Address offset: 0x0058
Reset value: 0x0000 0000

When the VTHM bit of VLAN tag register (ETH_MACVTR) register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For Hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of VLAN tag register (ETH_MACVTR) register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a Hash value of 1000 selects Bit 8 of the VLAN Hash table.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
2. Perform bitwise reversal for the value obtained in step 1.
3. Take the upper four bits from the value obtained in step 2.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 VLHT[15:0]: VLAN Hash Table
This field contains the 16-bit VLAN Hash Table.
VLAN inclusion register (ETH_MACVIR)

Address offset: 0x0060
Reset value: 0x0000 0000

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

| Bit 31:21 | Reserved, must be kept at reset value. |
| Bit 20 | VLTI: VLAN Tag Input |
| When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor. |
| Bit 19 | CSVL: C-VLAN or S-VLAN |
| When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. |
| 0: C-LAN |
| 1: S-LAN |
| Bit 18 | VLP: VLAN Priority Control |
| When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored. |
| Bits 17:16 | VLC[1:0]: VLAN Tag Control in Transmit Packets |
| 00: No VLAN tag deletion, insertion, or replacement |
| 01: VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. |
| 10: VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. |
| 11: VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). |
| Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. |
| Bits 15:0 | VLT[15:0]: VLAN Tag for Transmit Packets |
| This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. |
| The following list describes the bits of this field: |
| Bits[15:13]: User Priority |
| Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) |
| Bits[11:0]: VLAN Identifier (VID) field of VLAN tag |
Inner VLAN inclusion register (ETH_MACIVIR)

Address offset: 0x0064

Reset value: 0x0000 0000

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 VLTi: VLAN Tag Input
   When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor

Bit 19 CSVL: C-VLAN or S-VLAN
   When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
   0: C-LAN
   1: S-LAN

Bit 18 VLP: VLAN Priority Control
   When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.

Bits 17:16 VLC[1:0]: VLAN Tag Control in Transmit Packets
   00: No VLAN tag deletion, insertion, or replacement
   01: VLAN tag deletion
      The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags.
   10: VLAN tag insertion
      The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.
   11: VLAN tag replacement
      The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8).

Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
Bits 15:0  **VLT[15:0]: VLAN Tag for Transmit Packets**
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.
The following list describes the bits of this field:
Bits[15:13]: User Priority
Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

**Tx Queue flow control register (ETH_MACQTXFCR)**

Address offset: 0x0070
Reset value: 0x0000 0000

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

Bits 31:16  **PT[15:0]: Pause Time**
This field holds the value to be used in the Pause Time field in the Tx control packet. It is 32 bits wide.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **DZPQ: Disable Zero-Quanta Pause**
When this bit is set, it disables the automatic generation of the zero-quanta Pause packets. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
Bits 6:4 **PLT[2:0]: Pause Low Threshold**

This field configures the threshold of the Pause timer at which the input flow is checked for automatic retransmission of the Pause packet.

The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted at 228 (256-28) slot times after the first Pause packet is transmitted.

The following list provides the threshold values for different values:

- 000: Pause Time minus 4 Slot Times (PT -4 slot times)
- 001: Pause Time minus 28 Slot Times (PT -28 slot times)
- 010: Pause Time minus 36 Slot Times (PT -36 slot times)
- 011: Pause Time minus 144 Slot Times (PT -144 slot times)
- 100: Pause Time minus 256 Slot Times (PT -256 slot times)
- 101: Pause Time minus 512 Slot Times (PT -512 slot times)
- 110 to 111: Reserved, must not be used

The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TFE: Transmit Flow Control Enable**

**Full-duplex mode:** when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.

**Half-duplex mode:** when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.

Bit 0 **FCB_BPA: Flow Control Busy or Backpressure Activate**

This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the Half-duplex mode if the TFE bit is set.

**Full-Duplex mode:** this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared.

**Half-duplex mode:** When this bit is set (and TFE bit is set) in the Half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the Full-duplex mode, the BPA is automatically disabled.
Rx flow control register (ETH_MACRXFCR)

Address offset: 0x0090
Reset value: 0x0000 0000

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Bits 31:2  Reserved, must be kept at reset value.

**Bit 1 UP**: Unicast Pause Packet Detect

A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC Address 0 high register (ETH_MACA0HR) and MAC Address 0 low register MAC Address x low register (ETH_MACAxLR).

When this bit is reset, the MAC only detects Pause packets with unique multicast address.

*Note*: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.

**Bit 0 RFE**: Receive Flow Control Enable

When this bit is set and the MAC is operating in Full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in Half-duplex mode, the decode function of the Pause packet is disabled.

When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.
Interrupt status register (ETH_MACISR)

Address offset: 0x00B0
Reset value: 0x0000 0000

The Interrupt Status register contains the status of interrupts.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **RXSTSIS**: Receive Status Interrupt

This bit indicates the status of received packets. This bit is set when the RWT bit is set in the Rx Tx status register (ETH_MACRXTXSR). This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.

Bit 13  **TXSTSIS**: Transmit Status Interrupt

This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the Rx Tx status register (ETH_MACRXTXSR):
- Excessive Collision (EXCOL)
- Late Collision (LCOL)
- Excessive Deferral (EXDEF)
- Loss of Carrier (LCARR)
- No Carrier (NCARR)
- Jabber Timeout (TJT)

This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR software control register (ETH_MACCSRSWCR) is set) in the ETH_MACISR register.
Bit 12 **TSIS**: Timestamp Interrupt Status
If the Timestamp feature is enabled, this bit is set when any of the following conditions is true:
- The system time value is equal to or exceeds the value specified in the Target Time High and Low registers.
- There is an overflow in the Seconds register.
- The Target Time Error occurred, that is, programmed target time already elapsed.
If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted.
When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)** registers.
When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)** registers, for PTO generated Delay Request and Pdelay request packets.
This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of **CSR software control register (ETH_MACCSRSWCR)** is set) in the **Timestamp status register (ETH_MACTSSR)**.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **MMCTXIS**: MMC Transmit Interrupt Status
This bit is set high when an interrupt is generated in the **MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**. This bit is cleared when all bits in this interrupt register are cleared.

Bit 9 **MMCRXIS**: MMC Receive Interrupt Status
This bit is set high when an interrupt is generated in the **MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**. This bit is cleared when all bits in this interrupt register are cleared.

Bit 8 **MMCIS**: MMC Interrupt Status
This bit is set high when MMCTXIS or MMCRXIS is set high. This bit is cleared only when all these bits are low.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **LPIS**: LPI Interrupt Status
This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of **LPI control and status register (ETH_MACLCSR)** is read.

Bit 4 **PMTIS**: PMT Interrupt Status
This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in **ETH_MACPCSR** register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the **PMT control status register (ETH_MACPCSR)**.

Bit 3 **PHYIS**: PHY Interrupt
This bit is set when rising edge is detected on the ETH_PHY_INTN input. This bit is cleared when this register is read.

Bits 2:0 Reserved, must be kept at reset value.
Interrupt enable register (ETH_MACIER)

Address offset: 0x00B4

Reset value: 0x0000 0000

The Interrupt Enable register contains the masks for generating the interrupts.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **RXSTSIE**: Receive Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the **Interrupt status register (ETH_MACISR)**.

Bit 13 **TXSTSIE**: Transmit Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the **Interrupt status register (ETH_MACISR)**.

Bit 12 **TSIE**: Timestamp Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in **Interrupt status register (ETH_MACISR)**.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **LPIIE**: LPI Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in **Interrupt status register (ETH_MACISR)**.

Bit 4 **PMTIE**: PMT Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in **Interrupt status register (ETH_MACISR)**.

Bit 3 **PHYIE**: PHY Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in **Interrupt status register (ETH_MACISR)**.

Bits 2:0 Reserved, must be kept at reset value.
Rx Tx status register (ETH_MACRXTXSR)

Address offset: 0x00B8
Reset value: 0x0000 0000

The Receive Transmit Status register contains the Receive and Transmit Error status.

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 RWT: Receive Watchdog Timeout
This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the Operating mode configuration register (ETH_MACCR).
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 EXCOL: Excessive Collisions
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after the first collision and the packet transmission is aborted.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 4 LCOL: Late Collision
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode.
This bit is not valid if the Underflow error occurs.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 3 EXDEF: Excessive Deferral
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR) and the DC bit is set in the Operating mode configuration register (ETH_MACCR), this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 when Jumbo packet is enabled).
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).
Bit 2 **LCARR**: Loss of Carrier
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the loss of carrier occurred during packet transmission, that is, the ETH_CRS signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 1 **NCARR**: No Carrier
When the DTXSTS bit is set in the Operating mode Register (ETH_MTLOMR), this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission.
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bit 0 **TJT**: Transmit Jabber Timeout
This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the Operating mode configuration register (ETH_MACCR). This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the Operating mode configuration register (ETH_MACCR).
Cleared on read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

**PMT control status register (ETH_MACPCSR)**
Address offset: 0x00C0
Reset value: 0x0000 0000

</tr>
<tr>
<td>Bit 23:11</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 10  **RWKPFE**: Remote wakeup Packet Forwarding Enable  
When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected wakeup frame. All frames after that event including the received wakeup frame are forwarded to application. This bit is then self-cleared on receiving the wakeup packet.  
The application can also clear this bit before the expected wakeup frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high.  
**Note:** If Magic Packet Enable and wakeup Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wakeup frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.

Bit 9  **GLBLUCAST**: Global Unicast  
When this bit is set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wakeup packet.

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **RWKPRCVD**: Remote wakeup Packet Received  
When this bit is set, it indicates that the power management event is generated because of the reception of a remote wakeup packet. This bit is cleared when this register is read.

Bit 5  **MGKPRCVD**: Magic Packet Received  
When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRSWCR) is set).

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **RWKPKTEN**: Remote wakeup Packet Enable  
When this bit is set, a power management event is generated when the MAC receives a remote wakeup packet.

Bit 1  **MGKPKTEN**: Magic Packet Enable  
When this bit is set, a power management event is generated when the MAC receives a magic packet.

Bit 0  **PWRDWN**: Power Down  
When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wakeup packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wakeup packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote wakeup Packet Enable bit is set high.  
**Note:** You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
Remote wakeup packet filter register (ETH_MACRWKPFR)

Address offset: 0x00C4
Reset value: 0x0000 0000

Bits 31:0 **MACRWKPFR[31:0]**: Remote wakeup packet filter
Refer to **Table 574, Table 575 and Table 576** for details on register content and programming sequence.

The ETH_MACRWKPFR register at address 0x00C4 loads the wakeup Packet Filter register.

To load values in a wakeup Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.

LPI control and status register (ETH_MACLCSR)

Address offset: 0x00D0
Reset value: 0x0000 0000

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Bits 31:0 **MACRWKPFR[31:0]**: Remote wakeup packet filter
Refer to **Table 574, Table 575 and Table 576** for details on register content and programming sequence.

The ETH_MACRWKPFR register at address 0x00C4 loads the wakeup Packet Filter register.

To load values in a wakeup Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **LPITCSE**: LPI Tx Clock Stop Enable
When this bit is set, the MAC asserts `sbd tx clk gating ctrl_o` signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert `sbd tx clk gating ctrl_o` signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed.

Bit 20  **LPITE**: LPI Timer Enable
This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the ETH_MACLETR register.
After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again.
When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions.

Bit 19  **LPITXA**: LPI TxAutomate
This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side.
If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of ETH_MTLTxQOMR, when the MAC is in the LPI mode, it exits the LPI state.
When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **PLS**: PHY Link Status
This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER.
When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

Bit 16  **LPIEN**: LPI Enable
When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission.
This bit is cleared when the LPI TE bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **RLPIST**: Receive LPI State
When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.

Bit 8  **TLPIST**: Transmit LPI State
When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Bits 7:4  Reserved, must be kept at reset value.
Bit 3 **RLPIEX**: Receive LPI Exit
When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWSWR) is set).

**Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 2 **RLPIEN**: Receive LPI Entry
When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWSWR) is set).

**Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 1 **TLPIEX**: Transmit LPI Exit
When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWSWR) is set).

Bit 0 **TLPIEN**: Transmit LPI Entry
When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or write of 1 when RCWE bit in CSR software control register (ETH_MACCSRWSWR) is set).

**LPI timers control register (ETH_MACLTCR)**

Address offset: 0x00D4

Reset value: 0x03E8 0000

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:16  **LST[9:0]: LPI LS Timer**

This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.

Bits 15:0  **TWT[15:0]: LPI TW Timer**

This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

**LPI entry timer register (ETH_MACLETR)**

Address offset: 0x00D8

Reset value: 0x0000 0000

This register controls the Tx LPI entry timer. This counter is enabled only when LPITE bit of **LPI control and status register (ETH_MACLCSR)** register is set to 1.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **LPIET[19:0]: LPI Entry Timer**

This field specifies the time in microseconds the MAC will wait to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

**One-microsecond-tick counter register (ETH_MAC1USTCR)**

Address offset: 0x00DC

Reset value: 0x0000 0000

This register controls the generation of the Reference time (one-microsecond tick) for all the LPI timers. This timer has to be programmed by the software initially.

3028/3357  RM0468 Rev 3
Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **TIC\_1US\_CNTR[11:0]**: 1 µs tick Counter
The application must program this counter so that the number of clock cycles of CSR clock is 1 µs (subtract 1 from the value before programming).
For example if the CSR clock is 100 MHz then this field needs to be programmed to 100 - 1 = 99 (which is 0x63).
This is required to generate the 1 µs events that are used to update some of the EEE related counters.

**Version register (ETH\_MACVR)**
Address offset: 0x0110
Reset value: 0x0000 3142
The version register identifies the version of the Ethernet peripheral.

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:8 | **USERVER[7:0]**: ST-defined version |
| Bits 7:0 | **SNPSVER[7:0]**: IP version |

**Debug register (ETH\_MACDR)**
Address offset: 0x0114
Reset value: 0x0000 0000
The Debug register provides the debug status of various MAC blocks.
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **TFCSTS[1:0]: MAC Transmit Packet Controller Status**

This field indicates the state of the MAC Transmit Packet Controller module:

- 00: Idle state
- 01: Waiting for one of the following:
  - Status of the previous packet
  - IPG or backoff period to be over
- 10: Generating and transmitting a Pause control packet (in Full-duplex mode)
- 11: Transferring input packet for transmission

Bit 16  **TPESTS: MAC MII Transmit Protocol Engine Status**

When this bit is set, it indicates that the MAC MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.

Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **RFCFCSTS[1:0]: MAC Receive Packet Controller FIFO Status**

When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.

Bit 0  **RPESTS: MAC MII Receive Protocol Engine Status**

When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving data, and it is not in the Idle state.

**HW feature 0 register (ETH_MACHWF0R)**

Address offset: 0x011C

Reset value: 0x0A0D 73F7

This register indicates the presence of first set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **ACTPHYSel[2:0]:** Active PHY Selected
When you have multiple PHY interfaces in your configuration, this field indicates the sampled value of phy_intf_sel_i during reset de-assertion:
- 000: GMII or MII
- 001: RGMII
- 010: SGMII
- 011: TBI
- 100: RMII
- 101: RTBI
- 110: SMII
Others: Reserved, must not be used

Bit 27  **SAVLAININS:** Source Address or VLAN Insertion Enable
This bit is set to 1 when the Enable SA and VLAN Insertion on Tx option is selected

Bits 26:25  **TSSTSSel[1:0]:** Timestamp System Time Source
This bit indicates the source of the Timestamp system time:
- 01: Internal
- 10: External
- 11: Both
- 00: Reserved, must not be used
This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bit 24  **MACADR64Sel:** MAC Addresses 64-127 Selected
This bit is set to 1 when the Enable Additional 64 MAC Address Registers (64-127) option is selected

Bit 23  **MACADR32Sel:** MAC Addresses 32-63 Selected
This bit is set to 1 when the Enable Additional 32 MAC Address Registers (32-63) option is selected

Bits 22:18  **ADDMACADRSEL[4:0]:** MAC Addresses 1-31 Selected
This bit is set to 1 when the Enable Additional 1-31 MAC Address Registers option is selected

Bit 17  Reserved, must be kept at reset value.

Bit 16  **RXCOESEL:** Receive Checksum Offload Enabled
This bit is set to 1 when the Enable Receive TCP/IP Checksum Check option is selected

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TXCOESEL:** Transmit Checksum Offload Enabled
This bit is set to 1 when the Enable Transmit TCP/IP Checksum Insertion option is selected

Bit 13  **EEESEL:** Energy Efficient Ethernet Enabled
This bit is set to 1 when the Enable Energy Efficient Ethernet (EEE) option is selected

Bit 12  **TSSEL:** IEEE 1588-2008 Timestamp Enabled
This bit is set to 1 when the Enable IEEE 1588 Timestamp Support option is selected

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **ARPOFFSEL:** ARP Offload Enabled
This bit is set to 1 when the Enable IPv4 ARP Offload option is selected

Bit 8  **MMCSEL:** RMON Module Enable
This bit is set to 1 when the Enable MAC management counters (MMC) option is selected
Bit 7 **MGKSEL**: PMT Magic Packet Enable  
This bit is set to 1 when the Enable Magic Packet Detection option is selected

Bit 6 **RWKSEL**: PMT Remote Wakeup Packet Enable  
This bit is set to 1 when the Enable Remote wakeup Packet Detection option is selected

Bit 5 **SMASEL**: SMA (MDIO) Interface  
This bit is set to 1 when the Enable Station Management (MDIO Interface) option is selected

Bit 4 **VLHASH**: VLAN Hash Filter Selected  
This bit is set to 1 when the Enable VLAN Hash Table Based Filtering option is selected

Bit 3 **PCSSEL**: PCS Registers (TBI, SGMII, or RTBI PHY interface)  
This bit is set to 1 when the TBI, SGMII, or RTBI PHY interface option is selected

Bit 2 **HDSEL**: Half-duplex Support  
This bit is set to 1 when the Half-duplex mode is selected

Bit 1 **GMISEL**: 1000 Mbps Support  
This bit is set to 1 when 1000 Mbps is selected as operating mode.

Bit 0 **MISEL**: 10 or 100 Mbps Support  
This bit is set to 1 when 10/100 Mbps is selected as operating mode.

**HW feature 1 register (ETH_MACHWF1R)**

Address offset: 0x0120  
Reset value: 0x1104 1904

This register indicates the presence of second set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bit 31  Reserved, must be kept at reset value.

Bits 30:27  **L3L4FNUM[3:0]**: Total number of L3 or L4 Filters
This field indicates the total number of L3 or L4 filters:
- 0000: No L3 or L4 Filter
- 0001: 1 L3 or L4 Filter
- 0010: 2 L3 or L4 Filters
- ...
- 1000: 8 L3 or L4

Bit 26  Reserved, must be kept at reset value.

Bits 25:24  **HASHTBLSZ[1:0]**: Hash Table Size
This field indicates the size of the Hash table:
- 00: No Hash table
- 01: 64
- 10: 128
- 11: 256

Bit 23  **POUOST**: One Step for PTP over UDP/IP Feature Enable
This bit is set to 1 when the Enable one step timestamp for PTP over UDP/IP feature is selected.

Bit 22  Reserved, must be kept at reset value.

Bit 21  **RAVSEL**: Rx Side Only AV Feature Enable
This bit is set to 1 when the Enable Audio Video Bridging option on Rx Side Only is selected.

Bit 20  **AVSEL**: AV Feature Enable
This bit is set to 1 when the Enable Audio Video Bridging option is selected.

Bit 19  **DBGMEMA**: DMA Debug Registers Enable
This bit is set to 1 when the Debug Mode Enable option is selected.

Bit 18  **TSOEN**: TCP Segmentation Offload Enable
This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected.

Bit 17  **SPHEN**: Split Header Feature Enable
This bit is set to 1 when the Enable Split Header Structure option is selected.

Bit 16  **DCBEN**: DCB Feature Enable
This bit is set to 1 when the Enable Data Center Bridging option is selected.

Bits 15:14  **ADDR64[1:0]**: Address width
This field indicates the configured address width.
- 00: 32 bits
- Others: Reserved, must not be used

Bit 13  **ADVTHWORD**: IEEE 1588 High Word Register Enable
This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected.

Bit 12  **PTOEN**: PTP Offload Enable
This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected.

Bit 11  **OSTEN**: One-Step Timestamping Enable
This bit is set to 1 when the Enable One-Step Timestamp Feature is selected.
Bits 10:6  **TXFIFOSIZE[4:0]:** MTL Transmit FIFO Size

This field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, \( \log_2(\text{TXFIFO_SIZE}) - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011 to 11111: Reserved, must not be used

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **RXFIFOSIZE[4:0]:** MTL Receive FIFO Size

This field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, \( \log_2(\text{RXFIFO_SIZE}) - 7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011: 256 Kbytes
- 01100 to 11111: Reserved, must not be used
HW feature 2 register (ETH_MACHWF2R)

Address offset: 0x0124
Reset value: 0x4100 0000

This register indicates the presence of third set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bits 5:4

**DVLAN:** Double VLAN processing enable

This bit is set to 1 when Double VLAN processing is enabled.

**CBTISEL:** Queue/Channel based VLAN tag insertion on Tx enable

This bit is set to 1 when the Enable Queue/Channel based VLAN tag insertion on Tx feature is selected.

Bits 2:0

**NRVF[2:0]:** Number of Extended VLAN Tag Filters Enabled

This field indicates the Number of Extended VLAN Tag Filters selected:
MDIO address register (ETH_MACMDIOAR)

Address offset: 0x0200
Reset value: 0x0000 0000

The MDIO Address register controls the management cycles to external PHY through a management interface.

| Bit 31:28 Reserved, must be kept at reset value. |
| Bit 27 PSE: Preamble Suppression Enable |
| When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit. |
| When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. |
| Bit 26 BTB: Back to Back transactions |
| When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame. |
| When this bit is reset, then the read/write command completion (MII busy is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. |
| This bit must not be set when NTC=0. |
| Bits 25:21 PA[4:0]: Physical Layer Address |
| This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. |
| This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing. |
| Bits 20:16 RDA[4:0]: Register/Device Address |
| These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY. |
| Bit 15 Reserved, must be kept at reset value. |
| Bits 14:12 NTC[2:0]: Number of Training Clocks |
| This field controls the number of trailing clock cycles generated on ETH_MDC after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 011 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer. |
Bits 11:8 **CR[3:0]: CSR Clock Range**

The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design:

- **0000**: CSR clock = 60-100 MHz; MDC clock = CSR clock/42
- **0001**: CSR clock = 100-150 MHz; MDC clock = CSR clock/62
- **0010**: CSR clock = 20-35 MHz; MDC clock = CSR clock/16
- **0011**: CSR clock = 35-60 MHz; MDC clock = CSR clock/26
- **0100**: CSR clock = 150-250 MHz; MDC clock = CSR clock/102
- **0101**: CSR clock = 250-300 MHz; MDC clock = CSR clock/124
- **0110 to 0111**: Reserved, must not be used

The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits to 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks:

- **1000**: CSR clock/4
- **1001**: CSR clock/6
- **1010**: CSR clock/8
- **1011**: CSR clock/10
- **1100**: CSR clock/12
- **1101**: CSR clock/14
- **1110**: CSR clock/16
- **1111**: CSR clock/18

Bits 7:5 **Reserved, must be kept at reset value.**

**Bit 4 SKAP: Skip Address Packet**

When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
Bits 3:2 **GOC[1:0]:** MII Operation Command  
This bit indicates the operation command to the PHY.  
00: Reserved, must not be used  
01: Write  
10: Post Read Increment Address for Clause 45 PHY  
11: Read  
When Clause 22 PHY is enabled, only Write and Read commands are valid.

