Refer to *Section 2.3 on page 131* for the register boundary addresses.
25 Octo-SPI interface (OCTOSPI)

25.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR Flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data and transfer parameters.
- Automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the Regular-command frame format with the command, address, alternate byte, dummy cycles and data phase
- the HyperBus™ frame format

25.2 OCTOSPI main features

- Functional modes: Indirect, Automatic status-polling, and Memory-mapped
- Read and write support in Memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad and octal communication
- Dual-quad configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA channel for Indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI interface with transaction acceptance limited to one: the interface accepts the next transfer on AXI bus only once the previous is completed on memory side.

25.4 OCTOSPI functional description

25.4.1 OCTOSPI block diagram

Figure 141. OCTOSPI block diagram in octal configuration

Figure 142. OCTOSPI block diagram in quad configuration
25.4.2 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:
- Regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in Regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]: data bus MSB used in dual-quad and octal configurations

25.4.3 OCTOSPI Regular-command protocol

When in Regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.
The NCS falls before the start of each command and rises again after each command finishes.

In Memory-mapped mode, both read and write operations are supported; as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

### Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:
- 1 bit at a time from the IO0/SO signal (single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In Memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

### Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of OCTOSPI_CCR.

In Indirect and Automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of OCTOSPI_AR. In Memory-mapped mode, the address is given directly via the AXI (from any master in the system).
The address phase can send:
- 1 bit at a time (over SOI in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] of OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR of OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In Memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

**Alternate-bytes phase**

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over SOI in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] of OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 4:3 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In Memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.
**Dummy-cycle phase**

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI or the octal-SPI mode, to receive data from the external device.

In Memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

**Data phase**

During the data phase, any number of bytes can be sent to or received from the external device.

In Indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in Indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In Automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR and the data received from the external device can be obtained by reading OCTOSPI_DR.

In Memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

The data phase can send/receive:
- 1 bit at a time (over SO/SI in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] of OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in Indirect-write mode.

In Memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

**DQS usage**

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.
The DQS management can be enabled by setting DQSE of OCTOSPI_CCR.

**Figure 145. DTR read in octal-SPI mode with DQS (Macronix mode) example**

25.4.4 OCTOSPI Regular-command protocol signal interface

**Single-SPI mode**

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

**Dual-SPI mode**

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.
In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

IO2 and IO3 are used only in quad-SPI mode. If none of the phases are configured to use the quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the OCTOSPI is active.

**Octal-SPI mode**

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

IO[4:7] are used only in Octal-SPI mode. If none of the phases are configured to use octal-SPI mode, then the pins corresponding to IO[4:7] can be used for other functions even while the OCTOSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.
**Double-transfer rate (DTR) mode**

Each of the instruction, address, alternate-byte and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In Memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

In DTR mode, when the OCTOSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid to hold issues on the memory side.

**Note:** *DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.*

**Dual-quad configuration**

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 100, two external Quad-SPI devices (device A and device B) are used in order to...
send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of OCTOSPI_DCR1, must reflect the total external device capacity, that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in Regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

25.4.5 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.
The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

**Figure 148. Example of HyperBus read operation**

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

**Table 210. Command/address phase description**

</tbody>
</table>

The address space is configured through the memory type MTYP[2:0] of OCTOSPI_DCR1.

The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.
Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- $t_{RWR}$: minimal read/write recovery time for the device (defined in TRWR[7:0] of OCTOSPI_HLCR)
- $t_{ACC}$: access time for the device (defined in TAC[7:0] of OCTOSPI_HLCR)

During the read operation, the RWDS is used by the device, in two ways (see Figure 148):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation the RWDS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

Figure 149. HyperBus write operation with initial latency
Read/write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional $t_{ACC}$ duration is added by the OCTOSPI to meet the device request.

**Figure 150. HyperBus read operation with additional latency**

**Figure 151. HyperBus write operation with additional latency**

Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to $2 \times t_{ACC}$ by setting LM of OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI and an additional latency is always added, leading to a fixed $2 \times t_{ACC}$ latency time.
Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

![Figure 152. HyperBus write operation with no latency](image)

Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the tACC time.

![Figure 153. HyperBus read operation page crossing with latency](image)

### 25.4.6 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

#### Wrap support

The OCTOSPI supports an hybrid wrap as defined by the HyperBus protocol. An hybrid wrap is also supported in the Regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.
The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and Regular-command protocols. To enable wrapped-read accesses, the dedicated registers OCTOSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated OCTOSPI_WPxxx registers apply for both HyperBus and Regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

**NCS boundary and refresh**

Two processes can be activated to regulate the OCTOSPI transactions:
- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured in CSBOUND[4:0] of OCTOSPI_DCR3 and it is equal to \(2^{\text{CSBOUND}}\).

As an example, if CSBOUND[4:0] = 0x4, the boundary is set to \(2^4 = 16\) bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled and a minimum value of 3 is recommended.

The NCS boundary feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

**Communication regulation**

The communication regulation feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of OCTOSPI_DCR3.

If the number of clock cycles reach the MAXTRAN + 1 value, and if the second OCTOSPI requests an access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

*Note:* The communication regulation feature cannot be used in write mode for the Flash memory devices that require extra command to re-enable the write operation after the NCS is active again.
If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

**Re-starting after an interrupted transfer**

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

### 25.4.7 OCTOSPI operating modes introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either Regular-command or HyperBus):

- Indirect mode (read or write)
- Automatic status-polling mode
- Memory-mapped mode

### 25.4.8 OCTOSPI Indirect mode

In Indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 0 in OCTOSPI_CR, the OCTOSPI is in Indirect-write mode: bytes are sent to the external device during the data phase. Data is provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in Indirect-read mode: bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

In Indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

**Note:** The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.

- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in OCTOSPI_SR and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.
Triggering the start of a transfer in Regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in Indirect mode when using Regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in Indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in Indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in Indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) in Indirect-read mode (when FMODE = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in Indirect-write mode (when FMODE = 00).
- when a write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for both Indirect read and write modes

Note: In case of HyperBus, a (dummy) write to OCTOSPI_IR is required to trigger the transfer, as for Regular-command protocol.

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in Indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

In Indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.
FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In Indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In Indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

25.4.9 OCTOSPI Automatic status-polling mode

In Automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The access to the device begins in the same manner as in Indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in Automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In Automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

25.4.10 OCTOSPI Memory-mapped mode

When configured in Memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.
If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were pre-fetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

### 25.4.11 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

### 25.4.12 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- Functional mode with FMODE[1:0]
- Automatic status-polling mode behavior if needed with PMM and APMS
- FIFO level with FTHRES
- DMA usage with DMAEN
- Timeout counter usage with TCEN
- Dual-quad configuration, if needed, with DMM (only for quad-SPI mode)

In case of an interrupt usage, the respective enable bit can also be set during this phase. If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.
25.4.13 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2. The user must program:

- Device size with DEVSIZE[4:0]
- Chip-select minimum high time with CSHT[5:0]
- Clock mode with FRCK and CKMODE
- Device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:

- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- HyperBus memory mode: the protocol follows the HyperBus specification, and an 8-data-bit DTR mode must be selected.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be non-cacheable, or the Indirect read/write modes must be used.

DEVSIZE[4:0] defines the size of external memory using the following formula:

\[
\text{Number of bytes in the device} = 2^{\text{DEVSIZE}+1}
\]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (\(t_{\text{ACC}}\) and \(t_{\text{RWR}}\)) and the Latency mode must be configured in OCTOSPI_HLCR.
25.4.14 OCTOSPI Regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected and data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in Indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The Automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled; The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.
When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

**Memory-mapped mode configuration**

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the Flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

When the OCTOSPI is used in Memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for read operation.
All the configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed.

**OCTOSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**OCTOSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

**Sending the instruction only once (SIOO)**

A Flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for Memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

SIOO mode is not supported when any of the communication regulation, NCS boundary or refresh features are used.

### 25.4.15 OCTOSPI HyperBus protocol configuration

**Indirect mode configuration**

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Make a write operation in OCTOSPI_IR and enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).
In Indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In Indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

**Automatic status-polling mode configuration**

The Automatic status-polling mode is enabled setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, it can be internally processed to:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set.

In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the targeted address in OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

**Memory-mapped mode configuration**

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The Memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

All the configuration operation must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.
25.4.16 OCTOSPI error management

A error can be generated in the following cases:

- in Indirect or Automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in Indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in Memory-mapped mode when an out-of-range access is done by an AXI master. This generates an AXI error as a response to the faulty AXI request.
- when the Memory-mapped mode is disabled. An access to the memory-mapped area generates an AXI error as a response to the faulty AXI request.

The OCTOSPI generates an AXI slave error in the following situations:

- Memory-mapped mode is disabled and an AXI read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- OCTOSPI is disabled while a read or write burst is ongoing.
- Write wrap burst is received.
- Write request is received while DQSE = 0 in OCTOSPI_WCCR, which means that the DQS output is disabled.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means the ARSIZE is different from 8 bytes (only for Memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 8 bytes (only for Memory-mapped mode).

25.4.17 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In Indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In Automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in Memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers.

Note: Some devices may misbehave if a write operation to a status register is aborted.
### 25.4.18 OCTOSPI reconfiguration or deactivation

Prior to any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a Memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a Memory-mapped read, the software must perform a synchronization barrier then an abort.

### 25.4.19 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 154. NCS when CKMODE = 0 (T = CLK period)**

![Figure 154](MSv44100V1)

When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 155. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

![Figure 155](MSv44101V1)

When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations
must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 156. NCS when CKMODE = 1 in DTR mode (T = CLK period)

![Diagram showing NCS and SCLK signals with T and T/2 labels.]

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 157. NCS when CKMODE = 1 with an abort (T = CLK period)

![Diagram showing NCS, SCLK, and Abort signals with T, T/2, and Clock stalled labels.]

25.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 211. Address alignment cases

<table>
<thead>
<tr>
<th>Memory type</th>
<th>Transaction type</th>
<th>Constraint on address(1)</th>
<th>Impact if constraint on address not respected</th>
<th>Constraint on number of bytes(1)</th>
<th>Impact if constraint on bytes not respected</th>
</tr>

</tbody>
</table>

Note: (1) Constraint on address and number of bytes are for memory type and transaction type. (2) IND read is for single, dual, quad Flash or SRAM (DMM = 0). (3) MM read is for single, dual, quad Flash or SRAM (DMM = 0).
25.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

</tbody>
</table>

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode
This field defines the OCTOSPI functional mode of operation.
00: Indirect-write mode
01: Indirect-read mode
10: Automatic status-polling mode
11: Memory-mapped mode
If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the Automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.
Bit 22  **APMS**: Automatic status-polling mode stop
This bit determines if the Automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
1: Automatic status-polling mode stops as soon as there is a match.

Bit 21  Reserved, must be kept at reset value.

Bit 20  **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19  **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18  **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17  **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16  **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **FTHRES[4:0]**: FIFO threshold level
This field defines, in Indirect mode, the threshold number of bytes in the FIFO that causes
the FIFO threshold flag FTF in OCTOSPI_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in Indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in Indirect-read mode.
...
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in Indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in Indirect-read mode.

*Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.*

Bit 7  **FSEL**: Flash select
This bit selects the Flash memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).
0: FLASH 1 selected (data exchanged over IO[3:0])
1: FLASH 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when octal-SPI mode is selected.
Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-quad configuration disabled
1: Dual-quad configuration enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the Memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: Timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in Memory-mapped mode.
1: Timeout counter is enabled, and thus the chip-select is released in the Memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Bit 2 **DMAEN**: DMA enable

In Indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for Indirect mode
1: DMA enabled for Indirect mode

*Note:* Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested
1: Abort requested

*Note:* This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the OCTOSPI.

0: OCTOSPI disabled
1: OCTOSPI enabled

*Note:* The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.

In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

### 25.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

**Address offset:** 0x0008

**Reset value:** 0x0000 0000

This register can be modified only when BUSY = 0.

</tbody>
</table>

**Note:**

- OCTOSPI device configuration register 1 (OCTOSPI_DCR1) is used to configure the Octo-SPI interface.
- The register can be modified only when BUSY = 0.
- Bits 31 to 20 are reserved and must be kept at reset value.
- Bits 19 to 8 are used for configuring the OCTOSPI device.
- Bits 7 to 0 are used for configuring the OCTOSPI mode of operation.

This register allows for fine-grained control over the OCTOSPI interface, enabling users to configure it according to their specific needs.
Bits 31:27  Reserved, must be kept at reset value.

Bits 26:24  **MTYP[2:0]: Memory type**

- **000**: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes.
- **001**: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes.
- **010**: Standard mode
- **011**: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad- and octal-SPI modes with dedicated address mapping.
- **100**: HyperBus memory mode, the protocol follows the HyperBus specification. 8-data-bit DTR mode must be selected.
- **101**: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or Indirect read/write modes must be used.
- **Others**: Reserved

Bits 23:21  Reserved, must be kept at reset value.

Bits 20:16  **DEVSIZE[4:0]: Device size**

This field defines the size of the external device using the following formula:

\[
\text{Number of bytes in device} = 2^{(\text{DEVSIZE}+1)}.
\]

DEVSIZE+1 is effectively the number of address bits required to address the external device.

The device capacity can be up to 4 Gbytes (addressed using 32-bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

In Regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the capacity of one of the two external devices.

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:8  **CSHT[5:0]: Chip-select high time**

- **CSHT + 1** defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.
  - **0x0**: NCS stays high for at least 1 cycle between external device commands.
  - **0x1**: NCS stays high for at least 2 cycles between external device commands.
  - ... 
  - **0x3F**: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  **DLYBYP: Delay block bypass**

- **0**: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).
- **1**: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.
Bit 2  Reserved, must be kept at reset value.

Bit 1  **FRCK**: Free running clock

- This bit configures the free running clock.
- 0: CLK is not free running.
- 1: CLK is free running (always provided).

*Note*: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set.

Bit 0  **CKMODE**: Clock mode 0emode 3

- This bit indicates the level taken by the CLK between commands (when NCS = 1).
- 0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.
- 1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.

### 25.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</tr>
</tbody>
</table>

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  **WRAPSIZE[2:0]**: Wrap size

- This field indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this field indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.
- 000: Wrapped reads are not supported by the memory.
- 001: Reserved
- 010: External memory supports wrap size of 16 bytes.
- 011: External memory supports wrap size of 32 bytes.
- 100: External memory supports wrap size of 64 bytes.
- 101: External memory supports wrap size of 128 bytes.
- 110-111: Reserved

Bits 15:8  Reserved, must be kept at reset value.
## OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

### Address offset: 0x0010

### Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>

<td>MAXTRAN[7:0]</td>
<td>15-8</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Bits 7:0  **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: F\(_{\text{CLK}}\) = F\(_{\text{KERNEL}}\), kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.

1: F\(_{\text{CLK}}\) = F\(_{\text{KERNEL}}\)/2

2: F\(_{\text{CLK}}\) = F\(_{\text{KERNEL}}\)/3

...255: F\(_{\text{CLK}}\) = F\(_{\text{KERNEL}}\)/256

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.
25.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0 REFRESH[31:0]: Refresh rate
This field enables the refresh rate feature.
The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads.

Note: These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled
others: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER field is changed, the REFRESH field must be updated accordingly.

25.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020
Reset value: 0x0000 0000

<table>
<thead>

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 FLEVEL[5:0]: FIFO level
This field gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.
In Automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.
25.7.7 **OCTOSPI flag clear register (OCTOSPI_FCR)**

Address offset: 0x0024

Reset value: 0x0000 0000

<table>

<th>0</th>
</tr>
</thead>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the OCTOSPI_SR register.

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the OCTOSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the OCTOSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the OCTOSPI_SR register.
25.7.8 **OCTOSPI data length register (OCTOSPI_DLR)**

Address offset: 0x0040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:0 **DL[31:0]:** Data length

- Number of data to be retrieved (value+1) in Indirect and Automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for Automatic status-polling mode.
- All 1’s in Indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.
  - 0x0000_0000: 1 byte is to be transferred.
  - 0x0000_0001: 2 bytes are to be transferred.
  - 0x0000_0002: 3 bytes are to be transferred.
  - 0x0000_0003: 4 bytes are to be transferred.
  - ... 0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.
  - 0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.
  - 0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This field has no effect in Memory-mapped mode.

25.7.9 **OCTOSPI address register (OCTOSPI_AR)**

ADDRESS[15:0]
Bits 31:0  **ADDRESS[31:0]: Address**
Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 1.
Writes to this field are ignored when BUSY = 1 or when FMODE = 11 (Memory-mapped mode).

### 25.7.10 OCTOSPI Data Register (OCTOSPI_DR)

<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

#### Bits 31:0  **DATA[31:0]: Data**
Data to be sent/received to/from the external SPI device
In Indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In Indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In Automatic status-polling mode, this register contains the last data read from the external device (without masking).
Word, half-word, and byte accesses to this register are supported. In Indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes. Similarly, in Indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in Indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

### 25.7.11 OCTOSPI Polling Status Mask Register (OCTOSPI_PSMKR)

Address offset: 0x0080
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 SIOO: Send instruction only once mode
This bit has no effect when IMODE = 00 (see Sending the instruction only once (SIOO)).
0: Send instruction on every transaction
1: Send instruction only for the first command

Bit 30 Reserved, must be kept at reset value.

Bit 29 DQSE: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 DDTR: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 DMODE[2:0]: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 ABSIZE[1:0]: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes
Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase
This field can be written only when BUSY = 0.

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.
Bits 5:4 **ISIZE[1:0]:** Instruction size

This bit defines instruction size.

- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR:** Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

- 0: DTR mode disabled for instruction phase
- 1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]:** Instruction mode

This field defines the instruction phase mode of operation.

- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- 101-111: Reserved

### 25.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

**Address offset:** 0x0108

**Reset value:** 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT:** Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.

This bit allows the data to be sampled later in order to consider the external signal delays.

- 0: No shift
- 1: 1/2 cycle shift

The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.
Bit 28  DHQC: Delay hold quarter cycle
0: No delay hold
1: 1/4 cycle hold

Bits 27:5  Reserved, must be kept at reset value.

Bits 4:0  DCYC[4:0]: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
It is recommended to have at least six dummy cycles when using memories with DQS activated.

25.7.16  OCTOSPI instruction register (OCTOSPI_IR)
Address offset: 0x0110
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:0  ALTERNATE[31:0]: Alternate bytes
Optional data to be sent to the external SPI device right after the address.
25.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR)

Address offset: 0x00130
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | TIMEOUT[15:0]: Timeout period |

After each access in Memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.

This field indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

25.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

| Bits 31:30 | Reserved, must be kept at reset value. |
| Bit 29 | DQSE: DQS enable |
| Bit 28 | Reserved, must be kept at reset value. |
| Bit 27 | DDTR: Data double transfer rate |

This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase
Bits 26:24 **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.
Bits 5:4 **ISIZE[1:0]: Instruction size**
This field defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for instruction phase
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]: Instruction mode**
This field defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
101-111: Reserved

**25.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)**
Address offset: 0x0148
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bit 28  **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: Quarter cycle delay inserted

Bits 27:5  Reserved, must be kept at reset value.

Bits 4:0  **DCYC[4:0]**: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

### 25.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **DQSE**: DQS enable
        This bit enables the data strobe management.
        0: DQS disabled
        1: DQS enabled

Bit 28  Reserved, must be kept at reset value.

Bit 27  **DDTR**: data double transfer rate
        This bit sets the DTR mode for the data phase.
        0: DTR mode disabled for data phase
        1: DTR mode enabled for data phase

Bits 26:24  **DMODE[2:0]**: Data mode
            This field defines the data phase mode of operation.
            000: No data
            001: Data on a single line
            010: Data on two lines
            011: Data on four lines
            100: Data on eight lines
            101-111: Reserved

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:20  **ABSIZE[1:0]**: Alternate bytes size
            This field defines alternate bytes size:
            00: 8-bit alternate bytes
            01: 16-bit alternate bytes
            10: 24-bit alternate bytes
            11: 32-bit alternate bytes

Bit 19  **ABDTR**: Alternate bytes double transfer rate
        This bit sets the DTR mode for the alternate-bytes phase.
        0: DTR mode disabled for alternate-bytes phase
        1: DTR mode enabled for alternate-bytes phase
Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
- 000: No alternate bytes
- 001: Alternate bytes on a single line
- 010: Alternate bytes on two lines
- 011: Alternate bytes on four lines
- 100: Alternate bytes on eight lines
- 101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
- 0: DTR mode disabled for address phase
- 1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
- 000: No address
- 001: Address on a single line
- 010: Address on two lines
- 011: Address on four lines
- 100: Address on eight lines
- 101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bit defines instruction size:
- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
- 0: DTR mode disabled for instruction phase
- 1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This field defines the instruction phase mode of operation.
- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- 101-111: Reserved
25.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 DCYC[4:0]: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

25.7.25 OCTOSPI write instruction register (OCTOSPI_WIR)

Address offset: 0x0190
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **WZL:** Write zero latency
This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0  **LM:** Latency mode
This bit selects the Latency mode.
0: Variable initial latency
1: Fixed latency

26 OCTOSPI I/O manager (OCTOSPIM)

26.1 Introduction
The OCTOSPI I/O manager is a low-level interface that enables an efficient OCTOSPI pin assignment with a full I/O matrix (before alternate function map) and multiplex of single/dual/quad/octal SPI interfaces over the same bus.

26.2 OCTOSPIM main features
- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

26.3 OCTOSPIM implementation
The table below describes the OCTOSPIM implementation.

<table>
<thead>

26.4 OCTOSPIM functional description

26.4.1 OCTOSPIM block diagram
The block diagram of the OCTOSPI I/O manager is shown in Figure 158.
1. The number of ports \( n \) is 2.
2. Arbitration is possible for both I/O matrix input ports.

### 26.4.2 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable pre-mapping of functions:

- Any OCTOSPIM\_Pn\_CLK / OCTOSPIM\_Pn\_NCLK pair can be mapped independently to OCTOSPI1\_CLK/OCTOSPI1\_NCLK or OCTOSPI2\_CLK/OCTOSPI2\_NCLK
- Any OCTOSPIM\_Pn\_DQS can be mapped independently to OCTOSPI1\_DQS or OCTOSPI2\_DQS
- Any OCTOSPIM\_Pn\_NCS can be mapped independently to OCTOSPI1\_NCS or OCTOSPI2\_NCS
- Any OCTOSPIM\_Pn\_IO[3:0] and OCTOSPIM\_Pn\_IO[7:4] can be mapped independently to OCTOSPI1\_IO[3:0], OCTOSPI1\_IO[7:4], OCTOSPI2\_IO[3:0] or OCTOSPI2\_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM\_PnCR).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when all OCTOSPIs are disabled.
26.4.3 OCTOSPI multiplexed mode

When this mode is set the OCTOSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to accurately manage the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPI(s). When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when another OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPIn_NCS are not part of the multiplexing. Only OCTOSPIn_IOs, OCTOSPIn_DQS and OCTOSPIn_CLK / OCTOSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may be increased.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.

This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting one).

The duration is defined by the REQ2ACK_TIME field of the configuration register OCTOSPIM_CR.

Pin mapping in Multiplexed mode

In Multiplexed mode, the mapping of the bus is done as described below:

- OCTOSP1_NCS and OCTOSP2_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSP1.
26.5 OCTOSPIM registers

26.5.1 OCTOSPIM control register (OCTOSPIM_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:16 | **REQ2ACK_TIME[7:0]**: REQ to ACK time |
|            | In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions. |
|            | The value is the number of OCTOSPI clock cycles - 1 |

| Bits 15:1  | Reserved, must be kept at reset value. |
| Bit 0     | **MUXEN**: Multiplexed mode enable |
|           | This bit enables the multiplexing of the two OCTOSPIs. |
|           | 0: No multiplexing, hence no arbitration |
|           | 1: OCTOSPI1 and OCTOSPI2 are multiplexed over the same bus. |

26.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR)

Address offset: 0x0000 + 0x04*n (n=1 to 2)
Reset value: 0x0301 0111, 0x0705 0333

| Bits 31:27 | Reserved, must be kept at reset value. |
| Bits 26:25 | **IOHSRC[1:0]**: IO[7:4] source for Port n |
|            | This bits select the source of Port n IO[7:4]. |
|            | 00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode |
|            | 10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode |
|            | 11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode |
Bit 24  **IOHEN**: IO[7:4] enable for Port n
This bit enables the Port n IO[7:4].
0: IO[7:4] for Port n disabled
1: IO[7:4] for Port n enabled

Bits 23:19  Reserved, must be kept at reset value.

Bits 18:17  **IOLSRC[1:0]**: IO[3:0] source for Port n
This bits select the source of Port n IO[3:0].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16  **IOLEN**: IO[3:0] enable for Port n
This bit enables the Port n IO[3:0].
0: IO[3:0] for Port n disabled
1: IO[3:0] for Port n enabled

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **NCSSRC**: NCS source for Port n
This bit selects the source of Port n NCS.
0: OCTOSPI1_NCS
1: OCTOSPI2_NCS

Bit 8  **NCSEN**: NCS enable for Port n
This bit enables the Port n NCS.
0: NCS for Port n is disabled
1: NCS for Port n is enabled

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **DQSSRC**: DQS source for Port n
This bit selects the source of Port n DQS.
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4  **DQSEN**: DQS enable for Port n
This bit enables the Port n DQS.
0: DQS for Port n is disabled
1: DQS for Port n is enabled

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **CLKSRC**: CLK/NCLK source for Port n
This bit selects the source of Port n CLK/NCLK.
0: OCTOSPI1_CLK/NCLK in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode
1: OCTOSPI2_CLK/NCLK in non multiplexed mode / unused port in multiplexed mode

Bit 0  **CLKEN**: CLK/NCLK enable for Port n
This bit enables the Port n CLK/NCLK.
0: CLK/NCLK for Port n is disabled
1: CLK/NCLK for Port n is enabled
26.5.3 OCTOSPIM register map

The following table summarizes the OCTOSPI I/O manager registers.

**Table 215. OCTOSPIM register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x0000 | OCTOSPIM _CR  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | OCTOSPIM _CR  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | OCTOSPIM _P1CR|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | OCTOSPIM _P2CR|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        |               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to *Section 2.3 on page 131* for the register boundary addresses.
27 Delay block (DLYB)

27.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

27.2 DLYB main features

The delay block has the following features:
- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

27.3 DLYB functional description

27.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):
- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 159. DLYB block diagram
27.3.2 **DLYB pins and internal signals**

</table>

27.3.3 **General description**

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFRG).

*Note:* *UNIT*[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFRG register.

*Note:* *SEL* can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFRG.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

**Table 218. Delay block control**

<table>
<thead>
<tr>
<th>DEN</th>

<td>Enabled (= Input clock)</td>
</tr>
</tbody>
</table>
27.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].
      If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

27.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

---

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>1</td>
<td>Unit delay</td>
<td>Output clock phase</td>
<td>Length</td>
<td>Length flag</td>
<td>Disabled</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Unit delay(1)</td>
<td>Output clock phase(2)</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

---

Table 218. Delay block control
1. Disable the output clock and enable the access to the phase selection \( SEL[3:0] \) bits by setting \( SEN \) bit to 1.
2. Program \( SEL[3:0] \) with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing \( SEN \) to 0.

QUAD/OCTOSPI use case:
The delay block is used in conjunction with QUADSPI or OCTOSPI interfaces to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain types of devices. Note that if DQS is used, the calibration procedure shall be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user shall typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value shall be close to \( \frac{N}{4} \), once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small "Unit" gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

SDMMC use case:
The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

### 27.4 DLYB registers
All registers can be accessed in word, half-word and byte access.

#### 27.4.1 DLYB control register (DLYB_CR)

Refer to Section 2.3 on page 131 for the register boundary addresses.
28 Analog-to-digital converters (ADC1/ADC2)

28.1 Introduction

This section describes the ADC implementation:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 16-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
28.2 **ADC main features**

- **High-performance features**
  - Up to 2x ADCs which can operate in dual mode
  - 16, 14, 12, 10 or 8-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Can manage Single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by GP-DMA for regular channel conversions with FIFO
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels

- **Oversampler**
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024x
  - Programmable data right and left shift

- **Low-power features**
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- **Each ADC features an external analog input channel**
  - Up to 6 fast channels from dedicated GPIO pads
  - Up to 14 slow channels from dedicated GPIO pads

- **In addition, there are 4 internal dedicated channels**
  - Internal reference voltage ($V_{REFINT}$)
  - $V_{BAT}$ monitoring channel ($V_{BAT}/4$)
  - Connection to DAC internal channels

- **Start-of-conversion can be initiated:**
  - by software for both regular and injected conversions
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- **Conversion modes**
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
Continuous mode converts selected inputs continuously
Discontinuous mode

- Dual ADC mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: \( V_{\text{REF}} - V_{\text{IN}} \leq V_{\text{REF}} + \)

*Figure 160* shows the block diagram of one ADC.

28.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see Figure 161: ADC Clock scheme):

1. The ADC clock can be a specific clock source, named adc_ker_ck_input which is independent and asynchronous with the AHB clock.
   It can be configured in the RCC (refer to RCC Section for more information on how to generate the ADC clock (adc_ker_ck_input) dedicated clock).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the system clock or system clock divided by two (adc_sclk). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be different from “00”. adc_sclk is equal to sys_ck when HPRE is set to 0, otherwise it corresponds to sys_ck/2.

In both case, the clock divider factor of 2 is applied to the clock provided to the ADC analog block (fadc_ker_ck).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of using the system without additional PLL. In addition, when adc_sclk is twice faster than the adc_hclk clock, the latency between the trigger and the start of conversion is fixed. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock configured through CKMODE[1:0] bits must be compliant with the analog ADC operating frequency specified in the product datasheet.

---

Table 223. ADC interconnection

</tbody>
</table>

1. ADC2 VINP[17] alternate connection can be switched though SYSCFG_ADC2ALT register.
2. ADC2 VINP[16] alternate connection can be switched though SYSCFG_ADC2ALT register.
Note: \( \text{adc\_sclk} \) is the system clock or system clock divided by two: when the ABH prescaler is set to 1 (\( \text{HPRE}[3:0] = 0XXX \) in RCC\_CFGR register), \( \text{adc\_sclk} \) is equal to sys\_clk, otherwise \( \text{adc\_sclk} \) corresponds to sys\_clk/2.

**Figure 161. ADC Clock scheme**

- **Clock ratio constraint between ADC clock and AHB clock**

  There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:
  - \( F_{\text{adc\_hclk}} \geq F_{\text{adc\_ker\_ck}} / 4 \) if the resolution of all channels are 16-bit, 14-bit, 12-bit or 10-bit
  - \( F_{\text{adc\_hclk}} \geq F_{\text{adc\_ker\_ck}} / 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)

- **Constraints between ADC clocks**

  When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio, for all ADC interfaces.

- **BOOST control**

  The ADC Boost mode can be controlled through the BOOST bitfield in the ADC\_CR register.

  This bitfield must be set according to the ADC clock setting. Refer to the ADC\_CR register description.
28.4.4 **ADC1/2 connectivity**

ADC1 and ADC2 are tightly coupled and share some external channels as described in the following figures.

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
Figure 163. ADC2 connectivity
28.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

28.4.6 ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit deep-power-down mode by clearing bit DEEPPWD=0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN=1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator (T_{ADCREG_STUP}) before launching a calibration or enabling the ADC. This delay must be implemented by software.

The LDO status can be verified by checking the LDORDY bit in ADC_ISR register (refer to Section 28.3: ADC implementation for the availability of the LDO regulator status).

For the startup time of the ADC voltage regulator, refer to device datasheet for T_{ADCREG_STUP} parameter.

After ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC deep-power-down mode by setting bit DEEPPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

Note: When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or apply again the calibration factor which was previously saved (refer to Section 28.4.8: Calibration (ADCAL, ADCALDIFF, ADCALLIN, ADC_CALFACT)).
28.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by writing into bits DIFSEL[19:0] in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage \( V_{\text{INP}[i]} \) (positive input) and \( V_{\text{REF}} \) (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage \( V_{\text{INP}[i]} \) (positive input) and \( V_{\text{INN}[i]} \) (negative input).

The output data for the differential mode is an unsigned data. When \( V_{\text{INP}[i]} \) equals \( V_{\text{REF}} \), \( V_{\text{INN}[i]} \) equals \( V_{\text{REF}} \) and the output data is 0x0000 (16-bit resolution mode). When \( V_{\text{INP}[i]} \) equals \( V_{\text{REF}} \), \( V_{\text{INN}[i]} \) equals \( V_{\text{REF}} \) and the output data is 0xFFFF.

When ADC is configured as differential mode, both input should be biased at \( \frac{V_{\text{REF}}}{2} \) voltage.

The input signal are supposed to be differential (common mode voltage should be fixed).

For a complete description of how the input channels are connected for each ADC, refer to Section 28.4.4: ADC1/2 connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage is connected to \( V_{\text{INN}[i]} \). As a consequence, channel “i+n”, which is connected to \( V_{\text{INN}[i]} \), should not be converted at same time by different ADCs. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable.

28.4.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 11-bits of offset or 160-bits of linearity and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

The calibration is preliminary to any ADC operation. It removes the systematic errors which may vary from chip to chip and allows to compensate offset and linearity deviation.

The calibration factor for the offset to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF=0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF=1 before launching a calibration which will be applied for differential input conversions.
The linearity correction must be done once only, regardless of single / differential configuration.

- Write ADCALLIN=1 before launching a calibration which will run the linearity calibration same time as the offset calibration.
- Write ADCALLIN=0 before launching a calibration which will not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting bit ADCAL=1. It can be initiated only when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[10:0] or CALFACT_D[10:0] of ADC_CALFACT register (depending on single-ended or differential input calibration). The 160-bit linearity calibration factor can be accessed using the ADC_CALFACT2 register with ADEN set to 1.

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, it is recommended that a new offset calibration cycle is run before enabling again the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT and ADC_CALFACT2 register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor will automatically be injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

Refer to the datasheets for the clock cycle requirement for both linear and offset calibration.

Software procedure to calibrate the ADC

1. Ensure DEEPPWD=0, ADVREGEN=1 and verify that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 28.3: ADC implementation for the availability of the LDO regulator status).
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (Single-ended input) or ADCALDIF=1 (Differential input). Select if Linearity calibration enable or not by ADCALLIN=1(enabled) or ADCALLIN=0(disabled).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The offset calibration factor can be read from ADC_CALFACT register.
7. The linearity calibration factor can be read from ADC_CALFACT2 register, following the procedure described in Section : Linearity calibration reading procedure (ADEN must be set to 1 prior to accessing ADC_CALFACT2 register).
Figure 164. ADC calibration

Software procedure to re-inject a calibration factor into the ADC

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new offset calibration factors.
3. Write LINCALFACT bits with the new linearity calibration factors, following the procedure described in Section: Linearity calibration writing procedure.
4. When a conversion is launched, the calibration factor will be injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 165. Updating the ADC offset calibration factor
Calibrating single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0) and Linearity calibration enable (with ADCALLIN=1). This updates the registers CALFACT_S[10:0] and LINCALFACT[159:0].
3. Calibrate the ADC in Differential input modes (with ADCALDIF=1) and Linearity calibration disable (with ADCALLIN=0). This updates the register CALFACT_D[10:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration will automatically be injected into the analog ADC.

Linearity calibration reading procedure

Once the calibration is done (ADCAL bit cleared by hardware) with ADCALLIN=1, the 160-bit linearity correction factor can be read using the ADC_CALFACT2 30-bit registers (6 read accesses are necessary).

The six LINCALRDYW1..6 control/status bits in ADC_CR are set when the calibration is complete. When ADEN is set to 1, clearing one of these bits launches the transfer of part of the linearity factor into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit will be reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared). The complete procedure is as following:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 28.3: ADC implementation for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
4. Poll LINCALRDYW6 bit until returned value is zero, indicating linearity correction bits[159:150] are available in ADC_CALFACT2[29:0].
5. Read ADC_CALFACT2[29:0].
7. Poll LINCALRDYW5 bit until returned value is zero, indicating linearity correction bits[149:120] are available in ADC_CALFACT2[29:0].
8. Read ADC_CALFACT2[29:0].
10. Poll LINCALRDYW4 bit until returned value is zero, indicating linearity correction bits[119:90] are available in ADC_CALFACT2[29:0].
11. Read ADC_CALFACT2[29:0].
13. Poll LINCALRDYW3 bit until returned value is zero, indicating linearity correction bits[89:60] are available in ADC_CALFACT2[29:0].
14. Read ADC_CALFACT2[29:0].
15. Clear LINCALRDYW2 bit.
16. Poll LINCALRDYW2 bit until returned value is zero, indicating linearity correction bits[59:30] are available in ADC_CALFACT2[29:0].
17. Read ADC_CALFACT2[29:0].
18. Clear LINCALRDYW1 bit.
19. Poll LINCALRDYW1 bit until returned value is zero, indicating linearity correction bits[29:0] are available in ADC_CALFACT2[29:0].
20. Read ADC_CALFACT2[29:0].

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software can access the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
Linearity calibration writing procedure

The six LINCALRDYW1..6 control/status bits in ADC_CR are reset when the calibration has not yet been done or a new linearity calibration factor have been rewritten. It is possible to force directly a linearity calibration factor or re-inject it using the following procedure:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to Section 28.3: ADC implementation for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
3. Write ADC_CALFACT2[9:0] with previously saved linearity correction factor bits[159:150].
4. Set LINCALRDYW6 bit.
5. Poll LINCALRDYW6 bit until returned value is one, indicating linearity correction bits[159:150] have been effectively written.
6. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[149:120].
7. Set LINCALRDYW5 bit.
8. Poll LINCALRDYW5 bit until returned value is one, indicating linearity correction bits[149:120] have been effectively written.
9. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[119:90].
10. Set LINCALRDYW4 bit.
11. Poll LINCALRDYW4 bit until returned value is one, indicating linearity correction bits[119:90] have been effectively written.
12. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[89:60].
13. Set LINCALRDYW3 bit.
14. Poll LINCALRDYW3 bit until returned value is one, indicating linearity correction bits[89:60] have been effectively written.
15. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[59:30].
17. Poll LINCALRDYW2 bit until returned value is one, indicating linearity correction bits[59:30] have been effectively written.
18. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[29:0].
19. Set LINCALRDYW1 bit.
20. Poll LINCALRDYW1 bit until returned value is one, indicating linearity correction bits[29:0] have been effectively written.

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software is allowed to update the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
28.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 28.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of t_{STAB} before it starts converting accurately, as shown in Figure 167. Two control bits enable or disable the ADC:

- ADEN=1 enables the ADC. The flag ADRDY will be set once the ADC is ready for operation.
- ADDIS=1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to Section 28.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS will automatically be reset once ADEN=0).

Figure 167. Enabling / Disabling the ADC
28.4.10 Constraints when writing the ADC control bits

The software can write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the control bits DIFSEL in the ADC_DIFSEL register, ADCx_CCR register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy and ADC_IER registers:
- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and eventually converting and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1).

The software is allowed to write the ADC_JSQR register only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).

28.4.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:
- 6 fast analog inputs coming from Analog PADs and GPIO pads (ADCx_INP/INN[0..5])
- Up to 14 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6..19]).
- The ADCs are connected to 4 internal analog inputs:
  - the internal reference voltage (VREFINT)
  - the VBAT monitoring channel (VBAT/4)
  - DAC internal channels

Refer to Table ADC interconnection in Section 28.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order:
ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to Section 28.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 only when the context queue is enabled (JQDIS=0 in ADC_CFRG register).

VREFINT and VBAT internal channels

The internal reference voltage (VREFINT), and the VBAT channel are connected to ADC internal channels. Refer to Table ADC interconnection in Section 28.4.2: ADC pins and internal signals for details.

*Note:* To convert one of the internal analog channels, enable the corresponding analog sources by programming VREFEN and VBATEN bits in the ADC3_CCR registers, and select the multiplexer by SYSCFG_ADC2ALT register.

### 28.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx, the corresponding ADC_PCSEL bit must be previously configured.

This ADC_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input MUX selects the ADC input according to the SQRx and JSQRx with very high speed, the analog switch integrated in the IO cannot react as fast as ADC mux does. To avoid the delay on analog switch control on IO, it is necessary to pre select the input channels which will be selected in the SQRx, JSQRx.

The selection is based on the VINP[i] of each ADC input. If ADC1 converts the ADC12_INP2 (VINP[2]) as differential mode, ADC12_INP6 (VINP[6]) also needs to be selected in ADC_PCSEL.

Some I/Os are connected to several VINP[i] of the ADCx. The control inputs of the analog switch are ORed with the corresponding ADC_PCSEL register bits.
28.4.13 Channel-wise programmable sampling time (SMPr1, SMPr2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPr1 and ADC_SMPr2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 8.5 ADC clock cycles
- SMP = 011: 16.5 ADC clock cycles
- SMP = 100: 32.5 ADC clock cycles
- SMP = 101: 64.5 ADC clock cycles
- SMP = 110: 387.5 ADC clock cycles
- SMP = 111: 810.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{CONV} = \text{Sampling time} + 7.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{adc, ker, ck}} = 24 \text{ MHz} \) and a sampling time of 1.5 ADC clock cycles (14-bit mode):

\[ T_{CONV} = (1.5 + 7.5) \text{ ADC clock cycles} = 9 \text{ ADC clock cycles} = 0.375 \mu\text{s} \text{ (14 bit mode for fast channels)} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time for fast and slow channels

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

I/O analog switches voltage booster

The I/O analog switches resistance increases when the \( V_{\text{DDA}} \) voltage is too low. This requires to have the sampling time adapted accordingly (refer to the datasheet for electrical characteristics). This resistance can be minimized at low \( V_{\text{DDA}} \) by enabling an internal voltage booster with BOOSTE bit in the SYSCFG_PMCR register.

28.4.14 Single conversion mode (CONT=0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)

ADSTART bit or JADSTART bit must be set before triggering an external event.
Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:
- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:
- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:
- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

28.4.15 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:
- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).
28.4.16 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN /= 0x0

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN /= 0x0

*Note:* In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software trigger (CONT=0, EXTEN=0x0)
  - at any end of conversion sequence (EOS =1)
- In discontinuous mode with software trigger (CONT=0, DISCEN=1, EXTEN=0x0)
  - at end of conversion (EOC=1)
- In all other cases (CONT=x, EXTEN=x)
  - after execution of the ADSTP procedure asserted by the software.

*Note:* In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTEN /=0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- in single mode with software injected trigger (JEXTEN=0x0)
  - at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN=1
- in all cases (JEXTEN=x)
  - after execution of the JADSTP procedure asserted by the software.

*Note:* When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.
28.4.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [1.5 \, \text{min} + 7.5 \, \text{14bit}] \times T_{\text{adc}, \text{ker}, \text{ck}} \\
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 62.5 \, \text{ns} \, \text{min} + 312.5 \, \text{ns} \, \text{14bit} = 375.0 \, \text{ns} \, (\text{for} \, F_{\text{adc}, \text{ker}, \text{ck}} = 24 \, \text{MHz})
\]

Figure 168. Analog to digital conversion time

1. \(T_{\text{SMPL}}\) depends on \(\text{SMP}[2:0]\)
2. \(T_{\text{SAR}}\) depends on \(\text{RES}[2:0]\)

28.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions will reset the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.
Note: In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

28.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 224 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

<table>
<thead>

</table>
| 00          | – If JQDIS=1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled  
              – If JQDIS=0 (Queue enabled), Hardware and software trigger detection disabled |
| 01          | Hardware Trigger with detection on the rising edge |
| 10          | Hardware Trigger with detection on the falling edge |
| 11          | Hardware Trigger with detection on both the rising and falling edges |

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 28.4.22: Queue of context for injected conversions.

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which out of 23 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 28.4.22: Queue of context for injected conversions on page 1005.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 171.

**Figure 171. Triggers are shared between ADC master and ADC slave**

![Diagram showing triggers shared between ADC master and ADC slave](MSiv41035V2)

give all the possible external triggers of the three ADCs for regular and injected conversion.

28.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is

</tbody>
</table>
reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence.

Figure 172 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 20 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 21 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence will be stopped upon DMA Transfer Complete event.
28.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (sub-group) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQR registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- **DISCEN=1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11**
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...

- **DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11**
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - all the next trigger events will relaunch the complete sequence.
Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

28.4.22 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL[4:0] in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The ADC_JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFG:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence will be served according to the last active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

**Note:** When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.

**Note:** When queue of context enabled (bit JQDIS=0), only hardware trigger can be used.
Behavior when changing the trigger or sequence context

The Figure 173 and Figure 174 show the behavior of the context Queue when changing the sequence or the triggers.

Figure 173. Example of JSQR queue of context (sequence change)

1. Parameters:
P1: sequence of 3 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 4 conversions, hardware trigger 1

Figure 174. Example of JSQR queue of context (trigger change)

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 175 and Figure 176 show the behavior of the context Queue if an overflow occurs before or during a conversion.

**Figure 175. Example of JSQR queue of context with overflow before conversion**

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 177* and *Figure 178* show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

**Figure 177. Example of JSQR queue of context with empty queue (case JQM=0)**

1. Parameters:  
   - P1: sequence of 1 conversion, hardware trigger 1  
   - P2: sequence of 1 conversion, hardware trigger 1  
   - P3: sequence of 1 conversion, hardware trigger 1  

*Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.*
Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 179. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 180. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 181. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 182. Flushing JSQR queue of context by setting JADSTP=1 (JQM=1)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 183. Flushing JSQR queue of context by setting ADDIS=1 (JQM=0)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 184. Flushing JSQR queue of context by setting ADDIS=1 (JQM=1)

<td>REQ-OFF</td>
</tr>
</tbody>
</table>

1. **Parameters:**
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Queue of context: Starting the ADC with an empty queue**

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

**Disabling the queue**

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFGR register.

**Queue of context: Programming of the register ADC_JSQR**

When the injected conversion queue of context is enabled (JQDIS=0), the ADC_JSQR must be programmed at one register write access. As JL[1:0] register define the number of the injected sequence, corresponding JSQ1 to JSQ4 must be written at same time. If ADC_JSQR is reprogrammed before the injected conversion start, reprogrammed data is put on the queue. When queue of context is empty, ADC_JSQR read back as 0x0000. Register access should not use the ‘read modify write’ sequence.

When ADC_JSQR is programmed when already 2 contexts are queued, it will raise JQOVF flag and generate the interrupt.
28.4.23 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 16, 14, 12, 10, 8 bits by programming the control bits RES[1:0]. Figure 189, Figure 190, Figure 191 and Figure 192 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 228.

Figure 189, Figure 190, Figure 191 and Figure 192

</tbody>
</table>

28.4.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JE OC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JE OCIE is set. JE OC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

28.4.25 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.
28.4.26 Timing diagrams example (single/continuous modes, hardware/software triggers)

**Figure 185. Single conversions of a sequence, software trigger**

2. Channels selected = 1, 2, 3, 4; AUTDLY=0.

28.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFRG2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 189, Figure 190, Figure 191 and Figure 192.

Note: The data can be re-aligned in normal and in oversampling mode.
Offset

An offset y (y=1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in OFFSETy[25:0] bitfield into ADC_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[25:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

The offset value should be lower than the max conversion value (ex. 16bit mode, offset value max is 0xFFFF).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 229 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

Signed 32-bit format

Signed 16-bit format

Signed 8-bit format

SSATE = 1

OR

RSHIFT1..4 = 1
16-bit and 8-bit signed format management: \texttt{RSHIFTx,SSATE}

The offset correction sign-extends the data format, resulting in an unsigned 16-bit conversion being extended to 17-bit signed format, for instance.

Three options are offered for formatting 8-bit and 16-bit conversion results.
For each offset correction channel 1 to 4, a RSHIFT1..4 bit in the ADC_CFGR2 register allows to have the result right-shifted 1-bit and have it fitting a standard 8 or 16-bit format.

Another option is to have the result saturated to the 16-bit and 8-bit signed formats, for the following cases only: RES[2:0] = 000 (16-bit format) and RES[2:0] = 0 (8-bit format).

This mode is enabled with the SSATE bit in the ADC_OFRy register.

The table below summarizes the 3 available use case for 16-bit format.

When oversampling mode is active, the SSATE and RSHIFT1..4 bits are not supported.
ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies of a buffer overrun event when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue to convert unless the software decides to stop and reset the sequence by setting ADSTP to 1.

OVR flag is cleared by software by writing 1 to it.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFRG register:

- **OVRMOD = 0**
  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (8 data) and the new conversion is discarded and lost. If OVR remains at 1, any further conversion is be performed but the resulting data is also discarded.