Bit 1 **C45E:** Clause 45 PHY Enable  
When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.

Bit 0 **MB:** MII Busy  
The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIOS. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in **MDIO address register (ETH_MACMDIOAR)** and **MDIO data register (ETH_MACMDIODR)** as long as this bit is set.  
For write transfers, the application must first write 16-bit data in the MD field (and also RA field when C45E is set) in **MDIO data register (ETH_MACMDIODR)** register before setting this bit. When C45E is set, it should also write into the RA field of **MDIO data register (ETH_MACMDIODR)** before initiating a read transfer. When a read transfer is completed (MII busy=0), the data read from the PHY register is valid in the MD field of the **MDIO data register (ETH_MACMDIODR)**.

*Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit.*

**MDIO data register (ETH_MACMDIODR)**  
Address offset: 0x0204  
Reset value: 0x0000 0000  
The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in **MDIO address register (ETH_MACMDIOAR)**. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

</tbody>
</table>
ARP address register (ETH_MACARPAR)

Address offset: 0x0210
Reset value: 0x0000 0000

The ARP Address register contains the IPv4 Destination Address of the MAC.

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
ARPPA[31:16] rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
  15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
ARPPA[15:0] rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
```

Bits 31:0  ARPPA[31:0]: ARP Protocol Address
This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

CSR software control register (ETH_MACCSRSWCR)

Address offset: 0x0230
Reset value: 0x0000 0000

This register contains software-programmable controls for changing the CSR access response and status bits clearing.

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
Bits 31:9 Reserved, must be kept at reset value.
  Bit 8  SEEN: Slave Error Response Enable
         When this bit is set, the MAC responds with a Slave Error for accesses to reserved registers in CSR space.
         When this bit is reset, the MAC responds with an Okay response to any register accessed from CSR space.
  Bit 7:1 Reserved, must be kept at reset value.
  Bit 0  RCWE: Register Clear on Write 1 Enable
         When this bit is set, the access mode to some register fields changes to rc_w1 (clear on write) meaning that the application needs to set that respective bit to 1 to clear it.
         When this bit is reset, the access mode to these register fields remains rc_r (clear on read).
```
**MAC Address 0 high register (ETH_MACA0HR)**

Address offset: 0x0300  
Reset value: 0x8000 FFFF  

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

| Bit 31 AE: Address Enable  
| This bit is always set to 1.  

| Bits 30:16 Reserved, must be kept at reset value.  

| Bits 15:0 ADDRHI[15:0]: MAC Address0[47:32]  
| This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

**MAC Address x low register (ETH_MACAxLR)**

Address offset: 0x0304 + 0x8 * x, (x = 0 to 3)  
Reset value: 0xFFFF FFFF  

The MAC Address x Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

| Bit 31 ADDRLO[31:16]  
| ADDRLO[15:0]  

1 | 5 | 1 | 4 | 1 | 3 | 1 | 2 | 1 | 1 | 1 | 0 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  

Bit 31 ADDRLO[31:16]:  
This field contains the lower 32 bits [15:0] of the first 6-byte MAC address.
Bits 31:0 **ADDRLO[31:0]**: MAC Address x [31:0] (x = 0 to 3)

This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

**MAC Address x high register (ETH_MACAxHR)**

Address offset: 0x0308 + 0x8 * (x-1), (x = 1 to 3)

Reset value: 0x0000 FFFF

The MAC Address x High register holds the upper 16 bits of the second 6-byte MAC address of the station.

Bit 31 **AE**: Address Enable

When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

Bit 30 **SA**: Source Address

When this bit is set, the MAC Address x[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address x[47:0] is used to compare with the DA fields of the received packet.

0: DA

1: SA

Bits 29:24 **MBC[5:0]**: Mask Byte Control

These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address 1 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH_MACAxHR[15:8]
- Bit 28: ETH_MACAxHR[7:0]
- Bit 27: ETH_MACAxLR[31:24]
- Bit 26: ETH_MACAxLR[23:16]
- Bit 25: ETH_MACAxLR[15:8]
- Bit 24: ETH_MACAxLR[7:0]

You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.

Bits 23:16 **Reserved**, must be kept at reset value.

Bits 15:0 **ADDRHI[15:0]**: MAC Address1 [47:32]

This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.
MMC control register (ETH_MMC_CONTROL)

Address offset: 0x0700
Reset value: 0x0000 0000

This register configures the MMC operating mode.

</tr>
</tbody>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **UCDBC**: Update MMC Counters for Dropped Broadcast Packets

The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of Packet filtering control register (ETH_MACPFR).

When reset, the MMC Counters are not updated for dropped Broadcast packets.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **CNTPRSTLVL**: Full-Half Preset

When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x77FF_F800 (Half 2Kbytes) and all packet-counters get preset to 0x77FF_F800 (Half 2Kbytes).

When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2Kbytes) and all packet-counters get preset to 0xFFFF_F800 (Full 16).

For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0x8000 and 0x7FF0.

Bit 4 **CNTPRST**: Counters Preset

When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle.

This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.

Bit 3 **CNTFREEZ**: MMC Counter Freeze

When this bit is set, it freezes all MMC counters to their current value.

Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
Bit 2 **RSTONRD**: Reset on Read
When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read.

Bit 1 **CNTSTOPRO**: Counter Stop Rollover
When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Bit 0 **CNTRST**: Counters Reset
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

**MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**
Address offset: 0x0704
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Receive statistics counters. The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:
- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the CNTSTOPRO is set in **MMC control register (ETH_MMC_CONTROL)**, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

<table>
<thead>
<tr>

<tr>
<td>Bits 25:18</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 17 **RXUCGPIS**: MMC Receive Unicast Good Packet Counter Interrupt Status
This bit is set when the *Rx unicast packets good register (ETH_RX_UNICAST_PACKETS_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 16-7 Reserved, must be kept at reset value.

Bit 6 **RXALGNERPIS**: MMC Receive Alignment Error Packet Counter Interrupt Status
This bit is set when the *Rx alignment error packets register (ETH_RX_ALIGNMENT_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 5 **RXCRCERPIS**: MMC Receive CRC Error Packet Counter Interrupt Status
This bit is set when the *Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

**MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**

Address offset: 0x0708
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When CNTSTOPRO is set in *MMC control register (ETH_MMC_CONTROL)*, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXLPITRCS:** MMC Transmit LPI transition counter interrupt status
This bit is set when the *Tx LPI transition counter register (ETH_TX_LPI_TRAN_CNTR)* counter reaches half of the maximum value or the maximum value.

Bit 26  **TXLPIUSCIS:** MMC Transmit LPI microsecond counter interrupt status
This bit is set when the *Tx LPI microsecond timer register (ETH_TX_LPI_USEC_CNTR)* counter reaches half of the maximum value or the maximum value.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  **TXGPKTIS:** MMC Transmit Good Packet Counter Interrupt Status
This bit is set when the *Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)* counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

Bit 15  **TXMCOLGPIS:** MMC Transmit Multiple Collision Good Packet Counter Interrupt Status
This bit is set when the *Tx multiple collision good packets register (ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bit 14  **TXSCOLGPIS:** MMC Transmit Single Collision Good Packet Counter Interrupt Status
This bit is set when the *Tx single collision good packets register (ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)* counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
MMC Rx interrupt mask register (ETH_MMC_RX_INTERRUPT_MASK)

Address offset: 0x070C
Reset value: 0x0000 0000

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 RXLPICTRIM: MMC Receive LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the Rx LPI transition counter register
(ETH_RX_LPI_TRAN_CNTR) counter reaches half of the maximum value or the maximum value.

Bit 26 RXLPUSICM: MMC Receive LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the Rx LPI microsecond counter register
(ETH_RX_LPI_USEC_CNTR) counter reaches half of the maximum value or the maximum value.

Bits 25:18 Reserved, must be kept at reset value.

Bit 17 RXUCGPIM: MMC Receive Unicast Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Rx unicast packets good register
(ETH_RX_UNICAST_PACKETS_GOOD) counter reaches half of the maximum value or the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 RXALGNERPIM: MMC Receive Alignment Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Rx alignment error packets register
(ETH_RX_ALIGNMENT_ERROR_PACKETS) counter reaches half of the maximum value or the maximum value.

Bit 5 RXCRCERPIM: MMC Receive CRC Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the Rx CRC error packets register
(ETH_RX_CRC_ERROR_PACKETS) counter reaches half of the maximum value or the maximum value.

Bits 4:0 Reserved, must be kept at reset value.
MMC Tx interrupt mask register (ETH_MMC_TX_INTERRUPT_MASK)

Address offset: 0x0710
Reset value: 0x0000 0000

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **TXLPITRCIM**: MMC Transmit LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the *Tx LPI transition counter register* (*ETH_TX_LPI_TRAN_CNTR*) counter reaches half of the maximum value or the maximum value.

Bit 26 **TXLPUSCIM**: MMC Transmit LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the *Tx LPI microsecond timer register* (*ETH_TX_LPI_USEC_CNTR*) counter reaches half of the maximum value or the maximum value.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **TXGPKTIM**: MMC Transmit Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the *Tx packet count good register* (*ETH_TX_PACKET_COUNT_GOOD*) counter reaches half of the maximum value or the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TXMCOLGPIM**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the *Tx multiple collision good packets register* (*ETH_TX_MULTIPLE_COLLISION_GOOD_PACKETS*) counter reaches half of the maximum value or the maximum value.

Bit 14 **TXSCOLGPIM**: MMC Transmit Single Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the *Tx single collision good packets register* (*ETH_TX_SINGLE_COLLISION_GOOD_PACKETS*) counter reaches half of the maximum value or the maximum value.

Bits 13:0 Reserved, must be kept at reset value.
**Tx single collision good packets register**  
(ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)

Address offset: 0x074C  
Reset value: 0x0000 0000  
This register provides the number of successfully transmitted packets by Ethernet peripheral after a single collision in the Half-duplex mode.

</table>

Bits 31:0 **RXLPITRC[31:0]**: Rx LPI Transition counter

This field indicates the number of times Rx LPI Entry has occurred.
**L3 and L4 control 0 register (ETH_MACL3L4C0R)**

Address offset: 0x0900

Reset value: 0x0000 0000

The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.

| Bit 31:22 Reserved, must be kept at reset value. |
| Bit 21 **L4DPIM0**: Layer 4 Destination Port Inverse Match Enable |
| When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. |
| This bit is valid and applicable only when the L4DPM0 bit is set high. |
| Bit 20 **L4DPM0**: Layer 4 Destination Port Match Enable |
| When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching. |
| Bit 19 **L4SPIM0**: Layer 4 Source Port Inverse Match Enable |
| When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. |
| This bit is valid and applicable only when the L4SPM0 bit is set high. |
| Bit 18 **L4SPM0**: Layer 4 Source Port Match Enable |
| When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. |
| Bit 17 Reserved, must be kept at reset value. |
| Bit 16 **L4PEN0**: Layer 4 Protocol Enable |
| When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. |
| The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set. |
Bits 15:11 **L3HDBM0[4:0]**: Layer 3 IP DA higher bits match
Condition: IPv4 packets
This field contains the number of higher bits of IP Destination Address that are masked in the IPv4 packets:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
.. 31: All bits except MSb are masked.
Condition: IPv6 packets
Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. Number of bits masked is given by concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
.. 31: All bits except MSb are masked.
This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 **L3HSBM0[4:0]**: Layer 3 IP SA higher bits match
Condition: IPv4 packets
This field contains the number of lower bits of IP source address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
.. 31: All bits except MSb are masked.
Condition: IPv6 packets:
This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP source or destination address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Bit 5 **L3DAIM0**: Layer 3 IP DA Inverse Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 **L3DAM0**: Layer 3 IP DA Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note*: When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Bit 3 **L3SAIM0**: Layer 3 IP SA Inverse Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3SAM0 bit is set.
Bit 2  **L3SAM0**: Layer 3 IP SA Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

**Note:** When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **L3PEN0**: Layer 3 Protocol Enable
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.

The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

**Layer 4 Address filter 0 register (ETH_MACL4A0R)**

Address offset: 0x0904
Reset value: 0x0000 0000

Bits 31:16  **L4DP0[15:0]**: Layer 4 Destination Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.
When the L4PEN0 and L4DPM0 bits are set in **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

Bits 15:0  **L4SP0[15:0]**: Layer 4 Source Port Number Field
When the L4PEN0 bit is reset and the L4DPM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.
When the L4PEN0 and L4DPM0 bits are set in **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer3 Address 0 filter 0 register (ETH_MACL3A00R)

Address offset: 0x0910
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A00[31:0]: Layer 3 Address 0 Field
When the L3PEN0 and L3SAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[31:0] of the IP Source Address field in the IPv6 packets.
When the L3PEN0 and L3DAM0 bits are set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with Bits[31:0] of the IP Destination Address field in the IPv6 packets.
When the L3PEN0 bit is reset and the L3SAM0 bit is set in the L3 and L4 control 0 register (ETH_MACL3L4C0R), this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer3 Address 1 filter 0 register (ETH_MACL3A10R)

Address offset: 0x0914
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.
Bits 31:0  **L3A10[31:0]: Layer 3 Address 1 Field**

When the L3PEN0 and L3SAM0 bits are set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets.

When the L3PEN0 and L3DAM0 bits are set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with Bits[63:32] of the IP Destination Address field in the IPv6 packets.

When the L3PEN0 bit is reset and the L3SAM0 bit is set in the **L3 and L4 control 0 register (ETH_MACL3L4C0R)**, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

---

**Layer3 Address 2 filter 0 register (ETH_MACL3A20R)**

Address offset: 0x0918

Reset value: 0x0000 0000

The Layer 3 Address 2 filter 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

---

**Layer3 Address 3 filter 0 register (ETH_MACL3A30R)**

Address offset: 0x091C

Reset value: 0x0000 0000

The Layer 3 Address 3 filter 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.
**L3 and L4 control 1 register (ETH_MACL3L4C1R)**

Address offset: 0x0930  
Reset value: 0x0000 0000

The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.

<table>
<thead>
<tr>
<th>Bit 31:22</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 21   | **L4DPM1**: Layer 4 Destination Port Match Enable  
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching.  
This bit is valid and applicable only when the L4DPIM1 bit is set high. |
| Bit 20   | **L4DPM1**: Layer 4 Destination Port Match Enable  
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching. |
| Bit 19   | **L4SPIM1**: Layer 4 Source Port Inverse Match Enable  
When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching.  
This bit is valid and applicable only when the L4SPM1 bit is set high. |
| Bit 18   | **L4SPM1**: Layer 4 Source Port Match Enable  
When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching. |
| Bit 17   | Reserved, must be kept at reset value. |
Bit 16 **L4PEN1**: Layer 4 Protocol Enable
When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.
The Layer 4 matching is done only when the L4SPM1 or L4DPM1 bit is set.

Bits 15:11 **L3HDBM1[4:0]**: Layer 3 IP DA higher bits match
Condition: IPv4 packets
This field contains the number of lower bits of IP Destination Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
31: All bits except MSb are masked.
Condition: IPv6 packets
Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM1, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM1[1:0] and L3HSBM1 bits:
0: No bits are masked
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
127: All bits except MSb are masked
This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set.

Bits 10:6 **L3HSBM1[4:0]**: Layer 3 IP SA Higher Bits Match
Condition: IPv4 packets
This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
...
31: All bits except MSb are masked.
Condition: IPv6 packets
This field contains Bits[4:0] of L3HSBM1. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM1 or L3SAM1 bit is set high.

Bit 5 **L3DAIM1**: Layer 3 IP DA Inverse Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3DAM1 bit is set high.

Bit 4 **L3DAM1**: Layer 3 IP DA Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.
*Note:* When the L3PEN1 bit is set, you should set either this bit or the L3SAM1 bit because either IPv6 DA or SA can be checked for filtering.
Bit 3 **L3SAIM1**: Layer 3 IP SA Inverse Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching.
When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3SAM1 bit is set.

Bit 2 **L3SAM1**: Layer 3 IP SA Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for matching.
When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.

*Note: When the L3PEN01 bit is set, you should set either this bit or the L3DAM1 bit because either IPv6 SA or DA can be checked for filtering.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **L3PEN1**: Layer 3 Protocol Enable
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets.
When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.
The Layer 3 matching is done only when the L3SAM1 or L3DAM1 bit is set.

**Layer 4 address filter 1 register (ETH_MACL4A1R)**

Address offset: 0x0934
Reset value: 0x0000 0000

Bits 31:16 **L4DP1[15:0]**: Layer 4 Destination Port Number Field

When the L4PEN1 bit is reset and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets.

When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

Bits 15:0 **L4SP1[15:0]**: Layer 4 Source Port Number Field

When the L4PEN1 bit is reset and the L4DPM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets.

When the L4PEN1 and L4DPM1 bits are set in L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
Layer3 address 0 filter 1 Register (ETH_MACL3A01R)

Address offset: 0x0940
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 0 filter 1 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A01[31:0]: Layer 3 Address 0 Field

When the L3PEN1 and L3SAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 bit is reset and the L3SAM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

Layer3 address 1 filter 1 register (ETH_MACL3A11R)

Address offset: 0x0944
Reset value: 0x0000 0000

For IPv4 packets, the Layer 3 Address 1 filter 1 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A11[31:0]: Layer 3 Address 1 Field

When the L3PEN1 and L3SAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Destination Address field in the IPv6 packets.

When the L3PEN1 and L3DAM1 bits are set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with Bits[31:0] of the IP Source Address field in the IPv6 packets.

When the L3PEN1 bit is reset and the L3SAM1 bit is set in the L3 and L4 control 1 register (ETH_MACL3L4C1R), this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.
Bits 31:0  **L3A1[31:0]: Layer 3 Address 1 Field**
When the L3PEN1 and L3SAM1 bits are set in the *L3 and L4 control 1 register (ETH_MACL3L4C1R)*, this field contains the value to be matched with Bits[63:32] of the IP Source Address field in the IPv6 packets.
When the L3PEN1 and L3DAM1 bits are set in the *L3 and L4 control 1 register (ETH_MACL3L4C1R)*, this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets.
When the L3PEN1 bit is reset and the L3SAM1 bit is set in the *L3 and L4 control 1 register (ETH_MACL3L4C1R)*, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

**Layer3 address 2 filter 1 Register (ETH_MACL3A21R)**
Address offset: 0x0948
Reset value: 0x0000 0000
The Layer 3 Address 2 filter 1 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[95:64] of 128-bit IP Source Address or Destination Address field.

When the L3PEN1 bit is reset in the *L3 and L4 control 1 register (ETH_MACL3L4C1R)*, this field is not used.

**Layer3 address 3 filter 1 register (ETH_MACL3A31R)**
Address offset: 0x094C
Reset value: 0x0000 0000
The Layer 3 Address 3 filter 1 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.

3064/3357                   RM0468 Rev 3
**Timestamp control Register (ETH_MACTSCR)**

Address offset: 0x0B00

Reset value: 0x0000 2000

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

<table>
<thead>
<tr>
<th>Bit 31:29</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 28</td>
<td><strong>AV8021ASMEN</strong>: AV 802.1AS Mode Enable</td>
</tr>
<tr>
<td></td>
<td>When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS operating mode. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit.</td>
</tr>
<tr>
<td>Bits 27:25</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 24</td>
<td><strong>TXTSSTSM</strong>: Transmit Timestamp Status Mode</td>
</tr>
<tr>
<td></td>
<td>When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR) register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the Tx timestamp status nanoseconds register (ETH_MACTXTSSNR).</td>
</tr>
<tr>
<td>Bits 23:19</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 18 **TSENMACADDR**: Enable MAC Address for PTP Packet Filtering
When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet.
When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet.
For normal timestamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching.
For PTP offload, only MAC address register 0 is considered for unicast destination address matching.

Bits 17:16 **SNAPTYPESEL[1:0]**: Select PTP packets for Taking Snapshots
These bits, along with Bits 15 and 14, define the set of PTP packet types for which snapshot needs to be taken. The encoding is given in *Table 560: Timestamp Snapshot Dependency on ETH_MACTSCR Bits*.

Bit 15 **TSMSTRENA**: Enable Snapshot for Messages Relevant to Master
When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Bit 14 **TSEVNTENA**: Enable Timestamp Snapshot for Event Messages
When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see *Table 560: Timestamp Snapshot Dependency on ETH_MACTSCR Bits*.

Bit 13 **TSIPV4ENA**: Enable Processing of PTP Packets Sent over IPv4-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

Bit 12 **TSIPV6ENA**: Enable Processing of PTP Packets Sent over IPv6-UDP
When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Bit 11 **TSIPENA**: Enable Processing of PTP over Ethernet Packets
When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.

Bit 10 **TSVER2ENA**: Enable PTP Packet Processing for Version 2 Format
When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.

Bit 9 **TSCTRLSSR**: Timestamp Digital or Binary Rollover Control
When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of subsecond register is 0x7FFF_FFFF. The subsecond increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Bit 8 **TSENALL**: Enable Timestamp for All Packets
When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.

Bits 7:6 Reserved, must be kept at reset value.
Subsecond increment register (ETH_MACSSIR)

Address offset: 0x0B04
Reset value: 0x0000 0000

In Coarse Update mode (bit TSCFUPDT in Timestamp control Register (ETH_MACTSCR)), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bit 5  **TSADDREG**: Update Addend Register
When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set.

Bit 4  Reserved, must be kept at reset value.

Bit 3  **TSUPDT**: Update Timestamp
When this bit is set, the system time is updated (added or subtracted) with the value specified in *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before updating it. This bit is reset when the update is complete in hardware.

Bit 2  **TSINIT**: Initialize Timestamp
When this bit is set, the system time is initialized (overwritten) with the value specified in the *System time seconds update register (ETH_MACSTSUR)* and *System time nanoseconds update register (ETH_MACSTNUR)*.
This bit should be zero before it is updated. This bit is reset when the initialization is complete.

Bit 1  **TSCFUPDT**: Fine or Coarse Timestamp Update
When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.