- **OVRMOD = 1**
  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data.
Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.
Managing a sequence of conversion without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events or FIFO overflows as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event will not prevent the ADC from continuing to convert and the ADC_DR register will always contain the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT bit = 01 or 11 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMNGT of the ADC_CFGR register in single ADC mode, or with bit DAMDF of the ADCx_CCR register in dual ADC mode:

- DMA one shot mode (DMNGT bit = 01).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- DMA circular mode (DMNGT bit = 11)
  This mode is suitable when programming the DMA in circular mode.

DMA one shot mode (DMNGT=01)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.
When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode (DMNGT=11)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

**DMA with FIFO**

The output data register has eight-stage FIFO. Two different DMA requests are generated parallel. When a data is available, “SREQ single request” generated, when 4 data are available, “BREQ burst request” generated. DMA2 can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA2. Please refer to the DMA2 chapter for further information.

### 28.4.28 Managing conversions using the DFSDM

The ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers 16 least significant bits of the regular data register data to the DFSDM, which in turns will reset the EOC flag once the transfer is effective.

The data format must be 16-bit signed:

ADC\_DR[31:16] = don’t care
ADC\_DR[15] = sign
ADC\_DR[14:0] = data

Any value above 16-bit signed format will be truncated.

### 28.4.29 Dynamic low-power features

**Auto-delayed conversion mode (AUTDLY)**

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.
When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 195).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 196).

This is a way to automatically adapt the speed of the ADC to the speed of the system which will read the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

**Note:** There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

**Note:** This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 196).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 198).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 199).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:

1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

28.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

![Analog watchdog guarded area](image)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (x=1,2,3).

AWDy (y=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels\(^{(1)}\) remain within a configured voltage range (window).

*Table 232* shows how the ADC_CFGRy registers should be configured to enable the analog watchdog on one or more channels.

\(^{(1)}\) Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HTR1[25:0] of the ADC_HTR1 register and LTR1[25:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024). When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

Table 233 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

</tbody>
</table>

1. The watchdog comparison is performed on the raw converted data before any alignment calculation and before applying any offsets (the data which is compared is not signed).

### Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set. The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

### ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCx_AWDy_OUT (x=ADC number, y=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCx_AWDy_OUT signal as ETR.
ADCx_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADCx_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCx_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (it remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCx_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS=1).

Note: Stopping regular or injected conversions (setting ADSTP=1 or JADSTP=1) has no influence on the generation of ADCy_AWDx_OUT.

AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCx_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

28.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 26-bit (16-bit values and OSVR[9:0] = 1024).

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.
The oversampling ratio $N$ is defined using the OSVR[9:0] bits in the ADC_CFGR2 register, and can range from 2x to 1024x. The division coefficient $M$ consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 26 bits (1024 x 16-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

The Table 205 gives a numerical example of the processing, from a raw 26-bit accumulated data to the final 16-bit result.

**Figure 205. 16-bit result oversampling with 10-bits right shift and rounding**

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every $N$ conversions, with an equivalent delay equal to $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$. The flags are set as follow:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- the end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after $N \times$ sequence length conversions total)
Single ADC operating modes support when oversampling

In oversampling mode, most of the ADC operating modes are maintained:
- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[2:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 16-bit conversions are

*Note:* The alignment mode is not available when working with oversampled data. The data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:
- the RES[2:0] bits are ignored, comparison is always done on using the full 26-bit values HTRx[25:0] and LTRx[25:0]
- the comparison is performed on the oversampled accumulated value before shifting

*Note:* Care must be taken when using high shifting values, this will reduce the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[0:7] / LT[0:7], and HT[11:8] / LT[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 206 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.
Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- in continued mode, the accumulation re-starts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling will be completed whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- in resumed mode, the accumulation re-starts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer will be blocked.

The Figure 207 gives examples for a 4x oversampling ratio.
Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 208 below.

Figure 208. Regular and injected oversampling modes used simultaneously
Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 209 below.

**Figure 209. Triggered regular oversampling with injection**

Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 210 below shows how the conversions are sequenced.

**Figure 210. Oversampling in auto-injected mode**

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO=1, DISCEN=0, JDISCEN=0, ROVSE=1, JOVSE=1 and TROVS=1.

Dual ADC modes support when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).
Combined modes summary

The Table 234 below summarizes all combinations, including modes not supported.

28.4.32 Dual ADC modes

In devices with two ADCs or more, dual ADC modes can be used (see Figure 211):

- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger,
and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
**Injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADC_JSQR register).

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 212), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 212. Injected simultaneous mode on 4 channels: dual ADC mode**

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.
**Regular simultaneous mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) will abort the current simultaneous conversions, which are re-started once the injected conversion is completed.

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master ans slave must be configured with the same sampling time.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 213), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.

- Configuring Dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CDR register.
  - both EOC flags are cleared when the DMA reads the ADCx_CDR register.

**Note:** When DAMDF[1:0]=0b10 or 0b11, the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions will not generate a DMA request.
If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with AUTDLY mode:
- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:
- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:
- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the
complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

**Note:** It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

**Figure 214. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**
If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is re-started from the master (see Figure 216 below).

**Figure 215. Interleaved mode on 1 channel in single conversion mode: dual ADC mode**

**Figure 216. Interleaved conversion with injection**

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.
Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

**Figure 217. Alternate trigger: injected group of each ADC**

**Note:** Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.
Injected discontinuous mode enabled (JDISCEN=1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 218. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0]=00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. Figure 219 shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected
conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

**Note:** The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Figure 219. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 220* shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 220. Case of trigger occurring during injected conversion**

**Combined injected simultaneous plus interleaved**

This mode is selected by programming bits DUAL[4:0]=00011.

It is possible to interrupt an interleaved conversion with a simultaneous injected event. In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. *Figure 221, Figure 222* and *Figure 223* show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 221. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 222. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 223. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 224: DMA Requests in regular simultaneous mode when DAMDF=0b00).

**Figure 224. DMA Requests in regular simultaneous mode when DAMDF=0b00**

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this DAMDF bits must be configured in the ADCx_CCR register:

- **DAMDF=0b10, 32-bit format**: A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADCx_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit. **Example:**

  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:
  1st DMA request: ADCx_CDR2[31:0] = MST_ADC_DR[31:0]
  2nd DMA request: ADCx_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF=0b10, 16-bit format**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-
converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter will be truncated to the least 16 significant bits.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
2nd DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

**Figure 225. DMA requests in regular simultaneous mode when DAMDF=0b10**

**Figure 226. DMA requests in interleaved mode when DAMDF=0b10**
**Note:** When using Multi ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF=0b11:** This mode is similar to the DAMDF=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when 4 new 8-bit values are available.

**Example:**

Interleaved dual mode: a DMA request is generated each time 4 data items are available (t0, t1,... are corresponding to the consecutive sampling instants)

1st DMA request:

\[
\begin{align*}
ADCx_{\text{CDR}}[7:0] &= \text{MST}_{\text{ADC}}_{\text{DR}}[7:0]_{t0} \\
ADCx_{\text{CDR}}[15:8] &= \text{SLV}_{\text{ADC}}_{\text{DR}}[7:0]_{t0} \\
ADCx_{\text{CDR}}[23:16] &= \text{MST}_{\text{ADC}}_{\text{DR}}[7:0]_{t1} \\
ADCx_{\text{CDR}}[31:24] &= \text{SLV}_{\text{ADC}}_{\text{DR}}[7:0]_{t1}
\end{align*}
\]

2nd DMA request:

\[
\begin{align*}
ADCx_{\text{CDR}}[7:0] &= \text{MST}_{\text{ADC}}_{\text{DR}}[7:0]_{t2} \\
ADCx_{\text{CDR}}[15:8] &= \text{SLV}_{\text{ADC}}_{\text{DR}}[7:0]_{t2} \\
ADCx_{\text{CDR}}[23:16] &= \text{MST}_{\text{ADC}}_{\text{DR}}[7:0]_{t3} \\
ADCx_{\text{CDR}}[31:24] &= \text{SLV}_{\text{ADC}}_{\text{DR}}[7:0]_{t3}
\end{align*}
\]

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration).

It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when Multi ADC mode is selected**

When DAMDF mode is selected (0b10 or 0b11), bit DMNGT[1:0]=0b10 in the master ADC’s ADCx_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA.*

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.
DFSDM mode in dual ADC mode interleaved mode

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

This mode is enabled by setting the bits DMNGT[1:0] = 0b10 in the master ADC’s ADC_CFGR register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the DFSDM.

The data format must be 16-bit signed:

ADC_DR[31:16] = 0x0000
ADC_DR[15] = sign
ADC_DR[14:0] = data

Any value above 16-bit signed format in any converter will be truncated.

DFSDM mode in dual ADC simultaneous mode

The dual mode is not required to use DFSDM in dual ADC simultaneous mode since conversion data will be treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with DFSDM interface.

28.4.33 V_{BAT} supply monitoring

The VBATEN bit of the ADC3_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage could be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect V_{BAT}/4 to an ADC input channel (refer to Table ADC interconnection in Section 28.4.2: ADC pins and internal signals). Then the SYSCFG_ADC2ALT register must be configured to select between dac1_out1 output or V_{BAT}/4.

As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V_{BAT}/4 voltage.

*Figure 227* shows the block diagram of the V_{BAT} sensing feature.
28.4.34 Monitoring the internal voltage reference

The internal voltage reference can be monitored to have a reference point for evaluating the ADC $V_{REF+}$ voltage level.

The internal voltage reference is internally connected to an ADC input channel (refer to Table ADC interconnection in Section 28.4.2: ADC pins and internal signals).

The sampling time for this channel must be greater than the stabilization time specified in the product datasheet. Figure 227 shows the block diagram of the $V_{REFINT}$ sensing feature.

Figure 227. $V_{BAT}$ channel block diagram

![Figure 227. $V_{BAT}$ channel block diagram](image)

Note: The VBATEN bit in ADC3_CCR as well as the SYSCFG_ADC2ALT register must be configured to enable the conversion of the corresponding ADC internal channel.

Figure 228. $V_{REFINT}$ channel block diagram

![Figure 228. $V_{REFINT}$ channel block diagram](image)

Note: The VREFEN bit of the ADC3_CCR register as well as the SYSCFG_ADC2ALT control register must be configured to enable the conversion of the corresponding ADC internal channel ($V_{REFINT}$).
Calculating the actual V_{DDA} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{DDA} = 3.3 V can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{DDA} voltage supplying the device:

\[ V_{\text{REF+}} = 3.3 \text{ V} \times \frac{V_{\text{REFINT \_CAL}}}{V_{\text{REFINT \_DATA}}} \]

Where:
- V_{REFINT \_CAL} is the V_{REFINT} calibration value
- V_{REFINT \_DATA} is the actual V_{REFINT} output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For most applications V_{DDA} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{DDA}:

\[ V_{\text{CHANNEL}_x} = \frac{V_{\text{REF+}}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA} \]

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula:

\[ V_{\text{CHANNEL}_x} = \frac{3.3 \text{ V} \times V_{\text{REFINT \_CAL}} \times \text{ADC\_DATA}}{V_{\text{REFINT \_DATA}} \times \text{FULL\_SCALE}} \]

For applications where V_{DDA} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

\[ V_{\text{CHANNEL}_x} = \frac{V_{\text{DDA}}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA} \]

Where:
- V_{REFINT \_CAL} is the V_{REFINT} calibration value
- ADC\_DATA is the value measured by the ADC on channel x (right-aligned)
- V_{REFINT \_DATA} is the actual V_{REFINT} output value converted by the ADC
- FULL\_SCALE is the maximum digital value of the ADC output. For example with 16-bit resolution, it will be \(2^{16} - 1 = 65535\) or with 8-bit resolution, \(2^8 - 1 = 255\).

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

28.4.35 Monitoring internal DAC output

The internal DAC voltage can be connected to the ADC input channel (refer to Table ADC interconnection in Section 28.4.2: ADC pins and internal signals) by configuring the SYSCFG\_ADC2ALT control register.
28.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

<td>0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)</td>
</tr>
<tr>
<td></td>
<td>1: Analog watchdog 2 event occurred</td>
</tr>
</tbody>
</table>
Bit 7 **AWD1**: Analog watchdog 1 flag
   This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT[11:0] and HT[11:0] of ADC_TR1 register. It is cleared by software writing 1 to it.
   0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
   1: Analog watchdog 1 event occurred

Bit 6 **JEOS**: Injected channel end of sequence flag
   This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
   0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
   1: Injected conversions complete

Bit 5 **JEOC**: Injected channel end of conversion flag
   This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.
   0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
   1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun
   This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
   0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
   1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag
   This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
   0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
   1: Regular Conversions sequence complete
Bit 2 EOC: End of conversion flag
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Regular channel conversion complete

Bit 1 EOSMP: End of sampling flag
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0 ADRDY: ADC ready
This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion

Bits 31:11 Reserved, must be kept at reset value.

#### Bit 10 JQOVFIE: Injected context queue overflow interrupt enable
- This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.
  - 0: Injected Context Queue Overflow interrupt disabled
  - 1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

#### Bit 9 AWD3IE: Analog watchdog 3 interrupt enable
- This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.
  - 0: Analog watchdog 3 interrupt disabled
  - 1: Analog watchdog 3 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

#### Bit 8 AWD2IE: Analog watchdog 2 interrupt enable
- This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.
  - 0: Analog watchdog 2 interrupt disabled
  - 1: Analog watchdog 2 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

#### Bit 7 AWD1IE: Analog watchdog 1 interrupt enable
- This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.
  - 0: Analog watchdog 1 interrupt disabled
  - 1: Analog watchdog 1 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

#### Bit 6 JEOSIE: End of injected sequence of conversions interrupt enable
- This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.
  - 0: JEOS interrupt disabled
  - 1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
Bit 5  **JEOCIE**: End of injected conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
   0: JEOC interrupt disabled.
   1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
   *Note:* The software is allowed to write this bit only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bit 4  **OVRIE**: Overrun interrupt enable
   This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
   0: Overrun interrupt disabled
   1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
   *Note:* The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
   This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
   0: EOS interrupt disabled
   1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
   *Note:* The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 2  **EOCIE**: End of regular conversion interrupt enable
   This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
   0: EOC interrupt disabled
   1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
   *Note:* The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
   This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
   0: EOSMP interrupt disabled
   1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
   *Note:* The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 0  **ADRDYIE**: ADC ready interrupt enable
   This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
   0: ADRDY interrupt disabled
   1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
   *Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.3 ADC control register (ADC_CR)

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.
The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

Bit 31 ADCAL: ADC calibration
This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.
0: Calibration complete
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.
The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

Bit 30 ADCALDIF: Differential mode for calibration
This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.
0: Writing ADCAL will launch a calibration in Single-ended inputs Mode.
1: Writing ADCAL will launch a calibration in Differential inputs Mode.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 29 DEEPPWD: Deep-power-down enable
This bit is set and cleared by software to put the ADC in deep-power-down mode.
0: ADC not in deep-power down
1: ADC in deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 28 ADVREGEN: ADC voltage regulator enable
This bit is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.
0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 28.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).
The software can program this bitfield only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
Bit 27 **LINCALRDYW6**: Linearity calibration ready Word 6
This control / status bit allows to read/write the 6th linearity calibration factor.
When the linearity calibration is complete, this bit is set. A bit clear will launch the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit will be reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared).
When the LINCALRDYW6 bit is reset, a new linearity factor 6 value can be written into the LINCALFACT[29:0] of the ADC_CALFACT2 register. A bit set will launch the linearity factor 6 update and the bit will be effectively set by hardware once the update will be done (software must poll the bit until it is set to indicate the write is effective).

**Note:** ADC_CALFACT2[29:10] contains 0. ADC_CALFACT2[9:0] corresponds linearity correction factor bits[159:150].
The software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 28.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT) for details.
The software is allowed to update the linearity calibration factor by writing LINCALRDYWx only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 26 **LINCALRDYW5**: Linearity calibration ready Word 5
Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[149:120].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 25 **LINCALRDYW4**: Linearity calibration ready Word 4
Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] correspond linearity correction factor bits[119:90].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 24 **LINCALRDYW3**: Linearity calibration ready Word 3
Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[89:60].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 23 **LINCALRDYW2**: Linearity calibration ready Word 2
Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[59:30].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.

Bit 22 **LINCALRDYW1**: Linearity calibration ready Word 1
Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[29:0].
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.

Bits 21:17 Reserved, must be kept at reset value.
Bit 16 **ADCALLIN**: Linearity calibration
This bit is set and cleared by software to enable the Linearity calibration.
0: Writing ADCAL will launch a calibration without the Linearity calibration.
1: Writing ADCAL will launch a calibration with the Linearity calibration.

*Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **BOOST[1:0]**: Boost mode control
This bitfield is set and cleared by software to enable/disable the Boost mode.
00: used when ADC clock ≤ 6.25 MHz
01: used when 6.25 MHz < ADC clock frequency ≤ 12.5 MHz
10: used when 12.5 MHz < ADC clock ≤ 25.0 MHz
11: used when 25.0 MHz < ADC clock ≤ 50.0 MHz

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing). When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the BOOST bitfield of the slave ADC is no more writable and its content must be equal to the master ADC BOOST bitfield.*

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command
This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).
0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC). In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).*

Bit 4 **ADSTP**: ADC stop of regular conversion command
This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).
0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC). In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP). In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.*
Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

*Note*: The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTEN=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTEN=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note*: The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note*: The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note*: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

</tr>
<tr>
<td>1: Analog watchdog 1 enabled on injected channels</td>
</tr>
<tr>
<td>Note: <em>The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).</em></td>
</tr>
</tbody>
</table>
Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels.
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 21 **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR Mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR Mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to [Section 28.4.22: Queue of context for injected conversions](#) for more information.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

*It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.

Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count
These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
000: 1 channel
001: 2 channels
...
111: 8 channels

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.
Bit 16 **DISCEN**: Discontinuous mode for regular channels
This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.
0: Discontinuous mode for regular channels disabled
1: Discontinuous mode for regular channels enabled

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.
It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.
The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).
When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode
This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode:
0: Auto-delayed conversion mode off
1: Auto-delayed conversion mode on

**Note:** The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions
This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.
0: Single conversion mode
1: Continuous conversion mode

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.
The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).
When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun Mode
This bit is set and cleared by software and configure the way data overrun is managed.
0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note:** The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.
00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

**Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

- 00000: Event 0
- 00001: Event 1
- 00010: Event 2
- 00011: Event 3
- 00100: Event 4
- 00101: Event 5
- 00110: Event 6
- 00111: Event 7
- ...  
- 11111: Event 31

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 4:2 **RES[2:0]**: Data resolution

These bits are written by software to select the resolution of the conversion:

- 000: 16 bits
- 001: 14 bits in legacy mode (not optimized power consumption)
- 010: 12 bits in legacy mode (not optimized power consumption)
- 101: 14 bits
- 110: 12 bits
- 011: 10 bits
- 111: 8 bits

Others: Reserved, must not be used.

*Note:* The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data Management configuration

This bit is set and cleared by software to select how ADC interface output data are managed:

- 00: Regular conversion data stored in DR only
- 01: DMA One Shot Mode selected
- 10: DFSDM mode selected
- 11: DMA Circular Mode selected

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bit DAMDF of the ADCx_CCR register.
28.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10
Reset value: 0x0000 0000

Bits 31:28 **LSHIFT[3:0]:** Left shift factor
This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.
0000: No left shift
0001: Shift left 1-bit
0010: Shift left 2-bits
0011: Shift left 3-bits
0100: Shift left 4-bits
0101: Shift left 5-bits
0110: Shift left 6-bits
0111: Shift left 7-bits
1000: Shift left 8-bits
1001: Shift left 9-bits
1010: Shift left 10-bits
1011: Shift left 11-bits
1100: Shift left 12-bits
1101: Shift left 13-bits
1110: Shift left 14-bits
1111: Shift left 15-bits

**Note:** The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OSVR[9:0]:** Oversampling ratio
This bitfield is set and cleared by software to define the oversampling ratio.
0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

**Note:** The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RSHIFT4:** Right-shift data after Offset 4 correction
Refer to RSHIFT1 description.
Bit 13 **RSHIFT3**: Right-shift data after Offset 3 correction
Refer to RSHIFT1 description

Bit 12 **RSHIFT2**: Right-shift data after Offset 2 correction
Refer to RSHIFT1 description

Bit 11 **RSHIFT1**: Right-shift data after Offset 1 correction
This bitfield is set and cleared by software to right-shift 1-bit data after offset1 correction. This bit can only be used for 8-bit and 16-bit data format (see Section: Data register, data alignment and offset for details).
0: Right-shifting disabled
1: Data is right-shifted 1-bit.

Bit 10 **ROVSM**: Regular Oversampling mode
This bit is set and cleared by software to select the regular oversampling mode.
0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bit 9 **TROVS**: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling
0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling right shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
0000: No right shift
0001: Shift right 1-bit
0010: Shift right 2-bits
0011: Shift right 3-bits
0100: Shift right 4-bits
0101: Shift right 5-bits
0110: Shift right 6-bits
0111: Shift right 7-bits
1000: Shift right 8-bits
1001: Shift right 9-bits
1010: Shift right 10-bits
1011: Shift right 11-bits
Others: Reserved, must not be used.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).
Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected Oversampling disabled
1: Injected Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular Oversampling disabled
1: Regular Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

### 28.6.6 ADC sample time register 1 (ADC_SMPR1)

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMP[9:0][2:0]**: Channel x sampling time selection (x = 0 to 9)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 8.5 ADC clock cycles
011: 16.5 ADC clock cycles
100: 32.5 ADC clock cycles
101: 64.5 ADC clock cycles
110: 387.5 ADC clock cycles
111: 810.5 ADC clock cycles

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
### 28.6.7 ADC sample time register 2 (ADC_SMPR2)

Notes:
- The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x1C
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 PCSEL[19:0]: Channel x (VinP[x]) pre selection (x = 0 to 19)
These bits are written by software to pre select the input channel at IO instance to be converted.
0: Input Channel x (VinP x) is not pre selected for conversion, the ADC conversion result with this channel shows wrong result.
1: Input Channel x (VinP x) is pre selected for conversion

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

28.6.9 ADC watchdog threshold register 1 (ADC_LTR1)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 LTR[25:0]: Analog watchdog 1 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 1.
Refer to Section 28.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRY, AWD_LTRY, AWDy)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.10  ADC watchdog threshold register 1 (ADC_HTR1)

</tbody>
</table>

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:0  **HTR1[25:0]**: Analog watchdog 1 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 1.
Refer to Section 28.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRY, AWD_LTRY, AWDy)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30
Reset value: 0x0000 0000

| Bits 31:29 | Reserved, must be kept at reset value. |
| Bits 28:24 | SQ4[4:0]: 4th conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence. |
| Bit 23    | Reserved, must be kept at reset value. |
| Bits 22:18 | SQ3[4:0]: 3rd conversion in regular sequence |
|           | These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence. |
|           | Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:24  **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23  Reserved, must be kept at reset value.

Bits 22:18  **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17  Reserved, must be kept at reset value.

Bits 16:12  **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11  Reserved, must be kept at reset value.

Bits 10:6  **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
28.6.13 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38
Reset value: 0x0000 0000

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]**: 14th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]**: 13th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]**: 12th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]**: 11th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]**: 10th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 31:27 **JSQ4[4:0]**: 4th conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]**: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]**: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]**: 1st conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

**Note:** The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).
Bits 8:7 **JEXTen[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

- **00**: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled and if JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)
- **01**: Hardware trigger detection on the rising edge
- **10**: Hardware trigger detection on the falling edge
- **11**: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

*If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 28.4.22: Queue of context for injected conversions)*

Bits 6:2 **JEXTSel[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

- **00000**: Event 0
- **00001**: Event 1
- **00010**: Event 2
- **00011**: Event 3
- **00100**: Event 4
- **00101**: Event 5
- **00110**: Event 6
- **00111**: Event 7
- ... **11111**: Event 31:

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

- **00**: 1 conversion
- **01**: 2 conversions
- **10**: 3 conversions
- **11**: 4 conversions

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).
28.6.17 ADC injected channel y offset register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y-1), (y= 1 to 4)
Reset value: 0x0000 0000

Bit 31 SSATE: Signed saturation Enable
This bit is written by software to enable or disable the Signed saturation feature.
This bit can be enabled only for 8-bit and 16-bit data format (see Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE) for details).
0: Offset is subtracted maintaining data integrity and extending result size (9-bit and 17-bit signed format).
1: Offset is subtracted and result is saturated to maintain result size.
Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 30:26 OFFSETy_CH[4:0]: Channel selection for the Data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[25:0] will apply.
Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 25:0 OFFSETy[25:0]: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]
These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).
When OFFSETy[25:0] bitfield is reset, the offset compensation is disabled.
Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.
Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[25:0] which is subtracted when converting channel 4.
28.6.18  ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y= 1 to 4)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>JDATA[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:0  JDATA[31:0]: Injected data
These bits are read-only. They contain the conversion result from injected channel y. The data are left-or right-aligned as described in Section 28.4.27: Data management.

28.6.19  ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0xA0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:20</th>
<th>AWD2CH[19:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  AWD2CH[19:0]: Analog watchdog 2 channel selection
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2
AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2
When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note:  The channels selected by AWD2CH must be also selected into the SQRI or JSQRi registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 AWD3CH[19:0]: Analog watchdog 3 channel selection
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.
AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3
AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3
When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQRI or JSQRi registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

28.6.21 ADC watchdog lower threshold register 2 (ADC_LTR2)

Address offset: 0xB0
Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 LTR2[25:0]: Analog watchdog 2 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 2.
Refer to Section 28.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy).

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
28.6.22  ADC watchdog higher threshold register 2 (ADC_HTR2)

Address offset: 0xB4
Reset value: 0x03FF FFFF

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0  

**HTR2[25:0]:** Analog watchdog 2 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 2.

Refer to Section 28.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRY, AWD_LTRY, AWDy).

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 DIFSEL[19:0]: Differential mode for channels 19 to 0
These bits are set and cleared by software. They allow to select if a channel is configured as single ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel-i is configured in single ended mode
DIFSEL[i] = 1: ADC analog input channel-i is configured in differential mode

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
28.6.26 ADC calibration factors register (ADC_CALFACT)

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **CalFact_D[10:0]:** Calibration Factors in differential mode

These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new differential conversion is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **CalFact_S[10:0]:** Calibration Factors In Single-Ended mode

These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended conversion is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

28.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

### 28.7.1 ADC common status register (ADCx_CSx) (x=1/2)

Address offset: 0x00
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

ADC1 and ADC2 are controlled by the same interface.

| Bits 31:27 | Reserved, must be kept at reset value. |
| Bits 26 | JQOVF_MSK: Injected Context Queue Overflow flag of the slave ADC |
| This bit is a copy of the JQOVF bit in the corresponding ADCx+1_ISR register. |
| Bits 25 | AWD3_MSK: Analog watchdog 3 flag of the slave ADC |
| This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register. |
| Bits 24 | AWD2_MSK: Analog watchdog 2 flag of the slave ADC |
| This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register. |
| Bits 23 | AWD1_MSK: Analog watchdog 1 flag of the slave ADC |
| This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register. |

| Bits 31:27 | Reserved, must be kept at reset value. |
| Bits 26 | JQOVF_MSK: Injected Context Queue Overflow flag of the slave ADC |
| This bit is a copy of the JQOVF bit in the corresponding ADCx+1_ISR register. |
| Bits 25 | AWD3_MSK: Analog watchdog 3 flag of the slave ADC |
| This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register. |
| Bits 24 | AWD2_MSK: Analog watchdog 2 flag of the slave ADC |
| This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register. |
| Bits 23 | AWD1_MSK: Analog watchdog 1 flag of the slave ADC |
| This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register. |
Bit 22 **JEOS\_SLV**: End of injected sequence flag of the slave ADC
   This bit is a copy of the JEOS bit in the corresponding ADC\(x+1\)_ISR register.

Bit 21 **JEOC\_SLV**: End of injected conversion flag of the slave ADC
   This bit is a copy of the JEOC bit in the corresponding ADC\(x+1\)_ISR register.

Bit 20 **OVR\_SLV**: Overrun flag of the slave ADC
   This bit is a copy of the OVR bit in the corresponding ADC\(x+1\)_ISR register.

Bit 19 **EOS\_SLV**: End of regular sequence flag of the slave ADC
   This bit is a copy of the EOS bit in the corresponding ADC\(x+1\)_ISR register.

Bit 18 **EOC\_SLV**: End of regular conversion of the slave ADC
   This bit is a copy of the EOC bit in the corresponding ADC\(x+1\)_ISR register.

Bit 17 **EOSMP\_SLV**: End of Sampling phase flag of the slave ADC
   This bit is a copy of the EOSMP2 bit in the corresponding ADC\(x+1\)_ISR register.

Bit 16 **ADRDY\_SLV**: Slave ADC ready
   This bit is a copy of the ADRDY bit in the corresponding ADC\(x+1\)_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF\_MST**: Injected Context Queue Overflow flag of the master ADC
   This bit is a copy of the JQOVF bit in the corresponding ADC\_ISR register.

Bit 9 **AWD3\_MST**: Analog watchdog 3 flag of the master ADC
   This bit is a copy of the AWD3 bit in the corresponding ADC\_ISR register.

Bit 8 **AWD2\_MST**: Analog watchdog 2 flag of the master ADC
   This bit is a copy of the AWD2 bit in the corresponding ADC\_ISR register.

Bit 7 **AWD1\_MST**: Analog watchdog 1 flag of the master ADC
   This bit is a copy of the AWD1 bit in the corresponding ADC\_ISR register.

Bit 6 **JEOS\_MST**: End of injected sequence flag of the master ADC
   This bit is a copy of the JEOS bit in the corresponding ADC\_ISR register.

Bit 5 **JEOC\_MST**: End of injected conversion flag of the master ADC
   This bit is a copy of the JEOC bit in the corresponding ADC\_ISR register.

Bit 4 **OVR\_MST**: Overrun flag of the master ADC
   This bit is a copy of the OVR bit in the corresponding ADC\_ISR register.

Bit 3 **EOS\_MST**: End of regular sequence flag of the master ADC
   This bit is a copy of the EOS bit in the corresponding ADC\_ISR register.

Bit 2 **EOC\_MST**: End of regular conversion of the master ADC
   This bit is a copy of the EOC bit in the corresponding ADC\_ISR register.

Bit 1 **EOSMP\_MST**: End of Sampling phase flag of the master ADC
   This bit is a copy of the EOSMP bit in the corresponding ADC\_ISR register.

Bit 0 **ADRDY\_MST**: Master ADC ready
   This bit is a copy of the ADRDY bit in the corresponding ADC\_ISR register.
28.7.2 ADC common control register (ADCx_CCR) (x=1/2)

Address offset: 0x08
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bits 21:18 **PRESC[3:0]: ADC prescaler**

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256

Others: Reserved, must not be used

**Note:** The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.
Bits 17:16 **CKMODE[1:0]:** ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- **00:** CK_ADCx (x=1 to 23) (Asynchronous clock mode), generated at product level (refer to Section Reset and Clock Control (RCC))
- **01:** adc_sclk/1 (Synchronous clock mode)
- **10:** adc_sclk/2 (Synchronous clock mode)
- **11:** adc_sclk/4 (Synchronous clock mode)

Whatever CKMODE[1:0] settings, an additional divider factor of 2 is applied to the clock delivered to the analog ADC block.

In synchronous clock mode, when adc_ker_ck = 2 x adc_hclk, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 15:14 **DAMDF[1:0]:** Dual ADC Mode Data Format

This bit-field is set and cleared by software. It specifies the data format in the common data register ADCx_CDR.

- **00:** Dual ADC mode without data packing (ADCx_CDR and ADCx_CDR2 registers not used).
- **01:** Reserved.
- **10:** Data formatting mode for 32 down to 10-bit resolution
- **11:** Data formatting mode for 8-bit resolution

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 236 for the value of ADC resolution versus DELAY bits values.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode.

All the ADCs are independent:

- **00000:** Independent mode

The configurations 00001 to 01001 correspond to the following operating modes:

- **00001:** Combined regular simultaneous + injected simultaneous mode
- **00010:** Combined regular simultaneous + alternate trigger mode
- **00011:** Combined Interleaved mode + injected simultaneous mode
- **00100:** Reserved.
- **00101:** Injected simultaneous mode only
- **00110:** Regular simultaneous mode only
- **00111:** Interleaved mode only
- **01001:** Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

### 28.7.3 ADC common regular data register for dual mode

(ADCx_CDR) \((x=1/2)\)

- **Address offset**: 0x0C
- **Reset value**: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

**Bits 31:16 RDATA_SLV[15:0]**: Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 28.4.32: Dual ADC modes.

The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE).

**Bits 15:0 RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to Section 28.4.32: Dual ADC modes.

The data alignment is applied as described in Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE).

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

### 28.7.4 ADC common regular data register for 32-bit dual mode

(ADCx_CDR2) \((x=1/2)\)

- **Address offset**: 0x10
- **Reset value**: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

29  Analog-to-digital converters (ADC3)

29.1  Introduction

The ADC consists of a 12-bit successive approximation analog-to-digital converter.

The ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in Single, Continuous, Scan or Discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADC is mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

29.2  ADC main features

- High-performance features
  - 16 external channels and to 3 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to DFSDM for post processing
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
– Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits

- Data preconditioning
  - Offset compensation

- Analog input channels
  - External analog inputs:
    - Up to 6 fast channels from GPIO pads
    - Up to 10 slow channels from GPIO pads
  - 1 channel for the internal temperature sensor (VSENSE)
  - 1 channel for the internal reference voltage (VREFINT)
  - 1 channel for monitoring the external VBAT power supply pin

- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- Conversion modes
  - The ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode

- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events

- 3 analog watchdogs
  - Watchdog can perform filtering to ignore out-of-range data

- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

*Figure 229* shows the block diagram of one ADC.

29.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The ADC input clock can be selected between two different clock sources (see Figure 230: ADC clock scheme):

1. The ADC clock can be a specific clock source (adc_ker_ck_input), independent and asynchronous with the AHB clock.
   Refer to section Reset and clock control (RCC) for more information on how to generate the ADC dedicated clock. To select this scheme, CKMODE[1:0] bits of ADC_CCR register must be set to 00.

2. The ADC clock can be derived from the AHB clock interface divided by a programmable factor of 1, 2 or 4. To select this scheme, CKMODE[1:0] bits of ADC_CCR must be different from 00. The programmable divider factor can be configured through to CKMODE[1:0] bits of ADC_CCR.
   The prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xx in the RCC_CIFGR register).

Option 1 has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256, using the prescaler configured with bits PRESC[3:0] in the ADC_CCR register.

Option 2 has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the device datasheet.
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( F_{\text{adc\_hclk}} \geq \frac{F_{\text{ADC}}}{4} \) if the resolution of all channels are 12-bit or 10-bit
- \( F_{\text{adc\_hclk}} \geq \frac{F_{\text{ADC}}}{3} \) if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)
- \( F_{\text{adc\_hclk}} \geq \frac{F_{\text{ADC}}}{2} \) if there are some channels with resolutions equal to 6-bit

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio for all ADC interfaces.
29.4.4 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described below.

Figure 231. ADC3 connectivity
29.4.5 Slave AHB interface

The ADC implements an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

29.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD = 0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN = 1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator (T_{ADCVREG_STUP}) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, refer to device datasheet for T_{ADCVREG_STUP} parameter.

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to Section 29.4.8: Calibration (ADCAL, ADCALDIFF, ADC_CALFACT)).
29.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage VINP[i] (positive input) and VREF- (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage VINP[i] (positive input) and VINN[i] (negative input).

The output data for the differential mode is an unsigned data. When VINP[i] equals VREF-, VINN[i] equals VREF+ and the output data is 0x000 (12-bit resolution mode). When VINP[i] equals VREF+, VINN[i] equals VREF- and the output data is 0xFFF.

\[
\text{Converted value} = \frac{\text{ADC Full Scale}}{2} \times \left[ 1 + \frac{V_{\text{INP}} - V_{\text{INN}}}{V_{\text{REF}+}} \right]
\]

When ADC is configured as differential mode, both inputs should be biased at (VREF+) /2 voltage.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as VREFINT and VSENSE) are used in single-ended mode only.

For a complete description of how the input channels are connected, refer to Section 29.4.4: ADC connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage VINN[i] is connected to another channel. As a consequence, this channel is no longer usable in Single-ended mode or in differential mode and must never be configured to be converted.

29.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

The ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which will be applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in...
the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration)

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

**Software procedure to calibrate the ADC**

1. Ensure DEEPWPD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL = 1.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

**Software procedure to re-inject a calibration factor into the ADC**

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits.
CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 233. Updating the ADC calibration factor

Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.
29.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately, as shown in Figure 235. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART = 1 (refer to Section 29.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART = 1 or when an external injected trigger event occurs, if injected triggers are enabled.

**Software procedure to enable the ADC**

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

**Caution:** ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).
Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.

2. Set ADDIS = 1.

3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 235. Enabling / disabling the ADC

29.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 29.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx) for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).
The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1). Refer to Section 29.6.16: ADC injected sequence register (ADC_JSQR) for additional details.

**Note:** There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN = 0 as well as all the bits of ADC_CR register).

### 29.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 19 multiplexed channels, out of which:

- Up to 16 analog inputs coming from GPIO pads (ADC_INP/INN[i]) depending on the products, not all of them are available on GPIO pads.
- ADC is connected to 3 internal analog inputs:
  - the internal temperature sensor (VSENSE)
  - the internal reference voltage (VREFINT)
  - the $V_{BAT}$ monitoring channel ($V_{BAT}/4$)

To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATEN or TSEN in the ADC_CCR registers.

Refer to Table ADC interconnection in Section 29.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC3_INP/INN3, ADC3_INP/INN8, ADC3_INP/INN2, ADC3_INN/INP2, ADC3_INP/INN0, ADC3_INP/INN2, ADC3_INP/INN2, ADC3_INP/INN15.

- **A regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- **An injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to Section 29.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFGR register). Refer to Section 29.4.21: Queue of context for injected conversions
29.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{CONV} = \text{Sampling time} + \text{12.5 ADC clock cycles} \]

Example:

With \( F_{\text{adc, ker, ck}} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{CONV} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The Bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The Bulb mode is neither compatible with the Continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFRGR2.
Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the Continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switches voltage booster

The I/O analog switches resistance increases when the VDDA voltage is too low. This requires to have the sampling time adapted accordingly (cf datasheet for electrical characteristics). This resistance can be minimized at low VDDA by enabling an internal voltage booster with BOOSTEN bit in the SYSCFG_CFGR1 register.

SMPPLUS control bit

The SMPPLUS bit can be used to change the sampling time from 2.5 ADC clock cycles to 3.5 ADC clock cycles.

29.4.13 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)
Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:
- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JE0C (end of injected conversion) flag is set
- An interrupt is generated if the JE0CIE bit is set

After the regular sequence is complete:
- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:
- The JE0S (end of injected sequence) flag is set
- An interrupt is generated if the JE0SIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

29.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In Continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:
- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both Discontinuous mode and Continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in Continuous mode (using JAUTO bit), refer to Auto-injection mode section).
29.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:

• Immediately: if EXTEN = 0x0 (software trigger)
• At the next active edge of the selected regular hardware trigger: if EXTEN is not equal to 0x0

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:

• Immediately, if JEXTEN = 0x0 (software trigger)
• At the next active edge of the selected injected hardware trigger: if JEXTEN is not equal to 0x0

Note: In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

• In Single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  – At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
• In all cases (CONT = x, EXTSEL = x)
  – After execution of the ADSTP procedure asserted by the software.

Note: In Continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in Single mode (CONT = 0 and EXTSEL ≠ 0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:

• In Single mode with software injected trigger (JEXTSEL = 0x0)
  – At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
• In all cases (JEXTSEL = x)
  – After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.
29.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [2.5 \, \text{min} + 12.5 \, \text{12bit}] \times T_{\text{ADC_CLK}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 83.33 \, \text{ns} \, \text{min} + 416.67 \, \text{ns} \, \text{12bit} = 500.0 \, \text{ns} \, \text{for} \, F_{\text{ADC_CLK}} = 30 \, \text{MHz}
\]

**Figure 237. Analog to digital conversion time**

1. $T_{\text{SMPL}}$ depends on SMP[2:0].
2. $T_{\text{SAR}}$ depends on RES[2:0].

29.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.
**Note:** In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

29.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (such as timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 243 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

<table>
<thead>
<tr>
<th>JEXTEN[1:0]</th>
<th>Source</th>
</tr>
</thead>
</table>
| 00         | - If JQDIS = 1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled  
- If JQDIS = 0 (Queue enabled), Hardware and software trigger detection disabled |
| 01         | Hardware Trigger with detection on the rising edge |
| 10         | Hardware Trigger with detection on the falling edge |
| 11         | Hardware Trigger with detection on both the rising and falling edges |

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 29.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 29.4.21: Queue of context for injected conversions on page 1127.

Figure 240. Trigger selection

Refer to Table ADC interconnection in Section 29.4.2: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

29.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 241 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.
In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and Discontinuous modes simultaneously. When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (Single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

**Figure 241. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

### 29.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

**Regular group mode**

This mode is enabled by setting the DISCEN bit in the ADC_CFRG register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFRG register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).

3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.

4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).

... 

- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in Discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both Discontinuous mode and Continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if Continuous mode was disabled.

### Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to Discontinuous mode for regular channels where 'n' is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel.

It is not possible to use both auto-injected mode and Discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.
Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)

All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:
- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.

Note: When configured in Discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only
consumes the queue but others are still valid triggers as shown by the Discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, Discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, Discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, Discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, Discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, Discontinuous. Sequence 2: 3rd conversion.

Behavior when changing the trigger or sequence context

Figure 242 and Figure 243 show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 242. Example of JSQR queue of context (sequence change)**

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 244 and Figure 245 show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 244. Example of JSQR queue of context with overflow before conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1

Figure 245. Example of JSQR queue of context with overflow during conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 246* and *Figure 247* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

**Figure 246. Example of JSQR queue of context with empty queue (case JQM = 0)**

<table>
<thead>
<tr>
<th>Write JSQR</th>

</tbody>
</table>

1. **Parameters:**
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
Flush the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 248. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
**Figure 249. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Figure 250. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1
Figure 251. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 1)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 252. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 0)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

29.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 258, Figure 259, Figure 260 and Figure 261 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 245.
29.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

29.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

29.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 258, Figure 259, Figure 260 and Figure 261.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 260 and Figure 261.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset $y$ ($y = 1, 2, 3, 4$) can be applied to a channel by setting the bit OFFSET_EN = 1 into ADC_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSET_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 248 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed before the offset compensation.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (three stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP to 1. Since ADC_DR FIFO features three stages, up to three data are stored in the FIFO.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0: The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (three stages) and the new conversion is discarded and lost. In this mode, ADC_DR FIFO is disabled. If the FIFO is full, any further conversion is performed but the resulting data is also discarded. EOC
is cleared by reading ADC_DR register. However, the FIFO can still contain previously converted data.

- OVRMOD = 1: The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversions is performed normally and the ADC_DR register always contains the latest converted data.

**Figure 262. Example of overrun (OVRMOD = 0)**
Figure 263. Example of overrun (OVRMOD = 1)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register, a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.
Despite this, if an overrun occurs \((OVR = 1)\) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun \((OVR, OVRMOD)\)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register:
- DMA one shot mode \((DMACFG = 0)\)
  - This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode \((DMACFG = 1)\)
  - This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode \((DMACFG = 0)\)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):
- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode \((DMACFG = 1)\)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

### 29.4.27 Managing conversions using the DFSDM

The ADC conversion results can be transferred directly to the digital filter for sigma delta modulators (DFSDM).

In this case, the DFSDMCFG bit must be set to 1 and DMAEN bit must be cleared to 0.

The ADC transfers all the 16 bits of the regular data register to the DFSDM and resets the EOC flag once the transfer is complete.

The data format must be 16-bit signed:

\[
\begin{align*}
\text{ADC\_DR}[15:12] &= \text{sign extended} \\
\text{ADC\_DR}[11] &= \text{sign} \\
\text{ADC\_DR}[11:0] &= \text{data}
\end{align*}
\]
To obtain 16-bit signed format in 12-bit ADC mode, the software needs to configure the OFFSET[11:0] to 0x800 after having set OFFSET_EN to 1.

Only right aligned data format is available for the DFSDM interface (see Figure 259: Right alignment (offset enabled, signed value)).

29.4.28 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 264).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 265).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 265).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 267).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 268).
To stop a conversion in Continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:
1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP = 1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

**Figure 264. AUTDLY = 1, regular conversion in Continuous mode, software trigger**

29.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 269. Analog watchdog guarded area**

![Analog voltage guarded area diagram](MS45396/V1)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

*Table 247* shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

**Table 247. Analog watchdog channel selection**

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned) before the offset compensation stage.

Table 248 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in Scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set and the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x = 2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x = 2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. Table 249 describes how the comparison is performed for all the possible resolutions.
Analog-to-digital converters (ADC3) RM0468

ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y = ADC number, x = watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

- Converting the injected channels 1, 2, 3, 4
- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in a analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

Analog watchdog with offset compensation

When the offset compensation is enabled, the analog watchdog compares the threshold before the data compensation.

29.4.30 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n = 0}^{n = N - 1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

**Note:** *If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.*
Figure 274. 20-bit to 16-bit result truncation

Figure 275 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 275. Numerical example with 5-bit shift and rounding

Table 250 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 250. Maximum output results versus N and M (gray cells indicate truncation)

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N
conversions, with an equivalent delay equal to $N \times T_{\text{CONV}} = N \times (t_{\text{SMPL}} + t_{\text{SAR}})$. The flags are set as follow:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after $N \times \text{sequence length conversions total}$)

**ADC operating modes supported when oversampling**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or Continuous conversion modes
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR1 is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

**Analog watchdog**

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- The RES[1:0] bits are ignored, comparison is always done on using the full 12-bit values HT[11:0] and LT[11:0]
- The comparison is performed on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4]

**Note:** Care must be taken when using high shifting values, this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[0:7] / LT[0:7], and HT[11:8] / LT[11:8] must be kept reset.

**Triggered mode**

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific Discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 276 below shows how conversions are started in response to triggers during Discontinuous mode.
If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

**Figure 276. Triggered regular oversampling mode (TROVS bit = 1)**

- **Injected and regular sequencer management when oversampling**
  - In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

- **Oversampling regular channels only**
  - The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:
    - In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
    - In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

  The **Figure 277** gives examples for a 4x oversampling ratio.
Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 278 below.

**Figure 278. Regular and injected oversampling modes used simultaneously**

![Diagram showing regular and injected oversampling modes](image)

**Triggered regular oversampling with injected conversions**

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 279 below.

**Figure 279. Triggered regular oversampling with injection**

![Diagram showing triggered regular oversampling with injection](image)
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 280 below shows how the conversions are sequenced.

Figure 280. Oversampling in auto-injected mode

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

29.4.31 Temperature sensor

The temperature sensor can be used to measure the junction temperature (Tj) of the device. The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value (see Table: ADC interconnection in Section 29.4.2: ADC pins and internal signals for more details). When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

Figure 281 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another). The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production. During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode. Figure 281 shows the block diagram of the temperature sensor.
Reading the temperature

To use the sensor:
1. Select the ADC input channels that is connected to V\text{SENSE}.
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the bit in the ADC\_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V\text{SENSE} data in the ADC data register.
6. Calculate the actual temperature using the following formula:

   \[
   \text{Temperature (in } ^\circ\text{C}) = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30 \ ^\circ\text{C}
   \]

   where:
   - TS\_CAL2 is the temperature sensor calibration value acquired at TS\_CAL2\_TEMP.
   - TS\_CAL1 is the temperature sensor calibration value acquired at TS\_CAL1\_TEMP.
   - TS\_DATA is the actual temperature sensor output value converted by ADC.

   Refer to the device datasheet for more information about TS\_CAL1 and TS\_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output V\text{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and bits should be set at the same time.
29.4.32  \( V_{\text{BAT}} \) supply monitoring

The \( V_{\text{BAT}} \)EN bit in the ADC_CCR register is used to switch to the battery voltage. As the \( V_{\text{BAT}} \) voltage could be higher than \( V_{\text{DDA}} \), to ensure the correct operation of the ADC, the \( V_{\text{BAT}} \) pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when \( V_{\text{BATEN}} \) is set, to connect \( V_{\text{BAT}}/4 \) to the ADC input channels (see Table: ADC interconnection in Section 29.4.2: ADC pins and internal signals for more details). As a consequence, the converted digital value is one third of the \( V_{\text{BAT}} \) voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the \( V_{\text{BAT}}/4 \) voltage.

*Figure 282* shows the block diagram of the \( V_{\text{BAT}} \) sensing feature.

**Figure 282. \( V_{\text{BAT}} \) channel block diagram**

1. The \( V_{\text{BATEN}} \) bit must be set to enable the conversion of internal channel for \( V_{\text{BAT}}/4 \).

29.4.33  Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference (\( V_{\text{REFINT}} \)) to have a reference point for evaluating the ADC \( V_{\text{REF+}} \) voltage level.

Refer to Table: ADC interconnection in Section 29.4.2: ADC pins and internal signals for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

*Figure 283* shows the block diagram of the \( V_{\text{REFINT}} \) sensing feature.
Figure 283. VREFINT channel block diagram

1. The VREFEN bit into ADC_CCR register must be set to enable the conversion of internal channels (VREFINT).

Calculating the actual VREF+ voltage using the internal reference voltage

VREF+ voltage may be subject to variations or not precisely known. The embedded internal reference voltage VREFINT and its calibration data acquired by the ADC during the manufacturing process at VREF+_charac can be used to evaluate the actual VREF+ voltage level.

The following formula gives the actual VREF+ voltage supplying the device:

\[ V_{\text{REF}+} = \frac{V_{\text{REF}+\_\text{Charac}} \times \text{VREFINT\_CAL}}{\text{VREFINT\_DATA}} \]

Where:
- \( V_{\text{REF}+\_\text{Charac}} \) is the value of VREF+ voltage characterized at VREFINT during the manufacturing process. It is specified in the device datasheet.
- \( \text{VREFINT\_CAL} \) is the VREFINVREFINT\_CAL is the VREFINT calibration value
- \( \text{VREFINT\_DATA} \) is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between VREF+ and the voltage applied on the converted channel.

For applications where VREF+ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from VREF+:

\[ V_{\text{CHANNELx}} = \frac{V_{\text{REF}+}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA} \]
By replacing $V_{REF+}$ by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

Where:

- $V_{REF+_Charac}$ is the value of $V_{REF+}$ voltage characterized at $V_{REFINT}$ during the manufacturing process.
- $VREFINT_CAL$ is the $VREFINT$ calibration value
- $ADC_DATA$ is the value measured by the ADC on channel $x$ (right-aligned)
- $VREFINT_DATA$ is the actual $VREFINT$ output value converted by the ADC
- $FULL_SCALE$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it is $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

### 29.5 ADC interrupts

An interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

29.6 ADC registers

Refer to Section 1.2 on page 104 for a list of abbreviations used in register descriptions.

29.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00
Reset value: 0x0000 0000

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 JQOVF: Injected context queue overflow
This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 29.4.21: Queue of context for injected conversions for more information.
0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
1: Injected context queue overflow has occurred

Bit 9 AWD3: Analog watchdog 3 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.
0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 3 event occurred

Bit 8 AWD2: Analog watchdog 2 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.
0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 2 event occurred

Bit 7 AWD1: Analog watchdog 1 flag
This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.
0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 1 event occurred

Bit 6 JEOS: Injected channel end of sequence flag
This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Injected conversions complete
Bit 5 **JEOC**: Injected channel end of conversion flag  
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.  
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)  
1: Injected channel conversion complete  

Bit 4 **OVR**: ADC overrun  
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.  
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)  
1: Overrun has occurred  

Bit 3 **EOS**: End of regular sequence flag  
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.  
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular Conversions sequence complete  

Bit 2 **EOC**: End of conversion flag  
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.  
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)  
1: Regular channel conversion complete  

Bit 1 **EOSMP**: End of sampling flag  
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.  
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)  
1: End of sampling phase reached  

Bit 0 **ADRDY**: ADC ready  
This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.  
It is cleared by software writing 1 to it.  
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)  
1: ADC is ready to start conversion
### 29.6.2 ADC interrupt enable register (ADC_IER)

Bits 31:11  Reserved, must be kept at reset value.

**Bit 10 JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.

- 0: Injected Context Queue Overflow interrupt disabled
- 1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

**Bit 9 AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

- 0: Analog watchdog 3 interrupt disabled
- 1: Analog watchdog 3 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

**Bit 8 AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

- 0: Analog watchdog 2 interrupt disabled
- 1: Analog watchdog 2 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

**Bit 7 AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

- 0: Analog watchdog 1 interrupt disabled
- 1: Analog watchdog 1 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

**Bit 6 JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

- 0: JEOS interrupt disabled
- 1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*
Bit 5  JEOCIE: End of injected conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4  OVRIE: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3  EOSIE: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2  EOCIE: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled.
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1  EOSMPIE: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0  ADRDYIE: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

</tr>
</tbody>
</table>
Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bit is set by software to enable the ADC voltage regulator.
Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).
Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion immediately starts (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in Single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

**Note:** The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared).
Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion immediately starts (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in Single conversion mode when software trigger is selected (EXTSEL = 0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note*: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note*: The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note*: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
29.6.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C
Reset value: 0x8000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>JQDIS: Injected Queue disable</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Injected Queue enabled</td>
</tr>
<tr>
<td>1</td>
<td>Injected Queue disabled</td>
</tr>
</tbody>
</table>

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 AWD1CH[4:0]: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel 0 monitored by AWD1
00001: ADC analog input channel 1 monitored by AWD1
.....
10010: ADC analog input channel 18 monitored by AWD1
others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.
The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 JAUTO: Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).
Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21 **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.
Refer to Section 29.4.21: Queue of context for injected conversions for more information.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable Discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

*It is not possible to use both auto-injected mode and Discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count
These bits are written by software to define the number of regular channels to be converted in Discontinuous mode, after receiving an external trigger.
000: 1 channel
001: 2 channels
...
111: 8 channels

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*
Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

- 0: Discontinuous mode for regular channels disabled
- 1: Discontinuous mode for regular channels enabled

**Note:** It is not possible to have both Discontinuous mode and Continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

It is not possible to use both auto-injected mode and Discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 15 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to Section : Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN).

- 0: Right alignment
- 1: Left alignment

**Note:** The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode:

- 0: Auto-delayed conversion mode off
- 1: Auto-delayed conversion mode on

**Note:** The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / Continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

- 0: Single conversion mode
- 1: Continuous conversion mode

**Note:** It is not possible to have both Discontinuous mode and Continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

- 0: ADC_DR register is preserved with the old data when an overrun is detected.
- 1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note:** The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

- 00: Hardware trigger detection disabled (conversions can be launched by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

- 00000: adc_ext_trg0
- 00001: adc_ext_trg1
- 00010: adc_ext_trg2
- 00011: adc_ext_trg3
- 00100: adc_ext_trg4
- 00101: adc_ext_trg5
- 00110: adc_ext_trg6
- 00111: adc_ext_trg7
- ...
- 11111: adc_ext_trg31

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 4:3 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

- 00: 12-bit
- 01: 10-bit
- 10: 8-bit
- 11: 6-bit

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SMPTRIG**: Sampling time control trigger mode
- This bit is set and cleared by software to enable the sampling time control trigger mode.
- 0: Sampling time control trigger mode disabled
- 1: Sampling time control trigger mode enabled
- The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.
- EXTEN bit should be set to 01. BULB bit must not be set when the SMPTRIG bit is set.
- When EXTEN bit is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 26 **BULB**: Bulb sampling mode
- This bit is set and cleared by software to enable the bulb sampling mode.
- 0: Bulb sampling mode disabled
- 1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.
- SMPTRIG bit must not be set when the BULB bit is set.
- The very first ADC conversion is performed with the sampling time specified in SMPx bits.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 25 **SWTRIG**: Software trigger bit for sampling time control trigger mode
- This bit is set and cleared by software to enable the bulb sampling mode.
- 0: Software trigger starts the conversion for sampling time control trigger mode
- 1: Software trigger starts the sampling for sampling time control trigger mode

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 24:17 Reserved, must be kept at reset value.

Bits 16:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular Oversampling mode
- This bit is set and cleared by software to select the regular oversampling mode.
- 0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
- 1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 9 **TROVS**: Triggered Regular Oversampling
- This bit is set and cleared by software to enable triggered oversampling
- 0: All oversampled conversions for a channel are done consecutively following a trigger
- 1: Each oversampled conversion for a channel needs a new trigger

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*
Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

- 0000: No shift
- 0001: Shift 1-bit
- 0010: Shift 2-bits
- 0011: Shift 3-bits
- 0100: Shift 4-bits
- 0101: Shift 5-bits
- 0110: Shift 6-bits
- 0111: Shift 7-bits
- 1000: Shift 8-bits
- Other codes reserved

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 4:2 **OVSR[2:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

- 000: 2x
- 001: 4x
- 010: 8x
- 011: 16x
- 100: 32x
- 101: 64x
- 110: 128x
- 111: 256x

*Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

- 0: Injected Oversampling disabled
- 1: Injected Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

- 0: Regular Oversampling disabled
- 1: Regular Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)*

Bit 31 SMPPLUS: Addition of one clock cycle to the sampling time.
1: 2.5 ADC clock cycle sampling time becomes 3.5 ADC clock cycles for the ADC_SMPR1 and ADC_SMPR2 registers.
0: The sampling time remains set to 2.5 ADC clock cycles remains

To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0.

Bit 30 Reserved, must be kept at reset value.

Bits 29:0 SMP[9:0][2:0]: Channel x sampling time selection
These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.
000: 2.5 ADC clock cycles
001: 6.5 ADC clock cycles
010: 12.5 ADC clock cycles
011: 24.5 ADC clock cycles
100: 47.5 ADC clock cycles
101: 92.5 ADC clock cycles
110: 247.5 ADC clock cycles
111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT1[11:0]**: Analog watchdog 1 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 1.
Refer to Section 29.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **AWDFILT[2:0]**: Analog watchdog filtering parameter
This bit is set and cleared by software.
- 000: No filtering
- 001: two consecutive detection generates an AWDx flag or an interrupt
- ... 111: Eight consecutive detection generates an AWDx flag or an interrupt

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 11:0  **LT1[11:0]**: Analog watchdog 1 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 1.
Refer to Section 29.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]: 4th conversion in regular sequence**

These bits are written by software with the channel number (0 to 18) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.
Bits 22:18 **SQ3[4:0]**: 3rd conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]**: 2nd conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]**: 1st conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]**: Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
... 1111: 16 conversions

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

### 29.6.12 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x34
Reset value: 0x0000 0000

---

![Table](attachment:image.png)
Bits 31:29  Reserved, must be kept at reset value.

Bits 28:24  **SQ9[4:0]**: 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23  Reserved, must be kept at reset value.

Bits 22:18  **SQ8[4:0]**: 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17  Reserved, must be kept at reset value.

Bits 16:12  **SQ7[4:0]**: 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11  Reserved, must be kept at reset value.

Bits 10:6  **SQ6[4:0]**: 6th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **SQ5[4:0]**: 5th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

rw rw rw rw rw rw rw rw rw rw rw rw rw rw
Bits 31:27 **JSQ4[4:0]**: 4th conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 4th in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]**: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]**: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]**: 1st conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).
Bits 8:7 JEXTEN[1:0]: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
00: If JQDIS = 0 (queue enabled), hardware and software trigger detection disabled.
Otherwise, the queue is disabled as well as hardware trigger detection (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

If JQM = 1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 29.4.21: Queue of context for injected conversions)

Bits 6:2 JEXTSEL[4:0]: External Trigger Selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:
00000: adc_jext_trg0
00001: adc_jext_trg1
00010: adc_jext_trg2
00011: adc_jext_trg3
00100: adc_jext_trg4
00101: adc_jext_trg5
00110: adc_jext_trg6
00111: adc_jext_trg7
... 11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 JL[1:0]: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.
00: 1 conversion
01: 2 conversions
10: 3 conversions
11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.
29.6.17 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y - 1), (y = 1 to 4)

Bit 31 OFFSET_EN: Offset y enable
This bit is written by software to enable or disable the offset programmed into bits OFFSET[11:0].

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 30:26 OFFSET_CH[4:0]: Channel selection for the data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSET[11:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the data offset y.
If OFFSET_EN is set, it is not allowed to select the same channel for different ADC_OFRy registers.

Bit 25 SATEN: Saturation enable
This bit is set and cleared by software to enable the saturation at 0x000 and 0xFFF for the offset function.

0: No saturation control, offset result can be signed
1: Saturation enabled, offset result unsigned and saturated at 0x000 and 0xFFF

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
29.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 JDATA[15:0]: Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left-or right-aligned as described in Section 29.4.26: Data management.
29.6.19 ADC Analog Watchdog 2 Configuration Register (ADC_AWD2CR)

Address offset: 0xA0
Reset value: 0x0000 0000

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 AWD2CH[18:0]: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel i is not monitored by AWD2
AWD2CH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWD2CH[18:0] = 000..0, the analog watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Some channels are not connected physically and must not be selected for the analog watchdog.

29.6.20 ADC Analog Watchdog 3 Configuration Register (ADC_AWD3CR)

Address offset: 0xA4
Reset value: 0x0000 0000

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 AWD3CH[18:0]: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWD3CH[i] = 0: ADC analog input channel i is not monitored by AWD3
AWD3CH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWD3CH[18:0] = 000..0, the analog watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
Some channels are not connected physically and must not be selected for the analog watchdog.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 **DIFSEL[18:0]: Differential mode for channels 18 to 0**.

These bits are set and cleared by software. They allow to select if a channel is configured as Single-ended or Differential mode.

\[ DIFSEL[i] = 0: \text{ADC analog input channel is configured in Single-ended mode} \]

\[ DIFSEL[i] = 1: \text{ADC analog input channel i is configured in Differential mode} \]

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (Single-ended input mode).

The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
29.6.22 ADC Calibration Factors (ADC_CALFACT)

Address offset: 0xB4
Reset value: 0x0000 0000

### ADC common registers

29.7 ADC common control register (ADC_CCR)

Address offset: 0x308
Reset value: 0x0000 0000
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **VBATEN**: VBAT enable
- This bit is set and cleared by software to control.
  - 0: VBAT channel disabled
  - 1: VBAT channel enabled

Bit 23  **TSEN**: VSENSE enable
- This bit is set and cleared by software to control \( V_{\text{SENSE}} \).
  - 0: Temperature sensor channel disabled
  - 1: Temperature sensor channel enabled

Bit 22  **VREFEN**: VREFINT enable
- This bit is set and cleared by software to enable/disable the VREFINT channel.
  - 0: VREFINT channel disabled
  - 1: VREFINT channel enabled

Bits 21:18  **PRESC[3:0]**: ADC prescaler
- These bits are set and cleared by software to select the frequency of the clock to the ADC.
- The clock is common for all the ADCs.
  - 0000: input ADC clock not divided
  - 0001: input ADC clock divided by 2
  - 0010: input ADC clock divided by 4
  - 0011: input ADC clock divided by 6
  - 0100: input ADC clock divided by 8
  - 0101: input ADC clock divided by 10
  - 0110: input ADC clock divided by 12
  - 0111: input ADC clock divided by 16
  - 1000: input ADC clock divided by 32
  - 1001: input ADC clock divided by 64
  - 1010: input ADC clock divided by 128
  - 1011: input ADC clock divided by 256
- other: reserved

*Note:* The software is allowed to write these bits only when the ADC is disabled \((ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0)\). The ADC prescaler value is applied only when \( \text{CKMODE}[1:0] = 0b00 \).

Bits 17:16  **CKMODE[1:0]**: ADC clock mode
- These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):
  - 00: \( \text{adc}_\text{ker}_\text{ck} \) \((x = 3)\) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
  - 01: \( \text{adc}_\text{hclk}/1 \) (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 \((\text{HPRE}[3:0] = 0\text{XX} \text{in} \text{RCC}\_\text{CFGR} \text{register})\) and if the system clock has a 50% duty cycle.
  - 10: \( \text{adc}_\text{hclk}/2 \) (Synchronous clock mode)
  - 11: \( \text{adc}_\text{hclk}/4 \) (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note:* The software is allowed to write these bits only when the ADCs are disabled \((ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 \text{ and } ADEN = 0)\).

Bits 15:0  Reserved, must be kept at reset value.

Refer to Section 2.3 on page 131 for the register boundary addresses.
30 Digital temperature sensor (DTS)

30.1 Introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

30.2 DTS main features

The temperature sensor block main features are the following:

- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wakeup signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)
- Quick measurement using LSE clock
30.3  DTS functional description

30.3.1  DTS block diagram

The temperature sensor block diagram is shown in Figure 284.

Figure 284. Temperature sensor functional block diagram

</tbody>
</table>
30.3.3  **DTS block operation**

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

30.3.4  **Operating modes**

Several operating modes can be selected by setting the REFCLK_SEL bit in the *Temperature sensor configuration register 1 (DTS_CFGR1)*:

- **PCLK only** (REFCLK_SEL = 0)
  - The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock

- **PCLK and LSE** (REFCLK_SEL = 1)
  - The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.

- **LSE only** (REFCLK_SEL = 1) and PCLK OFF
  - The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

30.3.5  **Calibration**

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered except for quick measurement mode (Q_MEAS_OPT set to 1 in DTS_CFGR1).

30.3.6  **Prescaler**

When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).
- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.
### 30.3.7 Temperature measurement principles

The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent (typically 641 kHz).

Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFG1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.

This counter behavior is shown in *Figure 285* and *Figure 286*.

**Figure 285. Method for low REF_CLK frequencies**

```
1. To increase the precision, FM(T) measurement can be done on several LSE periods.
```

**Figure 286. Method for high REF_CLK frequencies**

```
1. To increase the precision, PCLK measurement can be done on several FM(T) periods.
```

The counting result is stored in the DTS_DR register (see *Temperature sensor data register (DTS_DR)*).

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:
  
  \[ T = T_0 + \left( \frac{(F_{PCLK}/TS1_MFREQ) \times TS1_SMP\_TIME - 100 \times TS1\_FMT0)}{TS1\_RAMP\_COEFF} \right) \]

  where
  
  - \( T_0 \) (factory calibration temperature) is equal to 30 °C.
  - TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.
TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

\[ T = T_0 + \left( \frac{F_{LSE} \times TS1_MFREQ}{TS1_SMP\_TIME} - (100 \times TS1_FMT0) \right) / TS1_RAMP\_COEFF \]

### 30.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see Table 256).

### 30.3.9 Quick measurement mode

If a high precision is not required, the calibration step included in each measurement sequence can be skipped by setting Q_MEAS_OPT to 1 in the DTS_CFGR1 register. This method shall be used only when the LSE clock is selected as reference clock (LSREF_CLK set to 1). This mode can reduce the measurement time down to 162 µs.
30.3.10 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFGR1.

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 30.3.11: On-off control and ready flag, otherwise the trigger is ignored.

If a trigger source changes on-the-fly, the new trigger source signal should be low. If the new source signal is high, the temperature sensor detects a rising edge and start the measurement sequence.

30.3.11 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFGR1 register. The TS1_RDY flag in the Temperature sensor status register (DTS_SR) indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests will then be ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.
30.3.12 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to ‘0000’ in DTS_CFGR1.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFGR1 starts the measurement.
If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.
If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag becomes 1 and the measurement restarts.

Hardware trigger

TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see Section 30.3.5: Calibration). The measurement period depends on the following DTS_CFGR1 bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

</tr>
</tbody>
</table>

30.5  DTS interrupts

There are two ways to use the DTS block as an interrupt source. The DTS interrupt line can be connected to the CPU NVIC (see Section 30.5.2: Synchronous interrupt) or to the EXTI controller (see Section 30.5.3: Asynchronous wakeup).

30.5.1 Temperature window comparator

The DTS_ITR1 register allows defining the high and low threshold that will be used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ITLF, TS1ITHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see Section 30.6.6).

30.5.2 Synchronous interrupt

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see Section 30.5.1: Temperature window comparator).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see Section 30.6.7). All combinations of interrupts are allowed.

The TS1_ITEF, TS1_ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see Section 30.6.8).

30.5.3 Asynchronous wakeup

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see Section 30.5.1: Temperature window comparator).

Three asynchronous wakeup events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.
The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits an the their description.

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 HSREF_CLK_DIV[6:0]: High speed clock division ratio
These bits are set and cleared by software. They can be used to define the division ratio for the main clock in order to obtain the internal frequency lower than 1 MHz required for the calibration. They are applicable only for calibration when PCLK is selected as reference clock (REFCLK_SEL=0).
0000000: No divider
0000001: No divider
0000010: 1/2 division ratio
...
1111111: 1/127 division ratio

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 Q_MEAS_OPT: Quick measurement option bit
This bit is set and cleared by software. It is used to increase the measurement speed by suppressing the calibration step. It is effective only when the LSE clock is used as reference clock (REFCLK_SEL=1).
0: Measurement with calibration
1: Measurement without calibration

Bit 20 REFCLOCK_SEL: Reference clock selection bit
This bit is set and cleared by software. It indicates whether the reference clock is the high speed clock (PCLK) or the low speed clock (LSE).
0: High speed reference clock (PCLK)
1: Low speed reference clock (LSE)

Bits 19:16 TS1_SAMP_TIME[3:0]: Sampling time for temperature sensor 1
These bits allow increasing the sampling time to improve measurement precision.
When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement will be performed at TS1_SAMP_TIME period of CLK_PTAT.
When the LSE is selected as reference clock (REFCLK_SEL =1), the measurement will be performed at TS1_SAMP_TIME period of LSE.

Bits 15:12 Reserved, must be kept at reset value.
Bits 11:8 **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1
These bits are set and cleared by software. They select which input triggers a temperature measurement. Refer to Section 30.3.10: Trigger input.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TS1_START**: Start frequency measurement on temperature sensor 1
This bit is set and cleared by software.
0: No software trigger.
1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TS1_EN**: Temperature sensor 1 enable bit
This bit is set and cleared by software.
0: Temperature sensor 1 disabled
1: Temperature sensor 1 enabled

*Note*: Once enabled, the temperature sensor is active after a specific delay time. The TS1_RDY flag will be set when the sensor is ready.

### 30.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The system reset value is factory trimmed.

**Address offset**: 0x08

**System reset value**: 0x000X XXXX

#### Bits 31:18
Reserved, must be kept at reset value.

#### Bits 17:16 **TS1_T0[1:0]**: Engineering value of the T0 temperature for temperature sensor 1.
00: 30 °C
01: 130 °C
Others: Reserved, must not be used.

#### Bits 15:0 **TS1_FMT0[15:0]**: Engineering value of the frequency measured at T0 for temperature sensor 1
This value is expressed in 0.1 kHz.

### 30.6.3 Temperature sensor ramp value register (DTS_RAMPVALR)

The DTS_RAMPVALR is the ramp coefficient for the temperature sensor. The system reset value is factory trimmed.

**Address offset**: 0x10

**System reset value**: 0xXXXX XXXX
**30.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1)**

DTS_ITR1 contains the threshold values for sensor 1.

- **Address offset:** 0x14
- **System reset value:** 0x0000 0000

**TS1_RAMP_COEFF[15:0]**

- **Bits 31:16** Reserved, must be kept at reset value.
- **Bits 15:0** **TS1_RAMP_COEFF[15:0]:** Engineering value of the ramp coefficient for the temperature sensor 1.
  - This value is expressed in Hz/°C.

- **TS1_HITTHD[15:0]:** High interrupt threshold for temperature sensor 1
  - These bits are set and cleared by software. They indicate the highest value that can be reached before raising an interrupt signal.

- **TS1_LITTHD[15:0]:** Low interrupt threshold for temperature sensor 1
  - These bits are set and cleared by software. They indicate the lowest value that can be reached before raising an interrupt signal.

**30.6.5 Temperature sensor data register (DTS_DR)**

The DTS_DR contains the number of REF_CLK cycles used to compute the FM(T) frequency.

- **Address offset:** 0x1C
- **System reset value:** 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 TS1_AITHEN:** Asynchronous interrupt enable flag on high threshold for temperature sensor 1.

This bit is set and cleared by software. It enables the asynchronous interrupt when the temperature is above the high threshold (only when REFCLK_SEL = 1’b1)

0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

**Bit 5 TS1_AITLEN:** Asynchronous interrupt enable flag for low threshold on temperature sensor 1.

This bit is set and cleared by software. It enables the asynchronous interrupt when the temperature is below the low threshold (only when REFCLK_SEL = 1’b1)

0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
1: Asynchronous interrupt on low threshold enabled for temperature sensor 1
Bit 4  **TS1_AITEEN**: Asynchronous interrupt enable flag for end of measurement on temperature sensor 1
This bit is set and cleared by software.
It enables the asynchronous interrupt for end of measurement (only when REFCLK_SEL = 1).
0: Asynchronous interrupt for end of measurement disabled on temperature sensor 1
1: Asynchronous interrupt for end of measurement enabled on temperature sensor 1

Bit 3  Reserved, must be kept at reset value.

Bit 2  **TS1 _ITHEN**: Interrupt enable flag for high threshold on temperature sensor 1, synchronized on PCLK.
This bit is set and cleared by software.
It enables the interrupt when the measure reaches or is above the high threshold.
0: Synchronous interrupt for high threshold disabled on temperature sensor 1
1: Synchronous interrupt for high threshold enabled on temperature sensor 1

Bit 1  **TS1 _ITLEN**: Interrupt enable flag for low threshold on temperature sensor 1, synchronized on PCLK.
This bit is set and cleared by software.
It enables the synchronous interrupt when the measure reaches or is below the low threshold.
0: Synchronous interrupt for low threshold disabled on temperature sensor 1
1: Synchronous interrupt for low threshold enabled on temperature sensor 1

Bit 0  **TS1 _ITEEN**: Interrupt enable flag for end of measurement on temperature sensor 1, synchronized on PCLK.
This bit is set and cleared by software.
It enables the synchronous interrupt for end of measurement.
0: Synchronous interrupt for end of measurement disabled on temperature sensor 1
1: Synchronous interrupt for end of measurement enabled on temperature sensor 1

30.6.8  **Temperature sensor clear interrupt flag register (DTS_ICIFR)**
DTS_ICIFR is the control register for the interrupt flags.

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **TS1_CAITHF**: Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5  **TS1_CAITLF**: Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.
Bit 4 **TS1_CAITEF**: Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.

Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_CITHF**: Interrupt clear flag for high threshold on temperature sensor 1

Writing this bit to 1 clears the TS1_ITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF**: Interrupt clear flag for low threshold on temperature sensor 1

Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF**: Interrupt clear flag for end of measurement on temperature sensor 1

Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

### 30.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

**Address offset**: 0x2C

**System reset value**: 0x0000 0000

31 Digital-to-analog converter (DAC)

31.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, $V_{REF+}$ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer ($VREFBUF$) section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on-chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

31.2 DAC main features

The DAC main features are the following (see Figure 288: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from $V_{REF+}$ pin or internal $VREFBUF$ reference

Figure 288 shows the block diagram of a DAC channel and Table 262 gives the pin description.

31.4 DAC functional description

31.4.1 DAC block diagram

Figure 288. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and the switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 31.3: DAC implementation for channel2 availability.
31.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI clock source (dac_hold_ck).

31.4.3 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

*Note:* The ENx bit enables the analog DAC channel x only. The DAC channel x digital interface is enabled even if the ENx bit is reset.

31.4.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel
  
  There are three possibilities:

  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

  Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

</tr>
</tbody>
</table>
Dual DAC channels (when available)

There are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

- 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

- 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

31.4.5 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_pclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_pclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time tSETTLING that depends on the power supply voltage and the analog output load.

Figure 291. Timing diagram for conversion with trigger disabled TEN = 0

31.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and VREF+.

The analog output voltages on each DAC channel pin are determined by the following equation:

\[
\text{DAC output} = \frac{V_{REF}}{4096} \times \text{DOR}
\]

31.4.7 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 31.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_pclk cycles after the trigger occurs.
If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set. When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_pclk clock cycle.

31.4.8 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

31.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_pclk clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a '1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
31.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10b. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_pclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

**Figure 294. DAC triangle wave generation**

**Figure 295. DAC conversion (SW trigger enabled) with triangle wave generation**

**Note:** The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register. The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
31.4.11 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI low-speed clock (dac_hold_ck) in addition to the dac_pclk clock, allowing the DAC channels to be used in deep low power modes such as Stop mode.

The LSI low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register
The timings for the three phases above are in units of LSI clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
62 cycles are required for hold phase: THOLDx[9:0] = 62,
and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 265. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{\text{SAMP}}^{(1)(2)}$</th>
<th>$t_{\text{REFRESH}}^{(2)(3)}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu s \times (10 \times R_{\text{BON}} \times C_{\text{SH}})$</td>
<td>$7 \mu s + (R_{\text{BON}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu s \times (10 \times R_{\text{BOFF}} \times C_{\text{SH}})$</td>
<td>$3 \mu s + (R_{\text{BOFF}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. $C_{\text{SH}}$ is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase "Vd" is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*NLSB) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{\text{SH}} = 100 \text{ nF}$

$V_{\text{REF+}} = 3.0 \text{ V}$

Sampling phase:

$t_{\text{SAMP}} = 7 \mu s + (10 \times 2000 \times 100 \times 10^{-9}) = 2.007 \text{ ms}$

(where $R_{\text{BON}} = 2 \text{ k}\Omega$)

Refresh phase:

$t_{\text{REFRESH}} = 7 \mu s + (2000 \times 100 \times 10^{-9}) \times \ln(2 \times 10) = 606.1 \mu s$

(where $N_{\text{LSB}} = 10$ (10 LSB drop during the hold phase))

Hold phase:

$D_v = i_{\text{leak}} \times t_{\text{hold}} / C_{\text{SH}} = 0.0073 \text{ V}$ (10 LSB of 12bit at 3 V)

$i_{\text{leak}} = 150 \text{ nA}$ (worst case on the IO leakage on all the temperature range)

$t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \text{ ms}$
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, $C_{\text{int}}$, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{out} = \left( \frac{D}{2^N} \right) \times G \times V_{ref} + V_{OS} \]

Where \( V_{OUT} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{ref} \) is the nominal full-scale voltage, and \( V_{os} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{os} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{os} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{REF}+2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming
  
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{DDA} \) voltage, temperature, \( V_{REF}+ \) values change and can be done at any point during application by software.

**Note:** Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{DD} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

---

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

**Note:**
A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers, then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

**When CENx bit is set, it is not allowed to set ENx bit.**

### 31.4.13 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

**Independent trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_pclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_pclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.
**Independent trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Independent trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous software start**

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_pclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

**Simultaneous trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_pclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVE[x][1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[x][1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[x][1:0] bits as 1x and the same maximum amplitude value using the MAMP[x][3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[x][1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the DAC channel2 triangle counter is updated.

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 31.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_pclk clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_pclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_pclk clock cycle.

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*
Bit 16  **EN2**: DAC channel2 enable
        This bit is set and cleared by software to enable/disable DAC channel2.
        0: DAC channel2 disabled
        1: DAC channel2 enabled

        **Note**: These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CEN1**: DAC channel1 calibration enable
        This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
        0: DAC channel1 in Normal operating mode
        1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
        This bit is set and cleared by software.
        0: DAC channel1 DMA Underrun Interrupt disabled
        1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable
        This bit is set and cleared by software.
        0: DAC channel1 DMA mode disabled
        1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
        These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
        0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
        0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
        0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
        0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
        0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
        0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
        0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
        0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
        1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
        1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
        1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
        ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
        These bits are set and cleared by software.
        00: wave generation disabled
        01: Noise wave generation enabled
        1x: Triangle wave generation enabled
        Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2  **TSEL[3:0]:** DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in *Section 31.4.2: DAC pins and internal signals* for details on trigger configuration and mapping.

*Note:* Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1  **TEN1:** DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_pclk clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_pclk clock cycles later to the DAC_DOR1 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_pclk clock cycle.

Bit 0  **EN1:** DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register. This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

These bits are read-only, they contain DMA unit status for DAC channel2.
Bit 31 **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

*Note:* This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

*Note:* This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

*Note:* This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 Reserved, must be kept at reset value.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bits 23:19 Reserved, must be kept at reset value.
Bits 18:16 **MODE2[2:0]:** DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  
  000: DAC channel2 is connected to external pin with Buffer enabled
  
  001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  
  010: DAC channel2 is connected to external pin with buffer disabled
  
  011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- DAC channel2 in Sample and hold mode
  
  100: DAC channel2 is connected to external pin with Buffer enabled
  
  101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  
  110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  
  111: DAC channel2 is connected to on chip peripherals with Buffer disabled

*Note:* This register can be modified only when EN2 = 0.

Refer to Section 31.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]:** DAC channel1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:

- DAC channel1 in Normal mode
  
  000: DAC channel1 is connected to external pin with Buffer enabled
  
  001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  
  010: DAC channel1 is connected to external pin with Buffer disabled
  
  011: DAC channel1 is connected to on chip peripherals with Buffer disabled

- DAC channel1 in sample & hold mode
  
  100: DAC channel1 is connected to external pin with Buffer enabled
  
  101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  
  110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  
  111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note:* This register can be modified only when EN1 = 0.

</tr>
</tbody>
</table>
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **TREFRESH2[7:0]**: DAC channel2 refresh time (only valid in Sample and hold mode)
            Refresh time = (TREFRESH[7:0]) x LSI clock period
            Note:  This register can be modified only when EN2 = 0.
            These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **TREFRESH1[7:0]**: DAC channel1 refresh time (only valid in Sample and hold mode)
            Refresh time = (TREFRESH[7:0]) x LSI clock period
            Note:  This register can be modified only when EN1 = 0.

Note:  These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx = 0 and bit CENx = 0 in the DAC_CR register). If ENx = 1 or CENx = 1 the write operation is ignored.
31.7.21  DAC register map

Table 269 summarizes the DAC registers.

| Offset | Register name     | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to *Section 2.3 on page 131* for the register boundary addresses.
32 **Voltage reference buffer (VREFBUF)**

32.1 **Introduction**

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

32.2 **VREFBUF functional description**

The internal voltage reference buffer supports four voltages\(^{(a)}\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: around 2.5 V.
- VRS = 001: around 2.048 V.
- VRS = 010: around 1.8 V.
- VRS = 011: around 1.5 V (ADC and DAC peripherals are not compatible with this reference voltage setting).

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin pulled-down to V(_{SSA})</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

---

\(a\). The minimum V\(_{DDA}\) voltage depends on VRS setting, refer to the product datasheet.

</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale
These bits select the value generated by the voltage reference buffer.
- 000: Voltage reference set to 2.5 V
- 001: Voltage reference set to 2.048 V
- 010: Voltage reference set to 1.8 V
- 011: Voltage reference set to 1.5 V
- Others: Reserved

*Note: The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).*

Bit 3 **VRR**: Voltage reference buffer ready
- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ**: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to Table 270: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR**: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
32.3.2 **VREFBUF calibration control register (VREFBUF_CCR)**

<th>Bits 5:0</th>
</tr>
</thead>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]: Trimming code**

These bits are automatically initialized after reset with the trimming value stored in the Flash memory during the production test. Writing into these bits allows the tuning of the internal reference buffer voltage.

**Note:** If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

32.3.3 **VREFBUF register map**

The following table gives the VREFBUF register map and the reset values.

Refer to Section 2.3 on page 131 for the register boundary addresses.
33 Comparator (COMP)

33.1 Introduction

The device embeds two ultra-low-power comparator channels (COMP1 and COMP2). They can be used for a variety of functions including:
- wake up from low-power mode triggered by an analog signal
- analog signal conditioning
- cycle-by-cycle current control loop when combined with a PWM output from a timer

33.2 COMP main features

- Selectable inverting analog inputs:
  - I/O pins (different for either channel)
  - DAC Channel1 and Channel2 outputs
  - internal reference voltage and three sub multiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Two I/O pins per channel selectable as non-inverting analog inputs
- Programmable hysteresis
- Programmable speed / consumption
- Mapping of outputs to I/Os
- Redirection of outputs to timer inputs for triggering:
  - capture events
  - OCREF_CLR events (for cycle-by-cycle current control)
  - break events for fast PWM shutdowns
- Blanking of comparator outputs
- Window comparator
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)
- Direct interrupt output to the CPU
33.3 COMP functional description

33.3.1 COMP block diagram

The block diagram of the comparators is shown in Figure 297: Comparator functional block diagram.

![Figure 297. Comparator functional block diagram](image)

33.3.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet.
The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- cycle-by-cycle current control, using ETR inputs of timers
- input capture for timing measurements

The comparator output can be routed simultaneously internally and to the I/O pins.

33.3.3 COMP reset and clocks

The clock comp_pclk provided by the clock controller is synchronous with the APB clock.

**Note:** Important: The polarity selection logic and the output redirection to the port works independently from the APB clock. This allows the comparator to work even in Stop mode. The interrupt line, connected to the NVIC of CPU, requires the APB clock (comp_pclk) to work. In absence of the APB clock, the interrupt signal comp_it cannot be generated.

33.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications with specific functional safety requirements, the comparator configuration can be protected against undesired alteration that could happen, for example, at program counter corruption.

For this purpose, the comparator configuration registers can be write-protected (read-only).

Upon configuring a comparator channel, its LOCK bit is set to 1. This causes the whole register set of the comparator channel, as well as the common COMP_OR register, to become read-only, the LOCK bit inclusive.

The write protection can only be removed through the MCU reset.

The COMP_OR register is locked by the LOCK bit of COMP_CFGR1 OR COMP_CFGR2.

33.3.5 Window comparator

The purpose of the window comparator is to monitor the analog voltage and check that it is comprised within the specified voltage range defined by lower and upper thresholds.

The window comparator requires both COMP channels. The monitored analog voltage is connected to their non-inverting (plus) inputs and the upper and lower threshold voltages are connected to the inverting (minus) input of either comparator, respectively. The non-inverting input of the COMP channel 2 can be connected internally with the non-inverting input of the COMP channel 1 by enabling WINMODE bit. This can save the input pins of COMP channel 2 for other purposes. See Figure 297: Comparator functional block diagram.

33.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.
33.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals. The blanking signal gates the internal comparator output such as to clean the comp_out from spurious pulses due to current spikes, as depicted in Figure 299 (the COMP channel number is not represented).

**Figure 298. Comparator hysteresis**

**Figure 299. Comparator output blanking**
33.3.8 Comparator output on GPIOs

The COMP1_OUT and COMP2_OUT outputs of the comparator channels are mapped to GPIOs through the AFOP field of the COMP.OR register, bits [10:0], and through the GPIO alternate function.

<tr>
<td>PK2</td>
<td>AF10, AF11 (can be used as timer break in)</td>
</tr>
</tbody>
</table>
The assignment to GPIOs for both comparator channel outputs must be done before locking registers of any channel, because the common COMP_OR register is locked when locking the registers of either comparator channel.

33.3.9 Comparator output redirection

The outputs of either COMP channel can be redirected to timer break inputs (TIMx_BKIN or TIMx_BKIN2), as shown in Figure 300. For that end, the COMP channel output is connected to one of GPIOs programmable in alternate function as timer break input. See Table 274 and Table 275. The selected GPIO(s) must be set in open drain mode. The COMP output passes through the GPIO to the timer break input. With a pull-up resistor, the selected GPIO can be used as timer break input logic OR-ed with the comparator output.

33.3.10 COMP power and speed modes

The power consumption of the COMP channels versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMP_CFGRx registers can be programmed as follows:

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Very-low speed / ultra-low-power
33.4 COMP low-power modes

Table 276. Comparator behavior in the low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.</td>
</tr>
</tbody>
</table>

Note: The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

33.5 COMP interrupts

There are two ways to use the comparator as interrupt source.

The comparator outputs are internally connected to the Extended interrupt and event controller. Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

The comparators also provide an interrupt line to the NVIC of CPU. This functionality is used when the CPU is active to handle low latency interrupt. It requires APB clock running.

33.5.1 Interrupt through EXTI block

Refer to Interrupt and events section for more details.

Sequence to enable the COMPx interrupt through EXTI block:
1. Configure the EXTI line, receiving the comp_wkup signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

Table 277. Interrupt control bits

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
### 33.5.2 Interrupt through NVIC of the CPU

Sequence to enable the COMPx interrupt through NVIC of the CPU:
1. Configure and enable the NVIC IRQ channel mapped to the comp_it line.
2. Configure and enable the ITEN in COMP_CFGRx.
3. Enable the COMPx.

**Table 278. Interrupt control bits**

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Interrupt flag</th>
<th>Enable control bit</th>
<th>Interrupt clear bit</th>
<th>Exit from Sleep mode</th>
<th>Exit from Stop modes</th>

</tr>
<tr>
<td>comp_it</td>
<td>C2IF in</td>
<td>ITEN in COMP_CFGR2</td>
<td>CC2IF</td>
<td>yes (With APB clock)</td>
<td>no</td>
</tr>
</tbody>
</table>

**Note:** It is mandatory to enable APB clock to use this interrupt. If clock is not enabled, interrupt is not generated.

### 33.6 SCALER function

The scaler block is available to provide the different voltage reference levels to the comparator inputs. It is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference.

The amplifier and the resistor bridge can be enabled separately. The amplifier is enabled by the SCALEN bits of the COMP_CFGRx registers. The resistor bridge is enabled by the BRGEN bits of the COMP_CFGRx registers.

When the resistor divided voltage is not used, the resistor bridge can be disconnected in order to reduce the consumption. When it is disconnected, the 1/4 \( V_{REF\_COMP} \), 1/2 \( V_{REF\_COMP} \) and 3/4 \( V_{REF\_COMP} \) levels are equal to \( V_{REF\_COMP} \).

![Figure 301. Scaler block diagram](MSv38379V1)
33.7 COMP registers

33.7.1 Comparator status register (COMP_SR)

The COMP_SR is the comparator status register.

Address offset: 0x00

System reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 AFOP[10:0]: Selection of source for alternate function of output ports

Bits of this field are set and cleared by software (only if LOCK not set).

Output port (GPIO) correspondence:

- bit 10: PK2
- bit 9: PI4
- bit 8: PI1
- bit 7: PG4
- bit 6: PG3
- bit 5: PG2
- bit 4: PE15
- bit 3: PE6
- bit 2: PB12
- bit 1: PA8
- bit 0: PA6

For each bit:

0: COMP1.OUT is selected for the alternate function of the corresponding GPIO
1: COMP2.OUT is selected for the alternate function of the corresponding GPIO
Bit 31  **LOCK**: Lock bit
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 1 configuration register COMP_CFR1[31:0], and COMP.OR register
0: COMP_CFR1[31:0] register is read/write
1: COMP_CFR1[31:0] and COMP.OR registers are read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]**: COMP channel 1 blanking source selection bits
Bits of this field are set and cleared by software (only if LOCK not set).
The field selects the input source for COMP channel 1 output blanking:
0000: No blanking
0001: comp_blk1
0010: comp_blk2
0011: comp_blk3
0100: comp_blk4
0101: comp_blk5
0110: comp_blk6
All other values: reserved

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **INPSEL**: COMP channel 1 non-inverting input selection bit
This bit is set and cleared by software (only if LOCK not set).
0: COMP1_INP1 (PB0)
1: COMP1_INP2 (PB2)

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **INMSEL[2:0]**: COMP channel 1 inverting input selection field
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 1.
000 = 1/4 VREF_COMP
001 = 1/2 VREF_COMP
010 = 3/4 VREF_COMP
011 = VREF_COMP
100 = comp_inm1 (DAC channel 1 output)
101 = comp_inm2 (DAC channel 2 output)
110 = COMP1_INM1 (PB1)
111 = COMP1_INM2 (PC4)

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **PWRMODE[1:0]**: Power Mode of the COMP channel 1
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 1.
00: High speed / full power
01: Medium speed / medium power
10: Medium speed / medium power
11: Ultra low power / ultra-low-power

Bits 11:10 Reserved, must be kept at reset value.
### Comparator configuration register 2 (COMP_CFGR2)

The COMP_CFGR2 is the COMP channel 2 configuration register.

**Address offset**: 0x10

**System reset value**: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
</table>

**33.7.5 Comparator configuration register 2 (COMP_CFGR2)**

Bits 9:8 **HYST[1:0]**: COMP channel 1 hysteresis selection bits

These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 1.

- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 1 interrupt enable

This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 1.

- 0: Interrupt generation disabled for COMP channel 1
- 1: Interrupt generation enabled for COMP channel 1

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **POLARITY**: COMP channel 1 polarity selection bit

This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 1 polarity.

- 0: COMP channel 1 output is not inverted
- 1: COMP channel 1 output is inverted

Bit 2 **SCALEN**: Voltage scaler enable bit

This bit is set and cleared by software (only if LOCK not set). This bit enables the VREFINT scaler for the COMP channels.

- 0: VREFINT scaler disabled (if SCALEN bit of COMP_CFGR2 register is also low)
- 1: VREFINT scaler enabled

Bit 1 **BRGEN**: Scaler bridge enable

This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.

- 0: Scaler resistor bridge disabled (if BRGEN bit of COMP_CFGR2 register is also low)
- 1: Scaler resistor bridge enabled

If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level VREF_COMP (similar to VREFINT).

If SCALEN and BRGEN are set, the four scaler outputs provide VREF_COMP, 3/4 VREF_COMP, 1/2 VREF_COMP and 1/4 VREF_COMP levels, respectively.

Bit 0 **EN**: COMP channel 1 enable bit

This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 1.

- 0: Disable
- 1: Enable

#### Bit 31 LOCK:
- This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 2 configuration register COMP_CFRG2[31:0], and COMP_OR register.

#### Bits 30:28 Reserved:
- Must be kept at reset value.

#### Bits 27:24 BLANKING[3:0]:
- COMP channel 2 blanking source selection bits
- These bits are set and cleared by software (only if LOCK not set). These bits select which timer output controls the COMP channel 2 output blanking.

#### Bits 23:21 Reserved:
- Must be kept at reset value.

#### Bit 20 INPSEL:
- COMP channel 2 non-inverting input selection bit
- This bit is set and cleared by software (only if LOCK not set).

#### Bit 19 Reserved:
- Must be kept at reset value.

#### Bits 18:16 INMSEL[2:0]:
- COMP channel 2 inverting input selection field
- These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 2.

#### Bits 15:14 Reserved:
- Must be kept at reset value.

#### Bits 13:12 PWRMODE[1:0]:
- Power Mode of the COMP channel 2
- These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 2.

#### Bits 11:10 Reserved:
- Must be kept at reset value.
Bits 9:8 **HYST[1:0]**: COMP channel 2 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 2.

00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 2 interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the interrupt generation of the COMP channel 2.

0: Interrupt generation disabled for COMP channel 2
1: Interrupt generation enabled for COMP channel 2

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WINMODE**: Window comparator mode selection bit
This bit is set and cleared by software (only if LOCK not set). This bit selects the window mode of the comparators. If set, the non-inverting input of COMP channel 2 is connected to the non-inverting input of the COMP channel 1.

Depending on the bit value, the non-inverting input of COMP channel 2 is connected to:

0: COMP2_INP input selector
1: Non-inverting input comp1_inp of COMP channel 1

Bit 3 **POLARITY**: COMP channel 2 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 2 polarity.

0: COMP channel 2 output is not inverted
1: COMP channel 2 output is inverted

Bit 2 **SCALEN**: Voltage scaler enable bit
This bit is set and cleared by software (only if LOCK not set). This bit enables the $V_{REFINT}$ scaler for the COMP channels.

0: $V_{REFINT}$ scaler disabled (if SCALEN bit of COMP_CFGR1 register is also low)
1: $V_{REFINT}$ scaler enabled

Bit 1 **BRGEN**: Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.

0: Scaler resistor bridge disabled (if BRGEN bit of COMP_CFGR1 register is also low)
1: Scaler resistor bridge enabled

If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level $V_{REF_{COMP}}$ (similar to $V_{REFINT}$).

If SCALEN and BRGEN are set, the four scaler outputs provide $V_{REF_{COMP}}$, 3/4 $V_{REF_{COMP}}$, 1/2 $V_{REF_{COMP}}$ and 1/4 $V_{REF_{COMP}}$ levels, respectively.

Bit 0 **EN**: COMP channel 2 enable bit
This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 2.

0: Disable
1: Enable
### 33.7.6 COMP register map

The following table summarizes the comparator registers.

#### Table 279. COMP register map and reset values

| Offset | Register name | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| 0x00   | COMP_SR       |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|        | Reset value   | 0 | 0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Refer to Section 2.3 on page 131 for the register boundary addresses.
34 Operational amplifiers (OPAMP)

34.1 Introduction

The devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, thus enabling any type of external interconnections. The operational amplifiers can be configured internally as a follower, as an amplifier with a non-inverting gain ranging from 2 to 16 or with inverting gain ranging from -1 to -15.

Refer to Section 34.3.3: Signal routing for detailed information on OPAMP input and output connection to internal peripherals.

34.2 OPAMP main features

- Rail-to-rail input and output voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 10 mV with factory calibration)
- 7 MHz gain bandwidth
- High-speed mode to achieve a better slew rate

Note: Refer to the product datasheet for detailed OPAMP characteristics.

34.3 OPAMP functional description

The OPAMP has several modes. Each OPAMP can be individually enabled, when disabled the output is high-impedance. When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in Section 34.3.3: Signal routing.

34.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in Section 8.7.43: RCC APB1 clock register (RCC_APB1LENR)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.
34.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three input/outputs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values for its offset calibration. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see Section 34.3.5: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the standard performance. The bit OPAHSM can be set in order to switch the operational amplifier to high-speed mode for a better slew rate. Both normal and high-speed mode characteristics are defined in Section: Electrical characteristics of the datasheet.