Bit 0  **TSENA**: Enable Timestamp
When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode.
On the Receive side, the MAC processes the 1588 packets only if this bit is set.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **SSINC[7:0]:** Subsecond Increment Value

The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the subsecond register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [TSCTRLSSR bit is set in Timestamp control Register (ETH_MACTSCR)]. When TSCTRLSSR is cleared, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

Bits 15:0  Reserved, must be kept at reset value.
System time seconds register (ETH_MACSTSR)

Address offset: 0x0B08

Reset value: 0x0000 0000

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Bits 31:0 TSS[31:0]: Timestamp Second

The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

System time nanoseconds register (ETH_MACSTNR)

Address offset: 0x0B0C

Reset value: 0x0000 0000

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 TSSS[30:0]: Timestamp subseconds

The value in this field has the subsecond representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set in Timestamp control Register (ETH_MACTSCR), each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.
System time seconds update register (ETH_MACSTSUR)

Address offset: 0x0B10  
Reset value: 0x0000 0000  

The System Time Seconds Update register, along with the System Time Nanoseconds update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in *Timestamp control Register (ETH_MACTSCR)*.

Bits 31:0 **TSS[31:0]**: Timestamp Seconds  
The value in this field is the seconds part of the update.  
When ADDSUB is reset, this field must be programmed with the seconds part of the update value.  
When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value.  
For example, to subtract 2.000000001 seconds from the system time, the TSS field in the ETH_MACSTSUR register must be 0xFFFF_FFFE (that is, 2^32 – 2).

**Caution:** When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0 in *System time nanoseconds update register (ETH_MACSTNUR)*. The TSSS bitfield must be programmed to 0x7FFF FFFF (resulting in –0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, the TSS field in the **System time seconds update register (ETH_MACSTSUR)** must be 0xFFFF FFFE (that is, 2^32 – 1) and the **System time nanoseconds update register (ETH_MACSTNUR)** must be 0xFFFF FFFF (ADDSUB = 1 and TSSS[30:0] field = 0x7FFF_FFFF).

System time nanoseconds update register (ETH_MACSTNUR)

</table>
Bit 31 ADDSUB: Add or Subtract Time
When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

Bits 30:0 TSSS[30:0]: Timestamp subseconds
The value in this field is the subseconds part of the update.
- ADDSUB is 1: This field must be programmed with the complement of the subseconds part of the update value as described.
- ADDSUB is 0: This field must be programmed with the subseconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the Timestamp control Register (ETH_MACTSCR).
- TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 1:
  - The programmed value must be 10^9 – <subsecond value>.
  - Each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF.
- TSCTRLSSR field in the Timestamp control Register (ETH_MACTSCR) is 0:
  - The programmed value must be 2^31 - <subsecond value>.
  - Each bit represents an accuracy of 0.46 ns.

For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the ETH_MACSTNUR register must be 0x7FFF_FFFF (that is, 2^31 – 1), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset and 0x3B9A_C9FF (that is, 10^9 –1), when TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set.

Caution: When the ADDSUB bit is set, TSSS[30:0] field cannot be set to 0. The TSSS bitfield must be programmed to 0x7FFF_FFFF (resulting in –0.46 ns) even if 0 ns must be subtracted.

For example, to subtract 2.000000000 seconds from the system time, System time nanoseconds update register (ETH_MACSTNUR) must be 0xFFFF_FFFF (ADDSUB = 1 and TSSS[30:0] = 0) and the TSS field in the System time seconds update register (ETH_MACSTSUR) must be 0xFFFF_FFFE (that is, 2^32 – 1).

Timestamp addend register (ETH_MACTSAR)
Address offset: 0x0B18
Reset value: 0x0000 0000

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the Timestamp control Register (ETH_MACTSCR)). The content of this register is added to a 32-bit accumulator in every clock cycle of clk_ptp_ref_i and the system time is updated whenever the accumulator overflows.

Bits 31:0 TSAR[31:0]: Timestamp Addend Register
This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.
**Timestamp status register (ETH_MACTSSR)**

Address offset: 0xB20

Reset value: 0x0000 0000

All bits except Bits[27:25] gets cleared when the application reads this register.

| Bit 31:30 | Reserved, must be kept at reset value. |
| Bit 29:25 | **ATSNS[4:0]**: Number of Auxiliary Timestamp Snapshots |
| | This field indicates the number of Snapshots available in the FIFO. A value equal to the depth of FIFO (4) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. |
| Bit 24 | **ATSSTM**: Auxiliary Timestamp Snapshot Trigger Missed |
| | This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. |
| Bit 23:20 | Reserved, must be kept at reset value. |
| Bit 19:16 | **ATSSTN[3:0]**: Auxiliary Timestamp Snapshot Trigger Identifier |
| | These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: |
| | Bit 16: Auxiliary trigger 0 |
| | Bit 17: Auxiliary trigger 1 |
| | Bit 18: Auxiliary trigger 2 |
| | Bit 19: Auxiliary trigger 3 |
| | The software can read this register to find the triggers that are set when the timestamp is taken. |
| Bit 15 | **TXTSSIS**: Tx Timestamp Status Interrupt Status |
| | When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)**. |
| | When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the **Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)** and **Tx timestamp status seconds register (ETH_MACTXTSSSR)**, for PTO generated Delay Request and Pdelay request packets. |
| | This bit is cleared when the **Tx timestamp status seconds register (ETH_MACTXTSSSR)** is read (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set). |
| Bit 14:4 | Reserved, must be kept at reset value. |
Bit 3 **TSTRGTER0**: Timestamp Target Time Error
This bit is set when the latest target time programmed in the **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)** elapses. This bit is cleared when the application reads this bit (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 2 **AUXTSTRIG**: Auxiliary Timestamp Trigger Snapshot
This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is cleared when the application reads this bit (or write of 1 when RCWE bit in **CSR software control register (ETH_MACCSRSWCR)** is set).

Bit 1 **TSTARGT0**: Timestamp Target Time Reached
When set, this bit indicates that the value of system time is greater than or equal to the value specified in the **PPS target time seconds register (ETH_MACPPSTTSR)** and **PPS target time nanoseconds register (ETH_MACPPSTTNR)**.

Bit 0 **TSSOVF**: Timestamp Seconds Overflow
When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF.

**Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**
Address offset: 0x0B30
Reset value: 0x0000 0000
This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

Bit 31 **TXTSSMIS**: Transmit Timestamp Status Missed
When this bit is set, it indicates one of the following:
- The timestamp of the current packet is ignored if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is reset
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the **Timestamp control Register (ETH_MACTSCR)** is set.

Bits 30:0 **TXTSSLO[30:0]**: Transmit Timestamp Status Low
This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.
**Tx timestamp status seconds register (ETH_MACTXTSSSR)**

Address offset: 0x0B34  
Reset value: 0x0000 0000  
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

**Bits 31:8** **Reserved, must be kept at reset value.**

**Bit 7 ATSEN3: Auxiliary Snapshot 3 Enable**  
This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg3 input is enabled. When this bit is reset, the events on this input are ignored.

**Bit 6 ATSEN2: Auxiliary Snapshot 2 Enable**  
This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg2 input is enabled. When this bit is reset, the events on this input are ignored.

**Bit 5 ATSEN1: Auxiliary Snapshot 1 Enable**  
This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on eth_ptp_trg1 input is enabled. When this bit is reset, the events on this input are ignored.
Bit 4 **ATSEN0**: Auxiliary Snapshot 0 Enable

This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on `eth_ptp_trg0` input is enabled. When this bit is reset, the events on this input are ignored.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ATSFC**: Auxiliary Snapshot FIFO Clear

When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO.

**Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**

Address offset: 0x0B48

Reset value: 0x0000 0000

The **Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**, along with **Auxiliary timestamp seconds register (ETH_MACATSSR)**, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4 words.

You can store multiple snapshots in this FIFO. Bits[29:25] in **Timestamp status register (ETH_MACTSSR)** indicate the fill-level of the FIFO. The top of the FIFO is removed only when **Auxiliary timestamp seconds register (ETH_MACATSSR)** is read.

---

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 **AUXTSLO[30:0]**: Auxiliary Timestamp

Contains the lower 31 bits (nanoseconds field) of the auxiliary timestamp.

**Auxiliary timestamp seconds register (ETH_MACATSSR)**

Address offset: 0x0B4C

Reset value: 0x0000 0000

The Auxiliary Timestamp Seconds register contains the lower 32 bits of the Seconds field of the auxiliary timestamp register.
AMC 31:0 AXTS[31:0]: Auxiliary Timestamp
Contains the lower 32 bits of the Seconds field of the auxiliary timestamp.

**Timestamp Ingress asymmetric correction register (ETH_MACSIACR)**
Address offset: 0x0B50
Reset value: 0x0000 0000
The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

**OSTIA[15:0]**

Bits 31:0 **OSTIA[31:0]**: One-Step Timestamp Ingress Asymmetry Correction
This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.

**Timestamp Egress asymmetric correction register (ETH_MACTSEACR)**
Address offset: 0x0B54
Reset value: 0x0000 0000
The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

**OSTEA[15:0]**

Bits 31:0 **OSTEA[31:0]**: One-Step Timestamp Egress Asymmetry Correction
This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFFD_8000, which is the 2's complement of 0x0002_8000(2.5 * 2^16). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 2^16).
**Timestamp Ingress correction nanosecond register (ETH_MACTSICNR)**