As soon as the OPAEN bit in OPAMPx_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 34.3.3: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

34.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMPx_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

Table 280. Operational amplifier possible connections

### 34.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

**Note:** The amplifier output pin is directly connected to the output pad to minimize the output impedance. When the amplifier is enabled, it cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the internal channel.

The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

#### Standalone mode (external gain setting mode)

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMPx_CSR, and the default state of GPIOx_MODER, as soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPAHSM can be set to "operational amplifier high-speed" mode in order to have high slew rate.
- USERTRIM can be set to modify the trimming values for input offsets.

---

**Table 280. Operational amplifier possible connections (continued)**

</tr>
<tr>
<td>OPAMP2_VOUT(1)</td>
<td>PE7</td>
<td>COMP2_INN7</td>
<td>-</td>
</tr>
</tbody>
</table>

1. Both OPAMP1_VOUT and OPAMP2_VOUT are not available on all packages. The unconnected OPAMP must not be activated (see Section 34.6.1: OPAMP1 control/status register (OPAMP1_CSR)).
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure VM_SEL bits as “opamp_out connected to OPAMPx_VINM input”, 11
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00
- As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is buffered to pin OPAMPx_VOUT.

**Note:** The pin corresponding to OPAMPx_VINM is free for another usage.

The signal on the OPAMP1 output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.
Figure 303. Follower configuration

Programmable gain amplifier mode

The procedure to use the OPAMP as programmable gain amplifier is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16”, 0000 to 0011
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00

As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is amplified by the selected gain and visible on pin OPAMPx_VOUT.

Note: To avoid saturation, the input voltage should stay below VDDA divided by the selected gain.

Figure 304. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”.
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16 with filtering on INM0”, 0100 to 0111
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on INM can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and INM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 305. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input used for filtering

Figure 309. Example configuration
34.3.5 Calibration

The OPAMP interface continuously sends trimmed offset values to the operational amplifiers. At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each operational amplifier can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for high-speed mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the input offset voltage to less than +/-1.5 mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming value needs to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMPx_OTR) and one high-speed mode (OPAMPx_HSOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMPx_CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP option registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 01 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 11 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPAHSM. The software should increment the TRIMOFFSETN bits in the OPAMP control register from 0x00 to the first value that causes the CALOUT bit to change from 1 to 0 in the OPAMP register. If the CALOUT bit is reset, the offset is calibrated correctly and the corresponding trimming value must be stored. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see $t_{OFFTRIM\text{max}}$ delay specification in the electrical characteristics section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set the OPAEN bit in OPAMPx_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMPx_CSR register to 1.
3. Choose a calibration mode (refer to Table 281: Operating modes and calibration). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
   - Normal mode and N differential pair
   The above calibration mode correspond to OPAHSM=0 and CALSEL=11 in the OPAMPx_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 00000b until CALOUT changes to 0 in OPAMPx_CSR.

Note: Between the write to the OPAMPx_OTR register and the read of the CALOUT value, make sure to wait for the tOFFTRIMmax delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the is correctly compensated and that the corresponding trim code must be saved in the OPAMPx_OTR register.

Repeat steps 3 to 4 for:
- Normal mode and P differential pair, CALSEL=01
- High-speed mode and N differential pair
- High-speed mode and P differential pair

If a mode is not used, it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 µA.

</table>

34.5 OPAMP PGA gain

When OPAMP is configured asPGA mode, it can select the gain of x2, x4, x8, x16 for non-inverting mode and x-1, x-3, x-7, x-15 for inverting mode.

When OPAMP is configured as non-inverting mode, the Gain error can be refer to the product datasheet. When it is configured as inverting mode, Gain factor is defined not only the on chip feedback resistor but also the signal source output impedance. If signal source output impedance is not negligible compare to the input feedback resistance of PGA, it will create the gain error. Please refer to the PGA resistance value in the product datasheet.

34.6 OPAMP registers

The registers of this peripheral can only be accessed by-word (32-bit).

34.6.1 OPAMP1 control/status register (OPAMP1_CSR)

Address: 0x00
Reset value: 0x0000 0000

<td>1: INTVREF of OPAMP is output</td>
</tr>
</tbody>
</table>
Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **USERTRIM**: User trimming enable

This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values.

This bit is active for both mode normal and high-power.

0: ‘factory’ trim code used
1: ‘user’ trim code used

Bits 17:14 **PGA_GAIN**: Operational amplifier Programmable amplifier gain value

- 0000: Non-inverting internal Gain 2, VREF- referenced
- 0001: Non-inverting internal Gain 4, VREF- referenced
- 0010: Non-inverting internal Gain 8, VREF- referenced
- 0011: Non-inverting internal Gain 16, VREF- referenced
- 0100: Non-inverting internal Gain 2 with filtering on INM0, VREF- referenced
- 0101: Non-inverting internal Gain 4 with filtering on INM0, VREF- referenced
- 0110: Non-inverting internal Gain 8 with filtering on INM0, VREF- referenced
- 0111: Non-inverting internal Gain 16 with filtering on INM0, VREF- referenced
- 1000: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias
- 1001: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias
- 1010: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias
- 1011: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias
- 1100: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias, INM1 node for filtering
- 1101: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias, INM1 node for filtering
- 1110: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias, INM1 node for filtering
- 1111: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias, INM1 node for filtering

Bits 13:12 **CALSEL**: Calibration selection

It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.

- 00: 0.033*VDDA applied on OPAMP inputs
- 01: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
- 10: 0.5*VDDA applied on OPAMP inputs
- 11: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON**: Calibration mode enabled

0: Normal mode
1: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAHSN**: Operational amplifier high-speed mode

The operational amplifier must be disable to change this configuration.

0: operational amplifier in normal mode
1: operational amplifier in high-speed mode

Bit 7 Reserved, must be kept at reset value.
Bits 6:5 **VM_SEL**: Inverting input selection
   - 00: INM0 connected to OPAMP INM input
   - 01: INM1 connected to OPAMP NM input
   - 10: Feedback resistor is connected to OPAMP INM input (PGA mode). Inverting input selection is depends on the PGA_GAIN setting
   - 11: opamp_out connected to OPAMP INM input (Follower mode)

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **VP_SEL**: Non inverting input selection
   - 00: GPIO connected to OPAMPx_VINP
   - 01: dac_outx connected to OPAMPx_VINP
   - 10: Reserved
   - 11: Reserved

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
   - 0: Normal operating mode. Non-inverting input connected to inputs.
   - 1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
   - 0: operational amplifier disabled
   - 1: operational amplifier enabled

*Note: If OPAMP1 is unconnected in a specific package, it must remain disabled (keep OPAMP1_CSR register default value).*

Refer to Section 2.3 on page 131 for the register boundary addresses.
35 Digital filter for sigma delta modulators (DFSDM)

35.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external ΣΔ modulators. It is featuring up to 8 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from device memory.

An external ΣΔ modulator provides digital data stream of converted analog values from the external ΣΔ modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various ΣΔ modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 8 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 8 internal 16-bit data channels (from internal ADCs or from device memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a ΣΔ modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0’s or 1’s in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.
35.2 DFSDM main features

- Up to 8 multiplexed input digital serial channels:
  - configurable SPI interface to connect various ΣΔ modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for ΣΔ modulator(s)
- Alternative inputs from up to 8 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - Sinc\(x\) filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable Sinc\(x\) digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0’s or 1’s on input data stream
  - monitoring continuously each channel (8 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- Pulse skipper feature to support beamforming applications (delay line like behavior)
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions
  - “injected” conversions for precise timing and with high conversion priority
### 35.3 DFSDM implementation

This section describes the configuration implemented in DFSDMx.

35.4.3 DFSDM reset and clocks

DFSDM on-off control

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..7) and digital filters DFSDM_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM_CHyCFGR1 and DFSDM_FLTx enable bit DFEN in DFSDM_FLTxCR1).

Digital filter x DFSDM_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM_FLTxCR1 register. Once DFSDM_FLTx is enabled (DFEN=1), both Sincx digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM_FLTx is put into stop mode. All register settings remain unchanged except DFSDM_FLTxAWSR and DFSDM_FLTxISR (which are reset).

Channel y (y=0..7) is enabled by setting CHEN=1 in the DFSDM_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external ΣΔ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.
DFSDM clocks

The internal DFSDM clock f_{DFSDMCLK}, which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK or peripheral clock PCLK2 (see Section 8.7.19: RCC domain 2 kernel clock configuration register (RCC_D2CCIP1R)). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM_FLTx, x=0..3).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external \(\Sigma\Delta\) modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see Section 8.7.19: RCC domain 2 kernel clock configuration register (RCC_D2CCIP1R)).

35.4.4 Serial channel transceivers

There are 8 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external \(\Sigma\Delta\) modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM_CHyCFGR1 register).

The channel is enabled for operation by setting CHEN=1 in DFSDM_CHyCFGR1 register.

Channel inputs selection

Serial inputs (data and clock signals) from DATINy and CKINy pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).
Configuration of serial channels for PDM microphone input:

- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel \(y\) (DATIN\(y\), CKOUT) pins.
- Channel \(y\) will be configured: CHINSEL = 0 (input from given channel pins: DATIN\(y\), CKIN\(y\)).
- Channel \((y-1)\) (modulo 8) will be configured: CHINSEL = 1 (input from the following channel \(((y-1)+1)\) pins: DATIN\(y\), CKIN\(y\)).
- Channel \(y\): SITP\([1:0]\) = 0 (rising edge to strobe data) => left audio channel on channel \(y\).
- Channel \((y-1)\): SITP\([1:0]\) = 1 (falling edge to strobe data) => right audio channel on channel \(y-1\).
- Two DFSDM filters will be assigned to channel \(y\) and channel \((y-1)\) (to filter left and right channels from PDM microphone).

**Figure 311. Input channel pins redirection**

![Diagram showing input channel pins redirection](attachment:figure311.png)
Output clock generation

A clock signal can be provided on CKOUT pin to drive external ΣΔ modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) divided by a predivider (see CKOUTDIV bits in DFSDM_CH0CFGR1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM_CHyCFGR1 register or by DFSDMEN=0 in DFSDM_CH0CFGR1 register). The output clock stopping is performed:

- 4 system clocks after DFSDMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSDMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.

SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATINy pin. A clock signal can be provided externally from CKINy pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATINy pin) is sampled on rising or falling clock edge (of CKINy pin) according SITP[1:0] bits setting (in DFSDM_CHyCFGR1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM_CHyCFGR1 register:

- CKOUT signal:
  - For connection to external ΣΔ modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according SITP[1:0] setting.

- CKOUT/2 signal (generated on CKOUT rising edge):
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.

- CKOUT/2 signal (generated on CKOUT falling edge):
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

Note: An internal clock source can only be used when the external ΣΔ modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKINy pin connection (CKINy pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than f_{DFSDMCLK}/4.

Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATINy pin only. Decoded data and clock signal are recovered from serial stream after Manchester
decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than $f_{DFSDMCLK}/6$.

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

$$((CKOUTDIV + 1) \times T_{SYSCLK}) < T_{Manchester\ clock} < (2 \times CKOUTDIV \times T_{SYSCLK})$$

Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel \( y \) by bit \( \text{CKABEN} \) in DFSDM\_CH\( y \)CFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set (\( \text{CKABF}[y] = 1 \)) and an interrupt can be invoked (if \( \text{CKABIE} = 1 \)) in case of an input clock error (see \( \text{CKABF}[7:0] \) in DFSDM\_FLT0ISR register and \( \text{CKABEN} \) in DFSDM\_CH\( y \)CFGR1). After a clock absence flag clearing (by \( \text{CLRCKABF} \) in DFSDM\_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit \( \text{CKABF}[y] \) is set also by hardware when corresponding channel \( y \) is disabled (if \( \text{CHEN}[y] = 0 \) then \( \text{CKABF}[y] \) is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the \( \text{CKOUT} \) signal (\( \text{CKOUTSRC} = 0 \) in DFSDM\_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by \( \text{CLRCKABF}[y] \) bit (in DFSDM\_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by \( \text{CHEN} = 1 \)
- Try to clear the clock absence flag (by \( \text{CLRCKABF} = 1 \)) until the clock absence flag is really cleared (\( \text{CKABF} = 0 \)). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature \( \text{CKABEN} = 1 \) and the associated interrupt \( \text{CKABIE} = 1 \) to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (\( \text{CKOUT} \) signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of \( \text{CKOUT} \) signal (which is controlled by \( \text{CKOUTDIV} \) field in DFSDM\_CH0CFGR1 register).

![Figure 313. Clock absence timing diagram for SPI](image)

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 315 for Manchester synchronization).
The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DATINy pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM_CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal.

So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

\[ ((\text{CKOUTDIV} + 1) \times T_{\text{SYCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYCLK}}) \]

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[7:0] in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed.

Figure 314. Clock absence timing diagram for Manchester coding
Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM_CHyCFGR1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM_FLT0ICR, following the software sequence detailed hereafter:

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signalizing that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according the formula below.

\[
((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) \times T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})
\]

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

**Note:** When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register).
External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external ΣΔ modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks \( f_{DFSDMCLK} \) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM_FLTxCNVTIMR register).

In case of parallel data input (Section 35.4.6: Parallel data inputs) the measured frequency is the average input data rate during one conversion.
Note: When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

 injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):
- for Sinc\(^{x}\) filters (x=1..5):
  \[ t = \frac{\text{CNVCNT} / f_{\text{DFSDMCLK}}}{F_{\text{OSR}} \ast (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}}} / f_{\text{CKIN}} \]
- for FastSinc filter:
  \[ t = \frac{\text{CNVCNT} / f_{\text{DFSDMCLK}}}{F_{\text{OSR}} \ast (I_{\text{OSR}} - 1 + 4) + 2} / f_{\text{CKIN}} \]

 regular conversion with FAST = 1 (except first conversion):
- for Sinc\(^{x}\) and FastSinc filters:
  \[ t = \frac{\text{CNVCNT} / f_{\text{DFSDMCLK}}}{F_{\text{OSR}} \ast I_{\text{OSR}}} / f_{\text{CKIN}} \]
- in case if \( F_{\text{OSR}} = \text{FOSR}[9:0]+1 = 1 \) (filter bypassed, active only integrator):
  \[ t = \frac{I_{\text{OSR}}}{f_{\text{CKIN}}} \]

where:
- \( f_{\text{CKIN}} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate (in case of parallel data input)
- \( F_{\text{OSR}} \) is the filter oversampling ratio: \( F_{\text{OSR}} = \text{FOSR}[9:0]+1 \) (see DFSDM_FLTxFCR register)
- \( I_{\text{OSR}} \) is the integrator oversampling ratio: \( I_{\text{OSR}} = \text{IOSR}[7:0]+1 \) (see DFSDM_FLTxFCR register)
- \( F_{\text{ORD}} \) is the filter order: \( F_{\text{ORD}} = \text{FORD}[2:0] \) (see DFSDM_FLTxFCR register)

Channel offset setting

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM_CHyCFGR2 register.

Data right bit shift

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.

Pulses skipper

Purpose of the pulses skipper is to implement delay line like behavior for given input channel(s). Given number of samples from input serial data stream (serial stream only) can be discarded before they enter into the filter. This data discarding is performed by skipping given number of sampling input clock pulses (given serial data samples are then not sampled by filter). The sampling clock is gated by pulses skipper function for given number of clock pulses. When given clock pulses are skipped then the filtering continues for following input data. With comparison to non skipped data stream this operation causes that
the final output sample (and next samples) from filter will be calculated from later input data. This final sample then looks a bit in forward - because it is calculated from newer input samples than the “non-skipped” sample. The final “skipped” sample is converted later because the skipped input data samples must be replaced by followed input data samples. The final data buffers behavior (skipped and non-skipped output data buffers comparison) looks like the non-skipped data stream is a bit delayed - both data buffers will be phase shifted.

Number of clock pulses to be skipped should be written into PLSSKP[5:0] field in DFSDM_CHyDLYR register. Once PLSSKP[5:0] field is written the execution of pulses skipping is started on given channel. PLSSKP[5:0] field can be read in order to check the progress of pulses skipper. When PLSSKP[5:0]=0 means that pulses skipping has been executed.

Up to 63 clock pulses can be skip with a single write operation into PLSSKP[5:0]. If more pulses need to be skipped, then user has to write several times into the PLSSKP[5:0] field. The application software should handle cumulative skipped clock number per each filter.

### 35.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable prescaler to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM_CH0CFGR1 register.

- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP [1:0] bits in DFSDM_CHyCFGR1 register.

- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM_CHyCFGR1 register.

- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM_CHyCFGR2 register.

- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external ΣΔ modulator). It is defined by OFFSET[23:0] bits in DFSDM_CHyCFGR2 register.

- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM_CHyCFGR1.

- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM_CHyAWSCDR register.

### 35.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC or direct write by CPU/DMA.
Each channel contains a 32-bit data input register DFSDM_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM_CHyDATINR register is write protected.

**Input from internal ADC**

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM_CHDATIN0R register, ADC2 is filling DFSDM_CHDATIN1R register, ... , ADC8 is filling DFSDM_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

The setting of data packing mode (DATPACK[1:0] in the DFSDM_CHyCFGR1 register) has no effect in case of ADC data input.

*Note:* Extension of ADC specification: in case the internal ADC is configured in interleaved mode (e.g. ADC1 together with ADC2 - see ADC specification) then each result from ADC1 or from ADC2 will come to the same 16-bit bus - to the bus of ADC1 - which is coming into DFSDM channel 0 (fixed connection). So there will be double input data rate into DFSDM channel 0 (even samples come from ADC1 and odd samples from ADC2). Channel 1 associated with ADC2 will be free.

**Input from memory (direct CPU/DMA write)**

The direct data write into DFSDM_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM_CHyDATINR register:

1. **CPU data write:**
   
   Input data are written directly by CPU into DFSDM_CHyDATINR register.

2. **DMA data write:**
   
   The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM_CHyDATINR register. The destination memory address is the address of DFSDM_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.

   This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

   The accesses to DFSDM_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM_CHyCFGR1 register:

   1. **Standard mode (DATPACK[1:0]=0):**
      
      Only one sample is stored in field INDAT0[15:0] of DFSDM_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0])
to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM_CHyDATINR register to load one sample per write operation.

2. Interleaved mode (DATPACK[1:0]=1):

DFSDM_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital filter must perform two input samplings from channel y to empty DFSDM_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM_CHyDATINR register to load two samples per write operation.

3. Dual mode (DATPACK[1:0]=2):

Two samples are written into DFSDM_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register DFSDM_CH[y+1]DATINR). The digital filters must perform two samplings - one from channel y and one from channel (y+1) - in order to empty DFSDM_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers (y = 0, 2, 4, 6). If odd channel (y = 1, 3, 5, 7) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See Figure 316 for DFSDM_CHyDATINR registers data modes and assignments of data samples to channels.

</table>

The write into DFSDM_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel y) is enabled for data collection (starting conversion for channel y). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM_CHyDATINR before the single conversion is started (any data present in the DFSDM_CHyDATINR before starting a conversion is discarded).
35.4.7 Channel selection

There are 8 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 8 channels. JCHG[7:0] in the DFSDM_FLTxJCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel y is selected.

Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[7:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[7:0] if JSCAN=0 resets the channel selection to the lowest selected channel.

Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.

The **regular channel** is a selection of just one of the 8 channels. RCH[2:0] in the DFSDM_FLTxCR1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM_CHyCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM_CHyCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM_FLTxCR1 register.

35.4.8 Digital filter configuration

DFSDM contains a Sinc<sup>x</sup> type digital filter implementation. This Sinc<sup>x</sup> filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sinc<sup>x</sup> digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- Filter order/type: (see FORD[2:0] bits in DFSDM_FLTxFCR register):
  - FastSinc
  - Sinc<sup>1</sup>
  - Sinc<sup>2</sup>
  - Sinc<sup>3</sup>
  - Sinc<sup>4</sup>
  - Sinc<sup>5</sup>

- Filter oversampling/decimation ratio (see FOSR[9:0] bits in DFSDM_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sinc<sup>x</sup> filter x = FORD = 1..3
  - FOSR = 1-215 - for Sinc<sup>x</sup> filter x = FORD = 4
  - FOSR = 1-73 - for Sinc<sup>x</sup> filter x = FORD = 5
The filter has the following transfer function (impulse response in H domain):

- **Sinc\(^x\) filter type:** \(H(z) = \left(\frac{1 - z^{-\text{FOSR}}}{1 - z^{-1}}\right)^x\)

- **FastSinc filter type:** \(H(z) = \left(\frac{1 - z^{-\text{FOSR}}}{1 - z^{-1}}\right)^2 \cdot \left(1 + z^{-2 \cdot \text{FOSR}}\right)\)

**Figure 317. Example: Sinc\(^3\) filter response**

For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

### 35.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.
The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM_FLTxFCR register).

35.4.10 Analog watchdog

The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).
There are 2 options for comparing the threshold registers with the data values

- **Option1:** in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register)

- **Option2:** in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sincx channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM_CHyAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[7:0] field (DFSDM_FLTxCMP2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM_CHyAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWCH[7:0] field of DFSDM_FLTxCMP2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHTF[7:0], AWLTF[7:0] of DFSDM_FLTxAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWCH[7:0] = 0xFF). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.
Analog watchdog filter data for given channel y is available for reading by firmware on field WDATA[15:0] in DFSDM_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM_CHyCFCFG1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the integrator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency fCKIN):

first conversion:

for Sinc^x filters (x=1..5): number of samples = \[F_{OSR} \times F_{ORD} + F_{ORD} + 1\]
for FastSinc filter: number of samples = \[F_{OSR} \times 4 + 2 + 1\]

next conversions:

for Sinc^x and FastSinc filters: number of samples = \[F_{OSR} \times IOSR\]

where:

F_{OSR} ....... filter oversampling ratio: F_{OSR} = AWFOSR[4:0]+1 (see DFSDM_CHyAWSCDR register)
F_{ORD} ....... the filter order: F_{ORD} = AWFORD[1:0] (see DFSDM_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[7:0] field (in DFSDM_FLTxCFR2 register).

The status of an analog watchdog event is signalized in DFSDM_FLTxAWSR register where a given event is latched. AWHTF[y]=1 flag signalizes crossing AWHT[23:0] value on channel y. AWLTF[y]=1 flag signalizes crossing AWLT[23:0] value on channel y. Latched events in DFSDM_FLTxAWSR register are cleared by writing ‘1’ into the corresponding clearing bit CLRAWHTF[y] or CLRAWLTF[y] in DFSDM_FLTxAWCFR register.

The global status of an analog watchdog is signalized by the AWDF flag bit in DFSDM_FLTxAISR register (it is used for the fast detection of an interrupt source). AWDF=1 signalizes that at least one watchdog occurred (AWHTF[y]=1 or AWLTF[y]=1 for at least one channel). AWDF bit is cleared when all AWHTF[7:0] and AWLTF[7:0] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dfsdm_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM_FLTxAWHTR and DFSDM_FLTxAWLTR register.

### 35.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0’s or 1’s on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM_CHyAWSCDR register), then a short-
circuit event is invoked. Each input channel has its short-circuit detector. Any channel can
be selected to be continuously monitored by setting the SCDEN bit (in DFSDM_ChCFGR1
register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits,
status bit SCD[7:0], status clearing bits CLRSCD[7:0]). Status flag SCD[y] is cleared
also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal
dfsdm_break[3:0]. There are four break outputs to be assigned to a short-circuit detector
event. The break signal assignment to a given channel short-circuit detector event is done
by BKSCD[3:0] field in DFSDM_ChAWSCDR register.

Short circuit detector cannot be used in case of parallel input data channel selection
(DATMX[1:0] ≠ 0 in DFSDM_ChCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

35.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final
output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum
register (EXMAX[23:0] bits in DFSDM_FLTxEXMAX register), then this register is updated
with the current output data word value and the channel from which the data is stored is in
EXMAXCH[2:0] bits (in DFSDM_FLTxEXMAX register).

If the output data word is lower than the value stored in the extremes detector minimum
register (EXMIN[23:0] bits in DFSDM_FLTxEXMIN register), then this register is updated
with the current output data word value and the channel from which the data is stored is in
EXMINCH[2:0] bits (in DFSDM_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given
DFSDM_FLTxEXMAX or DFSDM_FLTxEXMIN register). After refresh, the extremes
detector minimum data register DFSDM_FLTxEXMIN is filled with 0x7FFFFFF (maximum
positive value) and the extremes detector maximum register DFSDM_FLTxEXMAX is filled
with 0x800000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data
correction. For each extremes detector, the input channels to be considered into computing
the extremes value are selected in EXCH[7:0] bits (in DFSDM_FLTxCR2 register).

35.4.13 Data unit block

The data unit block is the last block of the whole processing path: External ΣΔ modulators -
Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator
settings. The maximum output data rate is:

$$ \text{Datarate [samples/s]} = \frac{f_{\text{CKIN}}}{\text{FOSR} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST = 0, Sinc filter} $$

$$ \text{Datarate [samples/s]} = \frac{f_{\text{CKIN}}}{\text{FOSR} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST = 0, FastSinc filter} $$
or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST = 1}
\]

Maximum output data rate in case of parallel data input:

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST = 0, Sincx filter}
\]

or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST = 0, FastSinc filter}
\]

or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST=1 or any filter bypass case (F_{\text{OSR}} = 1)}
\]

where: \(f_{\text{DATAIN RATE}}\) -- input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

\[
\text{FOSR, FORD, IOSR } \leq 2^{31} \quad \text{...for Sinc}^x \text{ filters, } x = 1..5
\]

\[
2 \cdot \text{FOSR, IOSR } \leq 2^{31} \quad \text{...for FastSinc filter}
\]

Note: In case of filter and integrator bypass (IOSR[7:0]=0, FOSR[9:0]=0), the input data rate \(f_{\text{DATAIN RATE}}\) must be limited to be able to read all output data:

\[
f_{\text{DATAIN RATE}} \leq f_{\text{APB}}
\]

where \(f_{\text{APB}}\) is the bus frequency to which the DFSDM peripheral is connected.

### 35.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external \(\Sigma \Delta\) modulator. An external \(\Sigma \Delta\) modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A \(\Sigma \Delta\) modulator output is always assumed in a signed format (a data stream of zeros and ones from a \(\Sigma \Delta\) modulator represents values -1 and +1).
**Signed data format in registers:** Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two’s complement format).

### 35.4.15 Launching conversions

**Injected conversions** can be launched using the following methods:

- **Software:** writing ‘1’ to JSWSTART in the DFSDM_FLTxCR1 register.
- **Trigger:** JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM_FLTxCR1 register).
- **Synchronous with DFSDM_FLT0 if JSYNC=1:** for DFSDM_FLTx (x>0), an injected conversion is automatically launched when in DFSDM_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM_FLT0CR2 register). Each injected conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

**Regular conversions** can be launched using the following methods:

- **Software:** by writing ‘1’ to RSWSTART in the DFSDM_FLTxCR1 register.
- **Synchronous with DFSDM_FLT0 if RSYNC=1:** for DFSDM_FLTx (x>0), a regular conversion is automatically launched when in DFSDM_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM_FLT0CR2 register). Each regular conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signalized by RPEND bit in DFSDM_FLTxRDATAR register.

### 35.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM_FLTxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after ‘1’ is written to RSWSTART.
The regular conversions executing in continuous mode can be stopped by writing '0' to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM_FLTxCR1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:

- if FAST = 0 (or first conversion if FAST=1):
  - for Sinc<sup>x</sup> filters:
    \[ t = \frac{CNVCNT/DFSDMCLK}{\text{f}_{\text{DFSDMCLK}}} = \frac{[FOSR \cdot (IOSR-1 + FORD) + FORD]}{f_{\text{CKIN}}} \]
  - for FastSinc filter:
    \[ t = \frac{CNVCNT/DFSDMCLK}{\text{f}_{\text{DFSDMCLK}}} = \frac{[FOSR \cdot (IOSR-1 + 4) + 2]}{f_{\text{CKIN}}} \]

- if FAST = 1 (except first conversion):
  - for Sinc<sup>x</sup> and FastSinc filters:
    \[ t = \frac{CNVCNT/DFSDMCLK}{\text{f}_{\text{DFSDMCLK}}} = \frac{[FOSR \cdot IOSR]}{f_{\text{CKIN}}} \]
    in case FOSR = FOSR[9:0]+1 = 1 (filter bypassed, only integrator active):
    \[ t = \frac{IOSR}{f_{\text{CKIN}}} \] (... but CNVCNT=0)

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM_FLTxCR1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM_FLTxCR1 register).

### 35.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is ‘1’ (in the DFSDM_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is ‘1’ (in the DFSDM_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signalized in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When
the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM_FLTxCR1 writes ‘1’ to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

35.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

35.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- End of injected conversion interrupt:
  - enabled by JEOCIE bit in DFSDM_FLTxCR2 register
  - indicated in JEOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACH[2:0] bits in DFSDM_FLTxJDATAR register

- End of regular conversion interrupt:
  - enabled by REOCIE bit in DFSDM_FLTxCR2 register
  - indicated in REOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATCH[2:0] bits in DFSDM_FLTxRDATAR register

- Data overrun interrupt for injected conversions:
  - occurred when injected converted data were not read from DFSDM_FLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM_FLTxCR2 register
  - indicated in JOVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRJOVRF bit in DFSDM_FLTxICR register

- Data overrun interrupt for regular conversions:
  - occurred when regular converted data were not read from DFSDM_FLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM_FLTxCR2 register
  - indicated in ROVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRROVRF bit in DFSDM_FLTxICR register

- Analog watchdog interrupt:
Digital filter for sigma delta modulators (DFSDM) RM0468

- occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDMFLTxCR1 register) crosses over/under high/low thresholds in DFSDMFLTxAWHTR / DFSDMFLTxAWLTR registers
- enabled by AWDie bit in DFSDMFLTxCR2 register (on selected channels AWDCH[7:0])
- indicated in AWDF bit in DFSDMFLTxISR register
- separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDMFLTxAWSR register
- cleared by writing ‘1’ into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDMFLTxAWCFR register

- Short-circuit detector interrupt:
  - occurred when the number of stable data crosses over thresholds in DFSDM_ChyAWSCDR register
  - enabled by SCDie bit in DFSDMFLTxCR2 register (on channel selected by SCDEN bit in DFSDM_ChyCFG1 register)
  - indicated in SCDF[7:0] bits in DFSDMFLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  - cleared by writing ‘1’ into the corresponding CLRSCDF[7:0] bit in DFSDMFLTxICR register

- Channel clock absence interrupt:
  - occurred when there is clock absence on CKINy pin (see Clock absence detection in Section 35.4.4: Serial channel transceivers)
  - enabled by CKABIE bit in DFSDMFLTxCR2 register (on channels selected by CKABEN bit in DFSDM_ChyCFG1 register)
  - indicated in CKABF[y] bit in DFSDMFLTxISR register
  - cleared by writing ‘1’ into CLRCKABF[y] bit in DFSDMFLTxICR register

35.6 **DFSDM DMA transfer**

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM_FLTxCRI register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM_FLTxCRI register.

*Note:* With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM_FLTxCISR register) because DMA is reading DFSDM_FLTxDJDATAR or DFSDM_FLTxDRDATAR register.

35.7 **DFSDM channel y registers (y=0..7)**

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register. Write access to DFSDM_CHyDATINR register can be either word access (32-bit) or half-word access (16-bit).

35.7.1 **DFSDM channel y configuration register (DFSDM_CHyCFGR1)**

This register specifies the parameters used by channel y.

Address offset: 0x000 + 0x20 * y, (y = 0 to 7)
Reset value: 0x0000 0000

<table>
<thead>

</tr>
<tr>
<td></td>
<td><em>Note:</em> <strong>CKOUTSRC is present only in DFSDM_CH0CFGR1 register (channel y=0)</strong></td>
</tr>
</tbody>
</table>

Bits 29:24 Reserved, must be kept at reset value.
Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider
0: Output clock generation is disabled (CKOUT signal is set to low state)
1: 255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).
CKOUTDIV also defines the threshold for a clock absence detection.
This value can only be modified when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).
If DFSDMEN=0 (in DFSDM_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).
*Note:* **CKOUTDIV is present only in DFSDM_CH0CFGR1 register (channel y=0)**

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM_CHyDATINR register.
0: Standard: input data in DFSDM_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM_CHyDATINR register one sample must be read by the DFSDM filter from channel y.
1: Interleaved: input data in DFSDM_CHyDATINR register are stored as two samples:
–first sample in INDAT0[15:0] (assigned to channel y)
–second sample INDAT1[15:0] (assigned to channel y)
To empty DFSDM_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).
2: Dual: input data in DFSDM_CHyDATINR register are stored as two samples:
–first sample INDAT0[15:0] (assigned to channel y)
–second sample INDAT1[15:0] (assigned to channel y+1)
To empty DFSDM_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.
3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y
0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM_CHyDATINR register is write protected.
1: Data to channel y are taken from internal analog to digital converter ADCy+1 output register update as 16-bit values (if ADCy+1 is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM_CHyDATINR register.
2: Data to channel y are taken from internal DFSDM_CHyDATINR register by direct CPU/DMA write. There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection
0: Channel inputs are taken from pins of the same channel y.
1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bit 7 **CHEN**: Channel y enable
0: Channel y disabled
1: Channel y enabled
If channel y is enabled, then serial data receiving is started according to the given channel setting.
Bit 6 **CKABEN**: Clock absence detector enable on channel y  
0: Clock absence detector disabled on channel y  
1: Clock absence detector enabled on channel y  

Bit 5 **SCDEN**: Short-circuit detector enable on channel y  
0: Input channel y will not be guarded by the short-circuit detector  
1: Input channel y will be continuously guarded by the short-circuit detector  

Bit 4 Reserved, must be kept at reset value.  

**Bits 3:2 SPICKSEL[1:0]**: SPI clock select for channel y  
0: clock coming from external CKINy input - sampling point according SITP[1:0]  
1: clock coming from internal CKOUT output - sampling point according SITP[1:0]  
2: clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.  
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to  
   generate its output serial communication clock (and this output clock change is active on each  
   clock input rising edge).  
3: clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.  
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to  
   generate its output serial communication clock (and this output clock change is active on each  
   clock input falling edge).  
   This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).  

**Bits 1:0 SITP[1:0]**: Serial interface type for channel y  
00: SPI with rising edge to strobe data  
01: SPI with falling edge to strobe data  
10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1  
11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0  
This value can only be modified when CHEN=0 (in DFSDM_CHyCFGR1 register).  

### 35.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2)  
This register specifies the parameters used by channel y.  
Address offset: 0x04 + 0x20 * y, (y = 0 to 7)  
Reset value: 0x0000 0000  

35.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM_CHyAWSCDR)

Short-circuit detector and analog watchdog settings for channel y.

Address offset: 0x08 + 0x20 * y, (y = 0 to 7)
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 AWFORD[1:0]: Analog watchdog Sinc filter order on channel y
0: FastSinc filter type
1: Sinc1 filter type
2: Sinc2 filter type
3: Sinc3 filter type

Sincx filter type transfer function:

$$H(z) = \left(\frac{1 - z^{-\text{FOSR}}}{1 - z^{-1}}\right)^x$$

FastSinc filter type transfer function:

$$H(z) = \left(\frac{1 - z^{-\text{FOSR}}}{1 - z^{-1}}\right)^2 \cdot (1 + z^{-2 \cdot \text{FOSR}})$$

This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bit 21 Reserved, must be kept at reset value.

Bits 20:16 AWFOSR[4:0]: Analog watchdog filter oversampling ratio (decimation rate) on channel y
0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.
This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Note: If AWFOSR = 0 then the filter has no effect (filter bypass).
35.7.4 DFSDM channel y watchdog filter data register (DFSDM_CHyWDATR)

This register contains the data resulting from the analog watchdog filter associated to the input channel y.

Address offset: 0x0C + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

35.7.5 DFSDM channel y data input register (DFSDM_CHyDATINR)

This register contains 16-bit input data to be processed by DFSDM filter module. Write access can be either word access (32-bit) or half-word access (16-bit).

Address offset: 0x10 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000
35.7.6 DFSDM channel y delay register (DFSDM_CHyDLYR)

Address offset: 0x14 + 0x20 * y, (y = 0 to 7)
Reset value: 0x0000 0000

Bits 31:16  **INDAT1[15:0]**: Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)

Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM_FLT0 filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: sample in INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).

For odd y channels: INDAT1[15:0] is write protected.

See Section 35.4.6: Parallel data inputs for more details.

INDAT0[15:1] is in the 16-bit signed format.

Bits 15:0  **INDAT0[15:0]**: Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)

First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM_FLT0 filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: Channel y data sample is stored into INDAT0[15:0].

For odd y channels: INDAT0[15:0] is write protected.

See Section 35.4.6: Parallel data inputs for more details.

INDAT0[15:0] is in the 16-bit signed format.

---

35.4.6 Parallel data inputs

---

**Note:** The table above is not fully provided in the image. It appears to be a hexadecimal table with columns for bit positions 15 to 0, with corresponding read/write (rw) permissions.
35.8 **DFSDM filter x module registers (x=0..3)**

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register.

### 35.8.1 DFSDM filter x control register 1 (DFSDM_FLTxCR1)

Address offset: 0x100 + 0x80 * x, (x = 0 to 3)

</table>
Bits 26:24  **RCH[2:0]**: Regular channel selection
   0: Channel 0 is selected as the regular channel
   1: Channel 1 is selected as the regular channel
   ...
   7: Channel 7 is selected as the regular channel
Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22  Reserved, must be kept at reset value.

Bit 21  **RDMAEN**: DMA channel enabled to read data for the regular conversion
   0: The DMA channel is not enabled to read regular data
   1: The DMA channel is enabled to read regular data
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 20  Reserved, must be kept at reset value.

Bit 19  **RSYNC**: Launch regular conversion synchronously with DFSDM_FLT0
   0: Do not launch a regular conversion synchronously with DFSDM_FLT0
   1: Launch a regular conversion in this DFSDM_FLTx at the very moment when a regular conversion is launched in DFSDM_FLT0
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 18  **RCONT**: Continuous mode selection for regular conversions
   0: The regular channel is converted just once for each conversion request
   1: The regular channel is converted repeatedly after each conversion request
Writing '0' to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.

Bit 17  **RSWSTART**: Software start of a conversion on the regular channel
   0: Writing '0' has no effect
   1: Writing '1' makes a request to start a conversion on the regular channel and causes RCIP to become '1'. If RCIP=1 already, writing to RSWSTART has no effect. Writing '1' has no effect if RSYNC=1.
   This bit is always read as '0'.

Bits 16:15  Reserved, must be kept at reset value.

Bits 14:13  **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions
   00: Trigger detection is disabled
   01: Each rising edge on the selected trigger makes a request to launch an injected conversion
   10: Each falling edge on the selected trigger makes a request to launch an injected conversion
   11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
Bits 12:8 JEXTSEL[4:0]: Trigger signal selection for launching injected conversions
   0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).
   This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
   Note: synchronous trigger has latency up to one $f_{DFSDMCLK}$ clock cycle (with deterministic jitter),
   asynchronous trigger has latency 2-3 $f_{DFSDMCLK}$ clock cycles (with jitter up to 1 cycle).

   DFSDM_FLTx
   0x00  dfsdm_jtrg0
   0x01  dfsdm_jtrg1
   ...
   0x1E  dfsdm_jtrg30
   0x1F  dfsdm_jtrg31
   Refer to Table 287: DFSDM triggers connection.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 JDMAEN: DMA channel enabled to read data for the injected channel group
   0: The DMA channel is not enabled to read injected data
   1: The DMA channel is enabled to read injected data
   This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 4 JSCAN: Scanning conversion mode for injected conversions
   0: One channel conversion is performed from the injected channel group and next the selected
   channel from this group is selected.
   1: The series of conversions for the injected group channels is executed, starting over with the
   lowest selected channel.
   This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
   Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 JSYNC: Launch an injected conversion synchronously with the DFSDM_FLT0 JSWSTART trigger
   0: Do not launch an injected conversion synchronously with DFSDM_FLT0
   1: Launch an injected conversion in this DFSDM_FLTx at the very moment when an injected
   conversion is launched in DFSDM_FLT0 by its JSWSTART trigger
   This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 2 Reserved, must be kept at reset value.

Bit 1 JSWSTART: Start a conversion of the injected group of channels
   0: Writing ‘0’ has no effect.
   1: Writing ‘1’ makes a request to convert the channels in the injected conversion group, causing
   JCIP to become ‘1’ at the same time. If JCIP=1 already, then writing to JSWSTART has no effect.
   Writing ‘1’ has no effect if JSYNC=1.
   This bit is always read as ‘0’.

Bit 0 DFEN: DFSDM_FLTx enable
   0: DFSDM_FLTx is disabled. All conversions of given DFSDM_FLTx are stopped immediately and
   all DFSDM_FLTx functions are stopped.
   1: DFSDM_FLTx is enabled. If DFSDM_FLTx is enabled, then DFSDM_FLTx starts operating
   according to its setting.
   Data which are cleared by setting DFEN=0:
   – register DFSDM_FLTxISR is set to the reset state
   – register DFSDM_FLTxAWSR is set to the reset state
### 35.8.2 DFSDM filter x control register 2 (DFSDM_FLTxCR2)

Address offset: 0x104 + 0x80 * x, (x = 0 to 3)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **AWDCH[7:0]**: Analog watchdog channel selection  
These bits select the input channel to be guarded continuously by the analog watchdog.  
AWDCH[y] = 0: Analog watchdog is disabled on channel y  
AWDCH[y] = 1: Analog watchdog is enabled on channel y

Bits 15:8 **EXCH[7:0]**: Extremes detector channel selection  
These bits select the input channels to be taken by the Extremes detector.  
EXCH[y] = 0: Extremes detector does not accept data from channel y  
EXCH[y] = 1: Extremes detector accepts data from channel y

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CKABIE**: Clock absence interrupt enable  
0: Detection of channel input clock absence interrupt is disabled  
1: Detection of channel input clock absence interrupt is enabled  
Please see the explanation of CKABF[7:0] in DFSDM_FLTxISR.  
**Note:** CKABIE is present only in DFSDM_FLT0CR2 register (filter x=0)

Bit 5 **SCDIE**: Short-circuit detector interrupt enable  
0: short-circuit detector interrupt is disabled  
1: short-circuit detector interrupt is enabled  
Please see the explanation of SCDF[7:0] in DFSDM_FLTxISR.  
**Note:** SCDIE is present only in DFSDM_FLT0CR2 register (filter x=0)

Bit 4 **AWDIE**: Analog watchdog interrupt enable  
0: Analog watchdog interrupt is disabled  
1: Analog watchdog interrupt is enabled  
Please see the explanation of AWDF in DFSDM_FLTxISR.

Bit 3 **ROVRIE**: Regular data overrun interrupt enable  
0: Regular data overrun interrupt is disabled  
1: Regular data overrun interrupt is enabled  
Please see the explanation of ROVRF in DFSDM_FLTxISR.
Bit 2  **JOVRIE**: Injected data overrun interrupt enable  
0: Injected data overrun interrupt is disabled  
1: Injected data overrun interrupt is enabled  
Please see the explanation of JOVRF in DFSDM_FLTxISR.

Bit 1  **REOCIE**: Regular end of conversion interrupt enable  
0: Regular end of conversion interrupt is disabled  
1: Regular end of conversion interrupt is enabled  
Please see the explanation of REOCF in DFSDM_FLTxISR.

Bit 0  **JEOCIE**: Injected end of conversion interrupt enable  
0: Injected end of conversion interrupt is disabled  
1: Injected end of conversion interrupt is enabled  
Please see the explanation of JEOCF in DFSDM_FLTxISR.

### 35.8.3 DFSDM filter x interrupt and status register (DFSDM_FLTxISR)

Address offset: 0x108 + 0x80 * x, (x = 0 to 3)  
Reset value: 0x00FF 0000

<table>
<thead>
<tr>
<th>Bit 31:24</th>

<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**  
**SCDF[7:0]** is present only in DFSDM_FLT0ISR register (filter x=0)  
**CKABF[7:0]** is present only in DFSDM_FLT0ISR register (filter x=0)

Bits 23:16  **CKABF[7:0]**: Clock absence flag  
CKABF[y]=0: Clock signal on channel y is present.  
CKABF[y]=1: Clock signal on channel y is not present.  
Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM_CHyCFGR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM_FLTxICR register.  
**Note:**  **CKABF[7:0]** is present only in DFSDM_FLT0ISR register (filter x=0)

Bit 15  Reserved, must be kept at reset value.

Bit 14  **RCIP**: Regular conversion in progress status  
0: No request to convert the regular channel has been issued  
1: The conversion of the regular channel is in progress or a request for a regular conversion is pending  
A request to start a regular conversion is ignored when RCIP=1.
Bit 13  **JCIP**: Injected conversion in progress status
        0: No request to convert the injected channel group (neither by software nor by trigger) has been issued.
        1: The conversion of the injected channel group is in progress or a request for an injected conversion is pending, due either to ‘1’ being written to JSWSTART or to a trigger detection. A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5 Reserved, must be kept at reset value.

Bit 4  **AWDF**: Analog watchdog
        0: No Analog watchdog event occurred
        1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM_FLTxAWLTR or DFSDM_FLTxAWHTR registers.
        This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM_FLTxAWSR register (by writing ‘1’ into the clear bits in DFSDM_FLTxAWCFR register).

Bit 3  **ROVRF**: Regular conversion overrun flag
        0: No regular conversion overrun has occurred
        1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already ‘1’. RDATAR is not affected by overruns.
        This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM_FLTxICR register.

Bit 2  **JOVRF**: Injected conversion overrun flag
        0: No injected conversion overrun has occurred
        1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already ‘1’. JDATAR is not affected by overruns.
        This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM_FLTxICR register.

Bit 1  **REOCF**: End of regular conversion flag
        0: No regular conversion has completed
        1: A regular conversion has completed and its data may be read
        This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxRDATAR.

Bit 0  **JEOCF**: End of injected conversion flag
        0: No injected conversion has completed
        1: An injected conversion has completed and its data may be read
        This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxJDATAR.

**Note:** For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM_FLTxISR are automatically reset when DFEN=0.
35.8.4 **DFSDM filter x interrupt flag clear register (DFSDM_FLTxICR)**

Address offset: 0x10C + 0x80 * x, (x = 0 to 3)  
Reset value: 0x0000 0000

| Bits 31:24 | CLRSCDF[7:0]: Clear the short-circuit detector flag  
CLRSCDF[y]=0: Writing ‘0’ has no effect  
CLRSCDF[y]=1: Writing ‘1’ to position y clears the corresponding SCDF[y] bit in the DFSDM_FLTxISR register  
Note: CLRSCDF[7:0] is present only in DFSDM_FLT0ICR register (filter x=0) |
|---|---|
| Bits 23:16 | CLRCKABF[7:0]: Clear the clock absence flag  
CLRCKABF[y]=0: Writing ‘0’ has no effect  
CLRCKABF[y]=1: Writing ‘1’ to position y clears the corresponding CKABF[y] bit in the DFSDM_FLTxISR register. When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y].  
Note: CLRCKABF[7:0] is present only in DFSDM_FLT0ICR register (filter x=0) |
| Bits 15:4 | Reserved, must be kept at reset value. |
| Bit 3 | CLRROVRF: Clear the regular conversion overrun flag  
0: Writing ‘0’ has no effect  
1: Writing ‘1’ clears the ROVRF bit in the DFSDM_FLTxISR register |
| Bit 2 | CLRJOVRF: Clear the injected conversion overrun flag  
0: Writing ‘0’ has no effect  
1: Writing ‘1’ clears the JOVRF bit in the DFSDM_FLTxISR register |
| Bits 1:0 | Reserved, must be kept at reset value. |

*Note: The bits of DFSDM_FLTxICR are always read as ‘0’.***
35.8.5 DFSDM filter x injected channel group selection register (DFSDM_FLTxJCHGR)

Address offset: 0x110 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0001

<table>
<thead>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 JCHG[7:0]: Injected channel group selection

JCHG[y]=0: channel y is not part of the injected group
JCHG[y]=1: channel y is part of the injected group
If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.
If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.
At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.

35.8.6 DFSDM filter x control register (DFSDM_FLTxFCR)

Bits 31:2 Reserved, must be kept at reset value.
35.8.7 DFSDM filter x data register for injected group (DFSDM_FLTxJDATAR)

Address offset: 0x118 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000
Digital filter for sigma delta modulators (DFSDM)  

Bits 31:8 \( \text{JDATA}[23:0] \): Injected group conversion data
When each conversion of a channel in the injected group finishes, its resulting data is stored in this field. The data is valid when JEOCF=1. Reading this register clears the corresponding JEOCF.

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0 \( \text{JDATACH}[2:0] \): Injected channel most recently converted
When each conversion of a channel in the injected group finishes, JDATACH[2:0] is updated to indicate which channel was converted. Thus, JDATA[23:0] holds the data that corresponds to the channel indicated by JDATACH[2:0].

Note:    DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears JEOCF in DFSDM_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.

35.8.8 DFSDM filter x data register for the regular channel (DFSDM_FLTxRDATAR)
Address offset: 0x11C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:8 \( \text{RDATA}[23:0] \): Regular channel conversion data
When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 \( \text{RPEND} \): Regular channel pending data
Regular data in RDATA[23:0] was delayed due to an injected channel trigger during the conversion

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 \( \text{RDATACH}[2:0] \): Regular channel most recently converted
When each regular conversion finishes, RDATACH[2:0] is updated to indicate which channel was converted (because regular channel selection RCH[2:0] in DFSDM_FLTxCR1 register can be updated during regular conversion). Thus RDATA[23:0] holds the data that corresponds to the channel indicated by RDATACH[2:0].

Note:    Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears REOCF in DFSDM_FLTxISR.
35.8.9 **DFSDM filter x analog watchdog high threshold register (DFSDM_FLTxAWHTR)**

Bits 31:8 **EXMIN[23:0]**: Extremes detector minimum value
These bits are set by hardware and indicate the lowest value converted by DFSDM_FLTx. EXMIN[23:0] bits are reset to value (0x7FFFFFFF) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMINCH[2:0]**: Extremes detector minimum data channel
These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

35.8.15 DFSDM filter x conversion timer register (DFSDM_FLTxCVNTIMR)

Address offset: 0x138 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
Bits 31:4 **CNVCNT[27:0]:** 28-bit timer counting conversion time \( t = \frac{\text{CNVCNT}[27:0]}{f_{\text{DFSDMCLK}}} \)

The timer has an input clock from DFSDM clock (system clock \( f_{\text{DFSDMCLK}} \)). Conversion time measurement is started on each conversion start and stopped when conversion finishes (interval between first and last serial sample). Only in case of filter bypass (FOSR[9:0] = 0) is the conversion time measurement stopped and CNVCNT[27:0] = 0. The counted time is:

If \( \text{FAST}=0 \) (or first conversion in continuous mode if \( \text{FAST}=1 \)):

\[ t = \frac{\text{FOSR} \cdot (\text{IOSR}-1 + \text{FORD}) + \text{FORD}}{f_{\text{CKIN}}} \]  

--- for Sinc6 filters

\[ t = \frac{\text{FOSR} \cdot (\text{IOSR}-1 + 4) + 2}{f_{\text{CKIN}}} \]  

--- for FastSinc filter

If \( \text{FAST}=1 \) in continuous mode (except first conversion):

\[ t = \frac{\text{FOSR} \cdot \text{IOSR}}{f_{\text{CKIN}}} \]

in case if \( F_{\text{OSR}} = \text{FOSR}[9:0]+1 = 1 \) (filter bypassed, active only integrator):

\[ \text{CNVCNT} = 0 \]  

(counting is stopped, conversion time: \( t = \frac{\text{IOSR}}{f_{\text{CKIN}}} \))

where: \( f_{\text{CKIN}} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input (from internal ADC or from CPU/DMA write)

**Note:** When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.

Bits 3:0 Reserved, must be kept at reset value.

36 Digital camera interface (DCMI)

36.1 Introduction
The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

36.2 DCMI main features
- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

36.3 DCMI functional description
The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

</tr>
</tbody>
</table>
36.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

36.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

36.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 293.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.

![DCMI signal waveforms](image)

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
10-bit data

When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles. The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>

<td>$D_{n+1}[7:0]$</td>
<td>$D_{n}[7:0]$</td>
</tr>
<tr>
<td>4</td>
<td>$D_{n+7}[7:0]$</td>
<td>$D_{n+6}[7:0]$</td>
<td>$D_{n+5}[7:0]$</td>
<td>$D_{n+4}[7:0]$</td>
</tr>
</tbody>
</table>

Table 295. Positioning of captured data bytes in 32-bit words (8-bit width)

12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles. The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>

<td>0</td>
<td>$D_{n+2}[9:0]$</td>
</tr>
</tbody>
</table>

Table 296. Positioning of captured data bytes in 32-bit words (10-bit width)

14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles. The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

</tbody>
</table>

Table 297. Positioning of captured data bytes in 32-bit words (12-bit width)
36.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 320 shows the corresponding timing diagram.

**Table 298. Positioning of captured data bytes in 32-bit words (14-bit width)**

</tr>
</tbody>
</table>

**Figure 320. Timing diagram**

**Hardware synchronization mode**

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and
capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the
deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive
buffers or the same/circular buffer. To allow the DMA management of successive frames, a
VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

**Embedded data synchronization mode**

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in
the data flow. These codes use the 0x00/0xFF values that are not used in data anymore.
There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization
codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the
EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable
results and must not be used.

**Note:** Camera modules can have 8 such codes (in interleaved mode). For this reason, the
interleaved mode is not supported by the camera interface (otherwise, every other
half-frame would be discarded).

- **Mode 2**
  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

The XY values in the 0xFF0000XY format of the four codes are programmable (see
Section 36.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).
A 0xFF value programmed as a “frame end” means that all the unused codes are
interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts
after the first occurrence of the frame end (FE) code followed by a frame start (FS)
code.

- **Mode 1**
  An alternative coding is the camera mode 1. This mode is ITU656 compatible.
  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- FS ≤ 0xFF
- FE ≤ 0xFF
- LS ≤ SAV (active)
- LE ≤ EAV (active)

An embedded unmask code is also implemented for frame/line start and frame/line end
codes. Using it, it is possible to compare only the selected unmasked bits with the
programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

**Example**

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

### 36.3.7 DCMI capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

**Snapshot mode (single frame)**

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

**Continuous grab mode**

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

### 36.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

**Figure 323. Coordinates and size of the window after cropping**

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

**Figure 324. Data capture waveforms**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

### 36.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

### 36.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
### DCMI data format description

#### Data formats

Three types of data are supported:
- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

#### Monochrome format

Characteristics:
- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>

<td>n + 4</td>
</tr>
</tbody>
</table>

#### RGB format

Characteristics:
- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRGB)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

### Table 300. Data storage in RGB progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Red n + 1</td>
<td>Green n + 1</td>
<td>Blue n + 1</td>
<td>Red n</td>
<td>Green n</td>
<td>Blue n</td>
</tr>
<tr>
<td>4</td>
<td>Red n + 4</td>
<td>Green n + 3</td>
<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

### Table 301. Data storage in YCbCr progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Y n + 1</td>
<td>Cr n</td>
<td>Y n</td>
<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in Table 302.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

36.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

<table>
<thead>
<tr>

## 36.5 DCMI registers

Refer to Section 1.2 on page 104 for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

### 36.5.1 DCMI control register (DCMI_CR)

Address offset: 0x00

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

<td>Reserved</td>
<td>rw</td>
<td>rw</td>
</tr>
<tr>
<td>14</td>
<td>ENABLE: DCMI enable</td>
<td>0x00</td>
<td>0: DCMI disabled 1: DCMI enabled</td>
</tr>
</tbody>
</table>

Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.
Bits 11:10 EDM[1:0]: Extended data mode
   00: Interface captures 8-bit data on every pixel clock.
   01: Interface captures 10-bit data on every pixel clock.
   10: Interface captures 12-bit data on every pixel clock.
   11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 FCRC[1:0]: Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
   00: All frames are captured.
   01: Every alternate frame captured (50% bandwidth reduction)
   10: One frame out of four captured (75% bandwidth reduction)
   11: reserved

Bit 7 VSPOL: Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
   0: DCMI_VSYNC active low
   1: DCMI_VSYNC active high

Bit 6 HSPOL: Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
   0: DCMI_HSYNC active low
   1: DCMI_HSYNC active high

Bit 5 PCKPOL: Pixel clock polarity
This bit configures the capture edge of the pixel clock.
   0: Falling edge active
   1: Rising edge active

Bit 4 ESS: Embedded synchronization select
   0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
   1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.
This bit is disabled in JPEG mode.

Bit 3 JPEG: JPEG format
   0: Uncompressed video format
   1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 CROP: Crop feature
   0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
   1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 CM: Capture mode
   0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
   1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
Bit 0  **CAPTURE**: Capture enable
0: Capture disabled
1: Capture enabled
The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.
In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.
In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.
*Note*: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

### 36.5.2 DCMI status register (DCMI_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **FNE**: FIFO not empty
This bit gives the status of the FIFO.
1: FIFO contains valid data.
0: FIFO empty

Bit 1  **VSYNC**: Vertical synchronization
This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active frame
1: synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0  **HSYNC**: Horizontal synchronization
This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active line
1: synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
### 36.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

- **Address offset**: 0x08
- **Reset value**: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-5</th>
<th>31</th>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

#### Bits 31:5: Reserved, must be kept at reset value.

**Bit 4 LINE_RIS: **Line raw interrupt status

This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.

It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

**Bit 3 VSYNC_RIS: **DCMI_VSYNC raw interrupt status

This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.

It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

**Bit 2 ERR_RIS: **Synchronization error raw interrupt status

- 0: No synchronization error detected
- 1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.

*Note: This bit is available only in embedded synchronization mode.*

**Bit 1 OVR_RIS: **Overrun raw interrupt status

- 0: No data buffer overrun occurred
- 1: A data buffer overrun occurred and the data FIFO is corrupted.

The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

**Bit 0 FRAME_RIS: **Capture complete raw interrupt status

- 0: No new capture
- 1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (e.g. window cropped outside the frame).

The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.
### 36.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

**Address offset:** 0x0C  
**Reset value:** 0x0000 0000

<td></td>
</tr>
</tbody>
</table>

Note: This bit is available only in embedded synchronization mode.
36.5.5  DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10
Reset value: 0x0000 0000

<th>0</th>
</tr>
</thead>
</table>

Bits 31:5  Reserved, must be kept at reset value.

Bit 4 **LINE_MIS**: Line masked interrupt status
This bit gives the status of the masked line interrupt.
0: No interrupt generation when the line is received
1: An interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

Bit 3 **VSYNC_MIS**: VSYNC masked interrupt status
This bit gives the status of the masked VSYNC interrupt.
0: No interrupt is generated on DCMI_VSYNC transitions.
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR_MIS**: Synchronization error masked interrupt status
This bit gives the status of the masked synchronization error interrupt.
0: No interrupt is generated on a synchronization error.
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.
*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR_MIS**: Overrun masked interrupt status
This bit gives the status of the masked overflow interrupt.
0: No interrupt is generated on overrun.
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

Bit 0 **FRAME_MIS**: Capture complete masked interrupt status
This bit gives the status of the masked capture complete interrupt
0: No interrupt is generated after a complete capture.
1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.
36.5.6  **DCMI interrupt clear register (DCMI_ICR)**

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14

Bits 31:5  Reserved, must be kept at reset value.

- **Bit 4**  **LINE\_ISC**: line interrupt status clear  
  Setting this bit clears the LINE\_RIS flag in the DCMI_RIS register.

- **Bit 3**  **VSYNC\_ISC**: Vertical Synchronization interrupt status clear  
  Setting this bit clears the VSYNC\_RIS flag in the DCMI_RIS register.

- **Bit 2**  **ERR\_ISC**: Synchronization error interrupt status clear  
  Setting this bit clears the ERR\_RIS flag in the DCMI_RIS register.  
  **Note**: This bit is available only in embedded synchronization mode.

- **Bit 1**  **OVR\_ISC**: Overrun interrupt status clear  
  Setting this bit clears the OVR\_RIS flag in the DCMI_RIS register.

- **Bit 0**  **FRAME\_ISC**: Capture complete interrupt status clear  
  Setting this bit clears the FRAME\_RIS flag in the DCMI_RIS register.

**FEC[7:0]**  
**LEC[7:0]**  
**LSC[7:0]**  
**FSC[7:0]**
36.5.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

Address offset: 0x1C
Reset value: 0x0000 0000

Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask
This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask
This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask
This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.
36.5.9 DCMI crop window start (DCMI_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0000

Bits 7:0 FSU[7:0]: Frame start delimiter unmask
This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 VST[12:0]: Vertical start line count
The image capture starts with this line number. Previous line data are ignored.
0x0000: line 1
0x0001: line 2
0x0002: line 3
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 HOFFCNT[13:0]: Horizontal offset count
This value gives the number of pixel clocks to count before starting a capture.

36.5.10 DCMI crop window size (DCMI_CWSIZE)

Address offset: 0x24

Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.
36.5.11 DCMI data register (DCMI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

The digital camera Interface packages all the received data in 32-bit format before requesting a DMA transfer. A 8-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

| Bits 31:24 | BYTE3[7:0]: Data byte 3 |
| Bits 23:16 | BYTE2[7:0]: Data byte 2 |
| Bits 15:8  | BYTE1[7:0]: Data byte 1 |
| Bits 7:0   | BYTE0[7:0]: Data byte 0 |

Refer to Section 2.3 for the register boundary addresses.
37 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see Section 37.3.2: PSSI pins and internal signals).

37.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

37.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output

When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

37.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

*Figure 326* shows the PSSI block diagram.
37.3.1 PSSI block diagram

Figure 326. PSSI block diagram

Figure 327. Top-level block diagram

37.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. Table 305 shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.

<td>AHB clock</td>
</tr>
</tbody>
</table>

37.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

37.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:

- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. Table 307 illustrates the positioning of the data bytes in two 32-bit words.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 308 illustrates the positioning of the data in two 32-bit words.

<td>D&lt;sub&gt;n+3&lt;/sub&gt;[15:0]</td>
<td>D&lt;sub&gt;n+2&lt;/sub&gt;[15:0]</td>
</tr>
</tbody>
</table>

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

37.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples
the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives
the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the
PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current
data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function
allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up
with the data flow.

**Figure 330. Ready in receive mode waveform diagram (CKPOL=0)**

If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode
(OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to
the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the
same data (D[15:0]) and PSSI_DE signals that valid data are available during the next
PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data
from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are
available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE
signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors
when the system (via the DMA) is unable to keep up with the data flow.

**Bidirectional PSSI_DE/PSSI_RDY signal**

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions
if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the
PSSI_CR register. In this case, the GPIO corresponding to selected alternate function
(PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be
configured as open-drain. The other device must also be configured to drive the line as
open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate
that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling
the current data), then both devices know that the data is not being transferred in the current
cycle.
37.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 309 for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

| Bit 20:0   | 110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin |
| Bit 20:0   | 111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see Bidirectional PSSI DE/PSSI_RDY signal on page 1382) |

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

| Bits 17:15 | Reserved, must be kept at reset value. |
Bit 14 **ENABLE**: PSSI enable

- 0: PSSI disabled
- 1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

**Note:** When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode

- 00: Interface captures 8-bit data on every parallel data clock
- 01: Reserved, must not be selected
- 10: Reserved, must not be selected
- 11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL**: Ready (PSSI_RDY) polarity

This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.

- 0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)
- 1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL**: Data enable (PSSI_DE) polarity

This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.

- 0: PSSI_DE active low (0 indicates that data is valid)
- 1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL**: Parallel data clock polarity

This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.

- 0: Falling edge active for inputs or rising edge active for outputs
- 1: Rising edge active for inputs or falling edge active for outputs

Bits 4:0 Reserved, must be kept at reset value.
37.5.2 PSSI status register (PSSI_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>

37.5.3 PSSI raw interrupt status register (PSSI_RIS)

Address offset: 0x08
Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

<table>
<thead>
<tr>
<th>Bit</th>

<th>Bit 22</th>
<th>Bit 21</th>
<th>Bit 20</th>
<th>Bit 19</th>
<th>Bit 18</th>
<th>Bit 17</th>
<th>Bit 16</th>
</tr>
</thead>
</table>

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

Bits 31:2 Reserved, must be kept at reset value.

- Bit 1 **OVR_IE**: Data buffer overrun/underrun interrupt enable
  - 0: No interrupt generation
  - 1: An interrupt is generated if either an overrun or an underrun error occurred.

Bit 0 Reserved, must be kept at reset value.

37.5.5 PSSI masked interrupt status register (PSSI_MIS)

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is
set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 OVR_MIS:** Data buffer overrun/underrun masked interrupt status
- This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
- 0: No interrupt is generated when an overrun/underrun error occurs
- 1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

**Bit 0** Reserved, must be kept at reset value.

### 37.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 OVR_ISC:** Data buffer overrun/underrun interrupt status clear
- Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

**Bit 0** Reserved, must be kept at reset value.
37.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN=0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN=1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

38 LCD-TFT display controller (LTDC)

38.1 Introduction
The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

38.2 LTDC main features
- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x64-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer:
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2 bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AXI master interface with burst of 16 double-words
- Up to 4 programmable interrupt events

<td>Output</td>
<td>8-bit Green data</td>
</tr>
<tr>
<td>LCD_B[7:0]</td>
<td>Output</td>
<td>8-bit Blue data</td>
</tr>
</tbody>
</table>

The LTDC pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24 bits (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LTDC RGB data lines.

As an example, in the case of an LTDC interfacing with a RGB565 16-bit display, the LTDC display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to the LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3] pins.
The internal signals of the LTDC are given in the table below.

### Table 312. LTDC internal signals

#### 38.3.3 LTDC reset and clocks

The LTDC controller peripheral uses the following clock domains:
- AXI clock domain (ltdc_aclk)
  This domain contains the LTDC AXI master interface for data transfer from the memories to the layer FIFO and the frame-buffer configuration register.
- APB clock domain (ltdc_pclk)
  This domain contains the global configuration registers and the interrupt register.
- Pixel clock domain (LCD_CLK)
  This domain contains the pixel data generation, the layer configuration register as well as the LTDC interface signal generator. The LCD_CLK output must be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

The table below summarizes the clock domain for each register.

### Table 313. Clock domain for each register

<table>

The LTDC controller can be reset by setting the corresponding bit in the RCC. It resets the three clock domains.
38.4 LTDC programmable parameters

The LTDC controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

38.4.1 LTDC global configuration parameters

Synchronous timings

The figure below presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram Figure 333. It generates the horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

![Figure 334. LTDC synchronous timings](image)

The LTDC programmable synchronous timings are the following:

- HSYNC and VSYNC width: horizontal and vertical synchronization width, configured by programming a value of HSYNC width - 1 and VSYNC width - 1 in the LTDC_SSCR register.
- HBP and VBP: horizontal and vertical synchronization back porch width, configured by programming the accumulated value HSYNC width + HBP - 1 and the accumulated value VSYNC width + VBP - 1 in the LTDC_BPCR register.
- Active width and active height: the active width and active height are configured by programming the accumulated value HSYNC width + HBP + active width - 1 and the
accumulated value VSYNC width + VBP + active height - 1 in the LTDC_AWCR register.

- Total width: the total width is configured by programming the accumulated value HSYNC width + HBP + active width + HFP - 1 in the LTDC_TWCR register. The HFP is the horizontal front porch period.
- Total height: the total height is configured by programming the accumulated value VSYNC height + VBP + active height + VFP - 1 in the LTDC_TWCR register. The VFP is the vertical front porch period.

*Note:* When the LTDC is enabled, the timings generated start with X/Y = 0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.

When the LTDC is disabled, the timing generator block is reset to X = total width - 1, Y = total height - 1 and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

**Example of synchronous timings configuration**

LTDC timings (must be extracted from panel datasheet):

- horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
- horizontal and vertical back porch: 0x14 pixels and 0x2 lines
- active width and active height: 0x140 pixels, 0xF0 lines (320x240)
- horizontal front porch: 0xA pixels
- vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:

- LTDC_SSCR register to be programmed to 0x00090001 (HSW[11:0] is 0x9 and VSH[10:0] is 0x1)
- LTDC_BPCR register to be programmed to 0x001D0003 (AHBP[11:0] is 0x1D (0xA + 0x13) and AVBP[10:0]A is 0x3 (0x2 + 0x1))
- LTDC_AWCR register to be programmed to 0x015D00F3 (AAW[11:0] is 0x15D (0xA +0x14 +0x13F) and AAH[10:0] is 0xF3 (0x2 + 0x2 + 0xEF))
- LTDC_TWCR register to be programmed to 0x000000167 (TOTALW[11:0] is 0x167 (0xA +0x14 +0x140 + 0x9))
- LTDC_THCR register to be programmed to 0x000000F7 (TOTALH[10:0]is 0xF7 (0x2 +0x2 + 0xF0 + 3))

**Programmable polarity**

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC_GCR register.

**Background color**

A constant background color (RGB888) can programmed through the LTDC_BCCR register. It is used for blending with the bottom layer.

**Dithering**

The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in
some cases when displaying a 24-bit data on 18-bit display. Thus the dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is ≥ the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is two bits for each color channel: two bits for red, two bits for green and two bits for blue.

Once the LTDC is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched on and off on the fly through the LTDC_GCR register.

**Reload shadow registers**

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload must be activated only when all new registers have been written.

The shadow registers must not be modified again before the reload is done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all Layer1 and Layer2 registers except LTDC_LxCLUTWR.

**Interrupt generation event**

Refer to Section 38.5: LTDC interrupts for the interrupt configuration.

### 38.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

**Windowing**

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.
The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame (see the figure below):

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC_LxWVPCR register.

### Figure 335. Layer window programmable parameters

#### Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer.

Up to eight input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions) 43210432 (the three LSBs are filled with the three MSBs of the five bits)

The table below describes the pixel data mapping depending on the selected format.

### Table 315. Pixel data mapping versus color format

Color look-up table (CLUT)

The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

</tbody>
</table>

Table 315. Pixel data mapping versus color format (continued)
The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:

- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.

- In case of AL44 input pixel format, the CLUT must be loaded by only 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
  - L0 (indexed color 0), at address 0x00
  - L1, at address 0x11
  - L2, at address 0x22
  - ....
  - L15, at address 0xFF

**Color frame buffer address**

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

**Color frame buffer length**

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer:

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

**Color frame buffer pitch**

Every layer has a configurable pitch for the color frame buffer, that is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.
Layer blending
The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to the figure below.

**Figure 336. Blending two layers with background**

![Blending two layers with background](image)

Default color
Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

Color keying
A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

**Example**: if the a mid-yellow color (50 % red + 50 % green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000. Set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.
38.5 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LIPCR register
- Register reload interrupt: generated when the shadow registers reload is performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AXI bus error occurs during data transfer

Those interrupts events are connected to the NVIC controller as described in the figure below.

Table 316. LTDC interrupt requests
38.6 LTDC programming procedure

The steps listed below are needed to program the LTDC:

1. Enable the LTDC clock in the RCC register.
2. Configure the required pixel clock following the panel datasheet.
3. Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the Section 38.4.1.
4. Configure the synchronous signals and clock polarity in the LTDC_GCR register.
5. If needed, configure the background color in the LTDC_BCCR register.
6. Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
7. Configure the layer1/2 parameters by:
   - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_WVPCR registers. The layer window must be in the active data area.
   - programming the pixel input format in the LTDC_LxPFCR register
   - programming the color frame buffer start address in the LTDC_LxCFBAR register
   - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
   - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
   - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCLUTWR register
   - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
8. Enable layer1/2 and if needed the CLUT in the LTDC_LxCR register.
9. If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
10. Reload the shadow registers to active register through the LTDC_SRCR register.
11. Enable the LTDC controller in the LTDC_GCR register.
12. All layer parameters can be modified on the fly except the CLUT. The new configuration must be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

Note: All layer's registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.
### 38.7 LTDC registers

#### 38.7.1 LTDC synchronization size configuration register (LTDC_SSCR)

Address offset: 0x008  
Reset value: 0x0000 0000

This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 334 and Section 38.4 for an example of configuration.

38.7.2 LTDC back porch configuration register (LTDC_BPCR)

Address offset: 0x00C
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical synchronization and back porch lines minus 1 (VSYNC height + VBP - 1). Refer to Figure 334 and Section 38.4 for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]: accumulated horizontal back porch (in units of pixel clock period)**
- These bits define the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.
- The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AVBP[10:0]: accumulated vertical back porch (in units of horizontal scan line)**
- These bits define the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.
- The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.
38.7.3  LTDC active width configuration register (LTDC_AWCR)

Address offset: 0x010
Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + VBP + active height - 1). Refer to Figure 334 and Section 38.4 for an example of configuration.

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16  **AAW[11:0]**: accumulated active width (in units of pixel clock period)

These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.

The active width is the number of pixels in active display area of the panel scan line.

Refer to device datasheet for maximum active width supported following maximum pixel clock.

Bits 15:11  Reserved, must be kept at reset value.

Bits 10:0  **AAH[10:0]**: accumulated active height (in units of horizontal scan line)

These bits define the accumulated height which includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel.

Refer to device datasheet for maximum active height supported following maximum pixel clock.
38.7.4  **LTDC total width configuration register (LTDC_TWCR)**

Address offset: 0x014

Reset value: 0x0000 0000

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + VBP + active height + VFP - 1). Refer to Figure 334 and Section 38.4 for an example of configuration.

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | **TOTALW[11:0]**: total width (in units of pixel clock period) |
| These bits defines the accumulated total width which includes the horizontal synchronization, horizontal back porch, active width and horizontal front porch pixels minus 1. |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | **TOTALH[10:0]**: total height (in units of horizontal scan line) |
| These bits defines the accumulated height which includes the vertical synchronization, vertical back porch, the active height and vertical front porch height lines minus 1. |

| Bits 31  |
| HSPOL   |
| This bit is set and cleared by software. |
| 0: horizontal synchronization polarity is active low. |
| 1: horizontal synchronization polarity is active high. |

38.7.5  **LTDC global control register (LTDC_GCR)**

Address offset: 0x018

Reset value: 0x0000 2220

This register defines the global configuration of the LCD-TFT controller.

| Bits 31  |
| HSPOL   |
| This bit is set and cleared by software. |
| 0: horizontal synchronization polarity is active low. |
| 1: horizontal synchronization polarity is active high. |
Bit 30  **VSPOL**: vertical synchronization polarity  
This bit is set and cleared by software.  
0: vertical synchronization is active low.  
1: vertical synchronization is active high.  

Bit 29  **DEPOL**: not data enable polarity  
This bit is set and cleared by software.  
0: not data enable polarity is active low.  
1: not data enable polarity is active high.  

Bit 28  **PCPOL**: pixel clock polarity  
This bit is set and cleared by software.  
0: pixel clock polarity is active low.  
1: pixel clock is active high.  

Bits 27:17  Reserved, must be kept at reset value.  

Bit 16  **DEN**: dither enable  
This bit is set and cleared by software.  
0: dither disabled  
1: dither enabled  

Bit 15  Reserved, must be kept at reset value.  

Bits 14:12  **DRW[2:0]**: dither red width  
These bits return the Dither Red Bits.  

Bit 11  Reserved, must be kept at reset value.  

Bits 10:8  **DGW[2:0]**: dither green width  
These bits return the dither green bits.  

Bit 7  Reserved, must be kept at reset value.  

Bits 6:4  **DBW[2:0]**: dither blue width  
These bits return the dither blue bits.  

Bits 3:1  Reserved, must be kept at reset value.  

Bit 0  **LTDCEN**: LCD-TFT controller enable  
This bit is set and cleared by software.  
0: LTDC disabled  
1: LTDC enabled
### 38.7.6 LTDC shadow reload configuration register (LTDC_SRCR)

Address offset: 0x024  
Reset value: 0x0000 0000  

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC_L1CLUTWR and the LTDC_L2CLUTWR.  

The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.

0: no effect
1: clears the LIF flag in the LTDC_ISR register.
38.7.13 LTDC current display status register (LTDC_CDSR)

Address offset: 0x048
Reset value: 0x0000 000F

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNC bit is active high.

The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

### 38.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

Address offset: 0x088 + 0x080 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

Example: The LTDC_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure
the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in
the active data area:

- layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5).
- layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16  WHSPPOS[11:0]: window horizontal stop position

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  WHSTPOS[11:0]: window horizontal start position
38.7.16  LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)

Address offset: 0x08C + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.

The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

Example:
The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of eight lines in the active data area:

- layer window first line, WVSTPOS[10:0], must be programmed to 0xE (0x5 + 1 + 0x8).
- layer window last line, WVSPPOS[10:0] must be programmed to 0x1DA.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:27  Reserved, must be kept at reset value.

Bits 26:16  **WVSPPOS[10:0]**: window vertical stop position
These bits configure the last visible line of the layer window.

Bits 15:11  Reserved, must be kept at reset value.

Bits 10:0  **WVSTPOS[10:0]**: window vertical start position
These bits configure the first visible line of the layer window.
WVSTPOS[10:0] must be ≤ AAH[10:0] bits (programmed in LTDC_AWCR register).
### 38.7.17 LTDC layer x color keying configuration register (LTDC_LxCKCR)

Address offset: 0x090 + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the color key value (RGB), that is used by the color keying.

Bits 23:16  **CKRED[7:0]**: color key red value
Bits 15:8   **CKGREEN[7:0]**: color key green value
Bits 7:0    **CKBLUE[7:0]**: color key blue value

### 38.7.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR)

Address offset: 0x094 + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **CONSTA[7:0]**: constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is 255 / 255 = 1.
38.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR)

Address offset: 0x09C + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Bits 31:24  **DCALPHA[7:0]**: default color alpha
These bits configure the default alpha value.

Bits 23:16  **DCREDS[7:0]**: default color red
These bits configure the default red value.

Bits 15:8   **DCGREEN[7:0]**: default color green
These bits configure the default green value.

Bits 7:0    **DCBLUE[7:0]**: default color blue
These bits configure the default blue value.

38.7.21 LTDC layer x blending factors configuration register (LTDC_LxBFCR)

Address offset: 0x0A0 + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0607

This register defines the blending factors F1 and F2.
The general blending formula is: BC = BF1 x C + BF2 x Cs
- BC = blended color
- BF1 = blend factor 1
- C = current layer color
- BF2 = blend factor 2
- Cs = subjacent layers blended color

The constant alpha value, is the programmed value in LTDC_LxCACR divided by 255 by hardware.

**Example:** Only layer 1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in LTDC_LxCACR is 240 (0xF0). Thus, the constant alpha value is 240 / 255 = 0.94. C: current layer color is 128.
**Cs:** background color is 48. Layer1 is blended with the background color.

\[ BC = \text{constant alpha} \times C + (1 - \text{Constant Alpha}) \times Cs = 0.94 \times 128 + (1 - 0.94) \times 48 = 123. \]

Address offset: 0x0AC + 0x080 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

CBFADD[15:0]

Bits 31:0  **CFBADD[31:0]**: color frame buffer start address  
These bits define the color frame buffer start address.

38.7.23  **LTDC layer x color frame buffer length register**  
(LTDC\_LxCFBLR)

Address offset: 0x0B0 + 0x080 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

This register defines the color frame buffer line length and pitch.

**Example:**
- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.

</tbody>
</table>

CBFP[12:0]

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:16  **CFB[12:0]**: color frame buffer pitch in bytes  
These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13  Reserved, must be kept at reset value.
38.7.24 LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR)

Address offset: 0x0B4 + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the number of lines in the color frame buffer.

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.

<table>
<thead>
<tr>
<th>Bits 12:0 CFBLL[12:0]: color frame buffer line length</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits define the length of one line of pixels in bytes + 7.</td>
</tr>
<tr>
<td>The line length is computed as follows:</td>
</tr>
<tr>
<td>active high width * number of bytes per pixel + 7.</td>
</tr>
</tbody>
</table>

38.7.25 LTDC layer x CLUT write register (LTDC_LxCLUTWR)

Address offset: 0x0C4 + 0x080 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

This register defines the CLUT address and the RGB value.

The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register.

The CLUT is only meaningful for L8, AL44 and AL88 pixel format.
Bits 31:24 **CLUTADD[7:0]**: CLUT address
These bits configure the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 **RED[7:0]**: red value
These bits configure the red value.

Bits 15:8 **GREEN[7:0]**: green value
These bits configure the green value.

Bits 7:0 **BLUE[7:0]**: blue value
These bits configure the blue value.

Refer to Section 2.3 for the register boundary addresses.
39 True random number generator (RNG)

39.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a non-deterministic random bit generator (NDRBG).

The RNG true random number generator has been pre-certified NIST SP800-90B. It has also been tested using German BSI statistical tests of AIS-31 (T0 to T8).

39.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as entropy source to construct a non-deterministic random bit generator (NDRBG).
- It produces four 32-bit random samples every 412 AHB clock cycles if \( f_{\text{AHB}} < 77 \, \text{MHz} \) (256 RNG clock cycles otherwise).
- It embeds start-up and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
39.3 RNG functional description

39.3.1 RNG block diagram

*Figure 338* shows the RNG block diagram.

39.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 339. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

![Figure 339. NIST SP800-90B entropy source model](image)

The components pictured above are detailed hereafter:

**Noise source**

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 39.3.8: RNG low-power usage.
- The XORing of the six noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (\texttt{rng_clk} with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (\texttt{rng_hclk}), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

*Note:* In Section 39.6: RNG entropy source validation recommended RNG clock frequencies and associated divider value are given.
Post processing

In NIST configuration no post-processing is applied to sampled noise source. In non-NIST configuration B (as defined in Section 39.6.2) a normalization debiasing is applied, i.e. half of the bits are taken from the sampled noise source, half of the bits are taken from inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 39.5: RNG processing time.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 39.5: RNG processing time.

Whenever a random number is available through the RNG_DR register the DRDY flag transitions from 0 to 1. This flag remains high until output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (in Section 39.6.2).

1. Start-up health tests, performed after reset and before the first use of the RNG as entropy source
   - Adaptive proportion test running on one 1024 bit windows: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 628 times.
   - Known-answer tests, to verify the conditioning stage.
   - Repetition count test, flagging an error when the noise source has provided more than 40 consecutive bits at a constant value (0 or 1)

2. Continuous health tests, running indefinitely on the outputs of the noise source
   - Repetition count test, similar to the one running in start-up tests
   - Adaptive proportion test running on 1024 consecutive samples, like during start-up health tests.

3. Vendor specific continuous tests
   - Transition count test, flagging an error when the noise source has delivered more than 42 consecutive occurrences of 2-bit patterns (01 or 10).
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and re-running the startup tests (see software reset sequence in Section 39.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 39.3.7: Error management.

Note: An interrupt can be generated when an error is detected.
Above health test thresholds are modified by changing value in RNG_HTCR register. See Section 39.6: RNG entropy source validation for details.
39.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 340.

After enabling the RNG (RNGEN = 1 in RNG_CR) the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample analog output and filling 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering start-up behavior test on the raw data samples and known-answer tests.
3. When start-up health tests are completed. During this time three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 39.5: RNG processing time.

Figure 340. RNG initialization overview
Figure 340 also highlights a possible software reset sequence, implemented by:

1. Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
2. Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
3. Wait for random number to be ready, after initialization completes.

Note: When RNG peripheral is reset through RCC (hardware reset), the RNG configuration for optimal randomness is lost in RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

39.3.5 RNG operation

Normal operations

To run the RNG using interrupts, the following steps are recommended:

1. Consult Section 39.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   – If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
   – If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore at each interrupt, check that:
   – No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   – A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   – If above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 39.3.7 must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult Section 39.6: RNG entropy source validation and verify if a specific RNG configuration is required for the application.
   – If it is the case write in the RNG_CR register the bit CONDRST = 1 together with the correction RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   – If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   – No error occurred (the SEIS and CEIS bits must be set to 0)
   – A random number is ready (the DRDY bit must be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 39.3.7 must be used.

Note: When data is not ready (DRDY = 0) RNG_DR returns zero.
It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 39.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 39.5: RNG processing time.

Low-power operations
If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 39.3.8: RNG low-power usage.

Software post-processing
No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.
Built-in health check functions are described in Section 39.3.3: Random number generation.

39.3.6 RNG clocking
The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.
The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in Section 39.6: RNG entropy source validation.

Note: When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before internal divider must be higher than AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).
See Section 39.3.1: RNG block diagram for details (AHB and RNG clock domains).

39.3.7 Error management
In parallel to random number generation an health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection
When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application should check that the RNG clock is configured correctly (see Section 39.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when clocking condition is normal.

Note: The clock error has no impact on generated random numbers, i.e. application can still read RNG_DR register.
CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:
1. Software reset by writing CONDRST at 1 and at 0 (see bitfield description for details).
2. wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register.
3. wait for SECS to be cleared by RNG. The random number generation is now back to normal.

39.3.8 RNG low-power usage

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be re-enabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in Section 39.5: RNG processing time on page 1435.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (i.e. well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1, unless the application resets the conditioning logic using CONDRST bit in the RNG_CR register.

39.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 39.3.7: Error management
- Clock error, see Section 39.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 319.
Table 319. RNG interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG</td>
<td>Data ready flag</td>
<td>DRDY</td>
<td>IE</td>
<td>None (automatic)</td>
</tr>
<tr>
<td></td>
<td>Seed error flag</td>
<td>SEIS</td>
<td>IE</td>
<td>Write 0 to SEIS or write CONDRST to 1 then to 0</td>
</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

39.5 RNG processing time

In recommended configurations described in Table 320, the time between two sets of four 32-bit data is either:
- 412 AHB cycles if $f_{AHB} < f_{\text{threshold}}$ (conditioning stage is limiting), or
- 256 RNG cycles $f_{AHB} \geq f_{\text{threshold}}$ (noise source stage is limiting).

With $f_{\text{threshold}} = 1.6 \times f_{\text{RNG}}$, e.g. 77 MHz if $f_{\text{RNG}} = 48$ MHz.

Note: When CLKDIV is different from zero, $f_{\text{RNG}}$ must take into account the internal divider ratio.

39.6 RNG entropy source validation

39.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite. The results can be provided on demand or the customer can reproduce the tests.

39.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:
- RNG clock rng_clk= 48 MHz
- RNG configurations described in Table 320. Note that only configuration A can be certified NIST SP800-90B.
39.6.3 Data collection

In order to run statistical tests it is required to collect samples from the entropy source at raw data level as well as at the output of the entropy source. For details on data collection and the running of statistical test suites refer to “STM32 microcontrollers random number generation validation using NIST statistical test suite” application note (AN4230) available from [www.st.com](http://www.st.com).

Contact STMicroelectronics if above samples need to be retrieved for the product.

39.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

39.7.1 RNG control register (RNG_CR)

Address offset: 0x000

Reset value: 0x0080 0000

<table>

</tr>
</tbody>
</table>

1. When writing this register magic number 0x17590ABC must be written immediately before the indicated value.
Bit 31 **CONFIGLOCK**: RNG Config lock
- 0: Writes to the RNG_CR configuration bits [29:4] are allowed.
- 1: Writes to the RNG_CR configuration bits [29:4] are ignored until the next RNG reset.
This bitfield is set once: if this bit is set it can only be reset to 0 if RNG is reset.

Bit 30 **CONDRST**: Conditioning soft reset
- Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_CR and RNG_NSCR are not changed by CONDRST.
- This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.
- When CONDRST is set to 0 by software its value goes to 0 when the reset process is done. It takes about 2 AHB clock cycles + 2 RNG clock cycles.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:20 **RNG_CONFIG1[5:0]**: RNG configuration 1
- Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in Section 39.6: RNG entropy source validation.
- Writing any bit of RNG_CONFIG1 is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 19:16 **CLKDIV[3:0]**: Clock divider factor
- This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).
- 0x0: internal RNG clock after divider is similar to incoming RNG clock.
- 0x1: two RNG clock cycles per internal RNG clock.
- 0x2: $2^2$ (= 4) RNG clock cycles per internal RNG clock.
- ... 0xF: $2^{15}$ RNG clock cycles per internal clock (for example, an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)
- Writing these bits is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 15:13 **RNG_CONFIG2[2:0]**: RNG configuration 2
- Reserved to the RNG configuration (bitfield 2). Refer to RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC**: Non NIST compliant
- 0: Hardware default values for NIST compliant RNG. In this configuration per 128-bit output two conditioning loops are performed and 256 bits of noise source are used.
- 1: Custom values for NIST compliant RNG. See Section 39.6: RNG entropy source validation for proposed configuration.
- Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8 **RNG_CONFIG3[3:0]**: RNG configuration 3
- Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details.
- If NISTC bit is cleared in this register RNG_CONFIG1 bitfield values are ignored by RNG.

Bit 7 Reserved, must be kept at reset value.

Bit 6 Reserved, must be kept at reset value.
Bit 5 **CED**: Clock error detection
0: Clock error detection is enable
1: Clock error detection is disable
The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, i.e. to enable or disable CED the RNG must be disabled.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE**: Interrupt Enable
0: RNG Interrupt is disabled
1: RNG Interrupt is enabled. An interrupt is pending as soon as DRDY = 1, SEIS = 1 or CEIS = 1 in the RNG_SR register.

Bit 2 **RNGEN**: True random number generator enable
0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.
39.7.2 RNG status register (RNG_SR)

Address offset: 0x004
Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 SEIS: Seed error interrupt status
This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.
0: No faulty sequence detected
1: At least one faulty sequence is detected. See SECS bit description for details.
An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5 CEIS: Clock error interrupt status
This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.
0: The RNG clock is correct (fRNGCLK> fHCLK/32)
1: The RNG clock before internal divider is detected too slow (fRNGCLK< fHCLK/32)
An interrupt is pending if IE = 1 in the RNG_CR register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 SECS: Seed error current status
0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.
1: At least one of the following faulty sequence has been detected:
  – Run-time repetition count test failed (noise source has provided more than 24 consecutive bits at a constant value 0 or 1, or more than 32 consecutive occurrence of two bits patterns 01 or 10)
  – Start-up or continuous adaptive proportion test on noise source failed.
  – Start-up post-processing/conditioning sanity check failed.

Bit 1 CECS: Clock error current status
0: The RNG clock is correct (fRNGCLK> fHCLK/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.
1: The RNG clock is too slow (fRNGCLK< fHCLK/32).
Note: CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0 DRDY: Data Ready
0: The RNG_DR register is not yet valid, no random data is available.
1: The RNG_DR register contains valid random data.
Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.
Note: The DRDY bit can rise when the peripheral is disabled (RNGEN = 0 in the RNG_CR register).
If IE=1 in the RNG_CR register, an interrupt is generated when DRDY = 1.
39.7.3  RNG data register (RNG_DR)

Address offset: 0x008
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when DRDY = 1 and value is not 0x0, even if RNGEN = 0.

32-bit random data which are valid when DRDY = 1. When DRDY = 0 RNDATA value is zero.

It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

39.7.4  RNG health test control register (RNG_HTCR)

Address offset: 0x010
Reset value: 0x0000 5A4E

Writing in RNG_HTCR is taken into account only if CONDRST bit is set, and CONFIGLOCK bit is cleared in RNG_CR. Writing to this register is ignored if CONFIGLOCK=1.

Bits 31:0  HTCFCFG[31:0]: health test configuration

This configuration is used by RNG to configure the health tests. See Section 39.6: RNG entropy source validation for the recommended value.

Note: The RNG behavior, including the read to this register, is not guaranteed if a different value from the recommended value is written.

When reading or writing this register magic number; 0x17590ABC must be written immediately before to RNG_HTCR register.

Refer to [Section 2.3](#) for the register boundary addresses.
40 Cryptographic processor (CRYP)

40.1 Introduction

The cryptographic processor (CRYP) can be used both to encrypt and decrypt data using the DES, Triple-DES or AES algorithms. It is a fully compliant implementation of the following standards:

- The data encryption standard (DES) and Triple-DES (TDES) as defined by Federal Information Processing Standards Publication (FIPS PUB 46-3, Oct 1999), and the American National Standards Institute (ANSI X9.52)
- The advanced encryption standard (AES) as defined by Federal Information Processing Standards Publication (FIPS PUB 197, Nov 2001)

Multiple key sizes and chaining modes are supported:

- DES/TDES chaining modes ECB and CBC, supporting standard 56-bit keys with 8-bit parity per key
- AES chaining modes ECB, CBC, CTR, GCM, GMAC, CCM for key sizes of 128, 192 or 256 bits

The CRYP processor is a 32-bit AHB peripheral. It supports DMA transfers for incoming and outgoing data (two DMA channels are required). The peripheral also includes input and output FIFOs (each 8 words deep) for better performance.

40.2 CRYP main features

- Compliant implementation of the following standards:
  - NIST FIPS publication 46-3, Data Encryption Standard (DES)
  - ANSI X9.52, Triple Data Encryption Algorithm Modes of Operation
  - NIST FIPS publication 197, Advanced Encryption Standard (AES)
- AES symmetric block cipher implementation
  - 128-bit data block processing
  - Support for 128-, 192- and 256-bit cipher key lengths
  - Encryption and decryption with multiple chaining modes: Electronic Code Book (ECB), Cipher Block Chaining (CBC), Counter mode (CTR), Galois Counter Mode (GCM), Galois Message Authentication Code mode (GMAC) and Counter with CBC-MAC (CCM)
  - 14 (respectively 18) clock cycles for processing one 128-bit block of data with a 128-bit (respectively 256-bit) key in AES-ECB mode
  - Integrated key scheduler with its key derivation stage (ECB or CBC decryption only)
- DES/TDES encryption/decryption implementation
  - 64-bit data block processing
  - Support for 64-, 128- and 192-bit cipher key lengths (including parity)
  - Encryption and decryption with support of ECB and CBC chaining modes
  - Direct implementation of simple DES algorithms (a single key K1 is used)
- 16 (respectively 48) clock cycles for processing one 64-bit block of data in DES (respectively TDES) ECB mode
- Software implementation of ciphertext stealing
- Features common to DES/TDES and AES
  - AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
  - 256-bit register for storing the cryptographic key (8x 32-bit registers)
  - 128-bit registers for storing initialization vectors (4x 32-bit)
  - 1x32-bit INPUT buffer associated with an internal IN FIFO of eight 32-bit words, corresponding to four incoming DES blocks or two AES blocks
  - 1x32-bit OUTPUT buffer associated with an internal OUT FIFO of eight 32-bit words, corresponding to four processed DES blocks or two AES blocks
  - Automatic data flow control supporting direct memory access (DMA) using two channels (one for incoming data, one for processed data). The OUT FIFO supports both single and burst transfers, while the IN FIFO supports only burst transfers.
  - Data swapping logic to support 1-, 8-, 16- or 32-bit data
  - Possibility for software to suspend a message if the cryptographic processor needs to process another message with higher priority (suspend/resume operation)

40.3 CRYP implementation

This device has one CRYP instance.

40.4.3 CRYP DES/TDES cryptographic core

**Overview**

The DES/Triple-DES cryptographic core consists of three components:
- The DES Algorithm (DEA core)
- Multiple keys (one for the DES algorithm, one to three for the TDES algorithm)
- The initialization vector, which is used only in CBC mode

The DES/Triple-DES cryptographic core provides two operating modes:
- **ALGODIR = 0**: Plaintext encryption using the key stored in the CRYP_Kx registers.
- **ALGODIR = 1**: Ciphertext decryption using the key stored in the CRYP_Kx registers.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

**Typical data processing**

Typical usage of the cryptographic processor in DES modes can be found in *Section 40.4.10: CRYP DES/TDES basic chaining modes (ECB, CBC).*

*Note:* The outputs of the intermediate DEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IV registers in CBC mode.

**DES/TDES keying and chaining modes**

The DES/TDES allows three different keying options:

- **Three independent keys**
  The first option specifies that all the keys are independent, that is, K1, K2 and K3 are independent. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 1 and, to the TDES as 3-key TDES.

- **Two independent keys**
  The second option specifies that K1 and K2 are independent and K3 is equal to K1, that is, K1 and K2 are independent, K3 = K1. FIPS PUB 46-3 – 1999 (and ANSI X9.52
– 1998) refers to this second option as the Keying Option 2 and, to the TDES as 2-key TDES.

- **Three equal keys**
  The third option specifies that K1, K2 and K3 are equal, that is:
  \[ K1 = K2 = K3 \]

FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to the third option as the Keying Option 3. This “1-key” TDES is equivalent to single DES.

The following chaining algorithms are supported by the DES hardware and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)

These modes are described in details in [Section 40.4.10: CRYP DES/TDES basic chaining modes (ECB, CBC)](#).

### 40.4.4 CRYP AES cryptographic core

#### Overview

The AES cryptographic core consists of the following components:

- The AES algorithm (AEA core)
- The Multiplier over a binary Galois field (GF2mul)
- The key information
- The initialization vector (IV) or Nonce information
- Chaining algorithms logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks of (four words) with 128-, 192- or 256-bit key lengths. Depending on the chaining mode, the peripheral requires zero or one 128-bit initialization vector (IV).

The cryptographic peripheral features two operating modes:

- **ALGODIR = 0**: Plaintext encryption using the key stored in the CRYP_Kx registers.
- **ALGODIR = 1**: Ciphertext decryption using the key stored in the CRYP_Kx registers. When ECB and CBC chaining modes are selected, an initial key derivation process is automatically performed by the cryptographic peripheral.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

#### Typical data processing

A description of cryptographic processor typical usage in AES mode can be found in [Section 40.4.11: CRYP AES basic chaining modes (ECB, CBC)](#).