Address offset: 0x0B58
Reset value: 0x0000 0000

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

</table>
```
Bits 31:7 Reserved, must be kept at reset value.

Bits 6:5 **TRGTMODSEL[1:0]**: Target Time Register Mode for PPS Output

This field indicates the Target Time registers (*PPS target time seconds register (ETH_MACPPSTTSR)* and *PPS target time nanoseconds register (ETH_MACPPSTTNR)* ) mode for PPS output signal:
- 00: Target Time registers are programmed only for generating the interrupt event.
- 01: Reserved, must not be used
- 10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
- 11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0**: Flexible PPS Output Mode Enable

When this bit is set, PPSCTRL[3:0] function as PPSCMD[3:0]. When this bit is reset, PPSCTRL[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 **PPSCTRL[3:0]**: PPS Output Frequency Control

This field controls the frequency of the PPS output (eth_ptp_pps_out) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:
- 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
- 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
- 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
- 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.
  ...
- 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.

Note: In the binary rollover mode, the PPS output (eth_ptp_pps_out) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:
- When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
- When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of
  One clock of 50 percent duty cycle and 537 ms period
  Second clock of 463 ms period (268 ms low and 195 ms high)
- When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of
  Three clocks of 50 percent duty cycle and 268 ms period
  Fourth clock of 195 ms period (134 ms low and 61 ms high)

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the ETH_MACSTNR register.
### PPS control register [alternate] (ETH_MACPPSCR)

Address offset: 0x0B70

Bits 31:7 Reserved, must be kept at reset value.
Bits 6:5 **TRGMTMODSEL0[1:0]**: Target Time Register Mode for PPS Output

This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS output signal:
- 00: Target Time registers are programmed only for generating the interrupt event.
- 01: Reserved, must not be used
- 10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
- 11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0**: Flexible PPS Output Mode Enable

When this bit is set, Bits[3:0] function as PPSCMD[3:0]. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 **PPSCMD[3:0]**: Flexible PPS Output (eth_ptp_pps_out) Control

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all zero'. The following list describes the values of PPSCMD0:
- 0000: No Command
- 0001: START Single Pulse. This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS Width Register.
- 0010: START Pulse Train. This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands.
- 0011: Cancel START. This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time.
- 0100: STOP Pulse Train at time. This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010) after the time programmed in the Target Time registers elapses.
- 0101: STOP Pulse Train immediately. This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD[3:0] = 0010).
- 0110: Cancel STOP Pulse train. This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.
- 0111 to 1111: Reserved, must not be used
PPS target time seconds register (ETH_MACPPSTTSR)

Address offset: 0x0B80
Reset value: 0x0000 0000

The PPS Target Time Seconds register, along with PPS target time nanoseconds register (ETH_MACPPSTTN), is used to schedule an interrupt event [Bit TSSOVF of Timestamp status register (ETH_MACTSSR)] when the system time exceeds the value programmed in these registers.

Bits 31:0 TSTRH0[31:0]: PPS Target Time Seconds Register
This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the PPS control register (ETH_MACPPSCR).

PPS target time nanoseconds register (ETH_MACPPSTTN)

Address offset: 0x0B84
Reset value: 0x0000 0000

The PPS Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

Bit 31  **TRGTBUSY0**: PPS Target Time Register Busy

The MAC sets this bit when the PPSCMD0 field in the PPS control register (ETH_MACPPSCR) is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers with the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

Bits 30:0  **TTSL0[30:0]**: Target Time Low for PPS Register

This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS control register (ETH_MACPPSCR).

When the TSCTRLSSR bit is set in the Timestamp control Register (ETH_MACTSCR), this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of subsecond increment value.

### PPS interval register (ETH_MACPPSIR)

Address offset: 0x0B88

Reset value: 0x0000 0000

The PPS Interval register contains the number of units of subsecond increment value between the rising edges of PPS signal output (eth_ptp_pps_out).

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:0  **PPSINT0[31:0]**: PPS Output Signal Interval

These bits store the interval between the rising edges of PPS signal output. The interval is stored in terms of number of units of subsecond increment value.

You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS signal output is 100 ns (that is, 5 units of subsecond increment value), you should program value 4 (5-1) in this register.
**PPS width register (ETH_MACPPSWR)**

Address offset: 0x0B8C  
Reset value: 0x0000 0000

The PPS Width register contains the number of units of subsecond increment value between the rising and corresponding falling edges of PPS signal output (eth_ptp_pps_out).

<table>
<thead>
<tr>
<th>Address Offset</th>

</tr>
</tbody>
</table>

The PPS Width register contains the number of units of subsecond increment value between the rising and corresponding falling edges of PPS signal output.

- **PPSWIDTH0[31:16]**
  These bits store the width between the rising edge and corresponding falling edge of the PPS signal output. The width is stored in terms of number of units of subsecond increment value.
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width

  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width
  - Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width

**Note:** The value programmed in this register must be lesser than the value programmed in PPS interval register (ETH_MACPPSIR).

**PTP Offload control register (ETH_MACPOCR)**

Address offset: 0x0BC0  
Reset value: 0x0000 0000

This register controls the PTP Offload Engine operation.

<table>
<thead>
<tr>
<th>Address Offset</th>

<td>Address offset: 0x0BC0  Reset value: 0x0000 0000  PTP Offload control register</td>
</tr>
</tbody>
</table>

This register controls the PTP Offload Engine operation.

- **DN[7:0]**: Domain Number
  This field indicates the domain number in which the PTP node is operating.
  - Bit 7 Reserved, must be kept at reset value.
  - Bit 6 **DRRDIS**: Disable PTO Delay Request/Response response generation
    When this bit is set, the Delay Request and Delay response will not be generated for received SYNC and Delay request packet respectively, as required by the programmed mode.
Bit 5 **APDREQTRIG**: Automatic PTP Pdelay_Req message Trigger
When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the APDREQEN bit for this operation.

Bit 4 **ASYNCTRIG**: Automatic PTP SYNC message Trigger
When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the ASYNCECN bit for this operation.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **APDREQEN**: Automatic PTP Pdelay_Req message Enable
When this bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer Transparent mode.

Bit 1 **ASYNCEN**: Automatic PTP SYNC message Enable
When this bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Clock Master mode.

Bit 0 **PTOEN**: PTP Offload Enable
When this bit is set, the PTP Offload feature is enabled.

**PTP Source Port Identity 0 Register (ETH_MACSPI0R)**

Address offset: 0x0BC4
Reset value: 0x0000 0000

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node.

DRSYNCR[2:0]  LSI[7:0]

rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw

RM0468 Rev 3  3085/3357
Bits 31:24 **LMPDRI[7:0]**: Log Min Pdelay _Req Interval

This field indicates logMinPdelayReqInterval of PTP node. This is used to schedule the periodic Pdelay request packet transmission. Allowed values are -15 to 15. Negative value must be represented in 2’s-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

Bits 23:11 Reserved, must be kept at reset value.

Bits 10:8 **DRSYNCR[2:0]**:

- **Delay _Req to SYNC Ratio**
- In Slave mode, it is used for controlling frequency of Delay _Req messages transmitted.
- 0: DelayReq generated for every received SYNC
- 1: DelayReq generated every alternate reception of SYNC
- 2: for every 4 SYNC messages
- 3: for every 8 SYNC messages
- 4: for every 16 SYNC messages
- 5: for every 32 SYNC messages
- Others: Reserved, must not be used

The master sends this information (logMinDelayReqInterval) in the DelayResp PTP messages to the slave. The reception processes this value from the received DelayResp messages and updates this field accordingly. In the Slave mode, the host must not write/update this register unless it has to override the received value. In Master mode, the sum of this field and logSyncInterval (LSI) field is provided in the logMinDelayReqInterval field of the generated multicast Delay _Resp PTP message.

Bits 7:0 **LSI[7:0]**:

- **Log Sync Interval**
- This field indicates the periodicity of the automatically generated SYNC message when the PTP node is Master. Allowed values are -15 to 15. Negative value must be represented in 2’s-complement form. For example, if the required value is -1, the value programmed must be 0xFF.

**Note:** Each entry in the table represents a register in the Ethernet MAC module, with its offset (in hexadecimal) and register name. The reset value for each register is specified in binary format, showing the state of each bit after reset.

Refer to Section 2.3 on page 131 for the register boundary addresses.
64  HDMI-CEC controller (CEC)

64.1  Introduction

Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

64.2  HDMI-CEC controller main features

- Complies with HDMI-CEC v1.4 specification
- Independent 32 kHz CEC kernel (refer to section RCC kernel clock distribution)
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - with automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)
64.3 HDMI-CEC functional description

64.3.1 HDMI-CEC pin and internal signals

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on Figure 846.

Table 609 lists the internal signals that are exchanged between the HDMI-CEC and other functional blocks (such as RCC and EXTI).

64.3.2 HDMI-CEC block diagram

Figure 846. HDMI-CEC block diagram

64.3.3 Message description

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.

All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to ‘ping’ other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

Figure 847. Message structure
64.3.4 Bit timing

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.

64.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time...
starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the figure below.

**Figure 850. Signal free time**

![Signal free time diagram](MS31007V1)

Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.

**Figure 851. Arbitration phase**

![Arbitration phase diagram](MS31008V1)

**Figure 852** shows an example for a SFT of three nominal bit periods.

**Figure 852. SFT of three nominal bit periods**

![SFT of three nominal bit periods diagram](MS31009V1)

A configurable time window is counted before starting the transmission.

In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission
This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission.

Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

64.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM = 1).

In case of SFTOPT = 1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.

In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR = 1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACKE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncodified low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

64.5 Error handling

64.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period (3.6 ms nominally).

![Figure 853. Error bit timing](Image)
64.5.2 Message error

A message is considered lost and therefore may be retransmitted under the following conditions:

- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

64.5.3 Bit rising error (BRE)

BRE (bit rising error) is set when a bit rising edge is detected outside the windows where it is expected (see Figure 854). BRE flag also generates a CEC interrupt if the BREIE = 1.

In the case of a BRE detection, the message reception can be stopped according to the BRESTP bit value and an error bit can be generated if BREGEN bit is set.

When BRE is detected in a broadcast message with BRESTP = 1 an error bit is generated even if BREGEN = 0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN = 0, BRDNOGEN = 1.

64.5.4 Short bit period error (SBPE)

SBPE is set when a bit falling edge is detected earlier than expected (see Figure 854). SBPE flag also generates a CEC interrupt if the SBPEIE = 1.

An error bit is always generated on the line in case of a SBPE error detection. An error bit is not generated upon SBPE detection only when Listen mode is set (LSTN = 1) and the following conditions are met:

- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN = 1

64.5.5 Long bit period error (LBPE)

LBPE is set when a bit falling edge is not detected in a valid window (see Figure 854). LBPE flag also generates a CEC interrupt if the LBPEIE = 1.

LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.

When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN = 0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN = 0, BRDNOGEN = 1.

Note: The BREGEN = 1, BRESTP = 0 configuration must be avoided.

</table>
64.5.6 Transmission error detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE = 1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to five times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

### 64.6 HDMI-CEC interrupts

An interrupt can be produced:
- during reception if a receive block transfer is finished or if a receive error occurs.
- during transmission if a transmit block transfer is finished or if a transmit error occurs.

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 TXEOM:** Tx end of message

The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.

0: TXDR data byte is transmitted with EOM = 0
1: TXDR data byte is transmitted with EOM = 1

*Note:* **TXEOM must be set when CECEN = 1.**

*Note:* TXEOM must be set before writing transmission data to TXDR.

If TXEOM is set when TXSOM = 0, transmitted message consists of 1 byte (HEADER) only (PING message).

**Bit 1 TXSOM:** Tx start of message

TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.

Start-bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission starts after the end of reception.

TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND = 1), in case of transmission underrun (TXUDR = 1), negative acknowledge (TXACKE = 1), and transmission error (TXERR = 1). It is also cleared by CECEN = 0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST = 1).

TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.

0: No CEC transmission is on-going
1: CEC transmission command

*Note:* **TXSOM must be set when CECEN = 1.**

*Note:* TXSOM must be set when transmission data is available into TXDR.

**HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC_CFGR.OAR that is used only for reception.**
Bit 0 **CECEN**: CEC enable

The CECEN bit is set and cleared by software. CECEN = 1 starts message reception and enables the TXSOM control. CECEN = 0 disables the CEC peripheral, clears all bits of CEC_CR register and aborts any on-going reception or transmission.

0: CEC peripheral is off.
1: CEC peripheral is on.

### 64.7.2 CEC configuration register (CEC_CFGR)

This register is used to configure the HDMI-CEC controller.

**Address offset**: 0x04

**Reset value**: 0x0000 0000

**Caution**: It is mandatory to write CEC_CFGR only when CECEN = 0.

</table>

**Bit 31** **LSTN**: Listen mode

LSTN bit is set and cleared by software.

0: CEC peripheral receives only message addressed to its own address (OAR). Messages addressed to different destination are ignored. Broadcast messages are always received.

1: CEC peripheral receives messages addressed to its own address (OAR) with positive acknowledge. Messages addressed to different destination are received, but without interfering with the CEC bus: no acknowledge sent.

**Bits 30:16** **OAR[14:0]**: Own addresses configuration

The OAR bits are set by software to select which destination logical addresses has to be considered in receive mode. Each bit, when set, enables the CEC logical address identified by the given bit position.

At the end of HEADER reception, the received destination address is compared with the enabled addresses. In case of matching address, the incoming message is acknowledged and received. In case of non-matching address, the incoming message is received only in listen mode (LSTN = 1), but without acknowledge sent. Broadcast messages are always received.

Example:

OAR = 0b000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5. Consequently, each message directed to one of these addresses is received.

**Bits 15:9** Reserved, must be kept at reset value.

**Bit 8** **SFTOP**: SFT option bit

The SFTOPT bit is set and cleared by software.

0: SFT timer starts when TXSOM is set by software.

1: SFT timer starts automatically at the end of message transmission/reception.
Bit 7  **BRDNOGEN**: Avoid error-bit generation in broadcast
The BRDNOGEN bit is set and cleared by software.

0: BRE detection with BRESTP = 1 and BREGEN = 0 on a broadcast message generates an error-bit on the CEC line. LBPE detection with LBPEGEN = 0 on a broadcast message generates an error-bit on the CEC line.
1: Error-bit is not generated in the same condition as above. An error-bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

Bit 6  **LBPEGEN**: Generate error-bit on long bit period error
The LBPEGEN bit is set and cleared by software.

0: LBPE detection does not generate an error-bit on the CEC line.
1: LBPE detection generates an error-bit on the CEC line.

*Note: If BRDNOGEN = 0, an error-bit is generated upon LBPE detection in broadcast even if LBPEGEN = 0.*

Bit 5  **BREGEN**: Generate error-bit on bit rising error
The BREGEN bit is set and cleared by software.

0: BRE detection does not generate an error-bit on the CEC line.
1: BRE detection generates an error-bit on the CEC line (if BRESTP is set).

*Note: If BRDNOGEN = 0, an error-bit is generated upon BRE detection with BRESTP = 1 in broadcast even if BREGEN = 0.*

Bit 4  **BRESTP**: Rx-stop on bit rising error
The BRESTP bit is set and cleared by software.

0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.
1: BRE detection stops message reception.

Bit 3  **RXTOL**: Rx-tolerance
The RXTOL bit is set and cleared by software.

0: Standard tolerance margin:
- Start-bit: +/- 200 µs rise, +/- 200 µs fall
- Data-bit: +/- 200 µs rise, +/- 350 µs fall
1: Extended tolerance
- Start-bit: +/- 400 µs rise, +/- 400 µs fall
- Data-bit: +/- 300 µs rise, +/- 500 µs fall

Bits 2:0  **SFT[2:0]**: Signal free time
SFT bits are set by software. In the SFT = 0x0 configuration, the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.

0x0
- 2.5 data-bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST = 1, TXERR = 1, TXUDR = 1 or TXACKE = 1)
- 4 data-bit periods if CEC is the new bus initiator
- 6 data-bit periods if CEC is the last bus initiator with successful transmission (TXEOM = 1)

0x1: 0.5 nominal data bit periods
0x2: 1.5 nominal data bit periods
0x3: 2.5 nominal data bit periods
0x4: 3.5 nominal data bit periods
0x5: 4.5 nominal data bit periods
0x6: 5.5 nominal data bit periods
0x7: 6.5 nominal data bit periods
### 64.7.3 CEC Tx data register (CEC_TXDR)

Address offset: 0x8  
Reset value: 0x0000 0000

STI

RM0468 Rev 3 3111/3357
Bits 31:13  Reserved, must be kept at reset value.

Bit 12 TXACKE: Tx-missing acknowledge error
In transmission mode, TXACKE is set by hardware to inform application that no acknowledge was
received. In case of broadcast transmission, TXACKE informs application that a negative
acknowledge was received. TXACKE aborts message transmission and clears TXSOM and TXEOM
controls.
TXACKE is cleared by software write at 1.

Bit 11 TXERR: Tx-error
In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the
CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM
controls.
TXERR is cleared by software write at 1.

Bit 10 TXUDR: Tx-buffer underrun
In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before
of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM
control bits.
TXUDR is cleared by software write at 1

Bit 9 TXEND: End of transmission
TXEND is set by hardware to inform application that the last byte of the CEC message has been
successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.
TXEND is cleared by software write at 1.

Bit 8 TXBR: Tx-byte request
TXBR is set by hardware to inform application that the next transmission data has to be written to
TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the
next byte to TXDR within six nominal data-bit periods before transmission underrun error occurs
(TXUDR).
TXBR is cleared by software write at 1.

Bit 7 ARBLST: Arbitration lost
ARBLST is set by hardware to inform application that CEC device is switching to reception due to
arbitration lost event following the TXSOM command. ARBLST can be due either to a contending
CEC device starting earlier or starting at the same time but with higher HEADER priority. After
ARBLST assertion TXSOM bit keeps pending for next transmission attempt.
ARBLST is cleared by software write at 1.

Bit 6 RXACKE: Rx-missing acknowledge
In receive mode, RXACKE is set by hardware to inform application that no acknowledge was seen
on the CEC line. RXACKE applies only for broadcast messages and in listen mode also for not
directly addressed messages (destination address not enabled in OAR). RXACKE aborts message
reception.
RXACKE is cleared by software write at 1.

Bit 5 LBPE: Rx-long bit period error
LBPE is set by hardware in case a data-bit waveform is detected with long bit period error. LBPE is
set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still
longing. LBPE always stops reception of the CEC message. LBPE generates an error-bit on the
CEC line if LBPEGEN = 1. In case of broadcast, error-bit is generated even in case of
LBPEGEN = 0.
LBPE is cleared by software write at 1.
Bit 4  **SBPE**: Rx-short bit period error
SBPE is set by hardware in case a data-bit waveform is detected with short bit period error. SBPE is set at the time the anticipated falling edge occurs. SBPE generates an error-bit on the CEC line. SBPE is cleared by software write at 1.

Bit 3  **BRE**: Rx-bit rising error
BRE is set by hardware in case a data-bit waveform is detected with bit rising error. BRE is set either at the time the misplaced rising edge occurs, or at the end of the maximum BRE tolerance allowed by RXTOL. in case rising edge is still longing. BRE stops message reception if BRESTP = 1. BRE generates an error-bit on the CEC line if BREGEN = 1.
BRE is cleared by software write at 1.

Bit 2  **RXOVR**: Rx-overrun
RXOVR is set by hardware if RXBR is not yet cleared at the time a new byte is received on the CEC line and stored into RXD. RXOVR assertion stops message reception so that no acknowledge is sent. In case of broadcast, a negative acknowledge is sent.
RXOVR is cleared by software write at 1.

Bit 1  **RXEND**: End of reception
RXEND is set by hardware to inform application that the last byte of a CEC message is received from the CEC line and stored into the RXD buffer. RXEND is set at the same time of RXBR.
RXEND is cleared by software write at 1.

Bit 0  **RXBR**: Rx-byte received
The RXBR bit is set by hardware to inform application that a new byte has been received from the CEC line and stored into the RDX buffer.
RXBR is cleared by software write at 1.

### 64.7.6  CEC interrupt enable register (CEC_IER)

Address offset: 0x14
Reset value: 0x0000 0000

**Caution:** It is mandatory to write CEC_IER only when CECEN = 0.

Bits 31:13  Reserved, must be kept at reset value.

Bit 12  **TXACKIE**: Tx-missing acknowledge error interrupt enable
The TXACKIE bit is set and cleared by software.
0: TXACKIE interrupt disabled
1: TXACKIE interrupt enabled

Bit 11  **TXERRIE**: Tx-error interrupt enable
The TXERRIE bit is set and cleared by software.
0: TXERR interrupt disabled
1: TXERR interrupt enabled
Bit 10 **TXUDRIE**: Tx-underrun interrupt enable
   The TXUDRIE bit is set and cleared by software.
   0: TXUDR interrupt disabled
   1: TXUDR interrupt enabled

Bit 9 **TXENDIE**: Tx-end of message interrupt enable
   The TXENDIE bit is set and cleared by software.
   0: TXEND interrupt disabled
   1: TXEND interrupt enabled

Bit 8 **TXBRIE**: Tx-byte request interrupt enable
   The TXBRIE bit is set and cleared by software.
   0: TXBR interrupt disabled
   1: TXBR interrupt enabled

Bit 7 **ARBLSTIE**: Arbitration lost interrupt enable
   The ARBLSTIE bit is set and cleared by software.
   0: ARBLST interrupt disabled
   1: ARBLST interrupt enabled

Bit 6 **RXACKIE**: Rx-missing acknowledge error interrupt enable
   The RXACKIE bit is set and cleared by software.
   0: RXACKE interrupt disabled
   1: RXACKE interrupt enabled

Bit 5 **LBPEIE**: Long bit period error interrupt enable
   The LBPEIE bit is set and cleared by software.
   0: LBPE interrupt disabled
   1: LBPE interrupt enabled

Bit 4 **SBPEIE**: Short bit period error interrupt enable
   The SBPEIE bit is set and cleared by software.
   0: SBPE interrupt disabled
   1: SBPE interrupt enabled

Bit 3 **BREIE**: Bit rising error interrupt enable
   The BREIE bit is set and cleared by software.
   0: BRE interrupt disabled
   1: BRE interrupt enabled

Bit 2 **RXOVRIE**: Rx-buffer overrun interrupt enable
   The RXOVRIE bit is set and cleared by software.
   0: RXOVR interrupt disabled
   1: RXOVR interrupt enabled

Bit 1 **RXENDIE**: End of reception interrupt enable
   The RXENDIE bit is set and cleared by software.
   0: RXEND interrupt disabled
   1: RXEND interrupt enabled

Bit 0 **RXBRIE**: Rx-byte received interrupt enable
   The RXBRIE bit is set and cleared by software.
   0: RXBR interrupt disabled
   1: RXBR interrupt enabled
### 64.7.7 HDMI-CEC register map

The following table summarizes the HDMI-CEC registers.

#### Table 613. HDMI-CEC register map and reset values

| Offset | Register name | Reset value | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

| 0x14   | CEC_IER       |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        |               |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to Section 2.3 for the register boundary addresses.
65  Debug infrastructure

65.1  Introduction

The debug infrastructure allows software designers to debug and trace their embedded software.

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port allows data to be captured for logging and analysis.

The trace and debug system is designed to support a variety of typical use cases:

- **Low cost trace**
  Limited trace capability is available over the single-wire debug output. This supports code instrumentation using “printf”, tracing of data and address watchpoints, interrupt detection and program counter sampling. Single-wire trace can be maintained even when the processor is switched off or clock-stopped.

- **Breakpoint debugging**
  The processor can be debugged using equipment connected to the JTAG/SWD debug port. This allows breakpoint and watchpoint setting, code stepping, memory access and so on.

- **Tracing code execution via the trace port**
  Trace information is combined into a single trace stream and output to a trace port analyzer in real time. An ID embedded in the trace allows the analyzer to identify the source of each information packet.

- **Continuous trace capturing in a circular buffer**
  Instead of streaming it off-chip, the combined trace information can be stored on-chip in a circular buffer. The trace storage can be started and stopped by different means such as a debugger command, a software command, an external trigger signal, an internal event, and so on.

- **Draining the buffer to the trace port**
  The stored trace can be dumped off-chip to the trace port analyzer. The buffer draining can be initiated by the debugger, software, external trigger, internal event and so on.

- **Reading the buffer with the debugger**
  The debugger can read the contents of the trace buffer via the debug port. This is slower than the trace port, but allows basic trace functionality on the debugger without the cost of a trace port analyzer.

- **Analyzing stored trace in software**
  The trace buffer can be read by the processor core, or transferred into system memory by DMA. This powerful feature allows built-in test software to monitor code execution in real time, analyze and identify faults, handle exceptions autonomously, and so on.

- **Uploading stored trace**
  The stored trace can also be uploaded to a host machine using one of the MCU’s many communication interfaces (USB, USART, SPI, I2C, Ethernet, CAN and so on). This is especially useful if the trace port is not accessible, for example remote monitoring and failure analysis of a deployed product.
65.2 Debug infrastructure features

A comprehensive set of trace and debug features is provided to support software development and system integration:

- Breakpoint debugging
- Code execution tracing
- Software instrumentation
- Cross-triggering
- JTAG debug port
- Serial-wire debug port
- Trigger input and output
- Serial-wire trace port
- Trace port
- Arm® CoreSight™ debug and trace components.

The CoreSight components are described at high level in this document. Detailed information is available in the Arm® documents referenced in Section 65.7.

65.3 Debug infrastructure functional description

65.3.1 Debug infrastructure block diagram

The block diagram shows the logical partitioning of the debug infrastructure.
### 65.3.2 Debug infrastructure powering, clocking and reset

#### Power domains

The debug components are distributed across the power domains D1 and D3. The D3 power domain is always considered on when the debugger is connected. It therefore contains the SWJ-DP, so that the debugger does not lose the connection with the SoC when the other power domain is switched off. In addition, it contains the DBGMCU and the serial wire trace features.

The D1 power domain contains the Cortex-M7 core and the associated debug and trace components. It also contains the system trace components located on the APB-D. This power domain therefore needs to be on whenever a debug access to the Cortex-M7 is required, or whenever a trace functionality is active on the processor.
The debugger supplies the clock for the debug port, SWTCLK, via the debug interface pin, JTCK/SWCLK. This clock is used to register the serial input data in both serial wire and JTAG mode, as well as to operate the state machines and internal logic of the debug port. It must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the DAPCLK domain, which covers the rest of the SWJ-DP and the access ports. The DBGMCU and System ROM table 1 are also in the DAPCLK domain.

**CK_DBG_D3** clocks the SWO.

Both DAPCLK and **CK_DBG_D3** are gated versions of the D3 domain system clock (rcc_hclk4).

**CK_DBG_D1** clocks the trace components in the D1 power domain: System ROM table 2, CoreSight trace funnel, ETF, system CTI and TPIU. It is a gated version of the D1 domain system clock (rcc_hclk3).

TRACECLK is the trace port output clock. It is a gated version of the system clock (sys_ck), except when the PLL1 is the source for the system clock. In this case, TRACECLK is derived directly from the pll1_r_ck output. This is required in order to support the high data throughput on the trace port when the processor operates at its maximum frequency.

All the debug clocks (except DAPCLK) can be enabled and disabled by register bits in the DBGMCU. The DAPCLK domain is enabled by the debugger using the CDBGPWRUPREQ bit in the debug port CTRL/STAT register. The clock must be enabled before the debugger

can access any of the debug features on the device. It should be disabled at power up and when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processor (ETM, ITM, DWG, FPB and so on) are clocked with the corresponding core clock (rcc_c_ck).

**Debug with low-power modes**

The device includes power-saving features allowing individual power domains to be switched off or stopped when not required. If a power domain is switched off or not clocked, all debug components in that domain are inaccessible to the debugger. To avoid this, power saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power saving mode, while the debugger does not lose the connection.

The emulation mode is programmed in the MCU Debug (DBGMCU) unit. For more information, refer to Section 65.5.7

**Reset of debug infrastructure**

The debug components, except for the debug port and access ports, are reset by their respective power domain resets. The debug port (SWJ-DP) is reset by a power-on reset of the D3 domain only.

### 65.4 Debug access port functional description

The debug access port (DAP) is a debug subsystem comprising serial-wire and JTAG debug port (SWJ-DP) and three access ports.

#### 65.4.1 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight component that implements an external access port for connecting debugging equipment.

The port can be configured as:

- a 5-pin standard JTAG debug port (JTAG-DP)
- a 2-pin (clock + data) “serial-wire” debug port (SW-DP)

The two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected on system or power-on reset. The five IOs are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on the JTDI, JTMS/SWDIO, and nJTRST lines, as well as a pull-down resistor on the JTCK/SWCLK line.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO:

...,(50 or more ones),...,0,1,1,1,0,0,1,1,1,1,0,0,1,1,1,....,(50 or more ones),...

JTCK/SWCLK must be cycled for each data bit.

In SW-DP mode, the unused JTAG lines JTDI, JTDO and nJTRST can be used for other functions.
All SWJ port IOs can be reconfigured to other functions by software, in which case debugging is no longer possible.

**Serial wire debug port**

The serial wire debug protocol uses two pins:
- **SWCLK**: clock from host to target
- **SWDIO**: bi-directional serial data

Serial data is transferred LSB first, synchronously with the clock. A transfer comprises three phases:
1. packet request (8 bits) transmitted by the host
2. acknowledge response (3 bits) transmitted by the target
3. data transfer (33 bits) transmitted by the host (in the case of a write) or target (in the case of a read)

The data transfer only occurs if the acknowledge response is OK.

If the direction of the data is reversed between each phase, a single clock cycle turn-around time is inserted.

Figure 859 shows successful write and read transfers.

**Figure 859. SWD successful data transfer**

For any FAULT or WAIT ACK response from the target, the data transfer phase is canceled, unless overrun detection is enabled, in which case the data is be ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists of 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the Serial Wire debug protocol, refer to the Arm® Debug Interface Architecture Specification [1].

**Note:** The SWJ-DP implements SWD protocol version 2.
The JTAG-DP implements a TAP state machine (TAPSM) based on IEEE 1149.1-1990. The state machine is shown in Figure 860. It controls two scan chains, one associated with an instruction register (IR) and one with a number of data registers (DR).

When the TAPSM goes through the Capture-IR state, 0b0001 is transferred into the instruction register (IR) scan chain. The IR scan chain is connected between JTDI and JTDO.

While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:

- The LSB of the IR scan chain is output on JTDO
- Bit [n] of the IR scan chain is transferred to bit [n-1]