**Note:** The outputs of the intermediate AEA stages is never revealed outside the cryptographic boundary, with the exclusion of the IV registers.
AES chaining modes

The following chaining algorithms are supported by the cryptographic processor and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)
- Counter Mode (CTR)
- Galois/Counter Mode (GCM)
- Galois Message Authentication Code mode (GMAC)
- Counter with CBC-MAC (CCM)

A quick introduction on these chaining modes can be found in the following subsections.

For detailed instructions, refer to Section 40.4.11: CRYP AES basic chaining modes (ECB, CBC) and onward.

AES Electronic CodeBook (ECB)

ECB is the simplest operating mode. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

Note: For decryption, a special key scheduling is required before processing the first block.
AES Cipher block chaining (CBC)

CBC operating mode chains the output of each block with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

**Note:** For decryption, a special key scheduling is required before processing the first block.
AES Counter mode (CTR)

The CTR mode uses the AES core to generate a key stream; these keys are then XORed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

**Note:** Unlike ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the counter blocks.
AES Galois/Counter mode (GCM)

In Galois/Counter mode (GCM), the plaintext message is encrypted, while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

AES Galois Message Authentication Code (GMAC)
Galois Message Authentication Code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GMAC is similar to Galois/Counter mode (GCM), except that it is applied on a message composed only by clear-text authenticated data (i.e. only header, no payload).

**AES Counter with CBC-MAC (CCM)**

In Counter with Cipher Block Chaining-Message Authentication Code (CCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM CCM chaining mode, AES-CCM mode can be applied on a message composed only by cleartext authenticated data (i.e. only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its usage is not recommended by NIST.
40.4.5 CRYP procedure to perform a cipher operation

Introduction
To understand how the cryptographic peripheral operates, a typical cipher operation is described below. For the detailed peripheral usage according to the cipher mode, refer to the specific section, for example Section 40.4.11: CRYP AES basic chaining modes (ECB, CBC).

CRYP initialization
To initialize the cryptographic processor, first disable it by clearing the CRYPEN bit in the CRYP_CR register. Then execute the following steps:
1. Configure the algorithm and the chaining mode through the ALGOMODE and ALGODIR bits in the CRYP_CR register. Configure also the key size with the KEYSIZE bits.
   – When ALGODIR is set to 1 (decryption) and the selected algorithm/chaining mode is AES-ECB or AES-CBC, an initial key derivation of the encryption key must be performed as described in Section 40.4.7: Preparing the CRYP AES key for decryption.
2. When the previous step is complete, and when applicable, write the symmetric key into the CRYP_KxL/R registers. The way to write key registers is defined in Section 40.4.17: CRYP key registers.
3. Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits of the CRYP_CR register.
4. When it is required (for example for CBC or CTR chaining modes), write the initialization vectors into the CRYP_IVxL/R register.
5. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.

Preliminary warning for all cases
If the ECB or CBC mode is selected and data are not a multiple of 64 bits (for DES) or 128 bits (for AES), the second and the last block management is more complex than the sequences below. Refer to Section 40.4.8: CRYP stealing and data padding for more details.
Appending data using the CPU in Polling mode

1. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR register.
2. Write data in the IN FIFO (one block or until the FIFO is full).
3. Repeat the following sequence until the second last block of data has been processed:
   a) Wait until the not-empty-flag OFNE is set to 1, then read the OUT FIFO (one block or until the FIFO is empty).
   b) Wait until the not-full-flag IFNF is set to 1, then write the IN FIFO (one block or until the FIFO is full) except if it is the last block.
4. The BUSY bit is set automatically by the cryptographic processor. At the end of the processing, the BUSY bit returns to 0 and both FIFOs are empty (IN FIFO empty flag IFEM = 1 and OUT FIFO not empty flag OFNE = 0).
5. If the next processing block is the last block, the CPU must pad (when applicable) the data with zeroes to obtain a complete block and specify the number of non-valid bytes using NPBLB bits in CRYP_CR register in case of AES GCM payload encryption or AES CCM payload decryption (otherwise the tag computation will be wrong). This operation must be performed after checking that the BUSY bit in the CRYP_CR register is set to 0.
   Note: NPBLB bits are not used in the header phase of AES GCM, GMAC and CCM modes.
6. When the operation is complete, the cryptographic processor can be disabled by clearing the CRYPEN bit in CRYP_CR register.

Appending data using the CPU in Interrupt mode

1. Enable the interrupts by setting the INIM and OUTIM bits in the CRYP_IMSCR register.
2. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR register.
3. In the interrupt service routine that manages the input data:
   a) If the last block is being loaded, the CPU must pad (when applicable) the data with zeroes to have a complete block and specify the number of non-valid bytes using NPBLB bits in CRYP_CR register in case of AES GCM payload encryption or AES CCM payload decryption (otherwise the tag computation will be wrong). This operation must be performed after checking that the BUSY bit in the CRYP_CR register is set to 0. Then load the block into the IN FIFO.
   b) If it is not the last block, load the data into the IN FIFO. You can load only one block (2 words for DES, 4 words for AES), or load data until the FIFO is full.
   c) In all cases, after the last word of data has been written, disable the interrupt by clearing the INIM interrupt mask.
4. In the interrupt service routine that manages the input data:
   a) Read the output data from the OUT FIFO. You can read only one block (2 words for DES, 4 words for AES), or read data until the FIFO is empty.
   b) When the last word has been read, INIM and BUSY bits are set to 0 and both FIFOs are empty (IFEM = 1 and OFNE = 0). You can disable the interrupt by clearing the OUTIM bit, and disable the peripheral by clearing the CRYPEN bit.
   c) If you read the last block of cleartext data (i.e. decryption), optionally discard the data that is not part of message/payload.
   Note: NPBLB bits are not used in the header phase of AES GCM, GMAC and CCM.
Appending data using the DMA

1. Prepare the last block of data by optionally padding it with zeroes to have a complete block.
2. Configure the DMA controller to transfer the input data from the memory and transfer the output data from the peripheral to the memory, as described in Section 40.4.19: CRYP DMA interface. The DMA should be configured to set an interrupt on transfer completion to indicate that the processing is complete. In case of AES GCM payload encryption or AES CCM payload decryption, DMA transfers must not include the last block. The sequence using the CPU described above must be used instead for this last block, because NPBLB bits needs to be setup before processing the block (otherwise the tag computation will be wrong).

Note: NPBLB bits are not used in the header phase of AES GCM, GMAC and CCM.

3. Enable the cryptographic processor by setting to 1 the CRYPEN bit in CRYP_CR register, then enable the DMA IN and OUT requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.
4. All the transfers and processing are managed by the DMA and the cryptographic processor. The DMA interrupt indicates that the processing is complete. Both FIFOs are normally empty and BUSY flag is set 0.

Caution: It is important that DMA controller empties the cryptographic processor output FIFO before filling up the cryptographic processor input FIFO. To achieve this, the DMA controller should be configured so that the transfer from the cryptographic peripheral to the memory has a higher priority than the transfer from the memory to the cryptographic peripheral.

40.4.6 CRYP busy state

The cryptographic processor is busy and processing data (BUSY set to 1 in CRYP_SR register) when all the conditions below are met:
- CRYPEN = 1 in CRYP_CR register.
- There are enough data in the input FIFO (at least two words for the DES or TDES algorithm mode, four words for the AES algorithm mode).
- There is enough free-space in the output FIFO (at least two word locations for DES, four for AES).

Write operations to the CRYP_Kx(L/R)R key registers, to the CRYP_IVx(L/R)R initialization registers, or to bits [9:2] of the CRYP_CR register, are ignored when cryptographic processor is busy (i.e. the registers are not modified). It is thus not possible to modify the configuration of the cryptographic processor while it is processing a data block.

It is possible to clear the CRYPEN bit while BUSY bit is set to 1. In this case the ongoing DES/TDES or AES processing first completes (i.e. the word results are written to the output FIFO) before the BUSY bit is cleared by hardware.

Note: If the application needs to suspend a message to process another one with a higher priority, refer to Section 40.4.9: CRYP suspend/resume operations

When a block is being processed in DES or TDES mode, if the output FIFO becomes full and the input FIFO contains at least one new block, then the new block is popped off the input FIFO and the BUSY bit remains high until there is enough space to store this new block into the output FIFO.
40.4.7 Preparing the CRYP AES key for decryption

When performing an AES ECB or CBC decryption, the AES key has to be prepared. Indeed, in AES encryption the round 0 key is the one stored in the key registers, and AES decryption must start using the last round key. Hence, as the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key. This preparation is not required in any other AES modes than ECB or CBC decryption.

When the cryptographic processor is disabled (CRYPEN = 0), the CRYP key preparation process is performed as follows:

1. Program ALGOMODE bits to 0x7 in CRYP_CR. In addition, configure the key length with the KEYSIZE bits.
2. Write the symmetric key to the CRYP_KxL/R registers, as described in Section 40.4.17: CRYP key registers.
3. Enable the cryptographic processor by setting the CRYPEN bit in the CRYP_CR register. It immediately starts an AES round for key preparation (BUSY = 1).
4. Wait until the BUSY bit is cleared in the CRYP_SR register. Then update ALGOMODE bits in the CRYP_CR register to select the correct chaining mode, that is 0x4 for ECB or 0x5 for CBC.
5. The AES key is available in the CRYP key registers, ready to use for decryption.

Note: As the CRYPEN bitfield is reset by hardware at the end of the key preparation, the application software must set it again for the next operation.

The latency of the key preparation operation is 14, 16 or 18 clock cycles depending on the key size (128, 192 or 256 bits).

40.4.8 CRYP stealing and data padding

When using DES or AES algorithm in ECB or CBC modes to manage messages that are not multiple of the block size (64 bits for DES, 128 bits for AES), use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the cryptographic processor does not implement such techniques, the last two blocks must be handled in a special way by the application.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when the AES algorithm is used in other modes than ECB or CBC, incomplete input data blocks (i.e. block shorter than 128 bits) have to be padded with zeroes by the application prior to encryption (i.e. extra bits should be appended to the trailing end of the data string). After decryption, the extra bits have to be discarded. The cryptographic processor does not implement automatic data padding operation to the last block, so the application should follow the recommendation given in Section 40.4.5: CRYP procedure to perform a cipher operation to manage messages that are not multiple of 128 bits.

Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE field in CRYP_CR register (see Section 40.4.16: CRYP data registers and data swapping for details).
### 40.4.9 CRYP suspend/resume operations

A message can be suspended if another message with a higher priority has to be processed. When this highest priority message has been sent, the suspended message can be resumed in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can be resumed as soon as cryptographic processor is enabled again to receive the next data block.

*Figure 348* gives an example of suspend.resume operation: message 1 is suspended in order to send a higher priority message (message 2), which is shorter than message 1 (AES algorithm).

*Figure 348. Example of suspend mode management*

A detailed description of suspend/resume operations can be found in each AES mode section.
40.4.10  CRYP DES/TDES basic chaining modes (ECB, CBC)

Overview

FIPS PUB 46-3 – 1999 (and ANSI X9.52-1998) provides a thorough explanation of the processing involved in the four operation modes supplied by the DES computing core: TDES-ECB encryption, TDES-ECB decryption, TDES-CBC encryption and TDES-CBC decryption. This section only gives a brief explanation of each mode.

DES/TDES-ECB encryption

Figure 349 illustrates the encryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE 0x0 and ALGODIR to 0 in CRYP_CR.

Figure 349. DES/TDES-ECB mode encryption

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

A 64-bit plaintext data block (P) is used after bit/byte/half-word as the input block (I). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA where the DES is performed in the decrypt state using K2. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K3. The resultant 64-bit output block (O) is used, after bit/byte/half-word swapping, as ciphertext (C) and it is pushed into the OUT FIFO.

Note: For more information on data swapping, refer to Section 40.4.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 40.4.5: CRYP procedure to perform a cipher operation.
DES/TDES-ECB mode decryption

Figure 350 illustrates the decryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE to 0x0 and ALGODIR to 1 in CRYP_CR.

**Figure 350. DES/TDES-ECB mode decryption**

A 64-bit ciphertext block (C) is used, after bit/byte/half-word swapping, as the input block (I). The keying sequence is reversed compared to that used in the encryption process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K2. The new result is directly fed to the input of the DEA where the DES is performed in the decrypt state using K1. The resultant 64-bit output block (O), after bit/byte/half-word swapping, produces the plaintext (P).

Note: For more information on data swapping refer to Section 40.4.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 40.4.5: CRYP procedure to perform a cipher operation.
DES/TDES-CBC encryption

*Figure 351* illustrates the encryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by programming ALGOMODE to 0x1 and ALGODIR to 0 in CRYP_CR.

*Figure 351. DES/TDES-CBC mode encryption*

![Diagram of DES/TDES-CBC encryption]

K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

This mode begins by dividing a plaintext message into 64-bit data blocks. In TCBC encryption, the first input block (I1), obtained after bit/byte/half-word swapping, is formed by exclusive-ORing the first plaintext data block (P1) with a 64-bit initialization vector IV (I1 = IV ⊕ P1). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA, which performs the DES in the decrypt state using K2. The output of this process is fed directly to the input of the DEA, which performs the DES in the encrypt state using K3. The resultant 64-bit output block (O1) is used directly as the ciphertext (C1), that is, C1 = O1.

This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, (I2) = (C1 ⊕ P2). Note that I2 and P2 now refer to the second block. The second input block is processed through the TDEA to produce the second ciphertext block.

This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.
Cryptographic processor (CRYP)  

Note: For more information on data swapping refer to Section 40.4.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 40.4.5: CRYP procedure to perform a cipher operation.

DES/TDES-CBC decryption

Figure 351 illustrates the decryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0x1 and ALGODIR to 1 in CRYP_CR.

Figure 352. DES/TDES-CBC mode decryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

In this mode the first ciphertext block (C1) is used directly as the input block (I1). The keying sequence is reversed compared to that used for the encrypt process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed directly to the input of the DEA where the DES is processed in the encrypt state using K2. This resulting value is directly fed to the input of the DEA where the DES is processed in the decrypt state using K1. The resulting output block is exclusive-ORed with the IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the TDEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data.
The DES/TDES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

Ciphertext representing a partial data block must be decrypted in a manner specified for the application.

Note: For more information on data swapping refer to Section 40.4.16: CRYP data registers and data swapping.
Detailed DES/TDES encryption sequence can be found in Section 40.4.5: CRYP procedure to perform a cipher operation.

DES/TDES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following steps:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR) and the BUSY bit is cleared. Alternatively, as the input FIFO can contain up to four unprocessed DES blocks, the application could decide for real-time reason to interrupt the cryptographic processing without waiting for the IN FIFO to be empty. In this case, the alternative is:
   a) Wait until OUT FIFO is empty (OFNE = 0).
   b) Read back the data loaded in the IN FIFO that have not been processed and save them in the memory until the IN FIFO is empty.
3. If DMA is used stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2] in the CRYP_CR register). If CBC mode is selected, save the initialization vector registers, since CRYP_IVx registers have changed from initial values during the data processing.

Note: Key registers do not need to be saved as the original key value is known by the application.
5. If DMA is used, save the DMA controller status (such as the pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. If the CBC mode is selected, restore CRYP_IVx registers using the saved configuration.
5. Optionally, write the data that were saved during context saving into the IN FIFO.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again DMA requests for the cryptographic processor, by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.
40.4.11 CRYP AES basic chaining modes (ECB, CBC)

Overview

FIPS PUB 197 (November 26, 2001) provides a thorough explanation of the processing involved in the four basic operation modes supplied by the AES computing core: AES-ECB encryption, AES-ECB decryption, AES-CBC encryption and AES-CBC decryption. This section only gives a brief explanation of each mode.

AES ECB encryption

Figure 353 illustrates the AES Electronic codebook (AES-ECB) mode encryption. This mode is selected by writing ALGOMODE to 0x4 and ALGODIR to 0 in CRYP_CR.

Figure 353. AES-ECB mode encryption

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.
2. If Key size = 128: Key = [K3 K2].
   If Key size = 192: Key = [K3 K2 K1].
   If Key size = 256: Key = [K3 K2 K1 K0].

In this mode a 128-bit plaintext data block (P) is used after bit/byte/half-word swapping as the input block (I). The input block is processed through the AEA in the encrypt state using the 128, 192 or 256-bit key. The resultant 128-bit output block (O) is used after bit/byte/half-word swapping as ciphertext (C). It is then pushed into the OUT FIFO.

For more information on data swapping refer to Section 40.4.16: CRYP data registers and data swapping.
AES ECB decryption

*Figure 354* illustrates the AES Electronic codebook (AES-ECB) mode decryption. This mode is selected by programming ALGOMODE to 0x4 and ALGODIR to 1 in CRYP_CR.

**Figure 354. AES-ECB mode decryption**

To perform an AES decryption in ECB mode, the secret key has to be prepared (it is necessary to execute the complete key schedule for encryption) by collecting the last round key, and using it as the first round key for the decryption of the ciphertext. This preparation phase is computed by the AES core. Refer to *Section 40.4.7: Preparing the CRYP AES key for decryption* for more details on how to prepare the key.

When the key preparation is complete, the decryption proceed as follows: a 128-bit ciphertext block (C) is used after bit/byte/half-word swapping as the input block (I). The keying sequence is reversed compared to that of the encryption process. The resultant 128-bit output block (O), after bit/byte or half-word swapping, produces the plaintext (P). The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

For more information on data swapping refer to *Section 40.4.16: CRYP data registers and data swapping.*
AES CBC encryption

Figure 355 illustrates the AES Cipher block chaining (AES-CBC) mode encryption. This mode is selected by writing ALGOMODE to 0x5 and ALGODIR to 0 in CRYP.CR.

Figure 355. AES-CBC mode encryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.

2. IVx = [IVxR IVxL]. R = right, L = left.

3. If Key size = 128 => Key = [K3 K2].
   If Key size = 192 => Key = [K3 K2 K1]
   If Key size = 256 => Key = [K3 K2 K1 K0].

In this mode the first input block (I1) obtained after bit/byte/half-word swapping is formed by exclusive-ORing the first plaintext data block (P1) with a 128-bit initialization vector IV (I1 = IV ⊕ P1). The input block is processed through the AEA in the encrypt state using the 128-, 192- or 256-bit key (K0...K3). The resultant 128-bit output block (O1) is used directly as ciphertext (C1), that is, C1 = O1. This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, (I2) = (C1 ⊕ P2). Note that I2 and P2 now refer to the second block. The second input block is processed through the AEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application, as explained in Section 40.4.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 40.4.16: CRYP data registers and data swapping.
AES CBC decryption

Figure 356 illustrates the AES Cipher block chaining (AES-CBC) mode decryption. This mode is selected by writing ALGOMODE to 0x5 and ALGODIR to 1 in CRYP_CR.

**Figure 356. AES-CBC mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.

2. IVx = [IVxR IVxL], R = right, L = left.

3. If Key size = 128 => Key = [K3 K2].
   If Key size = 192 => Key = [K3 K2 K1].
   If Key size = 256 => Key = [K3 K2 K1 K0].

In CBC mode, like in ECB mode, the secret key must be prepared to perform an AES decryption. Refer to Section 40.4.7: Preparing the CRYP AES key for decryption for more details on how to prepare the key.

When the key preparation process is complete, the decryption proceeds as follows: the first 128-bit ciphertext block (C1) is used directly as the input block (I). The input block is processed through the AEA in the decrypt state using the 128-, 192- or 256-bit key. The resulting output block is exclusive-ORed with the 128-bit initialization vector IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the AEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data. The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.
Ciphertext representing a partial data block must be decrypted in a manner specified for the application, as explained in Section 40.4.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 40.4.16: CRYP data registers and data swapping.

AES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the CRYP by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2] in the CRYP_CR register). If ECB mode is not selected, save the initialization vector registers, because CRYP_IVx registers have changed from initial values during the data processing.

Note: Key registers do not need to be saved as the original key value is known by the application.
5. If DMA is used, save the DMA controller status (such as pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be set to 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. For AES-ECB or AES-CBC decryption, the key must be prepared again, as described in Section 40.4.7: Preparing the CRYP AES key for decryption.
5. If ECB mode is not selected, restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again the DMA requests from the cryptographic processor, by setting DIEN and DOEN bits to 1 in the CRYP_DMACR register.
40.4.12 CRYP AES counter mode (AES-CTR)

Overview

The AES counter mode (CTR) uses the AES block as a key stream generator. The generated keys are then XORed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation. A typical message construction in CTR mode is given in Figure 357.

Figure 357. Message construction for the Counter mode

The structure of this message is as below:

- A 16-byte Initial Counter Block (ICB), composed of three distinct fields:
  - A nonce: a 32-bit, single-use value (i.e. a new nonce should be assigned to each new communication).
  - The initialization vector (IV): a 64-bit value that must be unique for each execution of the mode under a given key.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. The initial value of the counter should be set to 1.

- The plaintext (P) is both authenticated and encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.
AES CTR processing

*Figure 358* (respectively *Figure 359*) describes the AES-CTR encryption (respectively decryption) process implemented within this peripheral. This mode is selected by programming ALGOMODE bitfield to 0x6 in CRYP_CR.

*Figure 358. AES-CTR mode encryption*

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.
In CTR mode, the output block is XORed with the subsequent input block before it is input to the algorithm. Initialization vectors in the peripheral must be initialized as shown on Table 323.

Table 323. Counter mode initialization vector

<table>
<thead>
<tr>
<th>CRYP_IV1R[31:0]</th>
<th>CRYP_IV1L[31:0]</th>
<th>CRYP_IV0R[31:0]</th>
<th>CRYP_IV0L[31:0]</th>
</tr>
</thead>
</table>

32-bit counter = 0x1

Unlike in CBC mode, which uses the CRYP_IVx registers only once when processing the first data block, in CTR mode IV registers are used for processing each data block, and the peripheral increments the least significant 32 bits (leaving the other most significant 96 bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that will be XORed with the plaintext or cipher as input. Thus when ALGOMODE is set to 0x6, ALGODIR is don't care.

Note: In this mode the key must NOT be prepared for decryption.
The following sequence must be used to perform an encryption or a decryption in CTR chaining mode:

1. Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
2. Configure CRYP_CR as follows:
   a) Program ALGOMODE bits to 0x6 to select CTR mode. ALGODIR can be set to any value.
   b) Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits.
   c) Define the key length using KEYSIZE bits.
3. Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as described in Table 323.
4. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.
5. If it is the last block, optionally pad the data with zeros to have a complete block.
6. Append data in the cryptographic processor and read the result. The three possible scenarios are described in Section 40.4.5: CRYP procedure to perform a cipher operation.
7. Repeat the previous step until the second last block is processed. For the last block, execute the two previous steps. For this last block, the driver must discard the data that is not part of the data when the last block size is less than 16 bytes.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message which was interrupted. Detailed CBC sequence can be found in Section 40.4.11: CRYP AES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, IV registers must be reloaded during the resume operation.
40.4.13 CRYP AES Galois/counter mode (GCM)

Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 360.

Figure 360. Message construction for the Galois/counter mode

The structure of this message is defined as below:

- A 16-byte Initial Counter Block (ICB), composed of two distinct fields:
  - The initialization vector (IV): a 96-bit value that must be unique for each execution of the mode under a given key. Note that the GCM standard supports IV that are shorter than 96-bit, but in this case strict rules apply.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- The authenticated header A (also known as Additional Authentication Data) has a known length Len(A) that can be non-multiple of 16 bytes and cannot exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- The plaintext message (P) is both authenticated and encrypted as ciphertext C, with a known length Len(P) that can be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ blocks of 128-bits.

Note: GCM standard specifies that ciphertext C has same bit length as the plaintext P.

- When a part of the message (AAD or P) has a length which is non-multiple of 16 bytes, a special padding scheme is required.
- The last block is composed of the length of A (on 64 bits) and the length of ciphertext C (on 64 bits) as shown in Table 324.
AES GCM processing

This mode is selected by writing ALGOMODE bitfield to 0x6 in CRYP_CR.

The mechanism for the confidentiality of the plaintext in GCM mode is a variation of the Counter mode, with a particular 32-bit incrementing function that generates the necessary sequence of counter blocks.

CRYP_IV registers are used for processing each data block. The cryptographic processor automatically increments the 32 least significant bits of the counter block. The first counter block (CB1) written by the application is equal to the Initial Counter Block incremented by one (see Table 325).

Table 325. GCM mode IV registers initialization

<table>
<thead>
<tr>
<th>Register</th>
<th>CRYP_IV0LR[31:0]</th>
<th>CRYP_IV0RR[31:0]</th>
<th>CRYP_IV1LR[31:0]</th>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>32-bit counter = 0x2</td>
</tr>
</tbody>
</table>

Note: *In this mode the key must NOT be prepared for decryption.*

The authentication mechanism in GCM mode is based on a hash function, called GF2mul, that performs multiplication by a fixed parameter, called the hash subkey (H), within a binary Galois field.

To process a GCM message, the driver must go through four phases, which are described in the following subsections.

- The Init phase: the peripheral prepares the GCM hash subkey (H) and performs the IV processing.
- The Header phase: the peripheral processes the Additional Authenticated Data (AAD), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P) with hash computation, keystream encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the authenticated tag (T) using the data last block.

1. **GCM initialization phase**
   
   During this first step, the GCM hash subkey (H) is calculated and saved internally to be used for processing all the blocks. It is recommended to follow the sequence below:
   
   a) Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
   
   b) Select the GCM chaining mode by programming ALGOMODE bits to 0x8 in CRYP_CR. In the same register define the key length using KEYSIZE bits and the data type using DATATYPE bits.
   
   c) Configure GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that the initialization phase is ongoing.
   
   d) Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as defined in Table 325.
   
   e) Set CRYPEN bit to 1 to start the calculation of the hash key.
   
   f) Wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor, before moving on to the next phase.

2. **GCM header phase**

   The below sequence shall be performed after the GCM initialization phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption.

   g) Set the GCM_CCMPH bits to 0b01 in CRYP_CR to indicate that the header phase is ongoing.

   h) Set the CRYPEN bit to 1 to start accepting data.

   i) If it is the last block of additional authenticated data, optionally pad the data with zeros to have a complete block.

   j) Append additional authenticated data in the cryptographic processor. The three possible scenarios are described in Section 40.4.5: CRYP procedure to perform a cipher operation.

   k) Repeat the previous step until the second last additional authenticated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared before moving on to the next phase.

   **Note:** This phase can be skipped if there is no additional authenticated data, i.e. \( \text{Len}(A) = 0 \).

   In header and payload phases, CRYPEN bit is not automatically cleared by the cryptographic processor.
3. **GCM payload phase (encryption or decryption)**

When the payload size is not null, this sequence must be executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.

- **l)** Set the CRYPEN bit to 0.
- **m)** Configure GCM_CCMPH to 0b10 in the CRYP_CR register to indicate that the payload phase is ongoing.
- **n)** Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.
- **o)** Set the CRYPEN bit to 1 to start accepting data.
- **p)** If it is the last block of cleartext or plaintext, optionally pad the data with zeros to have a complete block. For encryption, refer to Section 40.4.8: CRYP stealing and data padding for more details.
- **q)** Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in Section 40.4.5: CRYP procedure to perform a cipher operation.
- **r)** Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, the driver must discard the bits that are not part of the cleartext or the ciphertext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

*Note:* This phase can be skipped if there is no payload data, i.e. Len(C) = 0 (see GMAC mode).

4. **GCM final phase**

In this last step, the cryptographic processor generates the GCM authentication tag and stores it in CRYP_DOUT register.

- **s)** Configure GCM_CCMPH[1:0] to 0b11 in CRYP_CR to indicate that the Final phase is ongoing. Set the ALGODIR bit to 0 in the same register.
- **t)** Write the input to the CRYP_DIN register four times. The input must be composed of the length in bits of the additional authenticated data (coded on 64 bits) concatenated with the length in bits of the payload (coded of 64 bits), as show in Table 324.

*Note:* In this final phase, data have to be inserted normally (no swapping).

- **u)** Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.
- **v)** Read the CRYP_DOUT register four times: the output corresponds to the authentication tag.
- **w)** Disable the cryptographic processor (CRYPEN bit = 0 in CRYP_CR)
- **x)** If an authenticated decryption is being performed, compare the generated tag with the expected tag passed with the message.
Suspend/resume operations in GCM mode

Before interrupting the current message in header or payload phase, the user application must respect the following sequence:

1. If DMA is used, stop DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 of the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx registers have changed from their initial values during data processing.

Note: Key registers do not need to be saved as original their key value is known by the application.
5. Save context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
6. If DMA is used, save the DMA controller status (pointers to IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
5. Restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

Note: In Header phase, DMA OUT FIFO transfer is not used.
40.4.14 CRYP AES Galois message authentication code (GMAC)

Overview

The Galois message authentication code (GMAC) allows authenticating a plaintext and generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

A typical message construction in GMAC mode is given in Figure 361.

Figure 361. Message construction for the Galois Message Authentication Code mode

AES GMAC processing

This mode is selected by writing ALGOMODE bitfield to 0x6 in CRYP CR.

GMAC algorithm corresponds to the GCM algorithm applied on a message composed only of an header. As a consequence, all steps and settings are the same as in GCM mode, except that the payload phase (3) is not used.

Suspend/resume operations in GMAC

GMAC is exactly the same as GCM algorithm except that only header phase (2) can be interrupted.
40.4.15 CRYP AES Counter with CBC-MAC (CCM)

Overview

The AES Counter with Cipher Block Chaining-Message Authentication Code (CCM) algorithm allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, CCM algorithm is based on AES counter mode. It uses Cipher Block Chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside of the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction in CCM mode is given in Figure 362.

Figure 362. Message construction for the Counter with CBC-MAC mode

The structure of this message is as below:

- One 16-byte first authentication block (called B0 by the standard), composed of three distinct fields:
  - Q: a bit string representation of the byte length of P (Plen)
  - A nonce (N): single-use value (i.e. a new nonce should be assigned to each new communication). Size of nonce Nlen + size of Plen shall be equal to 15 bytes.
  - Flags: most significant byte containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and q (plaintext length such as Plen<2^q bytes). Note that the counter blocks range associated to q is equal to 2^(8q-4), i.e. if q maximum value is 8, the counter blocks used in cipher shall be on 60 bits.
- 16-bytes blocks (B) associated to the Associated Data (A).
  This part of the message is only authenticated, not encrypted. This section has a
  known length, $A_{len}$, that can be a non-multiple of 16 bytes (see Figure 362). The
  standard also states that, on the MSB bits of the first message block (B1), the
  associated data length expressed in bytes ($a$) must be encoded as defined below:
  - If $0 < a < 2^{16}-2^8$, then it is encoded as $[a]_{16}$, i.e. two bytes.
  - If $2^{16}-2^8 < a < 2^{32}$, then it is encoded as $0xff || 0xfe || [a]_{32}$, i.e. six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as $0xff || 0xff || [a]_{64}$, i.e. ten bytes.
- 16-byte blocks (B) associated to the plaintext message (P), which is both authenticated
  and encrypted as ciphertext C, with a known length of $P_{len}$. This length can be a non-
  multiple of 16 bytes (see Figure 362).
- The encrypted MAC (T) of length $T_{len}$ appended to the ciphertext C of overall length
  $C_{len}$.
- When a part of the message (A or P) has a length which is a non-multiple of 16 bytes, a
  special padding scheme is required.

**Note**: CCM chaining mode can also be used with associated data only (i.e. no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following:

N: 10111213 141516 (Nlen = 56 bits or 0x7 bytes)
A: 00010203 04050607 (Alen = 64 bits or 0x8 bytes)
P: 20212223 (Plen = 32 bits i.e. Q = 0x4 bytes)
T: 6084341b (Tlen = 32 bits or t = 4)
B0: 4f101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000
CTR0: 0710111213 141516 00000000 00000000
CTR1: 0710111213 141516 00000000 00000001

The usage of control blocks CTRx is explained in the following section. The generation of
CTR0 from the first block (B0) must be managed by software.
AES CCM processing

This mode is selected by writing ALGOMODE bitfield to 0x9 in CRYP_CR.

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted data to generate a MAC, whose length is known. Counter mode encryption, which requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting data, called the ciphertext C, is the output of the generation-encryption process on plaintext P.

CRYP_IV registers are used for processing each data block. The cryptographic processor automatically increments the CTR counter with a bit length defined by the first block (B0). The first counter written by application, CTR1, is equal to B0 with the first 5 bits zeroed and the most significant bits containing P byte length also zeroed, then incremented by one (see Table 326).

<table>
<thead>
<tr>
<th>Input data</th>
<th>CRYP_IV0LR[31:0]</th>
<th>CRYP_IV0RR[31:0]</th>
<th>CRYP_IV1LR[31:0]</th>
<th>CRYP_IV1RR[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>B0[127:96], where the 5 most significant bits are set to 0 (flag bits)</td>
<td>B0[95:64]</td>
<td>B0[63:32]</td>
<td>B0[31:0], where Q length bits are set to 0, except for bit 0 that is set to 1</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** In this mode, the key must NOT be prepared for decryption.

To process a CCM message, the driver must go through four phases, which are described below.

- The **Initialization phase**: the peripheral processes the first block and prepares the first counter block.
- The **Header phase**: the peripheral processes the Associated data (A), with hash computation only.
- The **Payload phase**: the peripheral processes the plaintext (P), with hash computation, counter block encryption and data XORing. It operates in a similar way for ciphertext (C).
- The **Final phase**: the peripheral generates the message authentication code (MAC).
1. **CCM initialization phase**

   In this first step, the first block (B0) of the CCM message is programmed into the CRYP_DIN register. During this phase, the CRYP_DOUT register does not contain any output data. It is recommended to follow the sequence below:

   a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.

   b) Select the CCM chaining mode by programming the ALGOMODE bits to 0x9 in the CRYP_CR register. In the same register define the key length using KEYSIZE bits and the data type using DATATYPE bits.

   c) Configure the GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that we are in the initialization phase.

   d) Initialize the key registers (128, 192 or 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) with CTR1 information, as defined in Table 326.

   e) Set the CRYPEN bit to 1 in CRYP_CR to start accepting data.

   f) Write the B0 packet into CRYP_DIN register, then wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor before moving on to the next phase.

   Note: In this initialization phase, data have to be inserted normally (no swapping).

2. **CCM header phase**

   The below sequence shall be performed after the CCM initialization phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption. During this phase, the CRYP_DOUT register does not contain any output data.

   g) Set the GCM_CCMPH bit to 0b01 in CRYP_CR to indicate that the header phase is ongoing.

   h) Set the CRYPEN bit to 1 to start accepting data.

   i) If it is the last block of associated data, optionally pad the data with zeros to have a complete block.

   j) Append the associated data in the cryptographic processor. The three possible scenarios are described in Section 40.4.5: CRYP procedure to perform a cipher operation.

   k) Repeat the previous step until the second last associated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared.

   Note: This phase can be skipped if there is no associated data (Alen = 0).

   The first block of the associated data B1 must be formatted with the associated data length. This task must be managed by the driver.
3. **CCM payload phase (encryption or decryption)**
   When the payload size is not null, this sequence must be performed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.
   l) Set the CRYPEN bit to 0.
   m) Configure GCM_CCMPH bits to 0b10 in CRYP_CR to indicate that the payload phase is ongoing.
   n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.
   o) Set the CRYPEN bit to 1 to start accepting data.
   p) If it is the last block of cleartext, optionally pad the data with zeros to have a complete block (encryption only). For decryption, refer to Section 40.4.8: CRYP stealing and data padding for more details.
   q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in Section 40.4.5: CRYP procedure to perform a cipher operation.
   r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block of ciphertext (decryption only), the driver must discard the data that is not part of the cleartext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

**Note:** This phase can be skipped if there is no payload data, i.e. Plen = 0 or Clen = Tlen

**Note:** Do not forget to remove LSB\(_{Tlen(C)}\) encrypted tag information when decrypting ciphertext C.

4. **CCM final phase**
   In this last step, the cryptographic processor generates the CCM authentication tag and stores it in the CRYP_DOUT register.
   s) Configure GCM_CCMPH[1:0] bits to 0b11 in CRYP_CR to indicate that the final phase is ongoing and set the ALGODIR bit to 0 in the same register.
   t) Load in CRYP_DIN, the CTR0 information which is described in Table 326 with bit[0] set to 0.

**Note:** In this final phase, data have to be inserted normally (no swapping).
   u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.
   v) Read the CRYP_DOUT register four times: the output corresponds to the encrypted CCM tag.
   w) Disable the cryptographic processor (CRYPEN bit set to 0 in CRYP_CR)
   x) If an authenticated decryption is being performed, compare the generated encrypted tag with the encrypted tag padded in the ciphertext, i.e. \(\text{LSB}_{Tlen(C)} = \text{MSB}_{Tlen(\text{CRYP}_\text{DOUT data})}\).
Suspend/resume operations in CCM mode

Before interrupting the current message in payload phase, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM = 1 and OFNE = 0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 in the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx registers have changed from their initial values during the data processing.

Note: Key registers do not need to be saved as their original key value is known by the application.
5. Save context swap registers: CRYP_CSGCMCCM0..7R
6. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (must be 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR and key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R
5. Restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

Note: In Header phase DMA OUT FIFO transfer is not used.

40.4.16 CRYP data registers and data swapping

The CRYP_DIN register is the 32-bit wide data input register of the peripheral. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

The four adjacent (respectively two) words of the AES (respectively DES/TDES) data block are organized in big-endian order, with the most significant byte of a word on the lowest address.

The cryptographic accelerator can be configured to perform a bit, byte, half-word, or no swapping on the input data word in the CRYP_DINR register, before loading it to the CRYP processing core, and on the data output from the CRYP processing core, before sending it
to the CRYP_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES_CR register. The selection applies both to the input and the output of the CRYP processing core.

Note: The CRYP Key registers (CRYP_Kx(L/R)) and initialization registers (CRYP_IVx(L/R)) are not sensitive to the swap mode selected.

More information on data input and data swapping can be found in the next subsections.

**DES/TDES data input and output**

A 64-bit data block is entered into the cryptographic processor with two successive 32-bit word write operations to the CRYP_DINR register (DIN[31:0] bitfield), the most significant word (bits [64:33]) first, the least significant word (bits [32:1]) last.

A 64-bit data block is retrieved from the cryptographic processor with two successive 32-bit word read operations from the CRYP_DOUTR register (DOUT[31:0] bitfield), the most significant word (bits [64:33]) first, the least significant word (bits [32:1]) last.

**DES/TDES data swapping feature**

The cryptographic processor data swapping feature for DES/TDES is summarized in Table 327 and Figure 363.

Table 327. DES/TDES data swapping example
AES data input and output

A 128-bit data block is entered into the cryptographic processor with four successive 32-bit word writes into the CRYP_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the cryptographic processor with four successive 32-bit word reads from the CRYP_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

AES data swapping feature

The cryptographic processor data swapping feature for AES is summarized in Table 328 and Figure 364.

Note: Data swapping does not apply to GCM and CCM final phases. Data can be inserted normally by the application.

40.4.17 CRYP key registers

The CRYP\_Kx registers are write-only registers used to store the encryption or decryption keys. They are organized as four 64-bit registers, as shown in Table 329 and Table 330.

Note: In memory and in CRYP key registers, AES and DES/TDES keys are stored in big-endian format, with most significant byte on the lowest address.

Table 329. Key endianness in CRYP\_KxR/LR registers (AES 128/192/256-bit keys)

<td>k[63:32]</td>
<td>k[31:0]</td>
</tr>
</tbody>
</table>

1486/3357 RM0468 Rev 3
As shown on Table 330, when TDES is selected (ALGOMODE[2:0] = 000 or 001) a 3-key vector (K1, K2, and K3) is used. When DES is selected (ALGOMODE[2:0] = 010 or 011) only 1-key vector (K1) is used.

Note: DES/TDES keys include 8-bit parity information that are not used by the cryptographic processor. In other words, bits 8, 16, 24, 32, 40, 48, 56 and 64 of each 64-bit key value Kx[1:64] are not used.

Write operations to the CRYP_Kx(L/R) registers when the BUSY bit is set to 1 in the CRYP_SR register are ignored (which means that the register content is not modified). The application must thus check that the BUSY bit is cleared to 0 before modifying key registers.

Key registers are not affected by the data swapping controlled by DATATYPE value in CRYP_CR register.

Refer to Section 40.7: CRYP registers for a detailed description of CRYP_Kx(L/R) registers.

40.4.18 CRYP initialization vector registers

The CRYP_IVxL/IVxR registers are used to store the initialization vector or the nonce, depending on the chaining mode selected. When used, these registers are updated by the core after each computation round of the TDES or AES core.

They are organized as four 64-bit registers, as shown in shown in Table 331 and Table 332. In DES/TDES mode only CRYP_IV0x are used.

Note: In memory and in CRYP IV registers, AES and DES/TDES initialization vectors are stored in big-endian format, with most significant byte on the lowest address.

<table>
<thead>
<tr>
<th>CRYP_IV0L[31:0]</th>
<th>CRYP_IV0R[31:0]</th>
<th>CRYP_IV1L[31:0]</th>
<th>CRYP_IV1R[31:0]</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>CRYPIVATE[31:0]</th>
<th>CRYPIVATE[31:0]</th>
<th>CRYPIVATE[31:0]</th>
<th>CRYPIVATE[31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>IV[64:32]</td>
<td>IV[31:0]</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Any write operation to the CRYP_IV0...1(L/R) registers when the BUSY bit is set to 1 in the CRYP_SR register is disregarded (which means that register content not modified). The
software must thus check that the BUSY bit is cleared to 0 in the CRYP_SR register before modifying initialization vectors.

Reading the CRYP_IV0...1(L/R) register returns the latest counter value (useful for managing suspend mode) except for CCM/GCM.

The initialization vector registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP_CR register.

Refer to Section 40.7: CRYP registers for a detailed description of CRYP_IVxL/IVxR registers.

### 40.4.19 CRYP DMA interface

The cryptographic processor provides an interface to connect to the DMA (Direct Memory Access) controller. The DMA operation is controlled through the CRYP DMA control register (CRYP_DMACR).

**Data input using DMA**

DMA can be enabled for writing data into the cryptographic peripheral by setting the DIEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the INPUT phase each time it requires a word to be written to the CRYP_DIN register.

*Table 333* shows the recommended configuration to transfer data from memory to cryptographic processor through the DMA controller.

<table>
<thead>
<tr>
<th>DMA channel control register field</th>
<th>Programming recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transfer size</td>
<td>Message length, multiple of four 32-bit words. This 128-bit granularity corresponds to two blocks for DES/TDES, one block for AES. According to the algorithm and the mode selected, special padding/ciphertext stealing might be required. As an example, in case of AES GCM encryption or AES CCM decryption, DMA transfers must not include the last block. Refer to Section 40.4.5: CRYP procedure to perform a cipher operation for details.</td>
</tr>
<tr>
<td>Source burst size (memory)</td>
<td>CRYP FIFO_size/2 /transfer_width = 4</td>
</tr>
<tr>
<td>Destination burst size (peripheral)</td>
<td>CRYP FIFO_size/2 /transfer_width = 4</td>
</tr>
<tr>
<td></td>
<td>(FIFO_size = 8x32-bit, transfer_width = 32-bit)</td>
</tr>
<tr>
<td>DMA FIFO size</td>
<td>CRYP FIFO_size/2 = 16 bytes</td>
</tr>
<tr>
<td>Source transfer width (memory)</td>
<td>32-bit words</td>
</tr>
<tr>
<td>Destination transfer width (peripheral)</td>
<td>32-bit words</td>
</tr>
</tbody>
</table>
Data output using DMA

To enable the DMA for reading data from CRYP processor, set the DOEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the OUTPUT phase each time it requires a word to be read from the CRYP_DOUT register.

Table 334 shows the recommended configuration to transfer data from cryptographic processor to memory through the DMA controller.

**Table 334. Cryptographic processor configuration for peripheral-to-memory DMA transfers**

<table>
<thead>
<tr>
<th>DMA channel control register field</th>
<th>Programming recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transfer size</td>
<td>Message length, multiple of four 32-bit words. This 128-bit granularity corresponds to two blocks for DES/TDES, one block for AES. Depending on the chaining mode selected, extra bits have to be discarded.</td>
</tr>
</tbody>
</table>
| Source burst size (peripheral)    | When DES is used:  
  - Single transfer (burst size = 1)  
  When AES is used:  
  - CRYP FIFO_size / 2 /transfer_width = 4  
  (FIFO_size = 8x32-bit, transfer_width = 32-bit) |
| Destination burst size (memory)   | CRYP FIFO_size / 2 /transfer_width = 4 |
| DMA FIFO size                     | CRYP FIFO_size / 2 = 16 bytes |
| Source transfer width (peripheral) | 32-bit words |
| memory transfer width (memory)    | 32-bit words |
| Source address increment (peripheral) | Fixed address of CRYP_DOUT shall be used (no increment). |
| Destination address increment (memory) | Yes, after each 32-bit transfer. |
DMA mode

When AES is used, the cryptographic processor manages two DMA transfer requests through `cryp_in_dma` and `cryp_out_dma` internal input/output signals, which are asserted:

- for IN FIFO: every time a block has been read from FIFO by CRYP,
- for OUT FIFO: every time a block has been written into the FIFO by the cryptographic processor.

When DES/TDES is used, the cryptographic processor manages two DMA transfer requests through `cryp_in_dma` and `cryp_out_dma` internal input/output signals, which are asserted:

- for IN FIFO: every time two blocks have been read from FIFO by the cryptographic processor
- for OUT FIFO: every time a word has been written into the FIFO by the cryptographic processor (single transfer). Note that a burst transfer is also triggered when two blocks have been written into the FIFO.

All request signals are deasserted if the cryptographic peripheral is disabled or the DMA enable bit is cleared (DIEN bit for the IN FIFO and DOEN bit for the OUT FIFO in the CRYP_DMACR register).

Caution: It is important that DMA controller empties the cryptographic peripheral output FIFO before filling up the CRYP input FIFO. To achieve it, the DMA controller should be configured so that the transfer from the peripheral to the memory has a higher priority than the transfer from the memory to the peripheral.

For more detailed information on DMA operations, refer to Section 40.4.5: CRYP procedure to perform a cipher operation.

40.4.20 CRYP error management

No error flags are generated by the cryptographic processor.

40.5 CRYP interrupts

Overview

There are two individual maskable interrupt sources generated by the cryptographic processor to signal the following events:

- Input FIFO empty or not full
- Output FIFO full or not empty

These two sources are combined into a single interrupt signal which is the only interrupt signal from the CRYP processor that drives the Cortex® CPU interrupt controller. You can enable or disable CRYP interrupt sources individually by changing the mask bits in the CRYP_IMSCR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual maskable interrupt sources can be read either from the CRYP_RISR register, for raw interrupt status, or from the CRYP_MISR register for masked
interrupt status. The status of the individual source of event flags can be read from the CRYP_SR register.

Table 335 gives a summary of the available features.

### Table 335. CRYP interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

<td></td>
<td>CRYP enable bit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. The flags belong to CRYP_RISR registers (unmasked or raw) or CRYP_MISR registers (masked).
2. The flags belong to CRYP_IMSCR register.

**Output FIFO service interrupt - OUTMIS**

The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is when the interrupt follows the state of the output FIFO not empty flag OFNE).

The output FIFO service interrupt OUTMIS is NOT enabled with the CRYP processor enable bit. Consequently, disabling the CRYP processor does not force the OUTMIS signal low if the output FIFO is not empty.

**Input FIFO service interrupt - INMIS**

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is enabled with the CRYP enable bit. Consequently, when CRYP is disabled, the INMIS signal is low even if the input FIFO is empty.
40.6 **CRYP processing time**

The time required to process a block for each mode of operation is summarized below. The block size is 128 bits for AES and 64 bits for DES/TDES.

**Table 336. Processing latency for ECB, CBC and CTR**

<table>

40.7 **CRYP registers**

The cryptographic core is associated with several control and status registers, eight key registers and four initialization vectors registers.

40.7.1 **CRYP control register (CRYP_CR)**

Address offset: 0x00

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th>NPBLB[3:0]</th>
<th>ALGOMODE3</th>

<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NPBLB[3:0]: Number of Padding Bytes in Last Block of payload.**

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

- 0000: All bytes are valid (no padding)
- 0001: Padding for the last LSB byte
- ...
- 1111: Padding for the 15 LSB bytes of last block.

Writing NPBLB bits while BUSY = 1 has no effect.

**Bit 18** Reserved, must be kept at reset value.

**GCM_CCMPH[1:0]: GCM or CCM Phase selection**

This bitfield has no effect if GCM, GMAC or CCM algorithm is not selected in ALGOMODE field.

- 00: Initialization phase
- 01: Header phase
- 10: Payload phase
- 11: Final phase

Writing to GCM_CCMPH bits while BUSY = 1 has no effect.