- The value on JTDI is transferred to the MSB of the IR scan chain.

When the TAPSM goes through the Update-IR state, the value scanned in the IR scan chain is transferred to the instruction register.

When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers onto one of the DR scan chains, connected between JTDI and JTDO.
The value held in the instruction register determines which data register, and associated DR scan chain, is selected.

This data is then shifted while the TAPSM is in the Shift-DR state, in the same way as the IR shift in the Shift-IR state.

When the TAPSM goes through the Update-DR state, the value scanned in the DR scan chain is transferred to the selected data register.

When the TAPSM is in the Run-Test/Idle state, no special actions occur. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the Test-Logic-Reset state.

The data registers corresponding to the 4-bit IR instructions are listed in Table 617.

The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification [1].

### Debug port registers

The SW-DP and JTAG-DP both access the debug port (DP) registers. These are listed in Table 618.

The debugger can access the DP registers as follows:

1. Program the SELECT register DPBANKSEL field in the DP to select the register bank to be accessed (see Table 618).
2. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the R/W bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and R/W fields are part of the Packet Request word sent to the SW-DP with the APnDP bit reset (see Table 614). The write data is sent in the data phase.

Reset value: 0x0000 0000
Bits 25:24  Reserved, must be kept at reset value.

Bits 23:12  **TRNCNT[11:0]**: Transaction counter
To program a sequence of transactions to incremental addresses via an AP, TRNCNT bits are loaded with the number of transactions to perform. It is decremented on successful completion of each transaction.

Bits 11:8  **MASKLANE[3:0]**: Pushed-compare and pushed-verify masking bits
The field indicates the bytes to be masked in pushed-compare and pushed-verify operations (DP_CTRL/STAT register’s field TRNMODE = 1 or 2). In the pushed operations, the word supplied in an AP write transaction is compared with the current value at the target AP address.

0b1XXX: include byte lane 3 in comparisons
0bX1XX: include byte lane 2 in comparisons
0bXX1X: include byte lane 1 in comparisons
0bXXX1: include byte lane 0 in comparisons

Bit 7  **WDATAERR**: Write data error in SW-DP
The bit indicates;
– a parity or a framing error on the data phase of a write operation, or
– a write operation that had been accepted by the DP has then been discarded without being submitted to the AP
This bit is read-only. It is reset by writing 1 to the WDERRCLR bit of the DP_ABORT register.

0: No error
1: Error has occurred

This bit is reserved in JTAG-DP.

Bit 6  **READOK**: AP read response in SW-DP
This bit indicates the response to the last AP read access. It is read-only.

0: Read not OK
1: Read OK

This bit is reserved in JTAG-DP.

Bit 5  **STICKYERR**: Transaction error (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that an error occurred during an AP transaction.

0: No error
1: Error has occurred

In the SW-DP, this bit is reset by writing 1 to the STKERRCLR bit of the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.

Bit 4  **STICKYCMP**: Compare match (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that a match occurred in a pushed operation.

0: Match if TRNMODE = 0x1; no match if TRNMODE = 0x2
1: No match if TRNMODE = 0x1; match if TRNMODE = 0x2

In the SW-DP, this bit is reset by writing 1 to the STKCMPCLR bit in the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to 1.
Bits 3:2 **TRNMODE[1:0]: Transfer mode for AP write operations**

For read operations, this field must be set to 0x0.

0x0: Normal operation - AP transactions are passed directly to the AP.
0x1: Pushed-verify operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read operation is compared with the stored data. If they do not match, the STICKYCMP bit is set.
0x2: Pushed-compare operation. The DP stores the write data and performs a read transaction at the target AP address. The result of the read is compared with the stored data. If they match, the STICKYCMP bit is set.
0x3: Reserved

In pushed operations, only the data bytes indicated by the MASKLANE field are included in the comparison.

Bit 1 **STICKYORUN: Overrun (read-only in SW-DP, R/W in JTAG-DP)**

This bit indicates that an overrun occurred (a new transaction received before previous transaction completed). This bit is only set if the ORUNDETECT bit is set.

0: No overrun
1: Overrun occurred

In the SW-DP, this bit is reset by writing 1 to the ABORT register’s ORUNERRCLR bit. In the JTAG-DP, this bit is reset by writing a 1 to it.

Bit 0 **ORUNDETECT: Overrun detection mode enable**

0: Overrun detection disabled
1: Overrun detection enabled. In the event of an overrun, the STICKYORUN bit is set and subsequent transactions are blocked until the STICKYORUN bit is cleared.

**Debug port data link control register (DP_DLCR)**

- Bits 31:28  **TIN|STANCE[3:0]**: Target instance number
  - These bits define the instance number for this device in a multi-drop system.
  - 0x0
- Bits 27:4  Reserved, must be kept at reset value.
- Bits 3:0  **PROTSVN[3:0]**: Serial Wire Debug protocol version
  - 0x1: Version 2
Debug port resend register (DP_RESEND)

Address offset: 0x8
Reset value: 0x0000 0000

Bits 31:0 RESEND[31:0]: Last AP read or DP RDBUFF read value
These bits contain the value that was returned by the last AP read or DP RDBUFF read. Used in the event of a corrupted read transfer.

Debug port access port select register (DP_SELECT)

Address offset: 0x8
Reset value: 0xXXXX XXXX

Bits 31:28 APSEL[3:0]: Access port select bits
These bits select the access port for the next transaction.

- 0x0: AP0 - Cortex-M7 debug access port (AHB-AP)
- 0x1: AP1 - D3 access port (AHB-AP)
- 0x2: AP2 - System debug access port (APB-AP)
- 0x3 to 0xF: Reserved

Bits 27:8 Reserved, must be kept at reset value.

Bits 7:4 APBANKSEL[3:0]: AP register bank select bits
These bits select the 4-word register bank on the active AP for the next transaction.

Bits 3:0 DPBANKSEL[3:0]: DP register bank select bits
These bits select the register at address 0x4 of the debug port.

- 0x0: CTRL/STAT register
- 0x1: DLCR register
- 0x2: TARGETID register
- 0x3: DLPIIDR register

Bits 31:0 RDBUFF[31:0]: Last AP read value
The field contains the value returned by the last AP read access. There are two ways to retrieve the value returned by an AP read access:
- perform a second read access to the same address, which initiates a new transaction on the corresponding bus, or
- read the value returned by the last AP read access from the DP_RDBUFF register, in which case no new AP transaction occurs

Bits 31:28 TINSTANCE[3:0]: Target instance number
The field defines the instance number for the target device in a multi-drop system. It must be programmed with the same value as TINSTANCE field of DP_DLPIIDR register, in order to select this device.

Bits 27:12 TPARTNO[15:0]: Target part number
The field defines the part number for the target device. It must be programmed with the same value as TPARTNO field of DP_TARGETID register, in order to select this device.

Bits 11:1 TDESIGNER[10:0]: Target designer JEDEC code
The field defines the JEDEC code for the target device. It must be programmed with the same value as TDESIGNER field of DP_TARGETID register, in order to select this device.

Bit 0 Reserved, must be kept at reset value.
65.4.2 Access ports

Access ports (AP) attached to the DP:

1. **AP0**: Cortex-M7 access port (AHB-AP). Allows access to the debug and trace features integrated in the Cortex-M7 processor core via an AHB-Lite bus connected to the AHBD port of the processor.

2. **AP1**: D3 access port (AHB-AP). Allows access to the bus matrix in the D3 domain. This gives visibility of the D3 domain memory and peripherals when the D1 and D2 domains are switched off. No CoreSight components are accessible via this port.

3. **AP2**: System access port (APB-AP). Allows access to the debug and trace features on the system APB debug bus, that is, all components not included in the processor core.

All access ports are of MEM-AP type, that is, the debug and trace component registers are mapped in the address space of the associated debug bus. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 619.

The address of the AP registers is composed of:

- bits [7:4]: content of the DP_SELECT register’s APBANKSEL field
- bits [3:2]: content of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 617) or of the SW-DP Packet Request (see Table 614), depending on the debug interface used
- bits [1:0]: Always set to 0

The content of the SELECT register APSEL field in the DP defines which MEM-AP is being accessed.

The debugger can access the AP registers as follows:

1. Program the DP_SELECT register’s APSEL field to choose one of the APs, and the APBANKSEL field to select the register bank to be accessed.

2. Program the A(3:2) field in the APACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the Packet Request word sent to the SW-DP with the APnDP bit set (see Table 614). The write data is sent in the data phase.
The debugger can access the memory mapped debug component registers through the MEM-AP registers (using the AP register access procedure described above) as follows:

1. Program the transaction target address in the TAR register.
2. Program the CSW register, if necessary, with the transfer parameters (AddrInc for example).
3. Write to or read from the DRW register to initiate a bus transaction at the address held in the TAR register. Alternatively, a read or write to banked data register BDn triggers an access to address TAR[31:4] + n (this allows an access to the next four consecutive addresses without changing the address in the TAR register).

For more detailed information on the MEM-AP, refer to the Arm® Debug Interface Architecture Specification [1]. To use the MEM-AP to connect the debug port to the debug components (in the example, a processor, an ETM and a ROM table), go to Section 65.4.2: Access ports.

Access port base address register (AP_BASE)

Address offset: 0xF8
Reset value: 0xE00F E003 (AP0), 0x0000 0002 (AP1), 0xE00E 0003 (AP2)

Bit 6 **DEVICEEN**: Device Enable bit
This bit defines whether the AP can be accessed or not.
1: AP access enabled.

Bits 5:4 **ADDRINC[1:0]**: Auto-increment mode bits
These bits define whether the TAR address is automatically incremented after a transaction.
0x0: no auto-increment
0x1: Address is incremented by the size in bytes of the transaction (SIZE field).
0x2: Packed transfers enabled (Only in AHB-APs - reserved in APB-AP). A 32-bit AP access generates a 1 x 32-bit, 2 x 16-bit or 4 x 8-bit bus transaction corresponding to the programmed transaction size. The data is packed or unpacked accordingly.
0x3: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SIZE[2:0]**: Size of next memory access transaction (only for AHB-APs)
0x0: Byte (8-bit)
0x1: Half-word (16-bit)
0x2: Word (32-bit)
0x3-0x7: Reserved

For APB-AP, this field is read-only and fixed at 0x2 (32-bit).

Bits 31:12 **BASEADDR[19:0]**: Base address (bits 31 to 12) of the AP ROM table
The 12 LSBs are zero since the ROM table must be aligned on a 4 Kbyte boundary.
AP0 (Cortex-M7 AHB-AP): 0xE00FE
AP1 (D3 AHB-AP): 0x00000 (No ROM table present)
AP2 (System APB-AP): 0xE00E0
Bits 11:2  Reserved, must be kept at reset value.

Bit 1  **FORMAT**: Base address register format
1: Arm® debug interface v5.

Bit 0  **ENTRYPRESENT**: Debug component present status bit
This bit indicates that debug components are present on the access port bus.

0: Debug components are not present (AP1)
1: Debug components are present (AP0, AP2)

**Access port identification register (AP_IDR)**

Address offset: 0xFC

Reset value: 0x8477 0001 (AP0 and AP1), 0x5477 0002 (AP2)

65.5 Trace and debug subsystem functional description

The trace and debug subsystem features the following CoreSight components:

- System ROM tables
- System cross-trigger interface (CTI)
- Cross-trigger matrix (CTM)
- Trace port interface unit (TPIU)
- Trace bus funnel (CSTF)
- Embedded trace FIFO (ETF)
- Serial wire output (SWO)

These components are accessible by the debugger via the system APB-AP and its associated APB-D debug bus. They are also accessible by the Cortex-M7 processor.

The MCU debug unit (DBGMCU) is also accessed via the APB-D. This non-CoreSight component contains registers for configuring the device behavior in Debug mode.

Trace bus replicator branches the trace bus from the CPU's ITM CoreSight component to ETF and SWO, through trace bus funnels.

65.5.1 System ROM tables

There are two ROM tables on the APB-D bus. The ROM table is a CoreSight component that contains the base addresses of all the CoreSight components on the APB-D bus. These tables allow a debugger to discover the topology of the CoreSight components automatically.

The first table points to the second table, and to the CoreSight components located in D3 power domain: SWO. The table occupies a 4-Kbyte, 32-bit wide chunk of the APB-D address space, from 0xE00E0000 to 0xE00E0FFC when accessed by the debugger, and from 0x5C000000 to 0x5C000FFC when accessed from the system bus.
The second table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00F0000 to 0xE00F0FFC when accessed by the debugger, and from 0x5C010000 to 0x5C010FFC when accessed from the system bus.

The top of each ROM table contains a number of read-only registers, including the standard CoreSight component and peripheral identity registers, see section System ROM registers.

Each debug component occupies one or more 4 Kbyte blocks of address space. This block of address space is referred to as the debug register file for the component.

The component address offset field of a ROM Table entry points to the start of the last 4 Kbyte block of the address space of the component. This block always contains the component and peripheral ID registers for the component, starting at offset 0xFD0 from the start of the block. The 4 Kbyte count field PIDR4 [7:4], specifies the number of 4 Kbyte
blocks for the component. Therefore, the process for finding the start of the address space for a component is:

1. Read the ROM-table entry for the component and extract its Address_Offset [18:0] from bits [31:12] of the ROM-table entry.

2. Use the address offset, together with the base address of the ROM table, ROM_Base_Address, to calculate the base address of the component:
   \[
   \text{Component Base Address} = \text{ROM Base Address} + \text{Address Offset}
   \]
   The Component Base Address is the start address of the 4 Kbyte block of the address space for the component.

3. Read the peripheral ID4 register for the component. The address of this register is:
   \[
   \text{Peripheral ID4 address} = \text{Component Base Address} + 0xFD0
   \]

4. Extract the 4 Kbyte count field [7:4] from the value of the Peripheral ID4 Register.

5. Use the 4 Kbyte count field value to calculate the start address of the address space for the component. If the field value is 0b0000, which corresponds to a count value of 1, the address space for the component starts at Component_Base_Address obtained at stage 2.

The topology for the CoreSight components on the APB-D is shown in Figure 862.

For more information on the use of the ROM table, refer to the Arm® Debug Interface Architecture Specification [1].

### Cross trigger interfaces (CTI) and matrix (CTM)

The cross trigger interfaces (CTI) and cross trigger matrix (CTM) together form the CoreSight embedded cross trigger feature. There are two CTI components, one at system level and one dedicated to the Cortex-M7. The two CTIs are connected to each other via the CTM. The system-level CTI is accessible to the debugger via the system access port and associated APB-D. The Cortex-M7 CTI is physically integrated in the Cortex-M7 core, and is accessible via the Cortex-M7 access port and associated AHBD.

The CTIs allow events from various sources to trigger debug and/or trace activity. For example, a transition detected on an external trigger input can start code trace.

Each CTI has up to 8 trigger inputs and 8 trigger outputs. Any input can be connected to any output, on the same CTI, or on another CTI via the CTM.

The trigger input and output signals for each CTI are listed in *Table 624* to *Table 627*.

There are four event channels in the cross trigger matrix, which allows up to four parallel bidirectional connections between trigger inputs and outputs on different CTIs. To connect input number $m$ on CTI $x$ to output number $n$ on CTI $y$, the input must be connected to an event channel $p$ using the CTIINEN$_m$ register of CTI $x$. The same channel $p$ must be connected to the output using the CTIOUTEN$_n$ register of CTI $y$. Note: this applies even if the input and output belong to the same CTI.

An input can be connected to more than one channel (up to four), so an input can be routed to several outputs. Similarly, an output can be connected to several inputs. It is also possible to connect several inputs/outputs to the same channel.

There are four event channels in the cross trigger matrix, which allows up to four parallel bidirectional connections between trigger inputs and outputs on different CTIs. To connect input number $m$ on CTI $x$ to output number $n$ on CTI $y$, the input must be connected to an event channel $p$ using the CTIINEN$_m$ register of CTI $x$. The same channel $p$ must be connected to the output using the CTIOUTEN$_n$ register of CTI $y$. Note: this applies even if the input and output belong to the same CTI.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the CTI_LAR register

- 0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock

This bit always returns zero when read by an external debugger.

- 0: Write access is permitted
- 1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism

The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

- 0: No lock control mechanism exists
- 1: Lock control mechanism is implemented

#### Table notes:
- **Offset**: The starting address of each register block.
- **Register name**: The name of the register being described.
- **Reset value**: The default value for each register.
- **Table values**: The specific values for each register setting.
65.5.3 Trace funnel (CSTF)

The trace funnel is a CoreSight component that combines the ATB buses from two trace sources into one single ATB. The CSTF has two ATB slave ports, and one ATB master port. An arbiter selects the slave ports according to a programmable priority.

The slave ports are connected as follows:
- S0: Cortex-M7 ETM
- S1: Cortex-M7 ITM

The CSTF registers allow the slave ports to be individually enabled, and their priority settings to be configured. The priorities can be modified only when the trace is disabled. The arbitration works as follows:
- The arbiter selects the slave port with the highest assigned priority that has data valid
- Transfers are passed from the selected slave to the master port until \textit{min\_hold\_time} is reached, where \textit{min\_hold\_time} is programmable in the \textit{CONTROL} register.
- A new arbitration is then performed

High priority should be assigned to slave ports connected to sources with a small amount of buffering, or where data loss cannot be tolerated. Low priority should be assigned to less critical sources or those with large buffers.

For more information on the ATB Funnel CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

Trace funnel registers

CSTF control register (CSTF_CTRL)

Address offset: 0x000
Reset value: 0x0000 0300
Bits 31:12  Reserved, must be kept at reset value.

Bits 11:8  **MIN_HOLD_TIME[3:0]**: Number of transactions between arbitrations.
          0x0: 1 transaction
          0x1: 2 transactions
          0x2: 4 transactions
          0x3: 8 transactions
          0x4: 15 transactions
          0xF: Reserved

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **ENS1**: S1 slave port enable
       0: Disable port
       1: Enable port

Bit 0  **ENS0**: S0 slave port enable
       0: Disable port
       1: Enable port

Bits 15:0 Reserved, must be kept at reset value.

Bit 2  **LOCKTYPE**: Size of the CSTF_LAR register
0: 32-bit

Bit 1  **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0  **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

CSTF authentication status register (CSTF_AUTHSTAT)
Address offset: 0xFB8
Reset value: 0x0000 000A

Table 629. CSTF register map and reset values (continued)
Embedded trace FIFO (ETF)

The ETF is a 2 Kbyte memory that captures trace data from two trace sources, namely the ETM and ITM of the CPU core. The ETF is a design configuration of the CoreSight™ trace memory controller component.

The ETF can be used in three modes (selected in the mode register):

1. Hardware FIFO mode
   
   The trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured by the trace RAM and when full, the incoming trace stream is stalled. When the Trace buffer is not empty, trace data is drained out through the ATB master interface to the TPIU.

   In this mode, the role of the FIFO is to smooth the flow of trace information arriving at the trace port. Since the trace data can be very bursty by nature, the peak data rate can easily exceed the port capability, resulting in an overflow. The ETF allows a steady data rate at the trace port, which can then be sized according to the average rate rather than the peak. The trace is stored off-chip in real time by the trace port analyzer tool, and so the trace log can be very big.

2. Software FIFO mode
   
   The trace memory is used as a FIFO that can be read through the RRD Register while the trace is being captured. Trace data is captured by the trace RAM and when full, the incoming trace stream is stalled.

   This mode allows the trace to be transferred by DMA into the system memory, or to a high speed interface (SPI, USB and so on), or even monitored by software. Note that unlike the hardware FIFO mode, this mode is invasive, since it uses system resources which are shared by the processor.

3. Circular buffer mode
   
   The trace memory is used as a circular buffer. Trace data is captured in the trace memory starting from the location pointed to by the write pointer register. When the trace memory is full, incoming trace data continues to be overwritten in the trace memory until a stop condition occurs.

   In this mode, the ETF stores the trace data on-chip, so the trace log size is limited to that of the ETF SRAM, 2 Kbytes in this case. Being a circular buffer, when the FIFO is full, incoming trace data overwrites the oldest stored data and the oldest stored data is
lost. Therefore the content of the trace buffer represents the most recent activity of the processor, up to the point when the buffer was stopped, rather than all the activity since the trace was started.

There are three possible methods to read the buffer contents once the trace stops:

- via the Trace port - with the TPIU enabled, the contents of the buffer are output over the Trace port. This can be done by setting the DRAINBUF bit in the ETF_FFCR register.
- via the Debug port - the debugger can read the buffer via the RRD register that is accessible over the system APB-D.
- by software - the processor can read the buffer via the RRD register, since the APB-D is accessible from the system bus.

The ETF can be moved to any one of these states:

- **Disabled**
  This state is entered after a reset, or when trace capture is disabled. The ETF must only be programmed in this state.

- **Running**
  Trace capture is performed in this state. It is entered by enabling trace capture while in Disabled state.

- **Stopped**
  Trace capture is stopped in this state, but the contents of the buffer can be read out or drained. This state is entered after a stop event (trigger or flush).

- **Disabling**
  This is a transition state while disabling trace capture.

- **Stopping**
  This is a transition state while stopping trace capture.

- **Draining**
  This state is entered while draining the buffer in Stopped state.

The state transition diagram is shown in *Figure 865*.

Bit 31  Reserved, must be kept at reset value.

Bits 30:0  **RSZ[30:0]:** RAM size

The value of the field indicates the number of 32-bit words

0x200: 512 words = 2 Kbytes

For more information on the CoreSight™ trace memory controller component, refer to the Arm® CoreSight™ trace memory controller technical reference manual [3].
### ETF status register (ETF_STS)

Address offset: 0x00C  
Reset value: 0x0000 001C

<table>
<thead>
<tr>
<th>Bit 31:5</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 4 | **EMPTY**: Trace FIFO empty  
This bit is valid only when the TCEN bit of the ETF_CTL register is high. This bit reads as zero when TCEN is low.  
0: Trace FIFO contains data  
1: Trace FIFO is empty.  
**Note**: Empty trace FIFO does not mean that the ETF pipeline is empty. The latter is indicated by the FEMPTY bit. |
| Bit 3 | **FEMPTY**: Formatter empty  
This bit is set when a trace capture has stopped, and all internal pipelines and buffers have been drained. Unlike READY, it is not affected by buffer drains. The ACQCOMP output reflects the value of this bit. |
| Bit 2 | **READY**: ETF ready  
This bit is set when a trace capture has stopped and all internal pipelines and buffers have been drained (Stopped or Disabled state) |
| Bit 1 | **TRIGD**: Triggered  
The Triggered bit is set when a trace capture is in progress and the TMC has detected a Trigger Event. This bit is cleared when leaving Disabled state.  
This bit is operational only in the Circular buffer mode. In all other modes, this bit is always low.  
This bit does not indicate that a trigger has been embedded in the formatted output trace data from the TMC. Trigger indication on the output trace stream is determined by the programming of the Formatter and Flush Control Register, ETF_FFCR. |
| Bit 0 | **FULL**: Trace buffer full  
In circular buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer, and remains set until the TCEN bit of the ETF_CTL register is cleared and set.  
In software and hardware FIFO modes, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the ETF_BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM.  
This bit is cleared when leaving Disabled state. The FULL output reflects the value of this register bit. |

Bits 31:0 **RRD[31:0]**: RAM Read Data.

- **Circular buffer mode:**
  When in Stopped state and the buffer is not empty, reading this register returns the next word of data from the trace buffer. When the whole trace buffer has been read, the Empty bit in the ETF_STS Register is set, and subsequent reads return 0xFFFFFFFF. Reading this register when not in Stopped state returns 0xFFFFFFFF.
- **Software FIFO mode:**
  Reading this register returns data from the FIFO. If this register is read when the FIFO is empty, the data returned is 0xFFFFFFFF.
- **Hardware FIFO mode:**
  Reading this register returns 0xFFFFFFFF.

Bits 31:13 **Reserved, must be kept at reset value.**

Bits 12:0 **RRP[12:0]**: RAM Read Pointer

The RAM Read Pointer Register contains the value of the read pointer that is used to read entries from the trace memory over the APB interface via the ETF_RRD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been written. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in Circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.
ETF RAM write pointer register (ETF_RWP)

Address offset: 0x018
Reset value: 0x0000 0000

| Bits 31:13 | Reserved, must be kept at reset value. |
| Bits 12:0 | RWP[12:0]: RAM write pointer |

The RAM write pointer register contains the value of the write pointer that is used to write entries into the trace memory over the APB interface via the ETF_RWD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been read. When the pointer reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in Circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.

ETF trigger counter register (ETF_TRG)

Address offset: 0x01C
Reset value: 0x0000 0000

| Bits 31:13 | Reserved, must be kept at reset value. |
| Bits 10:0 | TRG[10:0]: |

The ETF trigger counter register contains the value of the trigger counter that is used to trigger events and write entries into the trace memory over the APB interface via the ETF_RWD register. The counter can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The counter is incremented by 8 each time a full 64-bit FIFO entry has been read. When the counter reaches its maximum value, it wraps around.

This register can only be written to while in Disabled state. It can be read in Disabled state, in Stopped state in Circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.
ETF control register (ETF_CTL)

Address offset: 0x020
Reset value: 0x0000 0000

| Bits 31:11 | Reserved, must be kept at reset value. |
| Bits 10:0 | **TRG[10:0]**: Trigger counter |

In Circular buffer mode, specifies the number of 32-bit words to capture in the trace RAM following the detection of either a rising edge on the TRIGIN input or a trigger packet in the incoming trace stream, ATID = 7'h7D. On capturing the specified number of data words, a trigger event occurs. The effect of a trigger event on the ETF behavior is controlled by the FFCR Register.

The number of 32-bit words written into the trace RAM following the trigger is the value stored in this register, plus one. This register is ignored when the ETF is in Software FIFO mode or Hardware FIFO mode. When the trigger counter starts counting, any additional triggers, either on TRIGIN or in the incoming trace stream, are ignored until the counter reaches zero. When the trigger counter has reached zero, it remains at zero until it is re-programmed with a write to this register.

This register is cleared when READY goes high, so that the state of the counter when trace capture has stopped does not affect a subsequent trace capture session. Writing to this register when not in Disabled state results in unpredictable behavior.

A read access to this register is permitted at any time when in Disabled state, or in Circular buffer mode. A read access returns the current value of the trigger counter.

| Bits 31:1 | Reserved, must be kept at reset value. |
| Bit 0 | **TCEN**: Trace capture enable |

When writing:

- 0: Disable trace capture (moves from Running, Stopping or Stopped state into Disabling or Disabled state)
- 1: Enable trace capture (moves from Disabled state to Running state)

When reading, this bit is low when in Disabling or Disabled states, and high otherwise.
ETF RAM write data register (ETF_RWD)

</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:0  **RWD[31:0]:** RAM write data
When in Disabled state, a write to this register stores data at the location pointed to by the RWP. Writes to this register when not in Disabled state are ignored. When a full memory width (64-bit) of data has been written, the data is written to memory and the RAM Write Pointer is incremented to the next memory word.
This register is used for test purposes.

Bits 31:2  **Reserved, must be kept at reset value.**

Bits 1:0  **MODE[1:0]:** Operation mode
00b: Circular buffer mode
In this mode, the trace memory is used as a circular buffer. Trace data is captured in the trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten into the trace memory until a stop condition has occurred.
01b: Software FIFO mode
In this mode, the trace memory is used as a FIFO that can be read through the RRD Register while a trace is being captured. Trace data is captured in the trace RAM and when full, the incoming trace stream is stalled.
10b: Hardware FIFO mode
In this mode, the trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured in the trace RAM and when full, the incoming trace stream is stalled. When the trace buffer is non-empty, trace data is drained out through the ATB master interface to the TPIU.
11b: Reserved

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LBUFLEVEL[11:0]:** Latched buffer fill level

Reading this register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level.

When entering Disabled state, this register retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL register is cleared.

This register is used for performance analysis of the trace system.

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **CBUFLEVEL[11:0]:** Current buffer fill level

Reading this register returns the current fill level of the trace memory in 32-bit words. This register is cleared when TCEN is low.
ETF buffer level watermark register (ETF_BUFWM)

Address offset: 0x034
Reset value: 0x0000 0000

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:0  BUFWM[10:0]: Buffer level watermark

The value programmed into this register indicates the required threshold vacancy level of the trace memory in 32-bit words. When the space in the FIFO is less than or equal to this value, that is, fill level >= MEM_SIZE - BUFWM, the FULL output is pulled high and the FULL bit in the STS Register is set.

This register is used only in Software FIFO and Hardware FIFO modes. In Circular buffer mode, this functionality can be obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the FULL bit is set indicating that the vacancy level has fallen below the required level.

The maximum value that can be written into this register is MEM_SIZE - 1. In this case, the FULL bit output is asserted after the first 32-bit word is written to trace memory.

Writing to this register other than when in disabled state results in unpredictable behavior.

ETF formatter and flush status register (ETF_FFSR)

Address offset: 0x030
Reset value: 0x0000 0002

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  FTSTOPPED: Formatter stopped

This bit behaves in the same way as the FEMPTY bit in the ETF_STS register.

Bit 0  FLINPROG: Flush in progress

Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the ETF_FFCR register, or requested by the ATB master port.

0: No flush in progress
1: Flush in progress
ETF formatter and flush control register (ETF_FFCR)

Address offset: 0x304
Reset value: 0x0000 0000

</table>
| DRAINBUF | STPONTRGEV | STPONFL | TRGO | TRGO

Bits 31:15 Reserved, must be kept at reset value.

**Bit 14 DRAINBUF**: Drain buffer

This bit is used to enable draining of the trace data through the ATB master interface after the formatter has stopped. This is useful in circular buffer mode to capture trace data into trace memory and then to drain the captured trace through the ATB master interface.

Writing a 1 to this bit when in Stopped state starts the drain of the trace buffer contents through the ATB Master interface. This bit always reads as zero. The READY bit in the ETF_STS register goes low while the drain is in progress.

This bit is only functional when the ETF is in Circular buffer mode and formatting is enabled, that is, the ENFT bit in the ETF_FFCR register is set. Setting this bit when the ETF is in any other mode, or when not in Stopped state, results in Unpredictable behavior.

When trace capture is complete in Circular buffer mode, all of the captured trace must be retrieved from the trace memory through the same mechanism, either read all trace data out through RRD reads, or drain all trace data by setting the DRAINBUF bit. Setting the DRAINBUF bit after some of the captured trace has been read out through RRD results in unpredictable behavior.

**Bit 13 STPONTRGEV**: Stop on trigger event

0: No effect
1: Stop trace capture when a trigger event occurs

Enabling the ETF in Software FIFO mode or Hardware FIFO mode with this bit set results in unpredictable behavior.

**Bit 12 STOPNFL**: Stop on flush

0: No effect
1: Stop trace capture when flush is completed

If a flush is initiated by the ATB master interface, its completion does not lead to a formatter stop regardless of the value programmed in this bit.

**Bit 11 Reserved, must be kept at reset value.**
Bit 10 **TRIGONFL**: Trigger on flush
0: No effect
1: Indicates a trigger in the trace stream when flush is completed

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
If a flush is initiated by the ATB master interface, its completion does not lead to a trigger indication regardless of the value programmed in this bit.

Bit 9 **TRGONTRGEV**: Trigger on trigger event
0: No effect
1: Indicates a trigger in the trace stream when a trigger event occurs

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
This bit is not supported in Software FIFO mode nor Hardware FIFO mode.

Bit 8 **TRGONTRGIN**: Trigger on trigger in
0: No effect
1: Indicate a trigger in the trace stream when a rising edge is detected on the TRIGIN input.

If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FLUSHMAN**: Manual flush
0: No effect
1: Flush the trace FIFO and pipeline

This bit is cleared automatically when the flush is complete. If the TCEN bit in the ETF_CTL register is 0, writes to this bit are ignored.

Bit 5 **FONTRGEV**: Flush on trigger event
0: No effect
1: Flush the trace FIFO and pipeline if a trigger event occurs

This bit is not supported in Software FIFO mode or Hardware FIFO mode. If STPONTRGEV is set, this bit is ignored.

Bit 4 **FONFLIN**: Flush on flush in
0: No effect
1: Flush the trace FIFO and pipeline if when a rising edge is detected on the FLUSHIN input
ETF periodic synchronization counter register (ETF_PSCR)

Address offset: 0x308
Reset value: 0x0000 000A

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **PSCOUNT[4:0]**: Synchronization counter reload value
Determines the reload value of the Synchronization Counter. The reload value takes effect the next time the counter reaches zero. Reads from this register return the reload value programmed into this register. This register is set to 0xA on reset, corresponding to a synchronization period of 1024 bytes.

0x0: Synchronization disabled
0x1-0x6: Reserved
0x7-0x1B: Synchronization period is \(2^{\text{PSCOUNT}}\) bytes
0x1C-0x1F: Reserved
ETF claim tag set register (ETF_CLAIMSET)

Write:
0000: No effect
xxx1: Clear bit 0
xx1x: Clear bit 1
x1xx: Clear bit 2
1xxx: Clear bit 3

Read: Returns current value of claim tag
ETF lock access register (ETF_LAR)

Address offset: 0xFB0
Reset value: 0xXXXX XXXX

Bits 31:0 **ACCESS_W[31:0]**: ETF register access enable
- Enables write access to some ETF registers by the processor cores (debuggers do not need to unlock the component)
- 0xC5ACCE55: Enable write access
- Other values: Disable write access

ETF lock status register (ETF_LSR)

Address offset: 0xFB4
Reset value: 0x0000 0003

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the ETF_LAR register
- 0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
- This bit always returns zero when read by an external debugger.
- 0: Write access is permitted
- 1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
- The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
- 0: No lock control mechanism exists
- 1: Lock control mechanism is implemented

65.5.5 Trace port interface unit (TPIU)

The TPIU is a CoreSight™ component that formats the trace stream and outputs it on the external trace port signals. The TPIU has a single ATB slave port for incoming trace data. The trace port is a synchronous parallel port, comprising a clock output, TRACECK, and four data outputs, TRACED(3:0). The trace port width is programmable in the range 1 to 4. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes. However it restricts the bandwidth of the trace port and hence the quantity of trace information that can be output in real time. The TRACECK output must be enabled by setting the TRACECLKEN bit in the DBGMCU_CR register.
before a trace is sent to the TPIU. Furthermore, the TRACECK frequency can be programmed in the RCC.

For more information on the Trace port interface CoreSight™ component, refer to the Arm® CoreSight™ SoC-400 technical reference manual [2].

Bits 31:0 **PORTSIZE[31:16]**: Current trace port size

Setting bit n-1 indicates that the current port size is n-pin wide. The value of n must be within the range of supported port sizes (1-4). Only one bit can be set, or unpredictable behavior may result. This register should only be modified when the formatter is stopped.

**Bits 31:8** Reserved, must be kept at reset value.

**Bits 7:0** TRIGCOUNT[7:0]: Enable trigger delay indication

Enables delaying the indication of triggers to any externally connected trace capture or storage devices. This counter is only eight bits wide and is intended to be used only with the counter multipliers in the Trigger multiplier register, 0x108. When a trigger is started, this value, in conjunction with the multiplier, specifies the number of words before the trigger is indicated. When the trigger counter reaches 0, the value written here is reloaded. Writing to this register causes the trigger counter value to reset but does not reset any value on the multiplier. Reading this register returns the preset value, not the current count.

### Bits 15:4
- **PATF0:** FF/00 pattern enable  
  Indicates whether the FF/00 pattern is enabled as output over the trace port  
  - 0: Disabled  
  - 1: Enabled

### Bits 2
- **PATA5:** AA/55 pattern is enable  
  Indicates whether the AA/55 pattern is enabled as output over the trace port  
  - 0: Disabled  
  - 1: Enabled

### Bits 1
- **PATW0:** Walking 0’s pattern enable  
  Indicates whether the walking 0’s pattern is enabled as output over the trace port  
  - 0: Disabled  
  - 1: Enabled

### Bits 0
- **PATW1:** Walking 1’s pattern enable  
  Indicates whether the walking 1’s pattern is enabled as output over the trace port  
  - 0: Disabled  
  - 1: Enabled
### TPIU test pattern repeat counter register (TPIU_TPRCR)

Address offset: 0x208  
Reset value: 0x0000 0000

![Register Table]

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **PATTCOUNT[7:0]:** Number of TRACECLKIN cycles  
The field provides a 8-bit counter value to indicate the number of TRACECLKIN cycles for which a pattern runs before it switches to the next pattern.

### TPIU formatter and flush status register (TPIU_FFSR)

Address offset: 0x300  
Reset value: 0x0000 0002

![Register Table]

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **TCPRESENT:** TRACECTL output pin availability  
Indicates whether the optional TRACECTL output pin is available for use.

0: TRACECTL pin is not present in this device.

Bit 1  **FTSTOPPED:** Formatter stopped  
The formatter has received a stop request signal and all trace data and post-amble is sent. Any additional trace data on the ATB interface is ignored.

0: Formatter has not stopped  
1: Formatter has stopped

Bit 0  **FLINPROG:** Flush in progress  
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.

0: No flush in progress  
1: Flush in progress
## TPIU formatter and flush control register (TPIU_FFCR)

Bits 31:14  Reserved, must be kept at reset value.

- **Bit 13**  **STOPTRIG**: Stop on trigger event  
  0: No effect  
  1: Stop formatter when a trigger event occurs

- **Bit 12**  **STOPFL**: Stop on flush  
  0: No effect  
  1: Stop formatter when flush is completed

- **Bit 11**  Reserved, must be kept at reset value.

- **Bit 10**  **TRIGFL**: Trigger on flush  
  0: No effect  
  1: Indicate a trigger in the trace stream when flush is completed

- **Bit 9**  **TRIGEV**: Trigger on trigger event  
  0: No effect  
  1: Indicate a trigger in the trace stream when trigger event occurs

- **Bit 8**  **TRIGIN**: Trigger on trigger in  
  0: No effect  
  1: Indicate a trigger in the trace stream when the TRIGIN input from the system CTI is asserted.

- **Bit 7**  Reserved, must be kept at reset value.

- **Bit 6**  **FONMAN**: Generate a manual flush  
  0: No effect  
  1: Flush the trace

  This bit is cleared automatically when the flush completes.

- **Bit 5**  **FONTRIG**: Flush on trigger event  
  A trigger event occurs when the trigger counter reaches 0, or, if the trigger counter is 0, when the TRIGIN input from the system CTI is high.  
  0: No effect  
  1: Flush the trace if a trigger event occurs

- **Bit 4**  **FONFLIN**: Flush on flush in  
  0: No effect  
  1: Flush the trace if the FLUSHIN input from the system CTI is asserted
Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ENFCONT**: Enable continuous formatting
   0: Continuous formatting is disabled
   1: Continuous formatting is enabled

Bit 0 **ENFTC**: Enable the embedding of triggers in formatted trace
   0: Formatting is disabled
   1: Formatting is enabled

**TPIU formatter synchronization counter register (TPIU_FSCR)**

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **CYCCOUNT[11:0]**: Enables effective use of TPAs
   Enables effective use of different-sized TPAs without wasting large amounts of storage capacity of the capture device. This counter contains the number of formatter frames since the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value of 4096. This equates to a synchronization every 65536 bytes, that is, 4096 packets x 16 bytes per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every 64 formatter frames. If the formatter is configured for continuous mode, full and half-word sync frames are inserted during normal operation. Under these circumstances, the count value is the maximum number of complete frames between full synchronization packets.

TPIU claim tag clear register (TPIU_CLAIMCLR)

Address offset: 0xFA4
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  CLAIMSET[3:0]: Set claim tag bits
  Write:
  0000: No effect
  xxx1: Set bit 0
  xx1x: Set bit 1
  x1xx: Set bit 2
  1xxx: Set bit 3

  Read:
  0xF: Indicates there are four bits in claim tag

TPIU lock access register (TPIU_LAR)

Address offset: 0xFB0
Reset value: 0xFFFFFF XXXX

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  CLAIMCLR[3:0]: Reset claim tag bits
  Write:
  0000: No effect
  xxx1: Clear bit 0
  xx1x: Clear bit 1
  x1xx: Clear bit 2
  1xxx: Clear bit 3

  Read: Returns current value of claim tag

TPIU lock access register (TPIU_LAR)

Address offset: 0xFB0
Reset value: 0xFFFFFF XXXX

3208/3357
Bits 31:0 **ACCESS_W[31:0]**: TPIU register access enable

Enables write access to some TPIU registers by the processor cores (debuggers do not need to unlock the component)

0xC5ACCE55: Enable write access
Other values: Disable write access

**TPIU lock status register (TPIU_LSR)**

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the TPIU_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Implementation of a lock control mechanism
The bit indicates whether a lock control mechanism is implemented. It always returns zero when read by an external debugger.

0: No lock control mechanism is available
1: Lock control mechanism is implemented

65.5.6 Serial wire output (SWO)

The SWO is a CoreSight component that formats the trace stream from the processor ITM and outputs it on the single wire TRACESWO.

Compared to the TPIU, the SWO contains:
- no formatter
- no pattern generator
- an 8-bit ATB input
- no synchronous trace output, that is, no TRACEDATA or TRACECLK pins
- no support for flush, because this is not required
- no support for triggering

The SWO output supports Manchester encoded and UART NRZ formats.

For more information about the serial wire output CoreSight™ component, refer to the Arm® CoreSight™ Components Technical Reference Manual [4].

SWO registers

SWO current output divisor register (SWO_CODR)

Address offset: 0x010
Reset value: 0x0000 0000

Table 631. TPIU register map and reset values (continued)
Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **PRESALER[12:0]**: SWO baud rate scaling

The baud rate is the trace clock frequency divided by (PRESALER + 1). The baud rate changes instantly, so it is recommended to stop the trace source and wait until the port is idle before writing to this register.

**SWO selected pin protocol register (SWO_SPPR)**

Address offset: 0x0F0

Reset value: 0x0000 0001

Bits 31:4 Reserved, must be kept at reset value.

- Bit 3 **FTNONSTOP**: Change of settings without stopping formatter
  - 1: Change of settings is allowed with formatter running
Bit 2 **TCPRESENT**: TRACECTL pin present on SWO
0: TRACECTL pin not present

Bit 1 **FTSTOPPED**: Formatter stopped
0: Formatter running
The bit always returns 0 as the SWO formatter cannot be stopped in this device.

Bit 0 **FLINPROG**: Flush in progress
0: Flush is not in progress
The bit always returns 0 as SWO flushing is not supported in this device.

**SWO claim tag set register (SWO_CLAIMSET)**

Bits 31:0  **ACCESS_W[31:0]**: SWO register write access enable
Enables write access to some SWO registers by the processor cores (debuggers do not need to unlock the component)

0xC5ACCE55: Enable write access
Other values: Disable write access

3220/3357  RM0468 Rev 3
Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the SWO_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked - only read access is permitted

Bit 0 **LOCKEXIST**: Implementation of a lock control mechanism
The bit indicates whether a lock control mechanism is implemented. It always returns zero when read by an external debugger.

0: No lock control mechanism available
1: Lock control mechanism is implemented

**SWO authentication status register (SWO_AUTHSTAT)**

Table 632. SWO register map and reset values (continued)
65.5.7 Microcontroller debug unit (DBGMCU)

The DBGMCU component contains a number of registers that control the power and clock behavior in Debug mode. Specifically it allows the debugger, or debug software, to:

- maintain the clock and power to the processor cores when in low-power modes (sleep, stop or standby)
- maintain the clock and power to the system debug and trace components when in low power modes
- stop the clock to certain peripherals (CAN, SMBUS timeout, Watchdogs, Timers, RTC) when the processor core is stopped in Debug mode. For timers having complementary outputs, these outputs are disabled (as if the MOE bit was reset) for safety purposes when the counter is stopped (TIM1/8/15/16/17 = 1 in DBGMCU_APB2FZ1).

The DBGMCU registers are not reset by a system reset, only by a power on reset. They are accessible to the debugger via the APB-D bus at base address 0xE00E1000. They are also accessible by the processor core at base address 0x5C001000.

</tbody>
</table>

**Bits 31:29**  
Reserved, must be kept at reset value.

**Bits 28**

TRGOEN: External trigger output enable

This bit controls the direction of the bi-directional trigger pin, TRGIO.

<table>
<thead>
<tr>
<th>Bit 28</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRGOEN</td>
<td></td>
</tr>
<tr>
<td>0: Input - TRGIO is connected to TRGIN</td>
<td></td>
</tr>
<tr>
<td>1: Output - TRGIO is connected to TRGOUT</td>
<td></td>
</tr>
</tbody>
</table>

**Bits 27:23**  
Reserved, must be kept at reset value.
Bit 22 **D3DBGCKEN**: D3 debug clock enable
This bit allows the debug components in the D3 domain (excluding the DAPCLK domain) to be switched off if they are not needed.

0: Disabled - D3 domain debug components are disabled and their clocks gated
1: Enabled - D3 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D3) is active

Bit 21 **D1DBGCKEN**: D1 debug clock enable
This bit allows the debug components in the D1 domain (excluding those in the processor core) to be switched off if they are not needed.

0: Disabled - D1 domain debug components are disabled and their clocks gated
1: Enabled - D1 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D1) is active

Bit 20 **TRACECLKEN**: Trace port clock enable
This bit enables the trace port clock, TRACECLK.

0: Disabled - TRACECLK is disabled
1: Enabled - TRACECLK is active

Bits 19:3 Reserved, must be kept at reset value.

Bit 2 **DBGSTBY_D1**: D1 domain debug in Standby mode enable
0: Normal operation - all clocks is disabled and the domain powered down automatically in Standby mode.
1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the domain supply is maintained, allowing full debug capability. On exit from Standby mode, a domain reset is performed.

Bit 1 **DBGSTOP_D1**: D1 domain debug in Stop mode enable
0: Normal operation - all clocks are disabled automatically in Stop mode
1: Automatic clock stop disabled - all active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings are set to the Stop mode exit state.

Bit 0 **DBGSLLEEP_D1**: D1 domain debug in Sleep mode enable
0: Normal operation - the processor clock is stopped automatically in Sleep mode
1: Automatic clock stop disabled - processor clock continues to run, allowing full debug capability

**DBGMCU APB3 peripheral freeze register (DBGMCU_APB3FSZ1)**

Bits 31:19  Reserved, must be kept at reset value.

**Bit 18**  **LPTIM5**: LPTIM5 stop in debug  
0: Normal operation - LPTIM5 continues operating while the core is in Debug mode  
1: Stop in debug - LPTIM5 is frozen and LPTIM5 outputs are disabled while Cortex-M7 is in Debug mode

**Bit 17**  **LPTIM4**: LPTIM4 stop in debug  
0: Normal operation - LPTIM4 continues operating while the core is in Debug mode  
1: Stop in debug - LPTIM4 is frozen and LPTIM4 outputs are disabled while Cortex-M7 is in Debug mode

**Bit 16**  **LPTIM3**: LPTIM3 stop in debug  
0: Normal operation - LPTIM3 continues operating while the core is in Debug mode  
1: Stop in debug - LPTIM3 is frozen and LPTIM3 outputs are disabled while Cortex-M7 is in Debug mode

**Bit 15**  **LPTIM2**: LPTIM2 stop in debug  
0: Normal operation - LPTIM2 continues operating while the core is in Debug mode  
1: Stop in debug - LPTIM2 is frozen and LPTIM2 outputs are disabled while Cortex-M7 is in Debug mode

**Bit 14**  **I2C4**: I2C4 stop in debug  
0: Normal operation - I2C4 continues operating while the core is in Debug mode  
1: Stop in debug - I2C4 is frozen and I2C4 outputs are disabled while Cortex-M7 is in Debug mode

**Bit 13**  **RTC**: RTC stop in debug  
0: Normal operation - RTC continues operating while the core is in Debug mode  
1: Stop in debug - RTC is frozen and RTC outputs are disabled while Cortex-M7 is in Debug mode.
Bits 31:19  Reserved, must be kept at reset value.

Bit 18  **IWDG1**: Independent watchdog for D1 stop in debug
  0: Normal operation - watchdog continues counting while the core is in Debug mode
  1: Stop in debug - watchdog is frozen while Cortex-M7 is in Debug mode

Bit 17  Reserved, must be kept at reset value.

Bit 16  **RTC**: RTC stop in debug
  0: Normal operation - RTC continues operating while the core is in Debug mode
  1: Stop in debug - RTC is frozen while Cortex-M7 is in Debug mode

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **LPTIM5**: LPTIM5 stop in debug
  0: Normal operation - LPTIM5 continues operating while the core is in Debug mode
  1: Stop in debug - LPTIM5 is frozen while Cortex-M7 is in Debug mode

Bit 11  **LPTIM4**: LPTIM4 stop in debug
  0: Normal operation - LPTIM4 continues operating while the core is in Debug mode
  1: Stop in debug - LPTIM4 is frozen while Cortex-M7 is in Debug mode

Bit 10  **LPTIM3**: LPTIM2 stop in debug
  0: Normal operation - LPTIM2 continues operating while the core is in Debug mode
  1: Stop in debug - LPTIM2 is frozen while Cortex-M7 is in Debug mode

Bit 9  **LPTIM2**: LPTIM2 stop in debug
  0: Normal operation - LPTIM2 continues operating while the core is in Debug mode
  1: Stop in debug - LPTIM2 is frozen while Cortex-M7 is in Debug mode

Bit 8  Reserved, must be kept at reset value.

Bit 7  **I2C4**: I2C4 SMBUS timeout stop in debug
  0: Normal operation - I2C4 SMBUS timeout continues operating while the core is in Debug mode
  1: Stop in debug - I2C4 SMBUS timeout is frozen while the core is in Debug mode

Bits 6:0  Reserved, must be kept at reset value.

65.6 cortex-m7 debug functional description

The cortex-m7 subsystem features the following coresight™ components:

- rom tables
- system control space (scs)
- breakpoint unit (fpb)
- data watchpoint and trace unit (dwt)
- instrumentation trace macrocell (itm)
- embedded trace macrocell (etm)
- cross trigger interface (cti)

These components are accessible by the debugger via the cortex-m7 ahb-ap and its associated ahbd bus.

65.6.1 cortex-m7 rom tables

The rom table is a coresight™ component that contains the base addresses of all the coresight debug components accessible via the ahbd. These tables allow a debugger to discover the topology of the coresight system automatically.

There are two rom tables in the cortex-m7 sub-system:

- cortex-m7 cpu rom table
  this table is pointed to by the base register in the cortex-m7 ahb-ap. it contains the base address pointers for the etm and cti, as well as for the cortex-m7 ppb rom table.

- cortex-m7 ppb (private peripheral bus) rom table
  this table contains pointers to the cortex-m7 system control space registers allowing the debugger to identify the cpu core, as well as to the remaining coresight components in the cortex-m7 subsystem: fpb, dwt and itm.

The cpu rom table occupies a 4-kbyte, 32-bit wide chunk of ahbd address space, from 0xe00fe000 to 0xe00feffe.

The Cortex-M7 PPB ROM table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00FF000 to 0xE00FFFFC.

The Topology for the CoreSight™ components in the Cortex-M7 subsystem is shown in Figure 866.

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **PREAMBLE[27:20]**: Component ID field, bits [31:24]

0xB1: Common ID value
65.6.2 Cortex-M7 data watchpoint and trace unit (DWT)

The DWT provides four comparators that can be used as:

- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (comparator 1 only)
- clock cycle counter comparator (comparator 0 only)

It also contains counters for:

- clock cycles
- folded instructions
- load store unit (LSU) operations
- sleep cycles
- number of cycles per instruction
- interrupt overhead

A DWT comparator compares one of the following with the value held in its DWT_COMP register:

- a data address
- an instruction address
- a data value
- the cycle count value, for comparator 0 only.

For address matching, the comparator can use a mask, so it matches a range of addresses.

| Offset | Register name               | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|-----------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0xFF0  | M7_PPBROM_CIDR0             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Table 637. Cortex-M7 PPB ROM table register map and reset values (continued)
On a successful match, the comparator generates one of the following:

- one or more DWT data trace packets, containing one or more of:
  - the address of the instruction that caused a data access
  - an address offset, bits[15:0] of the data access address
  - the matched data value
- a watchpoint debug event, on either the PC value or the accessed data address
- a CMPMATCH[N] event that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter Debug state.

For more details on how to use the DWT, refer to the Arm®v7-M Architecture Reference Manual [5].

Cortex-M7 DWT registers

**DWT control register (M7_DWT_CTRL)**

Address offset: 0x000
Reset value: 0x4000 0000

| NUMCOMP[3:0] | NOTRCPKT | NOEXTTRIG | NOCYCCNT | NOPRFCNT | Res. | CYCEVTENA | FOLDEVTENA | LSUEVTENA | SLEEP | EXCEVTENA | CPIEV | EXCTR |
|--------------|-----------|-----------|----------|----------|------|-----------|------------|-----------|-------|----------|-------|-------|  |
| f            | r         | r         | r        | r        |      | nw        | nw         | nw        | nw    | nw       | nw    |   0   | 16 |
| 15           | 14        | 13        | 12       | 11       | 10   | 9         | 8          | 7         | 6     | 5        | 4     | 3     | 2  |
|              |           |           |           |          |       | nw        | nw         | nw        | nw    | nw       | nw    | nw    | nw |

Bits 31:28 **NUMCOMP[3:0]**: Number of implemented comparators (read-only)
0x4: Four comparators

Bit 27 **NOTRCPKT**: Trace sampling and exception tracing support (read-only)

0: Supported

Bit 26 **NOEXTTRIG**: External match signal, CMPMATCH support (read-only)

0: Supported

Bit 25 **NOCYCCNT**: Cycle counter support (read-only)

0: Supported

Bit 24 **NOPRFCNT**: Profiling counter support (read-only)

0: Supported

Bit 23 Reserved, must be kept at reset value.

Bit 22 **CYCEVTENA**: Enable POSTCNT underflow event counter packet generation

0: Disabled
1: Enabled

Bit 21 **FOLDEVTENA**: Enable folded instruction counter overflow event generation

0: Disabled
1: Enabled
Bit 20 **LSUEVTENA**: Enable LSU counter overflow event generation
   0: Disabled
   1: Enabled

Bit 19 **SLEEPEVTENA**: Enable sleep counter overflow event generation
   0: Disabled
   1: Enabled

Bit 18 **EXCEVTENA**: Enable exception overhead counter overflow event generation
   0: Disabled
   1: Enabled

Bit 17 **CPIEVTENA**: Enable CPI counter overflow event generation
   0: Disabled
   1: Enabled

Bit 16 **EXCTRCENA**: Enable exception trace generation
   0: Disabled
   1: Enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **PCSAMPLENA**: POSTCNT counter use enable
   Enables the use of POSTCNT counter as a timer for Periodic PC sample packet generation.
   0: Disabled
   1: Enabled

Bits 11:10 **SYNCTAP[1:0]**: Position of synchronization packet counter tap on CYCNCNT counter
   This selection determines the synchronization packet rate.
   0x0: Disabled - no synchronization packets
   0x1: Tap at CYCNCNT[24]
   0x2: Tap at CYCNCNT[26]
   0x3: Tap at CYCNCNT[28]

Bit 9 **CYCTAP**: Position of the POSTCNT tap on the CYCNCNT counter
   0: Tap at CYCNCNT[6]
   1: Tap at CYCNCNT[10]

Bits 8:5 **POSTINIT[3:0]**: Initial value of the POSTCNT counter
   Writes to this field are ignored if POSTCNT counter is enabled (that is, CYCEVTENA or PCSAMPLENA must be reset prior to writing POSTINIT).

Bits 4:1 **POSTRESET[3:0]**: Reload value of the POSTCNT counter.

Bit 0 **CYCNCNTENA**: CYCNCNT counter enable
   0: Disabled
   1: Enabled
DWT cycle count register (M7_DWT_CYCCNT)
Address offset: 0x004
Reset value: 0x0000 0000

|          | rw              |
|          | rw              |
|          | rw              |
|          | rw              |

**Bits 31:0 EIASAMPLE[31:0]:** Executed instruction address sample value  
Samples the current value of the program counter.

### DWT comparator register x (M7_DWT_COMPx)

Address offset: 0x020 + x * 0x10 (for x = 0 to 3)  
Reset value: 0x0000 0000

| Bits 31:0 | COMP[31:16] | 
|-----------+------------|
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |

| Bits 15:0 | COMP[15:0] | 
|-----------+------------|
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |

**Bits 31:0 COMP[31:0]:** Reference value for comparison.

### DWT mask register x (M7_DWT_MASKx)

Address offset: 0x024 + x * 0x10 (for x = 0 to 3)  
Reset value: 0x0000 0000

| Bits 31:5 | Reserved, must be kept at reset value. | 
|-----------+--------------------------------------|
|          | MASK[4:0] | 
|          | rw         |
|          | rw         |
|          | rw         |
|          | rw         |

**Bits 31:5 Reserved, must be kept at reset value.**  
**Bits 4:0 MASK[4:0]:** Comparator mask size  
Provides the size of the ignore mask applied to the access address for address range matching by comparator n. A debugger can write 0b11111 to this field and then read the register back to determine the maximum mask size supported.
DWT function register x (M7_DWT_FUNCTx)

Address offset: 0x028 + x * 0x10 (for x = 0 to 3)

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 MATCHED: Comparator match (read-only)
Indicates if a comparator match has occurred since the register was last read.

0: No match
1: Match occurred

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 DATAVADDR1[3:0]: Comparator number of a second comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a second comparator to use for linked address comparison.

Bits 15:12 DATAVADDR0[3:0]: Comparator number of a comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a comparator to use for linked address comparison.

Bits 11:10 DATAVSIZE[1:0]: Size of required data comparison
For data value matching, specifies the size of the required data comparison.

0x0: Byte
0x1: Half word
0x2: Word
0x3: Reserved

Bit 9 LNK1ENA: Support of a second linked comparator (read-only)
Indicates whether the use of a second linked comparator is supported (read-only).

1: Supported

Bit 8 DATAVMATCH: Cycle comparison enable
0: Perform address comparison
1: Perform data value comparison

Bit 7 CYCMATCH: Cycle count comparison enable on comparator 0
This field is reserved for other comparators.

0: No cycle count comparison
1: Compare DWT_COMP0 with the cycle counter, DWT_CYCCNT

Bit 6 Reserved, must be kept at reset value.
Bit 5 **EMITRANGE**: Data trace address offset packet enable
- Enables the generation of data trace address offset packets (containing data address bits 0 to 15)
  - 0: Disabled
  - 1: Enabled

Bit 4 Reserved, must be kept at reset value.

Bits 3:0 **FUNCTION[3:0]**: Action on comparator match
- The meaning of this bit field depends on the setting of the DATAVMATCH and CYCMATCH fields. See [5].

**DWT CoreSight peripheral identity register 4 (M7_DWT_PIDR4)**

Address offset: 0xFD0

Reset value: 0x0000 0004

65.6.3 Cortex-M7 instrumentation trace macrocell (ITM)

The ITM generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. **Software trace**
   Software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access, and the data written, into a packet that it writes to a FIFO. The ITM outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

2. **Hardware trace**
   The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

3. **Local timestamping**
   The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

4. **Global system timestamping**
   Timestamps can also be generated using the system-wide 64-bit count value coming from the Timestamp Generator component.
Cortex-M7 ITM registers

ITM stimulus register x (M7_ITM_STIMx)
Address offset: 0x0000 + x * 0x4 (x = 0 to 31)
Reset value: 0xXXXX XXXX

STIMULUS[31:16]

Bits 31:0 STIMULUS[31:0]: Software event packet / FIFOREADY
Write data is output on the trace bus as a software event packet. When reading, bit 0 is a FIFOREADY indicator:

0: Stimulus port buffer is full (or port is disabled)
1: Stimulus port can accept new write data

ITM trace enable register (M7_ITM_TER)

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0 PRIVMASK[3:0]: Enable unprivileged access to ITM stimulus ports
Each bit controls eight stimulus ports:

0bXXX0: Unprivileged access permitted on ports 0 to 7
0bXXX1: Only privileged access permitted on ports 0 to 7
0bXX0X: Unprivileged access permitted on ports 8 to 15
0bXX1X: Only privileged access permitted on ports 8 to 15
0bX0XX: Unprivileged access permitted on ports 16 to 23
0bX1XX: Only privileged access permitted on ports 16 to 23
0b0XXX: Unprivileged access permitted on ports 24 to 31
0b1XXX: Only privileged access permitted on ports 24 to 31

Bits 31:24  Reserved, must be kept at reset value.

Bit 23 BUSY: ITM busy
Indicates whether the ITM is currently processing events (read-only):
0: Not busy
1: Busy

Bits 22:16 TRACEBUSID[6:0]: Identifier for multi-source trace stream formatting
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note: different IDs must be used for each trace source in the system.

Bits 15:12  Reserved, must be kept at reset value.
Bits 11:10 **GTSFREQ[1:0]**: Global timestamp frequency

Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps. The possible values are:

- 0x0: Disable generation of global timestamps
- 0x1: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:7]; this is approximately every 128 cycles
- 0x2: Generate timestamp request whenever the ITM detects a change in global timestamp counter bits [63:13]; this is approximately every 8192 cycles
- 0x3: Generate a timestamp after every packet, if the output FIFO is empty

Bits 9:8 **TSPRESCALE[1:0]**: Local timestamp prescale

Prescaler used with the trace packet reference clock. The possible values are:

- 0x0: No prescaling
- 0x1: Divide by 4
- 0x2: Divide by 16
- 0x3: Divide by 64

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SWENA**: Asynchronous clocking enable for the timestamp counter (read-only)

0: Timestamp counter uses processor clock

Bit 3 **TXENA**: Hardware event packet forwarding enable

Enables forwarding of hardware event packets from the DWT unit to the trace port.

- 0: Disabled
- 1: Enabled

Bit 2 **SYNCENA**: Synchronization packet transmission enable

If a debugger sets this bit it must also configure the DWT_CTRL register SYNCTAP field in the DWT for the correct synchronization speed.

- 0: Disabled
- 1: Enabled

Bit 1 **TSENA**: Local timestamp generation enable

- 0: Disabled
- 1: Enabled

Bit 0 **ITMENA**: ITM enable

- 0: Disabled
- 1: Enabled
### ITM CoreSight peripheral identity register 4 (M7_ITM_PIDR4)

65.6.4 Cortex-M7 breakpoint unit (FPB)

The FPB allows hardware breakpoints to be set. It contains eight comparators which monitor the instruction fetch address and return a breakpoint instruction when a match is detected. The Cortex-M7 FPB does not support flash patch functionality.

Cortex-M7 FPB registers

FPB control register (M7_FPB_CTRL)

Address offset: 0x000
Reset value: 0x0000 0080

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 NUM_CODE[6:4]: Instruction address comparator number field, three MSBs
This read-only field holds the three MSBs of the number of instruction address comparators supported.

0x0: the MSBs of the number are all 0

Bits 11:8 NUM_LIT[3:0]: Number of literal address comparators supported (read-only).
0x0: No literal comparators supported.

Bits 7:4 NUM_CODE[3:0]: Instruction address comparator number field, four LSBs
This read-only field holds the four LSBs of the number of instruction address comparators supported.

0x8: 8 instruction comparators supported

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 KEY: Write protect key
A write to M7_FPB_CTRL register is ignored if this bit is not set to 1.

Bit 0 ENABLE: FPB enable
0: Disable
1: Enable
**FPB remap register (M7_FPBT_REMAP)**

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **RMPSPT**: Flash patch remap support (read-only)
0: Remapping not supported

Bits 28:5 **REMAP[23:0]**: Reserved - not supported

Bits 4:0 Reserved, must be kept at reset value.

**Bits 31:30 REPLACE[1:0]**: Behavior upon COMP versus instruction fetch address match

Defines the behavior when a match occurs between the COMP field and the instruction fetch address:

0x0: Reserved
0x1: Breakpoint on lower half-word, upper half-word is unaffected.
0x2: Breakpoint on upper half-word, lower half-word is unaffected.
0x3: Breakpoint on both upper and lower half-words.

Bit 29 Reserved, must be kept at reset value.
Bits 28:2 **COMP[26:0]**: Value to compare with code memory access address
Value to compare with address bits 28:2 of accesses to instruction code memory (0x00000000 to 0xFFFFFFFF). If a match occurs, the action to take is defined by the REPLACE field.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Comparator enable
The comparator is only enabled if both this bit and the FPB ENABLE bit in the M7_FPB_CTRL register are set.

0: Disabled
1: Enabled

65.6.5  **Cortex-M7 embedded trace macrocell (ETM)**

The Cortex-M7 ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M7 core to be traced. In the STM32H7, the ETM is configured for instruction trace only, so data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:
- The number of instructions executed in the same cycle
- Changes in program flow
- The current processor instruction state
- The memory address locations accessed by load and store instructions
- The type, direction and size of a transfer
- Condition code information
- Exception information
- Wait for interrupt state information

For more information, refer to the Arm® CoreSight™ ETM™-M7 technical reference manual [6].

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **TYPE1**: Resource type for event 1
0: Single selected resource
1: Boolean combined resource pair

Bits 14:12  Reserved, must be kept at reset value.

Bits 11:8  **SEL1[3:0]**: Resource / Boolean combined resource pair, for event 1
When TYPE1 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
When TYPE1 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

Bit 7  **TYPE0**: Resource type for event 0
0: Single selected resource
1: Boolean combined resource pair

Bits 6:4  Reserved, must be kept at reset value.

Bits 3:0  **SEL0[3:0]**: Resource / Boolean combined resource pair for event 0
When TYPE0 is 0, selects a single selected resource from 0-15 defined by bits[3:0]
When TYPE0 is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

ETM event control 1 register (M7_ETM_EVENTCTL1)

Only accepts writes when trace unit is disabled

Address offset: 0x024

Reset value: 0x0000 0000