**Bit 15** **CRYPEN: CRYP processor Enable**

- 0: Cryptographic processor peripheral is disabled
- 1: Cryptographic processor peripheral is enabled

This bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE = 0111) or after GCM/GMAC or CCM Initialization phase.
Bit 14 **FLUSH**: CRYP FIFO Flush

0: No FIFO flush
1: FIFO flush enabled

When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (that is read and write pointers of the FIFOs are reset). Writing this bit to 0 has no effect. When CRYPEN = 1, writing this bit to 0 or 1 has no effect. Reading this bit always returns 0.

FFLUSH bit has to be set only when BUSY = 0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a non-empty FIFO condition.

Bits 13:10 Reserved, must be kept at reset value.

Bits 9:8 **KEYSIZE[1:0]**: Key size selection (AES mode only)

This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is ‘don’t care’ in the DES or TDES modes.

00: 128-bit key length
01: 192-bit key length
10: 256-bit key length
11: Reserved, do not use this value

Writing KEYSIZE bits while BUSY = 1 has no effect.

Bits 7:6 **DATATYPE[1:0]**: Data Type selection

This bitfield defines the format of data written in CRYP_DIN or read from CRYP_DOUT registers. For more details refer to Section 40.4.16: CRYP data registers and data swapping.

00: 32-bit data. No swapping for each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64 etc.
01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.
10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.
11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.

Writing DATATYPE bits while BUSY = 1 has no effect.
Bits 19, 5:3 **ALGOMODE[3:0]**: Algorithm mode

Below definition includes the bit 19:
- 0000: TDES-ECB (triple-DES Electronic Codebook).
- 0001: TDES-CBC (triple-DES Cipher Block Chaining).
- 0011: DES-CBC (simple DES Cipher Block Chaining).
- 0100: AES-ECB (AES Electronic Codebook).
- 0101: AES-CBC (AES Cipher Block Chaining).
- 0110: AES-CTR (AES Counter mode).
- 0111: AES key preparation for ECB or CBC decryption.
- 1000: AES-GCM (Galois Counter mode) and AES-GMAC (Galois Message Authentication Code mode).
- 1001: AES-CCM (Counter with CBC-MAC).

Writing ALGOMODE bits while BUSY = 1 has no effect.

Others: Reserved, must not be used.

Bit 2 **ALGODIR**: Algorithm Direction

- 0: Encrypt
- 1: Decrypt

Writing ALGODIR bit while BUSY = 1 has no effect.

Bits 1:0 Reserved, must be kept at reset value.

### 40.7.2 CRYP status register (CRYP_SR)

Address offset: 0x04

Reset value: 0x0000 0003

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>BUSY</td>
<td>OFFU</td>
<td>OFNE</td>
<td>IFNF</td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **BUSY**: Busy bit

- 0: The CRYP core is not processing any data. The reason is:
  - either that the CRYP core is disabled (CRYPEN = 0 in the CRYP_CR register) and the last processing has completed,
  - or the CRYP core is waiting for enough data in the input FIFO or enough free space in the output FIFO (that is in each case at least 2 words in the DES, 4 words in the AES).
- 1: The CRYP core is currently processing a block of data or a key preparation is ongoing (AES ECB or CBC decryption only).
Bit 3 **OFFU**: Output FIFO full flag
0: Output FIFO is not full
1: Output FIFO is full

Bit 2 **OFNE**: Output FIFO not empty flag
0: Output FIFO is empty
1: Output FIFO is not empty

Bit 1 **IFNF**: Input FIFO not full flag
0: Input FIFO is full
1: Input FIFO is not full

Bit 0 **IFEM**: Input FIFO empty flag
0: Input FIFO is not empty
1: Input FIFO is empty

### 40.7.3 CRYP data input register (CRYP_DIN)

**Address offset**: 0x08
**Reset value**: 0x0000 0000

The CRYP_DIN register is the data input register. It is 32-bit wide. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to Section 40.4.16: CRYP data registers and data swapping for more details.

When CRYP_DIN register is written to the data are pushed into the input FIFO.
- If CRYPEN = 1, when at least four 32-bit words in the AES mode have been pushed into the input FIFO (two words in the DES/TDES mode), and when at least four words are free in the output FIFO (two words in the DES/DTES mode), the CRYP engine starts an encrypting or decrypting process.

When CRYP_DIN register is read:
- If CRYPEN = 0, the FIFO is popped, and then the data present in the Input FIFO are returned, from the oldest one (first reading) to the newest one (last reading). The IFEM flag must be checked before each read operation to make sure that the FIFO is not empty.
- If CRYPEN = 1, an undefined value is returned.

**Note**: After the CRYP_DIN register has been read once or several times, the FIFO must be flushed by setting the FFLUSH bit prior to processing new data.
40.7.4 CRYP data output register (CRYP_DOUT)

Address offset: 0x0C
Reset value: 0x0000 0000

The CRYP_DOUT register is the data output register. It is read-only and 32-bit wide. It is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to Section 40.4.16: CRYP data registers and data swapping for more details.

When CRYP_DOUT register is read, the last data entered into the output FIFO (pointed to by the read pointer) is returned.

</table>

Bits 31:0 DATAIN[31:0]: Data Input
- On read FIFO is popped (last written value is returned), and its value is returned if CRYPEN = 0. If CRYPEN = 1 DATAIN register returns an undefined value.
- On write current register content is pushed inside the FIFO.

Bits 31:0 DATOUT[31:0]: Data Output
- On read returns output FIFO content (pointed to by read pointer), else returns an undefined value.
- On write, no effect.
40.7.6 CRYP interrupt mask set/clear register (CRYP_IMSCR)

Address offset: 0x14
Reset value: 0x0000 0000

The CRYP_IMSCR register is the interrupt mask set or clear register. It is a read/write register. When a read operation is performed, this register gives the current value of the mask applied to the relevant interrupt. Writing 1 to the particular bit sets the mask, thus enabling the interrupt to be read. Writing 0 to this bit clears the corresponding mask. All the bits are cleared to 0 when the peripheral is reset.

Bits 31:2  Reserved, must be kept at reset value.

Bit 1 **DOEN**: DMA Output Enable
When this bit is set, DMA requests are automatically generated by the peripheral during the output data phase.
0: DMA for outgoing data transfer is disabled
1: DMA for outgoing data transfer is enabled

Bit 0 **DIEN**: DMA Input Enable
When this bit is set, DMA requests are automatically generated by the peripheral during the input data phase.
0: DMA for incoming data transfer is disabled
1: DMA for incoming data transfer is enabled

40.7.7 CRYP raw interrupt status register (CRYP_RISR)

Address offset: 0x18
Reset value: 0x0000 0001

The CRYP_RISR register is the raw interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current raw status of the corresponding
interrupt, i.e. the interrupt information without taking CRYP_IMSCR mask into account. Write operations have no effect.

### 40.7.8 CRYP masked interrupt status register (CRYP_MISR)

Address offset: 0x1C
Reset value: 0x0000 0000

The CRYP_MISR register is the masked interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current masked status of the corresponding interrupt, i.e. the interrupt information taking CRYP_IMSCR mask into account. Write operations have no effect.

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 OUTMIS: Output FIFO service masked interrupt status**
This bit gives the output FIFO interrupt information without taking into account the corresponding CRYP_IMSCR mask.
0: Interrupt not pending
1: Interrupt pending

**Bit 0 INMIS: Input FIFO service masked interrupt status**
This bit gives the input FIFO interrupt information without taking into account the corresponding CRYP_IMSCR mask.
0: Raw interrupt not pending
1: Raw interrupt pending
Bit 0  **INMIS**: Input FIFO service masked interrupt status
This bit gives the input FIFO interrupt information without taking into account the corresponding CRYP_IMSCR mask.
0: Interrupt not pending
1: Interrupt pending when CRYPEN = 1

### 40.7.9  CRYP key register 0L (CRYP_K0LR)

Address offset: 0x20
Reset value: 0x0000 0000
CRYP key registers contain the cryptographic keys.
For more information refer to Section 40.4.17: CRYP key registers.

**Note:** Write accesses to these registers are disregarded when the cryptographic processor is busy (bit BUSY = 1 in the CRYP_SR register).

Bits 31:0 **K[31:0]**: Key bit x (x = 31 to 0)  
This write-only bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode. In DES/TDES mode this bitfield contains the bits [32:1] of the key K3, with parity bits unused.

### 40.7.17 CRYP initialization vector register 0L (CRYP_IV0LR)

Address offset: 0x40  
Reset value: 0x0000 0000  
The CRYP_IV registers store the initialization vector or the nonce, depending on the chaining mode selected. The size of the IV data is 64 bits for DES/TDES and 128 bits for AES. For more information refer to Section 40.4.18: CRYP initialization vector registers.

**Note:** Write accesses to these registers are disregarded when the cryptographic processor is busy (BUSY = 1 in the CRYP_SR register).
40.7.18 CRYP initialization vector register 0R (CRYP_IV0RR)

Address offset: 0x44
Reset value: 0x0000 0000

Refer to Section 40.7.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.

Bits 31:0  **IV[127:96]**: Initialization vector bit x (x = 127 to 96)
This bitfield stores the initialization vector bits [127:96] for AES chaining modes other than ECB. In DES/TDES mode it corresponds to IV bits [63:32].
IV registers are updated by the core after each computation round of the DES/TDES or AES core.

40.7.19 CRYP initialization vector register 1L (CRYP_IV1LR)

Address offset: 0x48
Reset value: 0x0000 0000

Refer to Section 40.7.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.

40.7.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR)

Address offset: 0x050 + x* 0x4 (x = 0 to 7)
Reset value: 0x0000 0000
These registers contain the complete internal register states of the CRYP processor when the GCM/GMAC or CCM algorithm is selected. They are useful when a context swap has to be performed because a high-priority task needs the cryptographic processor while it is already in use by another task.

When such an event occurs, the CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R (in GCM/GMAC mode) or CRYP_CSGCMCCM0..7R (in CCM mode) registers have to be read and the values retrieved have to be saved in the system memory space. The cryptographic processor can then be used by the preemptive task. Then when the cryptographic computation is complete, the saved context can be read from memory and written back into the corresponding context swap registers.
Cryptographic processor (CRYP) RM0468

40.7.22 CRYP context swap GCM registers (CRYP_CSGCMxR)

Address offset: 0x070 + x* 0x4 (x = 0 to 7)
Reset value: 0x0000 0000

Refer to Section 40.7.21: CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR) for details.

Bits 31:0 CSGCMCCMx[31:0]: CRYP processor internal register states for GCM, GMAC and CCM modes.

Note: This register is not used in DES/TDES or other AES modes than the ones indicated.

Refer to Section 2.3 on page 131 for the register boundary addresses.
41 Hash processor (HASH)

41.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-224, SHA-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to \(2^{64} - 1\) bits. It also computes 128-bit digests for the MD5 algorithm.

41.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321, MD5 Message-Digest Algorithm
- Fast computation of SHA-1, SHA-224, SHA-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits (\(16 \times 32\) bits)
- Single 32-bit input register associated to an internal input FIFO, corresponding to one block size
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- \(8 \times 32\)-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel.
- Single or fixed DMA burst transfers of four words
• Interruptible message digest computation, on a per-block basis
  – Re-loadable digest registers
  – Hashing computation suspend/resume mechanism, including DMA

41.3 HASH implementation
The devices have a single instance of HASH peripheral.

41.4 HASH functional description

41.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below $2^{64}$ bits is provided on input, the HASH processing core produces respectively a fixed-length output string called a message digest, defined as follows:

- For MD5 digest size is 128-bit
- For SHA-1 digest size is 160-bit
- For SHA-224 and SHA-256, the digest size is 224 bits and 256 bits, respectively

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit, with very high probability, results in a different message digest, and the signature fails to verify.

41.4.4 Message data feeding

The message (or data file) to be processed by the HASH should be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).
In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core.

*Figure 366* shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

*Figure 366. Message data swapping feature*
**41.4.5 Message digest computing**

The hash processor sequentially processes several blocks when computing the message digest. For MD5, SHA1 and SHA2, the block size is 512 bits.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in *Section 41.4.4: Message data feeding*, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO.

In order to perform the hash computation on this data below sequence must be used by the application:

1. Initialize the hash processor using the HASH_CR register:
   a) Select the right algorithm using the ALGO bitfield. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH_CR.
   b) When the HMAC mode is required, set the MODE bit, as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (else keep LKEY cleared). Refer to *Section 41.4.7: HMAC operation* for details.
   c) Set MODE = 1 and select the key length using LKEY if HMAC mode has been selected.
   d) Update NBLW[4:0] to define the number of valid bits in last word of the message if it is different from 32 bits. NBLW[4:0] information are used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting to 1 the INIT bit in HASH_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

**Caution:** When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW[4:0]).

3. Start filling data by writing to HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   a) When data are filled by software:
      – Partial digest computation are triggered each time the application writes the first word of the next block. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
      – The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of the block size, the NBLW[4:0] bitfield in HASH_STR register must be written prior to writing DCAL bit (see *Section 41.4.6* for details).
   b) When data are filled by DMA as a single DMA transfer (MDMAT bit = 0):
      – Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of the block size, the NBLW[4:0] field
in HASH_STR register must be written prior to enabling the DMA (see Section 41.4.6 for details).

c) When data are filled using multiple DMA transfers (MDMAT bit = 1):
   – Partial digest computations are triggered as for single DMA transfers. However the final digest computation is not triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is not set to 1 by hardware). It allows the hash processor to receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers (see description before).

4. Once the digest computation is complete (DCIS = 1), the resulting digest can be read from the output registers as described in Table 340.

For more information about HMAC detailed instructions, refer to Section 41.4.7: HMAC operation.

41.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW[4:0], has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

Padding processing

Detailed padding sequences with DMA enabled or disabled are described in Section 41.4.5: Message digest computing.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, the message padding consists in appending a “1” followed by \(k\) “0”s, itself followed by a 64-bit integer that is equal to the length \(L\) in bits of the message. These three padding operations generate a padded message of length \(L + 1 + k + 64\), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW[4:0] bitfield, and the remaining upper bits are cleared (“0”s).
Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length $L = 24$:

```
byte 0  byte 1  byte 2  byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

$NBLW[4:0]$ has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the $HASH_DIN$ register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since $L = 24$, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 0000018
```

The message length value, $L$, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 0000018
```

If the hash processor is programmed to swap byte within $HASH_DIN$ input register (DATATYPE = 10 in $HASH_CR$), the above message has to be entered by following the below sequence:

1. **0xUU636261** is written to the $HASH_DIN$ register (where ‘U’ means don’t care).
2. **0x18** is written to the $HASH_STR$ register (the number of valid bits in the last word written to the $HASH_DIN$ register is 24, as the original message length is 24 bits).
3. **0x10** is written to the $HASH_STR$ register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the $HASH_HRx$ registers ($x = 0...4$) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

   \[
   \begin{align*}
   HASH_{HR0} &= 0xA9993E36 \\
   HASH_{HR1} &= 0x4706816A \\

   \]
41.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC(message)} = \text{Hash}((\text{Key} \mid \text{pad}) \text{ XOR opad} \mid \text{Hash}((\text{Key} \mid \text{pad}) \text{ XOR ipad} \mid \text{message}))
\]

where:

- \(\text{opad} = [0x5C]_n\) (outer pad) and \(\text{ipad} = [0x36]_n\) (inner pad)
- \([X]_n\) represents a repetition of \(X\) \(n\) times, where \(n\) equal to the size of the underlying hash function data block (\(n = 64\) for 512-bit blocks).
- \(\text{pad}\) is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- \(\mid\) represents the concatenation operator.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software writes the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.

2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register.

3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software writes DCAL bit to 1 in HASH_STR register, the NBLW[4:0] bitfield must be written at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 41.4.4: Message data feeding.

4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW[4:0] to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HR7) as soon as DCIS bit is set to 1.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 41.6: HASH processing time.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST.
Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen = blocklen", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is no padding), specified by NIST. As key length = 64, LKEY bit is set to 0 in HASH_CR register

```
00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
30313233 34353637 38393A3B 3C3D3E3F
```

2. **Message** input (length = 34, that is padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don't care)

```
53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
6E3D626C 6F636B6C 656EUUUU
```

3. **Outer hash key** input (length = 64, that is no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers (x = 0 to 4), as shown below:

```
HASH_HR0 = 0x5FD596EE
HASH_HR1 = 0x78D5553C
HASH_HR2 = 0x8FF4E72D
HASH_HR3 = 0x266DFD19
HASH_HR4 = 0x2366D2A9
```
### HASH suspend/resume operations

#### Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in *Figure 367*.

*Figure 367. HASH suspend/resume mechanism*

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described below.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

**To suspend the processing of a message,** proceed as follows after writing 16 words 32-bit (plus one if it is the first block):

1. In Polling mode, wait for BUSY = 0, then poll if the DINIS status bit is set to 1. 
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.

**To resume the processing of a message,** proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR and HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

*Note:* To optimize the resume process when NBW[3:0] = 0x0, HASH_CSR22 to HASH_CSR37 registers do not need to be saved then restored as the FIFO is empty.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing is described below.

**To suspend the processing of a message using DMA,** proceed as follows:

1. In Polling mode, wait for BUSY = 0. If DCIS is set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 2.
2. In Polling mode, wait for BUSY = 1.
3. Disable the DMA channel. Then clear DMAE bit in HASH_CR register.
4. In Polling mode, wait for BUSY = 0. If DCIS is set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR, HASH_CR, and HASH_CSR0 to HASH_CSR37 registers. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again. Do not forget to take into account the words that have been already pushed into the FIFO if NBW[3:0] is higher than 0x0.
2. Program the values saved in memory to HASH.IMR, HASH.STR and HASH.CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH.CR register.
4. Program the values saved in memory to the HASH.CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

Note: To optimize the resume process when NBW[3:0] = 0x0, HASH.CSR22 to HASH.CSR37 registers do not need to be saved then restored as the FIFO is empty.

41.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH.CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH.DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to Section 41.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH.DIN register. This is done by writing in HASH.STR register the following value:

\[ \text{NBLW[4:0]} = \text{Len(Message)} \% 32 \]

where “x%32” gives the remainder of x divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

41.4.10 HASH error management

No error flags are generated by the hash processor.

41.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the NVIC (nested vectored interrupt controller). Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH.IMR register. Setting the appropriate mask bit to 1 enables the interrupt.
The status of each maskable interrupt source can be read from the HASH_SR register. *Table 341* gives a summary of the available features.

**Table 341. HASH interrupt requests**

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

1. Add the time required to load the block into the processor.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key
41.7 HASH registers

The HASH core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

41.7.1 HASH control register (HASH_CR)

Address offset: 0x00

Bits 31:19 Reserved, must be kept at reset value.

Bit 17 Reserved, must be kept at reset value.

Bit 16 **LKEY**: Long key selection

This bit selects between short key (≤ 64 bytes) or long key (> 64 bytes) in HMAC mode.

0: the HMAC key is shorter or equal to 64 bytes. The actual key value written to HASH_DIN is used during the HMAC computation.

1: the HMAC key is longer than 64 bytes. The hash of the key is used instead of the real key during the HMAC computation.

This selection is only taken into account when the INIT bit is set and MODE = 1. Changing this bit during a computation has no effect.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.

1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.

0: No data are present in the data input buffer

1: The input buffer contains at least one word of data

This bit is read-only.
Bits 11:8 **NBW[3:0]**: Number of words already pushed

This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO. NBW is incremented by one when a write access to the HASH_DIN register is performed (except if DINNE = 0 and the DMA is not used, see below description). NBW goes to zero when the INIT bit is written to 1.

This bitfield is read-only.

**If the DMA is not used**

0000: if DINNE = 0, no word has been pushed into the DIN buffer (both HASH_DIN register and IN FIFO are empty), otherwise one word has been pushed into the DIN buffer (HASH_DIN register contains one word and IN FIFO is empty)

0001: two words have been pushed into the DIN buffer (that is HASH_DIN register and the IN FIFO contain one word each)

... 1111: 16 words have been pushed into the DIN buffer.

**If the DMA is used**

NBW contains the exact number of words that have been pushed into the IN FIFO by the DMA.

Bits 18, 7 **ALGO[1:0]**: Algorithm selection

These bits select the hash algorithm.

00: SHA-1
01: MD5
10: SHA-224
11: SHA-256

This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.

Bit 6 **MODE**: Mode selection

This bit selects the HASH or HMAC mode for the selected algorithm:

0: Hash mode selected
1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.

This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

Bits 5:4 **DATATYPE[1:0]**: Data type selection

Defines the format of the data entered into the HASH_DIN register:

00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data, or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data, or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data, or bit-string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).
Bit 3 **DMAE**: DMA enable
   0: DMA transfers disabled
   1: DMA transfers enabled. A DMA request is sent as soon as the HASH core is ready to receive data.
   After this bit is set it is cleared by hardware while the last data of the message is written into the hash processor.
   Setting this bit to 0 while a DMA transfer is ongoing is not aborting this current transfer. Instead, the DMA interface of the IP remains internally enabled until the transfer is completed or INIT is written to 1.
   Setting INIT bit to 1 does not clear DMAE bit.

Bit 2 **INIT**: Initialize message digest calculation
   Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
   Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0 Reserved, must be kept at reset value.

### 41.7.2 HASH data input register (HASH_DIN)

Address offset: 0x04
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks. When the HASH_DIN register is programmed, the value presented on the AHB databus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:
- by writing new data into the HASH_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by writing the DCAL bit to 1 in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is set to 0.

Reading the HASH_DIN register returns the last word written to this location (zero after reset).

**Note:** When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

</tbody>
</table>
41.7.3 HASH start register (HASH_STR)

Address offset: 0x08
Reset value: 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1

Bits 31:9  Reserved, must be kept at reset value.

Bit 8 DCAL: Digest calculation
Writing this bit to 1 starts the message padding, using the previously written value of NBLW[4:0], and starts the calculation of the final message digest with all data words written to the input FIFO since the INIT bit was last written to 1.
Reading this bit returns 0.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0 NBLW[4:0]: Number of valid bits in the last word
When the last word of the message bit string is written in HASH_DIN register, the hash processor takes only the valid bits specified as below, after internal data swapping:
0x00: All 32 bits of the last data written are valid message bits that is M[31:0]
0x01: Only one bit of the last data written (after swapping) is valid that is M[0]
0x02: Only two bits of the last data written (after swapping) are valid that is M[1:0]
0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]
... 0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]
The above mechanism is valid only if DCAL = 0. If NBLW[4:0] bitfield is written while DCAL is set to 1, the NBLW[4:0] bitfield remains unchanged. In other words it is not possible to configure NBLW[4:0] and set DCAL at the same time. Reading NBLW[4:0] bitfield returns the last value written to NBLW[4:0].
41.7.4 HASH digest registers

These registers contain the message digest result named as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0, HASH_HR1, HASH_HR2 and HASH_HR3 registers return A, B, C and D (respectively), as defined by MD5.
- HASH_HR0 to HASH_HR6 registers return the SHA-224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA-256 digest result.

In all cases, the digest most significant bit is stored in HASH_H0[31] and unused HASH_HRx registers are read as zeros.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation is stalled until the hash calculation has completed.

**Note:** When starting a digest computation for a new message (by writing the INIT bit to 1), HASH_HRx registers are forced to their reset values.

**HASH aliased digest register x (HASH_HRAx)**

Address offset: 0x0C + 0x04 * x, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy bit
0: No block is currently being processed
1: The hash core is processing a block of data

Bit 2 **DMAS**: DMA Status
This bit provides information on the DMA interface activity. It is set with DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.
0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS**: Digest calculation completion interrupt status
This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by writing the INIT bit to 1 in the HASH_CR register.
0: No digest available in the HASH_HRx registers (zeros are returned)
1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

Bit 0 **DINIS**: Data input interrupt status
This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH_DIN register.
0: Less than 16 locations are free in the input buffer
1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.
When DINIS=0, HASH_CSRx registers reads as zero.

41.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.
HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + x * 0x4, (x = 0 to 53)
Reset value: 0x0000 0002 (HASH_CSR0)
Reset value: 0x0000 0000 (HASH_CSR1 to 53)

Bits 31:0 **CSx[31:0]**: Context swap x
Refer to *Section 41.7.7: HASH context swap registers* introduction.
### Table 343. HASH register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

42 On-The-Fly decryption engine - AXI (OTFDEC)

42.1 Introduction

On-the-fly decryption engine OTFDEC allows to decrypt on-the-fly AXI traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC, with optional execute-only or execute-never enforcement per region.

OTFDEC is using AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored for example in external NOR Flash memory.

Note: When OTFDEC is used in conjunction with OCTOSPI it is mandatory to access the external read-only memory using the memory map mode of the Flash memory controller. CPU memories and OTFDEC follow little endian notation whereas AES hardware accelerator follows big endian notation. See AN5281 "How to use OTFDEC for encryption/decryption in trusted environment on STM32 MCUs" for more details.

42.2 OTFDEC main features

- On-the-fly 128-bit decryption during STM32 OCTOSPI memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with keystream FIFO (depth=4)
  - Support for any read size
  - Physical address of the reads is used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write locking mechanism
  - Two optional decryption modes: execute-only and execute-never.
    - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for STM32 Octo-SPI pre-fetching mechanism.
- In execute-only mode, possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher.
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored).
- Encryption mode

42.3.3 OTFDEC on-the-fly decryption

Introduction

Typical usage for OTFDEC is shown on *Figure 369*.

*Figure 369. Typical OTFDEC usage in the device*

Original purpose of OTFDEC is to protect the confidentiality of execute-only firmware libraries, executed from external SPI NOR Flash memory devices. This scheme is part of
STM32 family of proprietary code read-out protection, leveraging on the capability to securely load secrets during microcontroller start up. OTFDEC protection also applies to read-only “code + data libraries”, and to execute-never, read-only data stored in external memory.

**Note:** OTFDEC provides optional execute-only and execute-never enforcement on any of the four encrypted regions.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks.

When OTFDEC is used in conjunction with OCTOSPI it is mandatory to access the external read-only memory using the memory map mode of the Flash memory controller.

**OTFDEC architecture**

OTFDEC principle is to analyze all read address channel transactions on the AXI interconnect between the host and a target, like the OCTOSPI controller shown on Figure 369.

If the read request is within one of the four regions programmed in OTFDEC the control logic will trigger a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read response channel, tying low the RREADY signal while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC regions are programmed through registers RxCFGR, RxSTARTADDR, RxENDADDR, RxNONCER and RxKEYR, where x=1 to 4. In register RxCFGR the MODE bits define whether the region is code (execute-only), data (execute-never), or both.

Granularity for the region determination is 4096 bytes.

**Note:** Although OTFDEC does not prevent region overlapping it is not a valid programming and it should be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

**42.3.4 AES in counter mode decryption**

*Figure 370* shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*. 
Every 128-bit data block a special keystream information is computed using AES block cipher, as defined below:

- The initialization vector $\text{AES}_{\text{IV}}[127:0]= R \times \text{NONCER}[63:0] || 0b0000 0000 0000 0000 || R \times \text{CFGR}[31:16] || 0b00 || (x-1) || \text{ReadAddress}[31:4]$ (address modulo 128-bit)
- The key material $\text{AES}_{\text{KEY}}[127:0]= R \times \text{KEYR3}[31:0] || R \times \text{KEYR2}[31:0] || R \times \text{KEYR1}[31:0] || R \times \text{KEYR0}[31:0]$

**Note:** $x$ is the RegionID of the selected encrypted region ($x=1$ to $4$).

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- $\text{AES}_{\text{DIN}}$ and $\text{AES}_{\text{DOUT}}$ data blocks are constructed following the rule below:
  $\text{AES}_{\text{Dx}}[127:0]= \text{AXI}_{\text{word}}(@+0x8)[63:0] || \text{AXI}_{\text{word}}(@)[63:0]$, where $@$ is the hexadecimal address used to compute the keystream.

When the read request is not within an encrypted region, or the decryption is not enabled in this region the 128-bit AXI data is not changed.

**Note:** When application sets the MODE bitfield to 11 in OTFDEC_RxCFGR an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode is valid only in execute-only.
42.3.5 Flow control management

*Figure 371* shows how OTFDEC manages two back-to-back AXI requests for a burst read of 4 words (256-bit). All 128-bit data blocks have contiguous address values.

*Figure 371. OTFDEC flow control overview (dual burst read request)*

Few notes on this diagram:

1. OTFDEC enforces RREADY low as it is not ready to decrypt data (keystream computation).
2. OTFDEC does not enforce RREADY low as a valid mask is ready to XOR the incoming data. The decryption is done with zero latency, as expected.
3. The keystream FIFO is full. Next time a keystream is needed 11 clock cycles will be needed.
4. STM32 OctoSPI controller has a pre-fetching mechanism that greatly speed up any read request to an address that is consecutive to the last one. OTFDEC is able to manage this shorter latency thanks to the mask FIFO mechanism.
Figure 372 shows how OTFDEC manages an AXI request for a burst read of 4 words (256-bit), followed by a single read on an address that is not contiguous to the previous one.

Figure 372. OTFDEC flow control overview (burst then single read request)

Few notes on this diagram:
1. OTFDEC enforces RREADY low as it is not ready to decrypt data.
2. OTFDEC enforces RREADY low as pre-computed mask cannot be used for this request (the encrypted region address is not contiguous).
42.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:

- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK="1" in OTFDEC_RxCFGR.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK="1" in OTFDEC_RxCFGR (x=1 to 4).
- Illegal read to an execute-only region (MODE[1:0]=00 or 11), and illegal execution request to an execute-never region (MODE[1:0]=01). Such illegal requests return 0x0, without bus error.
- Key error: read requests to a encrypted region after the key registers have been cleared by an abort event (tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read requests return 0x0, without bus error.

An interrupt can be generated by one or more of above errors if the bit SEIE, XONEIE or KEIE is set in OTFDEC_IER register, as explained in next Section 42.4.

Note: After a key error OTFDEC keys must be initialized again, and a reset of OTFDEC might be needed if registers are locked.

42.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see Section 42.3.6
- Illegal write to a region’s configuration while CONFIGLOCK=1 (SEIF flag), see Section 42.3.6
- Read access to an execute-only region (MODE[1:0]=00 or 11), execute access to a execute-never data region (MODE[1:0]=01). Both are triggering the XONEIF flag.
- Key error (encrypted regions read as zero), triggering the KEIF flag. See Section 42.3.6.

Interrupt sources are connected to the same global interrupt request signal.

You can enable or disable OTFDEC interrupt sources by setting corresponding SEIE, XONEIE or KEIE bits in OTFDEC_IER register, as described in Table 345. Status of the interrupt event is found in OTFDEC_ISR register, and this event can be cleared using OTFDEC_ICR register.

42.5 OTFDEC application information

42.5.1 OTFDEC initialization process

Introduction

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys and critical options like MODE bits.

Two trusted initialization schemes are recommended here below.

Note: Those sequence are for production code, as during firmware development it is not always recommended to lock the key or the region configuration.

Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

One key for all regions initialization scheme

In this scheme one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

3. For \( x = 1 \) to 4 write the correct MODE[1:0] value in RxCFGR register.
4. For \( x = 1 \) to 4 program RxCXER registers using the sequence described in KEYCRC (to have a valid CRC). Warning key registers are write only!
5. For \( x = 1 \) to 4 check the key CRC. If OK set KEYLOCK bit in RxCFGR register. This bit cannot be cleared, i.e. the key registers in this region \( x \) are no more writable.
6. Do while you have a region \( x \) to decrypt. This task does not necessarily have to be performed by the entity that owns the decryption keys.
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG_EN.
   d) Set CONFIGLOCK bit in RxCFGR. This bit cannot be cleared, i.e. the region configuration is no more writable.

Caution: For a given region, when MODE bits are changed the key registers and associated CRC are cleared by hardware. As a consequence step 1 above must be done before step 2, and MODE bits must not be modified after step 2.
One key per region initialization scheme

In this scheme one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

Do while you have a region x to decrypt. This task must be performed by the entity that owns the corresponding key.

a) Write the correct MODE[1:0] value in RxCFGR register.

b) Program RxKEYR registers using the sequence described in KEYCRC (to have a valid key CRC). Warning key registers are write only!

c) Check the key CRC. If OK set KEYLOCK bit in RxCFGR register. This bit cannot be cleared, i.e. the key registers are no more writable.

d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).

e) Enable decryption of this region using REG_EN.

f) Set CONFIGLOCK bit in RxCFGR. This bit cannot be cleared, i.e. the region configuration is no more writable.

Caution: For a given region, when MODE bits are changed the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and MODE bits must not be modified after step b).

42.5.2 OTFDEC and power management

Each time OTFDEC is reset the correct key loading sequence described in Section 42.5.1 must be performed (in this case KEYCRC equals to zero in OTFDEC_RxCFGR registers).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

42.5.3 Encrypting for OTFDEC

When MODE equals 00, 01 and 10

OTFDEC uses a standard AES in counter (CTR) mode to encrypt binary stored in a region with this MODE value. CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. Definition and endianness of the AES inputs and outputs are defined in Section 42.3.4: AES in counter mode decryption.

For more details, refer to AN5281 application note available on www.st.com.

When MODE equals to 11

OTFDEC uses a proprietary layer of protection on top of standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.
When it is selected, two encryption scenarios are proposed:

a) Use any device in RDP0 and a debugger to encrypt the code using a RSS service. Refer to AN5281 application note for more details.

b) During a firmware install or update, use the OTFDEC in the device to encrypt the target code. For more details, refer to AN4992 application note (install) and UM2262 user manual (update) available on www.st.com.

42.5.4 OTFDEC Key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```c
uint8_t getCRC(uint32_t * keyin)
{
    const uint8_t CRC7_POLY = 0x7;
    const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0};
    uint8_t  i, j, k, crc = 0x0;
    uint32_t  keyval;

    for (j = 0; j < 4; j++)
    {
        keyval = * (keyin + j);
        if (j == 0)
        {
            keyval ^= key_strobe[0];
        }
        else
        {
            keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8) | crc;
        }

        for (i = 0, crc = 0; i < 32; i++)
        {
            k = (((crc >> 7) ^ (keyval >> (31-i)) & 0xF)) & 1;
            crc <<= 1;
            if (k)
            {
                crc ^= CRC7_POLY;
            }
        }
        crc ^= 0x55;
    }
    return crc;
}
```
42.6 OTFDEC registers

42.6.1 OTFDEC region x configuration register (OTFDEC_RxCFG)

Address offset: 0x20 + 0x30 * (x - 1) (x = 1 to 4)
Reset value: 0x0000 0000
Writes are ignored if CONFIGLOCK bit is set to 1.

</tr>
</tbody>
</table>

| Bit 3      | Reserved | must be kept at reset value. |
Bit 2 **KEYLOCK**: region key lock
   0: Writes to this region KEYRx registers are allowed.
   1: Writes to this region KEYRx registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.
   This bitfield is set once, i.e. if this bit is set it can only be reset to “0” if the OTFDEC is reset.

Bit 1 **CONFIGLOCK**: region config lock
   0: Writes to this region CFGRx, STARTADDRx, ENDADDRx and NONCERx registers are allowed.
   1: Writes to this region CFGRx, STARTADDRx, ENDADDRx and NONCERx registers are ignored until next OTFDEC reset.
   This bit-field is set once, i.e. if this bit is set it can only be reset to “0” if OTFDEC is reset.
   Setting this bit forces KEYLOCK bit to “1”.

Bit 0 **REG_EN**: region on-the-fly decryption enable
   0: On-the-fly decryption is disabled for this region.
   1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.

   *Note*: When this bit is set region context (version, key, nonce) must be valid or garbage will be decrypted.

### 42.6.2 OTFDEC region x start address register (OTFDEC2_RxSTARTADDR)

Address offset: 0x24 + 0x30 * (x -1) (x = 1 to 4)

Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>

Bits 31:0 **REGx_START_ADDR[31:0]**: Region AXI start address
   This register must be written before the region corresponding REG_EN bit in the RxCFGR register is set.
   Writing this register while the region CONFIGLOCK bit in the RxCFGR register is set will be discarded.
   *Note*: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.
   When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zero.

### 42.6.3 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: 0x28 + 0x30 * (x -1) (x = 1 to 4)

Reset value: 0x0000 0FFF
### 42.6.4 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0)

Address offset: $0x2C + 0x30 \times (x - 1)$ (x = 1 to 4)

Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0 **REGx_END_ADDR[31:0]**: Region AXI end address

This register must be written before the region corresponding REG_EN bit in the RxCFGR register is set, and RxENDADDR must be strictly greater than RxSTARTADDR to be valid.

Writing this register while the region CONFIGLOCK bit in the RxCFGR register is set will be discarded. *Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.*

When this register is accessed in read the 4 MSB bits returns zeros and the 12 LSB bits returns ones.

### 42.6.5 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1)

Bits 31:0 **REGx_NONCE[63:32]**: Region nonce, bits [63:32]

Refer to the OTFDEC_RxNONCER0 register for description of the NONCE[63:0] bitfield.
42.6.6 OTFDEC region x key register 0 (OTFDEC_RxKEYR0)
Address offset: 0x34 + 0x30 * (x -1) (x = 1 to 4)
Reset value: 0x0000 0000

Bits 31:0 REGx_KEY[31:0]: Region key, bits [31:0]
This register must be written before the region corresponding REG_EN bit in the RxCFGR register is set.
Reading this register returns a zero value. Writing this register while the region CONFIGLOCK or KEYLOCK bit is set in the RxCFGR register will be discarded.

Note: When application successfully changes MODE bits in RxCFGR register RxKEYR registers and associated KEYCRC are erased.

42.6.7 OTFDEC region x key register 1 (OTFDEC_RxKEYR1)
Address offset: 0x38 + 0x30 * (x -1) (x = 1 to 4)
Reset value: 0x0000 0000

Bits 31:0 REGx_KEY[31:0]: Region key, bits [31:0]
Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

42.6.8 OTFDEC region x key register 2 (OTFDEC_RxKEYR2)
Address offset: 0x3C + 0x30 * (x -1) (x = 1 to 4)
Reset value: 0x0000 0000
### OTFDEC region x key register 3 (OTFDEC_RxKEYR3)

### OTFDEC interrupt status register (OTFDEC_ISR)

**Address offset**: $0x300$

- **Reset value**: $0x0000 0000$

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 2 **KEIF**: Key Error Interrupt Flag status

This bit is set by hardware and read only by application. Bit is set when a read access occurs on any encrypted region following the reset of the key registers by an abort event (tamper detection, unauthorized debugger connection, untrusted boot, RDP level regression).

Bit is cleared when application sets in OTFDEC_ICR the corresponding bit to "1".

0: OTFDEC is operating properly.
1: Read access detected on an enabled encrypted region following an abort event. OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to "1" in OTFDEC_IER register.

After KEIF is set any subsequent read to any enabled encrypted region returns a zeroed value. This state remains until OTFDEC keys are initialized again.

Bit 1 **XONEIF**: Execute-only execute-Never Error Interrupt Flag status

This bit is set by hardware and read only by application. Bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 00 or 11. It is also set when an instruction fetch and not a read access is detected on any encrypted region with MODE bits set to 01.

Bit is cleared when application sets in OTFDEC_ICR the corresponding bit to "1".

0: No execute-only error status. No interrupt pending.
1: Read access detected on one region with MODE bits set to 00 or 11, or execute access detected on one region with MODE bits set to 01. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to "1" in OTFDEC_IER register.

Bit 0 **SEIF**: Security Error Interrupt Flag status

This bit is set by hardware and read only by application. Bit is set when at least one security error has been detected (illegal access to keys, illegal write on locked configuration).

Bit is cleared when application sets in OTFDEC_ICR the corresponding bit to "1".

0: No security error status. No interrupt pending.
1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

### 42.6.11 OTFDEC interrupt clear register (OTFDEC_ICR)

**Address offset**: 0x304

**Reset value**: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF**: Key Error Interrupt Flag clear
This bit is written by application, and always reads as 0.
0: KEIF flag status is not affected
1: KEIF flag status is cleared in OTFDEC_ISR register

*Note:* Clearing KEIF does not solve the source of the problem (bad key registers). To be able to read or execute again any encrypted region, OTFDEC key registers must properly initialized, again.

Bit 1 **XONEIF**: Execute-only execute-Never Error Interrupt Flag clear
This bit is written by application, and always reads as 0.
0: XONEIF flag status is not affected
1: XONEIF flag status is cleared in OTFDEC_ISR register

Bit 0 **SEIF**: Security Error Interrupt Flag clear
This bit is written by application, and always reads as 0.
0: SEIF flag status is not affected
1: SEIF flag status is cleared in OTFDEC_ISR register

### 42.6.12 OTFDEC interrupt enable register (OTFDEC_IER)

Address offset: 0x308
Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE**: Key Error Interrupt Enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when KEIF flag status is set.
0: Interrupt generation on key error flag KEIF is disabled (masked)
1: Interrupt generation on key error flag KEIF is enabled (not masked)

Bit 1 **XONEIE**: Execute-only execute-Never Error Interrupt Enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when XONEIF flag status is set.
0: Interrupt generation on execute-only error XONEIF is disabled (masked)
1: Interrupt generation on execute-only error XONEIF is enabled (not masked)

Bit 0 **SEIE**: Security Error Interrupt Enable
This bit is read and written by application. It controls the OTFDEC interrupt generation when SEIF flag status is set.
0: Interrupt generation on security error SEIF is disabled (masked)
1: Interrupt generation on security error SEIF is enabled (not masked)

Refer to Section 2.3 for the register boundary addresses.
43 Advanced-control timers (TIM1/TIM8)

43.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 43.3.26: Timer synchronization.

43.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input Capture (but channels 5 and 6)
  - Output Compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
Figure 373. Advanced-control timer block diagram

1. See Figure 416: Break and Break2 circuitry overview for details
43.3 TIM1/TIM8 functional description

43.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 374* and *Figure 375* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 374. Counter timing diagram with prescaler division change from 1 to 2

- Prescaler control register: 0 3
- Prescaler buffer: 0 3
- Prescaler counter: 0 0 1 2 3 0 1 2 3
43.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Advanced-control timers (TIM1/TIM8)

Figure 381. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)
Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or
DMA request is sent. This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

43.3.3 Repetition counter

Section 43.3.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 393). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

43.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:

- external clock (external clock mode 2, see Section 43.3.5)
- trigger for the slave mode (see Section 43.3.26)
- PWM reset input for cycle-by-cycle current regulation (see Section 43.3.7)

Figure 394 below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield.

Figure 394. External trigger input block

The ETR input comes from multiple sources: input pins (default configuration), comparator outputs and analog watchdogs. The selection is done with the ETRSEL[3:0] bitfield.

Figure 395. TIM1/TIM8 ETR input circuitry
43.3.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Encoder mode

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 396 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

![Figure 396. Control circuit in normal mode, internal clock divided by 1](MSv31085V3)

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.
1. Codes ranging from 01000 to 11111 are reserved

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The Figure 399 gives an overview of the external trigger input block.

1. Refer to Figure 395: TIM1/TIM8 ETR input circuitry.

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:
1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by proper ETPS prescaler setting.

Figure 400. Control circuit in external clock mode 2
43.3.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

Figure 401 to Figure 404 give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 401. Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 402. Capture/compare channel 1 main circuit
1. OCxREF, where x is the rank of the complementary channel
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 43.3.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written with ‘0’.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been
detected (sampled at \(f_{\text{DTS}}\) frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 43.3.8 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):
1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

**Figure 406. PWM input mode timing**

43.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.
43.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while Channel 5 and 6 are only available inside the device (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCRER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxCE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 407.
43.3.11 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
### PWM edge-aligned mode

- **Upcounting configuration**
  
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the [Upcounting mode on page 1559](#).

  In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’.

  Figure 408 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

![Figure 408. Edge-aligned PWM waveforms (ARR=8)](image-url)

- **Downcounting configuration**
  
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the [Downcounting mode on page 1563](#).

  In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the...
TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 1566.

Figure 409 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Hints on using center-aligned mode
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

### 43.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

*Figure 410* represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
### Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 411** represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
43.3.14 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
43.3.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 351: Output control bits for complementary OCx and OCxN channels with break feature on page 1635 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 413. Complementary output with dead-time insertion**

[Diagram of OCxREF, OCx, OCxN with delays indicated]

**Figure 414. Dead-time waveforms with delay greater than the negative pulse**

[Diagram of OCxREF, OCx, OCxN with delays indicated]
Figure 415. Dead-time waveforms with delay greater than the positive pulse

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 43.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.

**Re-directing OCxREF to OCx or OCxN**

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

*Note:* When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

**43.3.16 Using the break function**

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 and TIM8 timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.
The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows the outputs to be enabled/disabled by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 351: Output control bits for complementary OCx and OCxN channels with break feature on page 1635 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKE/BK2E and BKP/BK2P can be modified at the same time. When the BKE/BK2E and BKP/BK2P bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (BRK) channel are:
- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source:
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral
- A system break:
  - the Cortex®-M7 LOCKUP output
  - the PVD output
  - all SRAM and TCM ECC dual error detections (AXI-SRAM, ITCM, DTCM, SRAM1, SRAM2, SRAM3, SRAM4, BKRAM, refer to SYS_CFG_CFRG register for details)
  - a Flash memory ECC dual error detection
  - a clock failure event generated by the CSS detector

The sources for break2 (BRK2) are:
- An external source connected to one of the BKIN pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source coming from a comparator output.
- The analog watchdog output of the DFSDM1 peripheral
Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register. The software break generation using BG and B2G is active whatever the BKE and BK2E enable bits values.

All sources are ORed before entering the timer BRK or BRK2 inputs, as per Figure 416 below.
Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 ck_tim clock cycles).
  - If OSSI=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs will be in idle state and forced to inactive level or Hi-Z depending on OSSI value.

If both the MOE and AOE bits are reset by the CPU, the outputs will be in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows the configuration of several parameters to be freezed (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 43.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8). The LOCK bits can be written only once after an MCU reset.

Figure 417 shows an example of behavior of the outputs in response to a break.
Figure 417. Various output behavior in response to a break event on BRK (OSSI = 1)

- OCxREF
- OCx (OCxN not implemented, CCxP=0, OISx=1)
- OCx (OCxN not implemented, CCxP=0, OISx=0)
- OCx (OCxN not implemented, CCxP=1, OISx=1)
- OCx (OCxN not implemented, CCxP=1, OISx=0)
- OCx
- OCxN (CCxE=1, CCxP=0, OISx=N, CCxNE=1, CCxNP=0, OISxN=1)
- OCxN (CCxE=1, CCxP=0, OISx=1, CCxNE=1, CCxNP=1, OISxN=1)
- OCxN (CCxE=1, CCxP=0, OISx=0, CCxNE=0, CCxNP=0, OISxN=1)
- OCxN (CCxE=1, CCxP=0, OISx=N, CCxNE=0, CCxNP=0, OISxN=0)
- OCxN (CCxE=1, CCxP=0, CCxNE=0, CCxNP=0, OISx=OISxN=0 or OISx=OISxN=1)
The two break inputs have different behaviors on timer outputs:
- The BRK input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- BRK2 can only disable (inactive state) the PWM outputs.

The BRK has a higher priority than BRK2 input, as described in Table 347.

Note: BRK2 must only be used with OSSR = OSSI = 1.

Figure 418 gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

Figure 418. PWM output state following BRK and BRK2 pins assertion (OSSI=1)
43.3.17 Bidirectional break inputs

The TIM1/TIM8 are featuring bidirectional break I/Os, as represented on Figure 420.

They allow the following:
- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain comparator outputs ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The break and break2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the break and break2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (e.g. CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BK(2)E = 1). When a software break event is generated with BK(2)E = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the break(2) I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which forces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:
- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BK(2)DSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 348)
Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:
- The BKDSRM (BK2DSRM) bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

### 43.3.18 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be
used in Output compare and PWM modes. It does not work in Forced mode. The ocref_clr_int is connected to the ETRF signal (ETR after filtering).

When ETRF is chosen, ETR must be configured as follows:
1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

*Figure 421* shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

*Figure 421. Clearing TIMx OCxREF*

---

**Note:** In case of a PWM with a 100% duty cycle (if CCRx>ARR), then OCxREF is enabled again at the next counter overflow.
43.3.19 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 422 describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Figure 422. 6-step generation, COM example (OSSR=1)**
43.3.20 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: \( CNT < CCRx \leq ARR \) (in particular, \( 0 < CCRx \))
- In downcounting: \( CNT > CCRx \)

For example one may want to generate a positive pulse on OC1 with a length of \( t_{PULSE} \) and after a delay of \( t_{DELAY} \) as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S=’01’ in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P=’0’ and CC2NP=’0’ in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

Particular case: OCx fast enable:

In One-pulse mode, the edge detection on Tlx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}}$ min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 43.3.21 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 43.3.20:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
43.3.22 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to a quadrature encoder. Refer to Table 349. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

Note: The prescaler must be set to zero when encoder mode is enabled

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The Figure 425 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- **CC1S=’01’** (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- **CC2S=’01’** (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- **CC1P=’0’ and CC1NP=’0’** (TIMx_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- **CC2P=’0’ and CC2NP=’0’** (TIMx_CCER register, TI1FP2 non-inverted, TI1FP2=TI2).
- **SMS=’011’** (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- **CEN=’1’** (TIMx_CR1 register, Counter enabled).