```

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **LPOVE RRIDE**: Leave processor in execution mode after debug event
0: Normal behavior
1: Leave processor in execution mode after debug event

Bit 14  **ATB**: Address translation bypass
0: Normal behavior
1: Address translation bypass

Bits 13:0  **INSTEN[3:0]**: Instruction enable
0: Normal behavior
1: Enable instruction for specified event
ETM stall control register (M7_ETM_STALLCTL)

Only accepts writes when trace unit is disabled

Address offset: 0x02C

Reset value: 0x0000 0000

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 DSTALL: Stall processor based on data trace buffer space
0: Do not stall processor
1: Stall processor

Bit 8 ISTALL: Stall processor based on instruction trace buffer space
0: Do not stall processor
1: Stall processor

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 LEVEL[1:0]: Stalling threshold level
A low level minimizes the amount of processor stalling, with a higher risk of FIFO overflow. A high level minimizes the risk of FIFO overflow but increases the amount of processor stalling.

Bits 1:0 Reserved, must be kept at reset value.
### ETM global timestamp control register (M7_ETM_TSCTL)

Only accepts writes when trace unit is disabled

ETM ViewInst start/stop control register (M7_ETM_VISSCTL)

Address offset: 0x088
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **EXLEVEL_S3**: Trace disable, exception level 3
Disables tracing in the specified exception level in Secure state for exception level 3.
0: Enable ViewInst in this exception level
1: Disable ViewInst in this exception level

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **EXLEVEL_S0**: Trace disable, exception level 0
Disables tracing in the specified exception level in Secure state for exception level 0.
0: Enable ViewInst in this exception level
1: Disable ViewInst in this exception level

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **TRCERR**: Tracing of system error exception
Selects whether a system error exception must always be traced.
0: System error exception is traced only if the instruction or exception immediately before the system error exception is traced
1: System error exception is always traced regardless of the value of ViewInst

Bit 10 **TRCRESET**: Tracing of reset exception
Selects whether a reset exception must always be traced.
0: Reset exception is traced only if the instruction or exception immediately before the reset exception is traced
1: Reset exception is always traced regardless of the value of ViewInst

Bit 9 **SSSTATUS**: Current status of the start/stop logic
0: Stop state
1: Started state

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TYPE**: Resource type
0: Single selected resource
1: Boolean combined resource pair

Bits 6:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]**: Resource / Boolean combined resource pair
When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0]
When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]
**ETM ViewInst start/stop processor comparator control register**

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16 **STOP[7:0]:** Single address comparator selector to stop trace  
Defines the single address comparators to stop trace with the ViewInst Start/Stop control.  
One bit is provided for each implemented single address comparator.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0 **START[7:0]:** Single address comparator selector to start trace  
Defines the single address comparators to start trace with the ViewInst Start/Stop control.  
One bit is provided for each implemented single address comparator.

**ETM counter reload value register** *(M7_ETM_CNTRLDV)*

0x0: No special conditional instruction right hand-keys implemented
ETM implementation specific register 0 (M7_ETM_IMSPEC0)

Address offset: 0x1C0
Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **SUPPORT[3:0]**: Support for implementation specific extensions
0x0: No implementation specific extensions are supported

ETM ID register 0 (M7_ETM_IDR0)

Address offset: 0x1E0
Reset value: 0x0C00 1EE1

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **COMM OPT**: Meaning of the commit field in some packets
0: Commit mode 0

Bits 28:24  **TSSIZE[4:0]**: Global timestamp size
0x08: Maximum of 64-bit global timestamp implemented

Bits 23:17  Reserved, must be kept at reset value.

Bits 16:15  **QSUPP[1:0]**: Q element support
0x0: Q elements not supported

Bit 14  Reserved, must be kept at reset value.

Bits 13:12  **CONDTYPE[1:0]**: Conditional result tracing type
0x1: APSR condition flag values traced

Bits 11:10  **NUMEVENT[1:0]**: Number of events supported in the trace
0x1: Two events supported for instruction only configuration

Bit 9  **RETSTACK**: Return stack support
1: Two entry return stack supported

Bit 8  Reserved, must be kept at reset value.
Bit 7  **TRCCCI**: Support for cycle counting in the instruction trace  
1: Cycle counting in the instruction trace is implemented

Bit 6  **TRCCOND**: Support for conditional instruction tracing  
1: Conditional instruction trace is implemented

Bit 5  **TRCBB**: Support for branch broadcast tracing  
1: Branch broadcast trace is implemented

Bits 4:0  Reserved, must be kept at reset value.

**ETM ID register 1 (M7_ETM_IDR1)**

Address offset: 0x1E4

Reset value: 0x4100 F401

Bit 31  **NOOVERFLOW**: Support of NOOVERFLOW
Indicates whether the NOOVERFLOW of trace stall control is implemented.
0: Not implemented

Bits 30:28  **NUMPROC[2:0]**: Number of processors available for tracing
0x0: Only one processor can be traced

Bit 27  **SYSSTALL**: System support for stall control of the processor
0: Not supported

Bit 26  **STALLCTL**: Stall control support
1: Trace stall control (TRCSTALLCTLR) is implemented

Bit 25  **SYNCP**: Trace synchronization period support
0: TRCSYNCP is read-only for instruction trace only configuration; the trace synchronization period is fixed

Bit 24  **TRCERR**: Support of TRCVICTLR.TRCERR
Indicates whether TRCVICTLR.TRCERR is implemented.
0x4: 32-bit maximum address size

Bits 23:20  Reserved, must be kept at reset value.
Bits 19:16 **EXLEVEL_S[3:0]**: Support of privilege levels
Privilege levels are implemented; one bit for each level.
0x9: Privilege levels Thread and Handler are implemented

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **CCITMIN[11:0]**: Instruction trace cycle counting minimum threshold
0x4: Minimum threshold is 4 instruction trace cycle

**ETM ID register 4 (M7_ETM_IDR4)**

Bits 15:16 \textbf{PAIRINV}: Support of pair inversion
1: Implemented

Bits 11:0 \textbf{GROUP}[2:0]: Support of SOAR group
0x0: None
ETM resource selection register 3 (M7_ETM_RSCTL3)

Address offset: 0x20C
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 PAIRINV: Inversion of result of a combined pair of resources
0: Not inverted
1: Inverted

Bit 20 INV: Inversion of the selected resources
0: Not inverted
1: Inverted

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 GROUP[2:0]: Selects a group of resources

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 SELECT[7:0]: Resource selector from desired group
Selects one or more resources from the desired group. One bit is provided per resource from the group.
ETM single-shot comparator control register 0 (M7_ETM_SSCC0)

Address offset: 0x280
Reset value: 0x0000 0000

</table>

Bit 31  **STATUS**: Single-shot status
This indicates whether any of the selected comparators have matched. If SSCC0.RST is set to 0, the STATUS bit must be written with 0 in order to enable single-shot comparator control.
0: No match occurred
1: Match has occurred at least once.

Bits 30:3  Reserved, must be kept at reset value.

Bit 2  **DV**: Data value comparator support
0: Single-shot data value comparisons not supported

Bit 1  **DA**: Data address comparator support
0: Single-shot data address comparisons not supported

Bit 0  **INST**: Instruction address comparator support
1: Single-shot instruction address comparisons supported
**ETM single-shot processor comparator input control register**

  - 0: 32-bit

- **Bit 1** **LOCKGRANT**: Current status of lock
  - This bit always returns zero when read by an external debugger.
  
    - 0: Write access is permitted
    - 1: Write access is blocked. Only read access is permitted.

- **Bit 0** **LOCKEXIST**: Existence of lock control mechanism
  - The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  
    - 0: No lock control mechanism exists
    - 1: Lock control mechanism is implemented

6. DDI 0494-2a (ID062813) - Arm® CoreSight™ ETM™-M7 r0p1 Technical Reference Manual, Issue D
Device electronic signature

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32H72x and STM32H73x microcontrollers.

66.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:
- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

L_ID[15:0]
Bits 31:0  **L_ID[31:0]:** Line identifier

This bitfield indicates the device line expressed in ASCII. As an example, STM32H725 corresponds to 0x4837 3235:

- 0x48 = 'H'
- 0x37 = '7'
- 0x32 = '2'
- 0x35 = '5'

### 66.4 Package data register

Bits 15:0  **F_ID(15:0):** Flash memory size

This bitfield indicates the size of the device Flash memory expressed in Kbytes.
As an example, 0x0400 corresponds to 1024 Kbytes.

Refer to SYSCFG package register (SYSCFG_PKGR) for package identification. The SYSCFG clock should be enabled first in the RCC_APB4ENR register.
### Revision history

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>30-Oct-2019</td>
<td>1</td>
<td>Initial release. Added STM43H730xB microcontrollers. Added Section 1.5: Availability of security features.</td>
</tr>
<tr>
<td>24-Jun-2020</td>
<td>2</td>
<td>Section 4: Embedded Flash memory (FLASH) Added STM32H730xB devices and changed user Flash memory density to “up to 1 Mbyte” to take into account 128 Kbyte and 512 Kbyte devices. Updated Table 16: FLASH recommended number of wait states and programming delay. Section 5: Secure memory management (SMM) Changed part numbers on which the Secure memory management is available to STM32H73x. Section 6: Power control (PWR) Replace voltage regulator by LDO voltage regulator in the whole chapter. Replaced Run mode by Run and Autonomous modes in Section: LDO voltage regulator, Section 6.4.3: PWR external supply and Section 6.6.3: Power control modes. In Section 6.4.4: Backup domain, updated list of GPIOs whose use is restricted when VDD is higher than the PDR threshold. Updated Section 6.6.3: Power control modes. Updated Section 6.7.8: Stop mode. Added note to DBP bit in PWR control register 1 (PWR_CR1). Section 8: Reset and clock control (RCC) Updated max HSE frequency in Section 8.1: RCC main features. Updated Section: External crystal/ceramic resonator. Updated Table 56: Kernel clock distribution overview. Changed 500 MHz and 250 MHz to 550 MHz and 275 MHz in Figure 49: Core and bus clock generation. Updated internal signal names in Figure 50: Kernel clock distribution for SAIs and SPDIFRX. Changed SPIDFSEL into SPDIFRXSEL and IS2123SEL into SPI123SEL in Figure 52: Kernel clock distribution for SPIs and SPI/I2S. Changed OSPISSEL into OCTOSPISSEL, OSPI[2:1]EN/OSPI[2:1]LEN into OCTOSP[2:1]EN/OCTOSP[2:1]LPEN, and updated internal signal names in Figure 56: Kernel clock distribution for SDMMC, OCTOSPI and FMC. Updated Figure 57: Kernel clock distribution for USB. Renamed SWPMI-related bits in Figure 59: Kernel clock distribution for ADCs, SWPMI, RNG and FDCAN. Renamed LPTIM internal signals in Figure 60: Kernel clock distribution for LPTIMs and HDMI-CEC. Updated HSECSSON bit description in RCC source control register (RCC_CR).</td>
</tr>
</tbody>
</table>
### Section 8: Reset and clock control (RCC) (continued)

- Replaced TMPSENS by DTS in RCC_APB4RSTR/ENR/LPENR and RCC_D3AMR and in RCC_C1_APB4ENR/LPENR.
- Renamed SPDIFSEL into SPDIFRXSEL and SWPSEL into SWPMISEL in **RCC** domain 2 kernel clock configuration register (**RCC_D2CCIP1R**).
- Renamed OSPISEL into OCTOSPISEL in **RCC** domain 1 kernel clock configuration register (**RCC_D1CCIPR**), renamed OCTO[2:1]RST into OCTOSPI[2:1]RST in **RCC** AHB3 reset register (**RCC_AHB3RSTR**), OSPI[2:1]EN into OCTOSPI[2:1]EN in **RCC** AHB3 clock register (**RCC_AHB3ENR**), and OSPI[2:1]LEN into OCTOSPI[2:1]LEN in **RCC** AHB3 Sleep clock register (**RCC_AHB3LPENR**). Renamed SWPRST into SWPMIRST in **RCC** APB1 peripheral reset register (**RCC_APB1HRSTR**), SWPEN into SWPMIEN in **RCC** APB1 clock register (**RCC_APB1HENR**), and SWPLPEN into SWPMILPEN in **RCC** APB1 clock register (**RCC_APB1LENR**).
- Updated DIVR2EN, DIVQ2EN, DIVP2EN, DIVR1EN of **RCC** PLL Configuration Register (**RCC_PLLCFGR**).

### Section 13: Block interconnect

In **Table 94:** Peripherals interconnect matrix details, change PTPx and PPS into eth_ptp_trgx and eth_ptp_pps_out, respectively.

### Section 12: System configuration controller (SYSCFG)

- Added note related to PC3SO, PC2SO, PA1SO and PA0SO reset value and updated BOOSTVDDSEL bit description in **Section 12.4.1:** SYSCFG peripheral mode configuration register (**SYSCFG_PMCR**).

### Section 15: Direct memory access controller (DMA)

- Bit 20 of **DMA stream x configuration register (DMA_SxCR)** changed from reserved to TRBUFF for the products listed.

### Section 17: DMA request multiplexer (DMAMUX)

- Updated **Section 17.4.4:** DMAMUX request line multiplexer.

### Section 24: Flexible memory controller (FMC)

- Updated **Section:** General transaction rules to clarify the behavior of the FMC when the AXI transaction data size is different from the device data width and add the case of unaligned addresses.
- Replaced FMC_CLK by fmc_ker_ck in the formulas of **Section:** WAIT management in asynchronous accesses.

### Section 25: Octo-SPI interface (OCTOSPI)

- Updated **Section 25.2:** OCTOSPI main features and **Section 25.3:** OCTOSPI implementation.
- Updated WRAP support part in **Section 25.4.6:** Specific features.
- Updated **Section 25.4.10:** OCTOSPI Memory-mapped mode.
- Updated **Section:** Sending the instruction only once (SIOO).
- Modified ABORT and EN bit description in **Section 25.7.1:** OCTOSPI control register (**OCTOSPI_CCR**), FLEVEL bit description in **Section 25.7.6:** OCTOSPI status register (**OCTOSPI_SSR**) and DLYBYP bit in **Section 25.7.2:** OCTOSPI device configuration register 1 (**OCTOSPI_DCR1**).
Section 26: OCTOSPI I/O manager (OCTOSPIM)
Updated ports for pin assignment from 3 to 2.

Section 28: Analog-to-digital converters (ADC1/ADC2)
Added adc_sclk in Figure 160: ADC block diagram and Table 221: ADC input/output pins and removed $V_{REF+}$ and $V_{REF-}$ ranges from this table.
Updated Section 28.4.3: ADC clocks.
Updated Section: ADC overrun (OVR, OVRMOD). Added case of FIFO overflow in Section: Managing a sequence of conversion without using the DMA.
Updated Section: Single ADC operating modes support when oversampling to remove the mention that the offset correction is not supported in oversampling mode.
Updated RES[2:0] bitfield definition in Section 28.6.4: ADC configuration register (ADC_CFGR). Replaced adc_hclk by adc_clk in CKMODE[1:0] bitfield definition of Section 28.7.2: ADC common control register (ADCx_CCR) (x=1/2).

Section 29: Analog-to-digital converters (ADC3)
Added description of output data and formula to compute the converted value in Section 29.4.7: Single-ended and differential input channels.
Updated Section: ADC overrun (OVR, OVRMOD) and Added case of FIFO overflow in Section: Managing a sequence of conversions without using the DMA.
Added SMP19[2:0] in Section 29.6.7: ADC sample time register 2 (ADC_SMPR2).
Added note to OFFSETy_CH[4:0] in Section 29.6.17: ADC offset y register (ADC_OFRy).

Section 30: Digital temperature sensor (DTS)
Removed EN pin from Figure 284: Temperature sensor functional block diagram.
Updated formula to calculate the temperature when PCLK is used in Section 30.3.7: Temperature measurement principles.
Removed startup time value from Section 30.3.11: On-off control and ready flag.
Removed TS1_EN of Temperature sensor configuration register 1 (DTS_CFGR1) and replaced list of triggers in TS1_INTRIG_SEL[3:0] by a reference to Table Trigger configuration in DTS_CFGR1.

Section 31: Digital-to-analog converter (DAC)
Removed DAC acronym in Section 31.4.9: Noise generation and Section 31.4.10: Triangle-wave generation.
Updated the way to stop LSI clock in Section 31.4.11: DAC channel modes/Section: Sample and hold mode.
In TSEL1/2 of Section 31.7.1: DAC control register (DAC_CR), changed internal trigger signal names from dac_ch1_trigx/dac_ch2_trigx to dac_ch1_trgx/dac_ch2_trgx.

### Section 54: Low-power universal asynchronous receiver transmitter (LPUART)

- Added Section 54.3: LPUART implementation.
- Updated SBKF bit description in Section 54.7.7: LPUART interrupt and status register [alternate] (LPUART_ISR).

### Section 55: Serial peripheral interface (SPI)

- Updated Section 55.2: SPI main features, Section 55.3: SPI implementation and Section 55.4.2: SPI signals.
- Updated Section 55.4.5: Standard multi-slave communication, Section 55.4.7: Slave select (SS) pin management, Section 55.4.8: Communication formats, Section 55.4.9: Configuration of SPI, Section 55.4.10: Procedure for enabling SPI and Section 55.4.11: SPI data transmission and reception procedures.
- Updated Figure 653: Packing data in FIFO for transmission and reception.
- Updated Section 55.5.1: TI mode, Section 55.5.2: SPI error flags and Section 55.5.3: CRC computation.
- Updated Section 55.5.7: SPI wakeup and interrupts.
- Updated Section 55.11.6: SPI/I2S status register (SPI_SR), Section 55.11.3: SPI configuration register 1 (SPI_CFG1), Section 55.11.4: SPI configuration register 2 (SPI_CFG2), Section 55.11.6: SPI/I2S status register (SPI_SR), Section 55.11.8: SPI/I2S transmit data register (SPI_TXDR), Section 55.11.9: SPI/I2S receive data register (SPI_RXDR), Section 55.11.10: SPI polynomial register (SPI_CRC POLY), Section 55.11.11: SPI transmitter CRC register (SPI_TXCRC), Section 55.11.12: SPI receiver CRC register (SPI_RXCRC) and Section 55.11.13: SPI underrun data register (SPI_UDRDR).
- Updated Table 441: SPI register map and reset values.

### Section 58: Single wire protocol master interface (SWPMI)

- Modified name of bit and register to select SWPMI in Section Figure 716.: SWPMI block diagram.
- Replaced SWPSR of RCC_D2CCIP1R by SWPSEL of RCC_CDCCIP1R in Figure 716: SWPMI block diagram.

### Section 63: Ethernet (ETH): media access control (MAC) with DMA controller

- Replaced ptp_pps_o internal signal by eth_ptp_pps_out, ptp_aux_ts_trig_i by eth_ptp_trg[x] (where x = 0 to 3) and ptp_aux_trig_i[x] by eth_ptp_trg[x] in IEEE 1588 auxiliary snapshots.
- Updated ARPEN bit description in Operating mode configuration register (ETH_MACCCR).
- Removed sentence “This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input” from System time nanoseconds register (ETH_MACSTNR), System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR) register descriptions.

### Section 66: Device electronic signature

- Added Section 66.3: Line identifier.

<td>Added errata sheet in the list of reference documents as well as mention that patents apply to the microcontrollers on document cover page.</td>
</tr>
</tbody>
</table>

**Section 2: Memory and bus architecture**
- Updated Section : Embedded bootloader.
- Updated DFSDM1 base address in Table 7: Register boundary addresses.

**Section 4: Embedded Flash memory (FLASH)**
- Added note indicating the only sections 0 to 3 are available on 512 Kbyte devices in Table 15: Flash memory organization (STM32H723/733 and STM32H725/735 devices).
- Better specified the registers reset by System reset in Section 8.4.2: System reset. Section 4.4.7: Description of boot address option bytes.
- Updated FAIL_ECC_ADDR[14:0] description in FLASH ECC fail address (FLASH_ECC_FAR).

**Section 6: Power control (PWR)**
- Updated Figure 18: Power supply overview.
- Added note on VDDLDO in Table 28: PWR input/output signals connected to package pins or balls.
- Updated Section : VCORE supplied in Bypass mode (LDO and SMPS OFF).
  - Added Section : How to exit from Run* mode.

**Section 8: Reset and clock control (RCC)**
- Updated VREFRST bit description in RCC APB4 peripheral reset register (RCC_APB4RSTR) and VREFEN bit description in RCC APB4 clock register (RCC_APB4ENR) to mention VREFBUF.
- Updated RCC reset status register (RCC_RSR), RCC APB1 Low Sleep clock register (RCC_APB1LLPENR) and RCC APB2 Sleep clock register (RCC_APB2LPENR) reset values.

**Section 9: Clock recovery system (CRS)**
- Added note relative to the trimming step size in Section : FELIM value.
  - Modified CRS control register (CRS_CR) reset value.

**Section 10: Hardware semaphore (HSEM)**
- Updated Section 10.3.2: HSEM internal signals, Section 10.3.3: HSEM lock procedures, Section 10.3.5: HSEM unlock procedures, Section 10.3.6: HSEM MASTERRID semaphore clear, Section 10.3.7: HSEM interrupts and Section 10.3.8: AHB bus master ID verification.
- Updated HSEM register semaphore x (HSEM_Rx), HSEM read lock register semaphore x (HSEM_RLRx) and HSEM interrupt status register (HSEM_MISR).

</table>
| 13-Dec-2021 | 3 (continued) | **Section 12: System configuration controller (SYSCFG)**  
Updated BOOSTVDDSEL description and added note related to PC3SO, PC2SO, PA1SO and PA0SO reset value in **SYSCFG peripheral mode configuration register (SYSCFG_PMCR)**.  
**Section 13: Block interconnect**  
Updated TIM23/TIM24 in **Table 92: Peripherals interconnect matrix (D2 domain)**.  
**Section 19: Nested vectored interrupt controller (NVIC)**  
Replaced UART9_IT_OR_UART9_WKUP by UART9 in **Table 140: NVIC**.  
**Section 20: Extended interrupt and event controller (EXTI)**  
Remove note 4 related to WKUP sources in **Table 143: EXTI Event input mapping**.  
**Section 14: MDMA controller (MDMA)**  
Removed SM bit in **MDMA channel x control register (MDMA_CxCR)**.  
**Section 17: DMA request multiplexer (DMAMUX)**  
Updated **Section 17.4.4: DMAMUX request line multiplexer**.  
**Section 18: Chrom-Art Accelerator controller (DMA2D)**  
Updated **Section 18.3.2: DMA2D internal signals**.  
**Section 21: Cyclic redundancy check calculation unit (CRC)**  
Added note in **Section: Polynomial programmability** to clarify what are even and odd polynomials.  
Added CRC register access granularity in **Section 21.2: CRC main features** and **Section 21.4: CRC registers**.  
Updated **Figure 97: CRC calculation unit block diagram**.  
**Section 25: Octo-SPI interface (OCTOSPI)**  
Renamed DDR mode into DTR, Status-polling into Automatic status-polling, nCS and CS pins into NCS, and nCLK into NCLK.  
Updated **Section 25.2: OCTOSPI main features**, all block diagram and extended CSHT in **Table 209: OCTOSPI implementation**  
Updated **Section: Dual-quad configuration**. Added new note after **Figure 146**, **Figure 147**, and **Figure 148**.  
Updated **Section 25.4.8: OCTOSPI Indirect mode**. Updated note at the beginning of **Section 25.4.10: OCTOSPI Memory-mapped mode**. Updated **Section 25.4.14: OCTOSPI Regular-command mode configuration**.  
Added **Section 25.5: Address alignment and data number**  
Renamed DQM bit into DMM and updated FSEL bit in **OCTOSPI control register (OCTOSPI_CR)**.  
Updated DEVSIZE description in **OCTOSPI device configuration register 1 (OCTOSPI_DCR1)**.  
Updated REFRESH description in **OCTOSPI device configuration register 4 (OCTOSPI_DCR4)**. |

| 13-Dec-2021 | 3 (continued) | **Section 30: Digital temperature sensor (DTS)**  
Updated Figure 284: Temperature sensor functional block diagram.  
Updated signals to which ts1_trg0 to 3 are connected in Table 257: Trigger configuration. Changed TS1_TO[1:0] = 01 definition to 130 °C in Temperature sensor T0 value register 1 (DTS_T0VALR1).  
Updated TS1_LITTHD bitfield description in Temperature sensor interrupt threshold register 1 (DTS_ITR1).  
**Section 39: True random number generator (RNG)**  
Updated Section 39.5: RNG processing time.  
Updated CLKDIV[3:0] description in RNG control register (RNG_CR).  
**Section 40: Cryptographic processor (CRYP)**  
Updated Figure 342: AES-ECB mode overview, Figure 343: AES-CBC mode overview, Figure 344: AES-CTR mode overview, Figure 345: AES-GCM mode overview, Figure 346: AES-GMAC mode overview, Figure 347: AES-CCM mode overview, Figure 357: Message construction for the Counter mode, Figure 361: Message construction for the Galois Message Authentication Code mode, Figure 362: Message construction for the Counter with CBC-MAC mode.  
Updated Table 323: Counter mode initialization vector, Table 325: GCM mode IV registers initialization, Table 326: CCM mode IV registers initialization.  
Updated introduction of Section 40.4.16: CRYP data registers and data swapping, Section 40.4.17: CRYP key registers and Section 40.4.18: CRYP initialization vector registers. Updated all CRYP_KxLR/RR and CRYP_IVxLR/RR register descriptions.  
**Section 43: Advanced-control timers (TIM1/TIM8)**  
Updated Figure 396: Control circuit in normal mode, internal clock divided by 1.  
Added note in Section 43.3.16: Using the break function.  
Updated OC1PE bit in TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8).  
**Section 45: General-purpose timers (TIM12/TIM13/TIM14)**  
Updated Figure 495: Control circuit in external clock mode 1.  
Updated OC1PE bit in TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1) and TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 13 to 14).  
**Section 46: General-purpose timers (TIM15/TIM16/TIM17)**  
Updated Figure 520: Control circuit in normal mode, internal clock divided by 1.  
Added Section 46.4.15: 6-step PWM generation.  
Added note in Section 46.4.13: Using the break function.  
Suppressed CC2DE bit in TIM15 DMA/Interrupt enable register (TIM15_DIER).  
Updated TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1) and TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 16 to 17).  
| 13-Dec-2021 | 3 | **Section 30: Digital temperature sensor (DTS)**  
Updated Figure 284: Temperature sensor functional block diagram.  
Updated signals to which ts1_trg0 to 3 are connected in Table 257: Trigger configuration. Changed TS1_TO[1:0] = 01 definition to 130 °C in Temperature sensor T0 value register 1 (DTS_T0VALR1).  
Updated TS1_LITTHD bitfield description in Temperature sensor interrupt threshold register 1 (DTS_ITR1).  
**Section 39: True random number generator (RNG)**  
Updated Section 39.5: RNG processing time.  
Updated CLKDIV[3:0] description in RNG control register (RNG_CR).

Added note in Section 46.4.13: Using the break function.  
Suppressed CC2DE bit in TIM15 DMA/Interrupt enable register (TIM15_DIER).  
Updated TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1) and TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 16 to 17).

### Table 642. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 13-Dec-2021| 3 (continued) | **Section 48: Low-power timer (LPTIM)**  
Updated Section 48.2: LPTIM main features and Section 48.4.4: LPTIM reset and clocks. Added note to Section 48.4.7: Trigger multiplexer. Updated Section 48.4.15: Encoder mode.  
Updated LPTIM interrupt and status register (LPTIM_ISR), LPTIM interrupt clear register (LPTIM_ICR) and LPTIM configuration register (LPTIM_CFGR).  

**Section 53: Universal synchronous/asynchronous receiver transmitter (USART/UART)**  
Renamed SCLK pin into CK in the whole section.  
Added wakeup from Stop in Section 53.2: USART main features.  
Updated Figure 623: RS232 RTS flow control and Figure 624: RS232 CTS flow control to replace nRTS and nCTS by RTS and CTS, respectively.  
Updated Table 427: Error calculation for programmed baud rates at `lpuart_ker_ck_pres = 32.768 kHz`.  
Removed mention that usart_wkup interrupt is not mandatory when wakeup event is detected from Section 53.5.21: USART low-power management.  
Added Section 53.6: USART in low-power modes.  
Updated Section 53.7: USART interrupts.  
Updated ADD[7:0] bitfield descriptions in USART control register 2 (USART_CR2).  
Updated EOBF and ABRE bit descriptions in USART interrupt and status register (alternate) (USART_ISR). Updated ABRRQ bit description in USART request register (USART_RQR).  

**Section 54: Low-power universal asynchronous receiver transmitter (LPUART)**  
Renamed SCLK pin to CK in the whole section.  
Removed mention that lpuart_wkup interrupt is not mandatory when wakeup event is detected in Section 54.4.14: LPUART low-power management.  
Added Section 54.5: LPUART in low-power modes.  
Updated Section 54.6: LPUART interrupts.  
Updated ABRE bit and ADD[7:0] bitfield description in LPUART control register 2 (LPUART_CR2).  

**Section 55: Serial peripheral interface (SPI)**  
Updated Section 55: Data handling via RxFIFO and TxFIFO and Section 55.5.3: CRC computation.  

**Section 56: Serial audio interface (SAI)**  
Added Table 449: TDM frame configuration examples.  
In Section 56.4.12: SPDIF output, replaced $F_{SAI\_CK\_x}$ by $F_{SAI\_x\_swer\_ck}$ in the formula enabling to compute the bit rate.  
Added note related to bitfield usage depending on Dx line availability in SAI PDM delay register (SAI_PDMDL). |

<td>13-Dec-2021</td>
<td>3 (continued)</td>
<td><strong>Section 63: Ethernet (ETH): media access control (MAC) with DMA controller</strong> (continued)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated DMA initialization sequence in <strong>Section 63.9.1: DMA initialization</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Section 63.9.3: MAC initialization</strong> and <strong>Section 63.9.5: Stopping and starting transmission</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Added <strong>Section 63.9.6: Programming guidelines for switching to new descriptor list in RxDMA</strong>, <strong>Section 63.9.7: Programming guidelines for switching the AHB clock frequency</strong> and <strong>Section 63.9.10: Programming guidelines for PTP offload feature</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Section 63.9.11: Programming guidelines for Energy Efficient Ethernet (EEE)</strong> and <strong>Section 63.9.13: Programming guidelines for TSO</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Table 580: TDES2 normal descriptor (read format)</strong>, <strong>Table 581: TDES3 normal descriptor (read format)</strong>, <strong>Table 585: TDES3 normal descriptor (write-back format)</strong> and <strong>Table 589: TDES3 context descriptor</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Figure 842: Receive normal descriptor (read format)</strong> as well as <strong>Table 590: RDES0 normal descriptor (read format)</strong> and <strong>Table 593: RDES3 normal descriptor (read format)</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Figure 843: Receive normal descriptor (write-back format)</strong> as well as <strong>Table 597: RDES3 normal descriptor (write-back format)</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated <strong>Table 601: RDES3 context descriptor</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Section 63.11.2: Ethernet DMA registers:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Several registers updated (register reset value changed, bitfields added or description updated, bit access modified).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed MMCIE/MMCRSIPIS and GPIIS/GPIIE from <strong>Figure 845: Generation of ETH_DMAISR flags</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Section 63.11.3: Ethernet MTL registers:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Several registers updated (bitfield description updated or bit access modified).</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Section 63.11.4: Ethernet MAC and MMC registers:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Several registers updated (register reset value changed, bitfields added or description updated, bit access modified).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added <strong>VLAN inclusion register (ETH_MACVIR)</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Moved Table Timestamp snapshot dependency on register bits from <strong>Timestamp control Register (ETH_MACTSCR)</strong> to <strong>Section: Clock types</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated <strong>System time seconds update register (ETH_MACSTSUR)</strong> and <strong>System time nanoseconds update register (ETH_MACSTNUR)</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Section 65: Debug infrastructure</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Removed 100 kΩ pull-up requirement in <strong>Section: Serial wire debug port</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Updated PRESCALER[12:0] bitfield description in <strong>SWO current output divisor register (SWO_CODR)</strong>.</td>
</tr>