**Figure 425. Example of counter operation in encoder interface mode.**

Figure 426 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

**Figure 426. Example of encoder interface mode with TI1FP1 polarity inverted.**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwirtten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

### 43.3.23 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.
43.3.24 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 427 below.

Figure 427. Measuring time interval between edges on 3 signals

43.3.25 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4) referred to as “interfacing timer” in Figure 428. The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See Figure 401: Capture/compare channel (example: channel 1 input stage) on page 1577). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.
Example: one wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx_CR2 register to ‘101’,

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The Figure 428 describes this example.

43.3.26 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 44.3.19: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 429. Control circuit in reset mode**

![Diagram showing control circuit in reset mode](image-url)
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=’0’ in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

![Figure 430. Control circuit in Gated mode](image)

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1.
register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 431. Control circuit in trigger mode**

Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

**Slave mode: external clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.
In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P = 0 and CC1NP = 0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

   A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

   The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

   **Figure 432. Control circuit in external clock mode 2 + trigger mode**

   ![Control circuit in external clock mode 2 + trigger mode](image)

   **Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
43.3.27 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:
- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the TRGO2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 412 on page 1589.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

43.3.28 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.
This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register to be updated once. If every CCRx
register is to be updated twice for example, the number of data to transfer should be 6. Let's
take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and
data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

43.3.29 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter
either continues to work normally or stops, depending on DBG_TIMx_STOP configuration
bit in DBG module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE
bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have
their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).
43.4 TIM1/TIM8 registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

**Bit 2 URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1 UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0 CEN:** Counter enable

0: Counter disabled

1: Counter enabled

*Note:* External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.
Advanced-control timers (TIM1/TIM8)

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (TRGO2) to be selected. The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on TRGO2 is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - the update event is selected as trigger output (TRGO2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (TRGO2).

0100: **Compare** - OC1REFC signal is used as trigger output (TRGO2)

0101: **Compare** - OC2REFC signal is used as trigger output (TRGO2)

0110: **Compare** - OC3REFC signal is used as trigger output (TRGO2)

0111: **Compare** - OC4REFC signal is used as trigger output (TRGO2)

1000: **Compare** - OC5REFC signal is used as trigger output (TRGO2)

1001: **Compare** - OC6REFC signal is used as trigger output (TRGO2)

1010: **Compare Pulse** - OC4REFC rising or falling edges generate pulses on TRGO2

1011: **Compare Pulse** - OC6REFC rising or falling edges generate pulses on TRGO2

1100: **Compare Pulse** - OC4REFC or OC6REFC rising edges generate pulses on TRGO2

1101: **Compare Pulse** - OC4REFC rising or OC6REFC falling edges generate pulses on TRGO2

1110: **Compare Pulse** - OC5REFC or OC6REFC rising edges generate pulses on TRGO2

1111: **Compare Pulse** - OC5REFC rising or OC6REFC falling edges generate pulses on TRGO2

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 10 **OIS2**: Output Idle state 2 (OC2 output)  
Refer to OIS1 bit

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)  
0: OC1N=0 after a dead-time when MOE=0  
1: OC1N=1 after a dead-time when MOE=0  
**Note:** This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)  
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0  
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0  
**Note:** This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: TI1 selection  
0: The TIMx_CH1 pin is connected to TI1 input  
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection  
These bits allow selected information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:  
000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.  
001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).  
010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.  
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO).  
100: **Compare** - OC1REFC signal is used as trigger output (TRGO)  
101: **Compare** - OC2REFC signal is used as trigger output (TRGO)  
110: **Compare** - OC3REFC signal is used as trigger output (TRGO)  
111: **Compare** - OC4REFC signal is used as trigger output (TRGO)  
**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection  
0: CCx DMA request sent when CCx event occurs  
1: CCx DMA requests sent when update event occurs
Bit 2  **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note: This bit acts only on channels that have a complementary output.*

Bit 1  Reserved, must be kept at reset value.

Bit 0  **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

Bits 31:22  Reserved, must be kept at reset value.

Bits 19:17  Reserved, must be kept at reset value.

**Bit 15**  **ETP**: External trigger polarity

This bit selects whether ETR or ETR is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge.
1: ETR is inverted, active at low level or falling edge.

**Bit 14**  **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled
1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111). It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111). If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of $f_{CK\_INT}$ frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

- 00: Prescaler OFF
- 01: ETRP frequency divided by 2
- 10: ETRP frequency divided by 4
- 11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which $N$ consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at $f_{DTS}$
- 0001: $f_{SAMPLING}=f_{CK\_INT}$, $N=2$
- 0010: $f_{SAMPLING}=f_{CK\_INT}$, $N=4$
- 0011: $f_{SAMPLING}=f_{CK\_INT}$, $N=8$
- 0100: $f_{SAMPLING}=f_{DTS}/2$, $N=6$
- 0101: $f_{SAMPLING}=f_{DTS}/2$, $N=8$
- 0110: $f_{SAMPLING}=f_{DTS}/4$, $N=6$
- 0111: $f_{SAMPLING}=f_{DTS}/4$, $N=8$
- 1000: $f_{SAMPLING}=f_{DTS}/8$, $N=6$
- 1001: $f_{SAMPLING}=f_{DTS}/8$, $N=8$
- 1010: $f_{SAMPLING}=f_{DTS}/16$, $N=5$
- 1011: $f_{SAMPLING}=f_{DTS}/16$, $N=6$
- 1100: $f_{SAMPLING}=f_{DTS}/16$, $N=8$
- 1101: $f_{SAMPLING}=f_{DTS}/32$, $N=5$
- 1110: $f_{SAMPLING}=f_{DTS}/32$, $N=6$
- 1111: $f_{SAMPLING}=f_{DTS}/32$, $N=8$

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- 00111: External Trigger input (ETRF)
- 01000 to 01111: Reserved
- 10000: Internal trigger 12 (ITR12)
- 10001: Internal trigger 13 (ITR13)
- Others: Reserved

See Table 350: TIMx internal trigger connection on page 1621 for more details on ITRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 **Reserved**, must be kept at reset value.
Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
0001: Encoder mode 1 - Counter counts up/down on Ti1FP1 edge depending on Ti2FP2 level.
0010: Encoder mode 2 - Counter counts up/down on Ti2FP2 edge depending on Ti1FP1 level.
0011: Encoder mode 3 - Counter counts up/down on both Ti1FP1 and Ti2FP2 edges depending on the level of the other input.
0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
Codes above 1000: Reserved.

Note: The gated mode must not be used if Ti1F_ED is selected as the trigger input (TS=00100). Indeed, Ti1F_ED outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

- **Bit 17** **CC6IF**: Compare 6 interrupt flag
  - Refer to CC1IF description (Note: Channel 6 can only be configured as output)
- **Bit 16** **CC5IF**: Compare 5 interrupt flag
  - Refer to CC1IF description (Note: Channel 5 can only be configured as output)
- **Bit 13** **SBIF**: System Break interrupt flag
  - This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
  - This flag must be reset to re-start PWM operation.
  - 0: No break event occurred.
  - 1: An active level has been detected on the system break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.
- **Bit 12** **CC4OF**: Capture/Compare 4 overcapture flag
  - Refer to CC1OF description
- **Bit 11** **CC3OF**: Capture/Compare 3 overcapture flag
  - Refer to CC1OF description
- **Bit 10** **CC2OF**: Capture/Compare 2 overcapture flag
  - Refer to CC1OF description
Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bit 8 **B2IF**: Break 2 interrupt flag
This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7 **B1F**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag
This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
0: No COM event occurred.
1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred.

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
43.4.6 TIMx event generation register (TIMx_EGR)(x = 1, 8)

Address offset: 0x14

Reset value: 0x0000

| Bit 15:9 Reserved, must be kept at reset value. |
| Bit 8 B2G: Break 2 generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled. |

| Bit 7 BG: Break generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled. |

| Bit 6 TG: Trigger generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled. |

| Bit 5 COMG: Capture/Compare control update generation |
| This bit can be set by software, it is automatically cleared by hardware |
| 0: No action |
| 1: When CCPC bit is set, it allows CCxE, CCxNE and OCxM bits to be updated. |

Note: This bit acts only on channels having a complementary output.

| Bit 4 CC4G: Capture/Compare 4 generation |
| Refer to CC1G description |

| Bit 3 CC3G: Capture/Compare 3 generation |
| Refer to CC1G description |
Bit 2 **CC2G**: Capture/Compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
   - **If channel CC1 is configured as output:**
     CC1IF flag is set, corresponding interrupt or DMA request is sent if enabled.
   - **If channel CC1 is configured as input:**
     The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. The prescaler internal counter is also cleared (the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 43.4.7 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 1, 8)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

**Input capture mode:**

<table>
<thead>

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter
Refer to IC1F[3:0] description.

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler
Refer to IC1PSC[1:0] description.
Bits 9:8  **CC2S[1:0]:** Capture/Compare 2 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output
- 01: CC2 channel is configured as input, IC2 is mapped on TI2
- 10: CC2 channel is configured as input, IC2 is mapped on TI1
- 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:**  `CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).`

Bits 7:4  **IC1F[3:0]:** Input capture 1 filter  
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fCK_INT, N=2
- 0010: fSAMPLING=fCK_INT, N=4
- 0011: fSAMPLING=fCK_INT, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bits 3:2  **IC1PSC[1:0]:** Input capture 1 prescaler  
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]:** Capture/Compare 1 Selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:**  `CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).`

43.4.8  **TIMx capture/compare mode register 1 [alternate]**  
(TIMx_CCMR1)(x = 1, 8)  
Address offset: 0x18  
Reset value: 0x0000 0000  
The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the
corresponding CCxS bits. All the other bits of this register have a different function for input
capture and for output compare modes. It is possible to combine both modes independently
(e.g. channel 1 in input capture mode and channel 2 in output compare mode).

**Output compare mode:**

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output Compare 2 clear enable
Refer to OC1CE description.

Bits 24, 14:12  **OC2M[3:0]**: Output Compare 2 mode
Refer to OC1M[3:0] description.

Bit 11  **OC2PE**: Output Compare 2 preload enable
Refer to OC1PE description.

Bit 10  **OC2FE**: Output Compare 2 fast enable
Refer to OC1FE description.

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if
an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).*

Bit 7  **OC1CE**: Output Compare 1 clear enable
0: OC1Ref is not affected by the ETRF input
1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=’0’) as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=’1’).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Note:** On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

**Note:** The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output Compare 1 preload enable

- **0**: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1**: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- **0**: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1**: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output
- **01**: CC1 channel is configured as input, IC1 is mapped on TI1
- **10**: CC1 channel is configured as input, IC1 is mapped on TI2
- **11**: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note**: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

### 43.4.9 TIMx capture/compare mode register 2 [alternate]
**TIMx_CCMR2**(x = 1, 8)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

  Refer to CC1NP description

- Bit 14  Reserved, must be kept at reset value.

- Bit 13  **CC4P**: Capture/Compare 4 output polarity  
  Refer to CC1P description

- Bit 12  **CC4E**: Capture/Compare 4 output enable  
  Refer to CC1E description

- Bit 11  **CC3NP**: Capture/Compare 3 complementary output polarity  
  Refer to CC1NP description

- Bit 10  **CC3NE**: Capture/Compare 3 complementary output enable  
  Refer to CC1NE description

- Bit  9  **CC3P**: Capture/Compare 3 output polarity  
  Refer to CC1P description

- Bit  8  **CC3E**: Capture/Compare 3 output enable  
  Refer to CC1E description

- Bit  7  **CC2NP**: Capture/Compare 2 complementary output polarity  
  Refer to CC1NP description

- Bit  6  **CC2NE**: Capture/Compare 2 complementary output enable  
  Refer to CC1NE description
Bit 5  **CC2P**: Capture/Compare 2 output polarity  
Refer to CC1P description

Bit 4  **CC2E**: Capture/Compare 2 output enable  
Refer to CC1E description

Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity  
**CC1 channel configured as output:**  
0: OC1N active high.  
1: OC1N active low.  
**CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.  
*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).  
On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2  **CC1NE**: Capture/Compare 1 complementary output enable  
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 1  **CC1P**: Capture/Compare 1 output polarity  
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)  
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)  
When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.  
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).  
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).  
CC1NP=1, CC1P=0: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.  
CC1NP=1, CC1P=1: The configuration is reserved, it must not be used.  
*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).  
On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 0  **CC1E**: Capture/Compare 1 output enable
   0: Capture mode disabled / OC1 is not active (see below)
   1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**When CC1 channel is configured as output**, the OC1 level depends on MOE, OSS1, OSS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 351 for details.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 31  **UIFCPY**: UIF copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in the TIMxCR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16  Reserved, must be kept at reset value.
Bits 15:0  **CNT[15:0]**: Counter value

43.4.13 TIMx prescaler (TIMx_PSC)(x = 1, 8)
Address offset: 0x28
Reset value: 0x0000

</tr>
</tbody>
</table>

Bits 15:0  **PSC[15:0]**: Prescaler value
The counter clock frequency (CK_CNT) is equal to \( f_{CK_{PSC}} / (PSC[15:0] + 1) \).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

43.4.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8)
Address offset: 0x2C
Reset value: 0xFFFF

</tbody>
</table>

Bits 15:0  **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 43.3.1: Time-base unit on page 1557 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
43.4.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8)

Address offset: 0x30
Reset value: 0x0000

<table>

</tr>
</tbody>
</table>

Bits 15:0 REP[15:0]: Repetition counter value
These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.
Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to:
the number of PWM periods in edge-aligned mode
the number of half PWM period in center-aligned mode.

43.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8)

Address offset: 0x34
Reset value: 0x0000

<table>

</tr>
</tbody>
</table>

Bits 15:0 CCR1[15:0]: Capture/Compare 1 value
If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx_CCR1 register is read-only and cannot be programmed.
43.4.17  TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8)

<td>BK2F[3:0]</td>
</tr>
<tr>
<td></td>
<td>BKF[3:0]</td>
</tr>
</tbody>
</table>

Note: As the bits BK2BID, BKBID, BK2DSRM, BK2DSRM, BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSR, OSSI, and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **BK2BID**: Break2 bidirectional
Refer to BKBID description
Bit 28 **BKBID**: Break Bidirectional  
0: Break input BRK in input mode  
1: Break input BRK in bidirectional mode  
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.  
*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).  
*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.  

Bit 27 **BK2DSRM**: Break2 Disarm  
Refer to BKDSRM description  

Bit 26 **BKDSRM**: Break Disarm  
0: Break input BRK is armed  
1: Break input BRK is disarmed  
This bit is cleared by hardware when no break source is active.  
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.  
*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.  

Bit 25 **BK2P**: Break 2 polarity  
0: Break input BRK2 is active low  
1: Break input BRK2 is active high  
*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).  
*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.  

Bit 24 **BK2E**: Break 2 enable  
This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 416: Break and Break2 circuitry overview).  
0: Break2 function disabled  
1: Break2 function enabled  
*Note:* The BKIN2 must only be used with OSSR = OSSI = 1.  
*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).  
*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, BRK2 acts asynchronously
- **0001**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 2
- **0010**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 4
- **0011**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 8
- **0100**: $f_{SAMPLING}$ = $f_{DTS}$/2, $N$ = 6
- **0101**: $f_{SAMPLING}$ = $f_{DTS}$/2, $N$ = 8
- **0110**: $f_{SAMPLING}$ = $f_{DTS}$/4, $N$ = 6
- **0111**: $f_{SAMPLING}$ = $f_{DTS}$/4, $N$ = 8
- **1000**: $f_{SAMPLING}$ = $f_{DTS}$/8, $N$ = 6
- **1001**: $f_{SAMPLING}$ = $f_{DTS}$/8, $N$ = 8
- **1010**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 5
- **1011**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 6
- **1100**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 8
- **1101**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 5
- **1110**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 6
- **1111**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, BRK acts asynchronously
- **0001**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 2
- **0010**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 4
- **0011**: $f_{SAMPLING}$ = $f_{CK\_INT}$, $N$ = 8
- **0100**: $f_{SAMPLING}$ = $f_{DTS}$/2, $N$ = 6
- **0101**: $f_{SAMPLING}$ = $f_{DTS}$/2, $N$ = 8
- **0110**: $f_{SAMPLING}$ = $f_{DTS}$/4, $N$ = 6
- **0111**: $f_{SAMPLING}$ = $f_{DTS}$/4, $N$ = 8
- **1000**: $f_{SAMPLING}$ = $f_{DTS}$/8, $N$ = 6
- **1001**: $f_{SAMPLING}$ = $f_{DTS}$/8, $N$ = 8
- **1010**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 5
- **1011**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 6
- **1100**: $f_{SAMPLING}$ = $f_{DTS}$/16, $N$ = 8
- **1101**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 5
- **1110**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 6
- **1111**: $f_{SAMPLING}$ = $f_{DTS}$/32, $N$ = 8

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 15  **MOE**: Main output enable
This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: In response to a break 2 event. OC and OCN outputs are disabled
  In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).
See OC/OCN enable description for more details (**Section 43.4.11: TIMx capture/compare enable register (TIMx_CCER) (x = 1, 8)**).

Bit 14  **AOE**: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 is active)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 13  **BKP**: Break polarity
0: Break input BRK is active low
1: Break input BRK is active high
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12  **BKE**: Break enable
This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per **Figure 416: Break and Break2 circuitry overview**).
0: Break function disabled
1: Break function enabled
*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11  **OSSR**: Off-state selection for Run mode
This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.
See OC/OCN enable description for more details (**Section 43.4.11: TIMx capture/compare enable register (TIMx_CCER) (x = 1, 8)**).
0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).
*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 43.4.11: TIMx capture/compare enable register (TIMx_CCRER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

Note: **This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).**

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BK2BID, BK2BID, BK2DSRM, BK2DSRM, BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKF, BKE, OSS, OSSI, OSSR and DTG[7:0] bits in TIMx_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCRER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5] = 0xx => DT = DTG[7:0] x tDTG with tDTG = tDTS.

DTG[7:5] = 0xx => DT = (64 + DTG[5:0]) x tDTG with tDTG = 2 x tDTS.

Example if tDTS = 125 ns (8 MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 μs to 31750 ns by 250 ns steps,
32 μs to 63 μs by 1 μs steps,
64 μs to 126 μs by 2 μs steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 43.4.21 TIMx DMA control register (TIMx_DCR)(x = 1, 8)

Address offset: 0x48

Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.
Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

<table>
<thead>
<tr>
<th>Value</th>
<th>Transfers</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000</td>
<td>1 transfer</td>
</tr>
<tr>
<td>00001</td>
<td>2 transfers</td>
</tr>
<tr>
<td>00010</td>
<td>3 transfers</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>10001</td>
<td>18 transfers</td>
</tr>
</tbody>
</table>

**Example**: Let us consider the following transfer: DBL = 7 bytes & DBA = TIMx_CR1.

- If DBL = 7 bytes and DBA = TIMx_CR1 represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:
  
  \[(\text{TIMx}_{-}\text{CR1 address}) + \text{DBA} + (\text{DMA index})\]

In this example, 7 bytes are added to \((\text{TIMx}_{-}\text{CR1 address}) + \text{DBA}\), which gives us the address from/to which the data is copied. In this case, the transfer is done to 7 registers starting from the following address: \((\text{TIMx}_{-}\text{CR1 address}) + \text{DBA}\)

According to the configuration of the DMA Data Size, several cases may occur:

- If the DMA Data Size is configured in half-words, 16-bit data is transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data is also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.

So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example**:

<table>
<thead>
<tr>
<th>Value</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000</td>
<td>TIMx_CR1</td>
</tr>
<tr>
<td>00001</td>
<td>TIMx_CR2</td>
</tr>
<tr>
<td>00010</td>
<td>TIMx_SMCR</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

### 43.4.22 TIMx DMA address for full transfer

**TIMx DMA address for full transfer**

**Bit 31**  GC5C3: Group Channel 5 and Channel 3
Distortion on Channel 3 output:
0: No effect of OC5REF on OC3REFC
1: OC3REFC is the logical AND of OC3REFC and OC5REF
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).
*Note:* it is also possible to apply this distortion on combined PWM signals.

**Bit 30**  GC5C2: Group Channel 5 and Channel 2
Distortion on Channel 2 output:
0: No effect of OC5REF on OC2REFC
1: OC2REFC is the logical AND of OC2REFC and OC5REF
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
*Note:* it is also possible to apply this distortion on combined PWM signals.

**Bit 29**  GC5C1: Group Channel 5 and Channel 1
Distortion on Channel 1 output:
0: No effect of OC5REF on OC1REFC5
1: OC1REFC is the logical AND of OC1REFC and OC5REF
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
*Note:* it is also possible to apply this distortion on combined PWM signals.

Bits 28:16  Reserved, must be kept at reset value.

**Bits 15:0**  CCR5[15:0]: Capture/Compare 5 value
CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC5 output.

Advanced-control timers (TIM1/TIM8) RM0468

Bit 11 **BKCMP2P**: BRK COMP2 input polarity
   This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.
   0: COMP2 input polarity is not inverted (active low if BKP=0, active high if BKP=1)
   1: COMP2 input polarity is inverted (active high if BKP=0, active low if BKP=1)
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMP1P**: BRK COMP1 input polarity
   This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.
   0: COMP1 input polarity is not inverted (active low if BKP=0, active high if BKP=1)
   1: COMP1 input polarity is inverted (active high if BKP=0, active low if BKP=1)
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: BRK BKIN input polarity
   This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
   0: BKIN input polarity is not inverted (active low if BKP=0, active high if BKP=1)
   1: BKIN input polarity is inverted (active high if BKP=0, active low if BKP=1)
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKDF1BK0E**: BRK dfsdm1_break[0] enable
   This bit enables the dfsdm1_break[0] for the timer’s BRK input. dfsdm1_break[0] output is ‘ORed’ with the other BRK sources.
   0: dfsdm1_break[0] input disabled
   1: dfsdm1_break[0] input enabled
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BKCMP2E**: BRK COMP2 enable
   This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.
   0: COMP2 input disabled
   1: COMP2 input enabled
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: BRK COMP1 enable
   This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.
   0: COMP1 input disabled
   1: COMP1 input enabled
   Note: *This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Note: Refer to Figure 395: TIM1/TIM8 ETR input circuitry and to Figure 416: Break and Break2 circuitry overview.

### 43.4.27 TIM1 Alternate function register 2 (TIM1_AF2)

Address offset: 0x64
Reset value: 0x0000 0001

| Bit 31:12 | Reserved, must be kept at reset value. |
| Bit 11   | **BK2CMP2P**: BRK2 COMP2 input polarity |
|          | This bit selects the COMP2 input sensitivity. It must be programmed together with the BK2P polarity bit. |
|          | 0: COMP2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1) |
|          | 1: COMP2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1) |
|          | **Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bit 10   | **BK2CMP1P**: BRK2 COMP1 input polarity |
|          | This bit selects the COMP1 input sensitivity. It must be programmed together with the BK2P polarity bit. |
|          | 0: COMP1 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1) |
|          | 1: COMP1 input polarity is inverted (active high if BK2P=0, active low if BK2P=1) |
|          | **Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bit 9    | **BK2INP**: BRK2 BKIN2 input polarity |
|          | This bit selects the BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit. |
|          | 0: BKIN2 input polarity is not inverted (active low if BK2P=0, active high if BK2P=1) |
|          | 1: BKIN2 input polarity is inverted (active high if BK2P=0, active low if BK2P=1) |
|          | **Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
Bit 8  **BK2DF1BK1E**: BRK2 dfsdm1_break[1] enable
This bit enables the dfsdm1_break[1] for the timer’s BRK2 input. dfsdm1_break[1] output is ‘ORed’ with the other BRK2 sources.
0: dfsdm1_break[1] input disabled
1: dfsdm1_break[1] input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 7:3  Reserved, must be kept at reset value.

Bit 2  **BK2CMP2E**: BRK2 COMP2 enable
This bit enables the COMP2 for the timer’s BRK2 input. COMP2 output is ‘ORed’ with the other BRK2 sources.
0: COMP2 input disabled
1: COMP2 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1  **BK2CMP1E**: BRK2 COMP1 enable
This bit enables the COMP1 for the timer’s BRK2 input. COMP1 output is ‘ORed’ with the other BRK2 sources.
0: COMP1 input disabled
1: COMP1 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0  **BK2INE**: BRK2 BKIN input enable
This bit enables the BKIN2 alternate function input for the timer’s BRK2 input. BKIN2 input is ‘ORed’ with the other BRK2 sources.
0: BKIN2 input disabled
1: BKIN2 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note:** Refer to Figure 416: Break and Break2 circuitry overview.

# TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

<p>| Offset | Register name                      | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|-----------------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | TIM1_CR1                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value                       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | TIM1_CR2                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to Section 2.3 on page 131 for the register boundary addresses.
44 General-purpose timers (TIM2/TIM3/TIM4/TIM5/TIM23/TIM24)

44.1 TIM2/TIM3/TIM4/TIM5/TIM23/TIM24 introduction

The general-purpose timers consist of a 16-bit/32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals \((\text{input capture})\) or generating output waveforms \((\text{output compare and PWM})\).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 44.3.19: Timer synchronization.

44.2 TIM2/TIM3/TIM4/TIM5/TIM23/TIM24 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3, TIM4) or 32-bit (TIM2, TIM5, TIM23 and TIM24) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

Notes:
- Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output
44.3 TIM2/TIM3/TIM4/TIM5/TIM23/TIM24 functional description

44.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-
reload register. The counter can count up, down or both up and down but also down or both
up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by
software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register
accesses the preload register. The content of the preload register are transferred into the
shadow register permanently or at each update event (UEV), depending on the auto-reload
preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter
reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the
TIMx_CR1 register. It can also be generated by software. The generation of the update
event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the
counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller
description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It
is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC
register). It can be changed on the fly as this control register is buffered. The new prescaler
ratio is taken into account at the next update event.

*Figure 434* and *Figure 435* give some examples of the counter behavior when the prescaler
ratio is changed on the fly:
Figure 434. Counter timing diagram with prescaler division change from 1 to 2

Figure 435. Counter timing diagram with prescaler division change from 1 to 4
44.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 436. Counter timing diagram, internal clock divided by 1
Figure 437. Counter timing diagram, internal clock divided by 2

Figure 438. Counter timing diagram, internal clock divided by 4
Figure 439. Counter timing diagram, internal clock divided by N

- **CK_PSC**
- Timer clock = CK_CNT
- Counter register
- Counter overflow
- Update event (UEV)
- Update interrupt flag (UIF)

Figure 440. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)

- **CK_PSC**
- CEN
- Timer clock = CK_CNT
- Counter register
- Counter overflow
- Update event (UEV)
- Update interrupt flag (UIF)
- Auto-reload preload register

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.
The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 442. Counter timing diagram, internal clock divided by 1**

**Figure 443. Counter timing diagram, internal clock divided by 2**
Figure 444. Counter timing diagram, internal clock divided by 4

Figure 445. Counter timing diagram, internal clock divided by N
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to ‘00’. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or
DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 447. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6**

1. Here, center-aligned mode 1 is used (for more details refer to Section 44.4.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5, 23, 24) on page 1706).
1. Center-aligned mode 2 or 3 is used with an UIF on overflow.

44.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer X can be configured to act as a prescaler for Timer Y. Refer to \( \text{Using one timer as prescaler for another timer on page 1700} \) for more details.

**Internal clock source (CK_INT)**

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

\( \text{Figure 453} \) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 01000 to 11111: ITRy.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S='01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
**Note:** The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 and CC2NP=0 in the TIMx_CCER register.

5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

6. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.

7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 455. Control circuit in external clock mode 1**

![Control circuit in external clock mode 1](image)

**External clock source mode 2**

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

*Figure 456* gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. Select the proper ETR source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS [1:0]=01 in the TIMx_SMCR register
4. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.
44.3.4 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding TiX input to generate a filtered signal TiXF. Then, an edge detector with polarity selection generates a signal (TiXFpX) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 44.3.5 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or
a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

44.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on T11 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper T11x source (internal or external) with the T11SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (T11 selected).
3. Select the active polarity for T11FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (T11 selected).
5. Select the active polarity for T11FP2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (T11FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

Figure 461. PWM input mode timing

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only T11FP1 and T12FP2 are connected to the slave mode controller.

44.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

44.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, one must write OCxM=011, OCxPE=0, CCxP=0 and CCxEx=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 462.
44.3.9 PWM mode

Pulse width modulation mode permits to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). However, to comply with the OCREF_CLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison or
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ‘111).

This forces the PWM by software while the timer is running.
The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

**PWM edge-aligned mode**

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to *Upcounting mode on page 1665*.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxREF is held at ‘0’. *Figure 463* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

![Figure 463. Edge-aligned PWM waveforms (ARR=8)](MS31093V1)

**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 1668*.

In PWM mode 1, the reference signal OCxREF is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at 100%. PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCx/OCxREF signals). The
The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to Center-aligned mode (up/down counting) on page 1671.

Figure 464 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit...
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT> TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

44.3.10 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 2.

Figure 465 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1).

Figure 465. Generation of 2 phase-shifted PWM signals with 50% duty cycle

![Figure 465](MS33117V1)
44.3.11 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

– OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
– OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 466 shows an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
### 44.3.12 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The ocref_clr_int is connected to the ETRF signal (ETR after filtering).

The OCxREF signal for a given channel can be reset by applying a high level on the ETRF input (OCxCE enable bit set to 1 in the corresponding TIMx_CCMRx register). OCxREF remains low until the next update event (UEV) occurs.

This function can be used only in the output compare and PWM modes. It does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.
Figure 467 shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

**Figure 467. Clearing TIMx OCxREF**

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), OCxREF is enabled again at the next counter overflow.
### 44.3.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $\text{CNT} < \text{CCR}_x \leq \text{ARR}$ (in particular, $0 < \text{CCR}_x)$.

![Figure 468. Example of one-pulse mode.](image)

For example one may want to generate a positive pulse on OC1 with a length of $t_{PULSE}$ and after a delay of $t_{DELAY}$ as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0 to ‘1 when a compare match occurs and a transition from ‘1 to ‘0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx.ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: OCx fast enable:**

In One-pulse mode, the edge detection on Tlx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 44.3.14 Retriggerable one pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 44.3.13:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

**Note:** In retriggerable one pulse mode, the CCxIF flag is not significant. The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
44.3.15 Encoder interface mode

To select Encoder Interface mode write SMS='001 in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to Table 354. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.
An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

**Figure 470** gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = '0' (TIMx_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = '0' (TIMx_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)

**Figure 470** gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = '0' (TIMx_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = '0' (TIMx_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

44.3.16 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMxCNT[31]). This permits to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

44.3.17 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1 to TIMx_CH3. The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 43.3.25: Interfacing with Hall sensors on page 1606.
44.3.18 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

![Control circuit in reset mode](MS31401V2)

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:
1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 473. Control circuit in gated mode**

1. The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Note:** The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write
CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Slave mode: External Clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=011 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 475. Control circuit in external clock mode 2 + trigger mode**

![Control circuit in external clock mode 2 + trigger mode](image)

### 44.3.19 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 476: Master/Slave timer example* and *Figure 477: Master/slave connection example with 1 channel only timers* present an overview of the trigger selection and the master mode selection blocks.

**Figure 476. Master/Slave timer example**

![Master/Slave timer example](image)

**1700/3357 RM0468 Rev 3**

---

**Figure 477. Master/slave connection example with 1 channel only timers**

Note: The timers with one channel only (see Figure 477) do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave. The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer will detect the trigger. For instance, if the destination’s timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

**Using one timer as prescaler for another timer**

For example, TIM3 can be configured to act as a prescaler for TIM2. Refer to Figure 476. To do this:

1. Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM3_CR2 register, a rising edge is output on TRGO each time an update event is generated.
2. To connect the TRGO output of TIM3 to TIM2, TIM2 must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM2_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes TIM2 to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

**Using one timer to enable another timer**

In this example, we control the enable of TIM2 with the output compare 1 of Timer 3. Refer to Figure 476 for connections. TIM2 counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT}/3$).
1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).
5. Enable TIM2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
6. Start TIM3 by writing ‘1 in the CEN bit (TIM3_CR1 register).

**Note:** The counter 2 clock is not synchronized with counter 1, this mode only affects the TIM2 counter enable signal.

**Figure 478. Gating TIM2 with OC1REF of TIM3**

In the example in Figure 478, the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM3. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to Figure 479), we synchronize TIM3 and TIM2. TIM3 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM3 is disabled by writing ‘0 to the CEN bit in the TIM3_CR1 register:
1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).
5. Reset TIM3 by writing ‘1 in UG bit (TIM3_EGR register).
6. Reset TIM2 by writing ‘1 in UG bit (TIM2_EGR register).
7. Initialize TIM2 to 0xE7 by writing ‘0xE7’ in the TIM2 counter (TIM2_CNTL).
8. Enable TIM2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
9. Start TIM3 by writing ‘1 in the CEN bit (TIM3_CR1 register).
10. Stop TIM3 by writing ‘0 in the CEN bit (TIM3_CR1 register).
Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 3. Refer to Figure 476 for connections. Timer 2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0 to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = \frac{f_{CK\_INT}}{3}$).

1. Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3_CR2 register).
2. Configure the TIM3 period (TIM3_ARR registers).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in trigger mode (SMS=110 in TIM2_SMCR register).
5. Start TIM3 by writing ‘1 in the CEN bit (TIM3_CR1 register).

Figure 479. Gating TIM2 with Enable of TIM3

Figure 480. Triggering TIM2 with update of TIM3
As in the previous example, both counters can be initialized before starting counting. Figure 481 shows the behavior with the same configuration as in Figure 480 but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).

**Figure 481. Triggering TIM2 with Enable of TIM3**

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to Figure 476 for connections. To ensure the counters are aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

1. Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the TIM3_CR2 register).
2. Configure TIM3 slave mode to get the input trigger from TI1 (TS=00100 in the TIM3_SMCR register).
3. Configure TIM3 in trigger mode (SMS=110 in the TIM3_SMCR register).
4. Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3_SMCR register).
5. Configure TIM2 to get the input trigger from TIM3 (TS=00000 in the TIM2_SMCR register).
6. Configure TIM2 in trigger mode (SMS=110 in the TIM2_SMCR register).

When a rising edge occurs on TI1 (TIM3), both counters starts counting synchronously on the internal clock and both TIF flags are set.

**Note:** In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM3.
Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

44.3.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: 
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

*Note:* A null value can be written to the reserved registers.

### 44.3.21 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter either continues to work normally or stops, depending on TIMx configuration bit in DBGMCU module. For more details, refer to [Section 65.5.7: Microcontroller debug unit (DBGMCU)](#). For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB1FZ2), the outputs are disabled.
44.4 TIM2/TIM3/TIM4/TIM5/TIM23/TIM24 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

44.4.1 TIMx control register 1 (TIMx_CR1)(x = 2 to 5, 23, 24)

Address offset: 0x00

Reset value: 0x0000

| Bit 15:12 | Reserved, must be kept at reset value. |
| Bit 11    | UIFREMAP: UIF status bit remapping |
|           | 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31. |
|           | 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31. |
| Bit 10    | Reserved, must be kept at reset value. |
| Bits 9:8  | CKD[1:0]: Clock division |
|           | This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and |
|           | sampling clock used by the digital filters (ETR, TIx), |
|           | 00: tDTS = tCK_INT |
|           | 01: tDTS = 2 × tCK_INT |
|           | 10: tDTS = 4 × tCK_INT |
|           | 11: Reserved |
| Bit 7     | ARPE: Auto-reload preload enable |
| 0: TIMx_ARR register is not buffered |
| 1: TIMx_ARR register is buffered |
| Bits 6:5  | CMS[1:0]: Center-aligned mode selection |
| 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). |
| 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. |
| 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. |
| 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. |
| Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1) |
| Bit 4     | DIR: Direction |
| 0: Counter used as upcounter |
| 1: Counter used as downcounter |
| Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode. |
44.4.2 TIMx control register 2 (TIMx_CR2) (x = 2 to 5, 23, 24)

Address offset: 0x04
Reset value: 0x0000

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
(ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

Note: *External clock, gated mode and encoder mode can work only if the CEN bit has been
previously set by software. However trigger mode can set the CEN bit automatically by
hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.
General-purpose timers (TIM2/TIM3/TIM4/TIM5/TIM23/TIM24) RM0468

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: TI1 selection

0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

See also Section 43.3.25: Interfacing with Hall sensors on page 1606

Bits 6:4  **MMS[2:0]**: Master mode selection

These bits permit to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.
When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
( TRGO )
100: **Compare** - OC1REFC signal is used as trigger output (TRGO)
101: **Compare** - OC2REFC signal is used as trigger output (TRGO)
110: **Compare** - OC3REFC signal is used as trigger output (TRGO)
111: **Compare** - OC4REFC signal is used as trigger output (TRGO)

*Note:* The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3  **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
44.4.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5, 23, 24)

Address offset: 0x08
Reset value: 0x0000 0000

| Bit 31:22 | Reserved, must be kept at reset value. |
| Bit 19:17 | Reserved, must be kept at reset value. |

**Bit 15 ETP**: External trigger polarity
This bit selects whether ETR or ETR is used for trigger operations
0: ETR is non-inverted, active at high level or rising edge
1: ETR is inverted, active at low level or falling edge

**Bit 14 ECE**: External clock enable
This bit enables External clock mode 2.
0: External clock mode 2 disabled
1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note*: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111).

It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111).

If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

**Bits 13:12 ETPS[1:0]**: External trigger prescaler
External trigger signal ETRP frequency must be at most 1/4 of CK_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.
00: Prescaler OFF
01: ETRP frequency divided by 2
10: ETRP frequency divided by 4
11: ETRP frequency divided by 8
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at f_{DTS}
- 0001: \( f_{SAMPLING} = f_{CK\_INT} \), \( N = 2 \)
- 0010: \( f_{SAMPLING} = f_{CK\_INT} \), \( N = 4 \)
- 0011: \( f_{SAMPLING} = f_{CK\_INT} \), \( N = 8 \)
- 0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
- 0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
- 0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
- 0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
- 1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
- 1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
- 1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
- 1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
- 1100: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 8 \)
- 1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
- 1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
- 1111: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

Bit 7 **MSM**: Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]:** Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- **00000:** Internal Trigger 0 (ITR0)
- **00001:** Internal Trigger 1 (ITR1)
- **00010:** Internal Trigger 2 (ITR2)
- **00011:** Internal Trigger 3 (ITR3)
- **00100:** TI1 Edge Detector (TI1F_ED)
- **00101:** Filtered Timer Input 1 (TI1FP1)
- **00110:** Filtered Timer Input 2 (TI2FP2)
- **00111:** External Trigger input (ETRF)
- **01000:** Internal Trigger 4 (ITR4)
- **01001:** Internal Trigger 5 (ITR5)
- **01010:** Internal Trigger 6 (ITR6)
- **01011:** Internal Trigger 7 (ITR7)
- **01100:** Internal Trigger 8 (ITR8)
- **01101:** Internal Trigger 9 (ITR9)
- **01110:** Internal Trigger 10 (ITR10)
- **01111:** Internal Trigger 11 (ITR11)
- **10000:** Internal Trigger 12 (ITR12)
- **10001:** Internal Trigger 13 (ITR13)

Others: Reserved

See Table 355: **TIMx internal trigger connection on page 1712** for more details on ITRx meaning for each Timer.

**Note:** *These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3  Reserved, must be kept at reset value.
Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

- **0000**: Slave mode disabled - if CEN = ‘1 then the prescaler is clocked directly by the internal clock.
- **0001**: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
- **0010**: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
- **0011**: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
- **0100**: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- **0101**: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- **0110**: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- **0111**: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- **1000**: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

**Note**: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note**: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description
Bit 2  **CC2G**: Capture/compare 2 generation
   Refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by hardware.
   0: No action
   1: A capture/compare event is generated on channel 1:
      **If channel CC1 is configured as output:**
      CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
      **If channel CC1 is configured as input:**
      The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 44.4.7  TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)  
(x = 2 to 5, 23, 24)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **IC2F[3:0]**: Input capture 2 filter

Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler
Bits 9:8  **CC2S[1:0]: Capture/compare 2 selection**
This bit-field defines the direction of the channel (input/output) as well as the used input.
   00: CC2 channel is configured as output.
   01: CC2 channel is configured as input, IC2 is mapped on TI2.
   10: CC2 channel is configured as input, IC2 is mapped on TI1.
   11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*

Bits 7:4  **IC1F[3:0]: Input capture 1 filter**
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
   0000: No filter, sampling is done at f_{DTS}
   0001: f_{SAMPLING}=f_{CK_INT}, N=2
   0010: f_{SAMPLING}=f_{CK_INT}, N=4
   0011: f_{SAMPLING}=f_{CK_INT}, N=8
   0100: f_{SAMPLING}=f_{DTS}/2, N=6
   0101: f_{SAMPLING}=f_{DTS}/2, N=8
   0110: f_{SAMPLING}=f_{DTS}/4, N=6
   0111: f_{SAMPLING}=f_{DTS}/4, N=8
   1000: f_{SAMPLING}=f_{DTS}/8, N=6
   1001: f_{SAMPLING}=f_{DTS}/8, N=8
   1010: f_{SAMPLING}=f_{DTS}/16, N=5
   1011: f_{SAMPLING}=f_{DTS}/16, N=6
   1100: f_{SAMPLING}=f_{DTS}/16, N=8
   1101: f_{SAMPLING}=f_{DTS}/32, N=5
   1110: f_{SAMPLING}=f_{DTS}/32, N=6
   1111: f_{SAMPLING}=f_{DTS}/32, N=8

Bits 3:2  **IC1PSC[1:0]: Input capture 1 prescaler**
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).
   00: no prescaler, capture is done each time an edge is detected on the capture input
   01: capture is done once every 2 events
   10: capture is done once every 4 events
   11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]: Capture/Compare 1 selection**
This bit-field defines the direction of the channel (input/output) as well as the used input.
   00: CC1 channel is configured as output
   01: CC1 channel is configured as input, IC1 is mapped on TI1
   10: CC1 channel is configured as input, IC1 is mapped on TI2
   11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*
44.4.8 **TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)**

(x = 2 to 5, 23, 24)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

<table>

</table>

Bits 31:25 Reserved, must be kept at reset value.

Bits 23:17 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode

refer to OC1M description on bits 6:4

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

**Note:** **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCR)**.

Bit 7 **OC1CE**: Output compare 1 clear enable

0: OC1Ref is not affected by the ETRF input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. (This mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0) as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved,

1011: Reserved,

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Note:** The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output compare 1 preload enable
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable
This bit decreases the latency between a trigger event and a transition on the timer output.
It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, IC1 is mapped on TI1.
10: CC1 channel is configured as input, IC1 is mapped on TI2.
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

**44.4.9 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)**
(x = 2 to 5, 23, 24)

Address offset: 0x1C
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

</table>

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.
Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.
Refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.
Refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.
Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.
Refer to CC1P description

Bit 8 **CC3E**: Capture/Compare 3 output enable.
Refer to CC1E description
Bit 7 **CC2NP**: Capture/Compare 2 output Polarity.
   Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity.
   refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable.
   Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 output Polarity.
   **CC1 channel configured as output**: CC1NP must be kept cleared in this case.
   **CC1 channel configured as input**: This bit is used in conjunction with CC1P to define
   TI1FP1/TI2FP1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.
   0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
   1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

   **When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active
   polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
   CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge
   (capture or trigger operations in reset, external clock or trigger mode),
   TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
   CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge
   (capture or trigger operations in reset, external clock or trigger mode),
   TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
   CC1NP=1, CC1P=1: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising
   and falling edges (capture or trigger operations in reset, external clock
   or trigger mode), TIxFP1 is not inverted (trigger operation in gated
   mode). This configuration must not be used in encoder mode.
   CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.
   0: Capture mode disabled / OC1 is not active
   1: Capture mode enabled / OC1 signal is output on the corresponding output pin

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Output disabled (not driven by the timer: Hi-Z)</td>
</tr>
<tr>
<td>1</td>
<td>Output enabled (tim_ocx = tim_ocxref + Polarity)</td>
</tr>
</tbody>
</table>

**Note:**

The state of the external IO pins connected to the standard OCx channels depends on the
OCx channel state and the GPIO control and alternate function registers.

44.4.12 **TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5, 23, 24)**

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in
TIMx_CR1 register:

- This section is for UIFREMAP = 0
- Next section is for UIFREMAP = 1
### 44.4.13 TIMx counter [alternate] (TIMx_CNT)\((x = 2 \text{ to } 5, 23, 24)\)

Bit 31 of this register has two possible definitions depending on the value of UIFREMAP in TIM\(x\)_CR1 register:
- Previous section is for UIFREMAP = 0
- This section is for UIFREMAP = 1

Address offset: 0x24
Reset value: 0x0000 0000

Bits 31:16  CCR2[31:16]: High Capture/Compare 2 value (TIM2, TIM5, TIM23 and TIM24)

Bits 15:0  CCR2[15:0]: Low Capture/Compare 2 value

If channel CC2 is configured as output:
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC2 output.

If channel CC2 is configured as input:
CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx_CCR2 register is read-only and cannot be programmed.

44.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 5, 23, 24)

Address offset: 0x3C
Reset value: 0x0000 0000
44.4.19  TIMx capture/compare register 4 (TIMx_CCR4) (x = 2 to 5, 23, 24)

Address offset: 0x40
Reset value: 0x0000 0000

Bits 31:16  CCR4[31:16]: High Capture/Compare 4 value (TIM2, TIM5, TIM23 and TIM24)

Bits 15:0  CCR4[15:0]: Low Capture/Compare value

1. if CC4 channel is configured as output (CC4S bits):
   CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).
   It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register
   (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when
   an update event occurs.
   The active capture/compare register contains the value to be compared to the counter
   TIMx_CNT and signalled on OC4 output.

2. if CC4 channel is configured as input (CC4S bits in TIMx_CCMR4 register):
   CCR4 is the counter value transferred by the last input capture 4 event (IC4). The
   TIMx_CCR4 register is read-only and cannot be programmed.
44.4.20 TIMx DMA control register (TIMx_DCR)(x = 2 to 5, 23, 24)

Address offset: 0x48
Reset value: 0x0000

<table>
<thead>
<tr>

<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 DBL[4:0]: DMA burst length
This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address
This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
- ...

Example: Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

44.4.21 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5, 23, 24)

Address offset: 0x4C
Reset value: 0x0000

<table>
<thead>
<tr>

Bits 15:0 DMAB[15:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

Others: Reserved

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: TI1[0] to TI1[15] input selection  
These bits select the TI1[0] to TI1[15] input source.  
0000: TIM23_CH1 input  
Others: Reserved
Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  **TI4SEL[3:0]**: TI4[0] to TI4[15] input selection
These bits select the TI4[0] to TI4[15] input source.
0000: TIM24_CH4 input
Others: Reserved

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **TI3SEL[3:0]**: TI3[0] to TI3[15] input selection
These bits select the TI3[0] to TI3[15] input source.
0000: TIM24_CH3 input
Others: Reserved

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8   **TI2SEL[3:0]**: TI2[0] to TI2[15] input selection
These bits select the TI2[0] to TI2[15] input source.
0000: TIM24_CH2 input
Others: Reserved

Bits 7:4    Reserved, must be kept at reset value.

Bits 3:0   **TI1SEL[3:0]**: TI1[0] to TI1[15] input selection
These bits select the TI1[0] to TI1[15] input source.
0000: TIM24_CH1 input
0001: fdcan1_tmp
0010: fdcan1_rtp
0011: fdcan1_soc
Others: Reserved
## 44.4.34 TIMx register map

TIMx registers are mapped as described in the table below:

| Offset | Register name       | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | TIMx_CR1            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | reset value         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x04   | TIMx_CR2            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | reset value         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x08   | TIMx_SMCR           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | reset value         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

45 General-purpose timers (TIM12/TIM13/TIM14)

45.1 TIM12/TIM13/TIM14 introduction

The TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 45.3.17: Timer synchronization (TIM12).

45.2 TIM12/TIM13/TIM14 main features

45.2.1 TIM12 main features

The features of the TIM12 general-purpose timer include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare
45.2.2 TIM13/TIM14 main features

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed "on the fly")
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare
Figure 484. General-purpose timer block diagram (TIM13/TIM14)

1. This signal can be used as trigger for some slave timers, see Section 45.3.18: Using timer output as trigger for other timers (TIM13/TIM14).
45.3 TIM12/TIM13/TIM14 functional description

45.3.1 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 485* and *Figure 486* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 485. Counter timing diagram with prescaler division change from 1 to 2

Figure 486. Counter timing diagram with prescaler division change from 1 to 4
45.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMX_SR register) is set (depending on the URS bit):
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 491. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)
45.3.3 Clock selection

The counter clock can be provided by the following clock sources:
- Internal clock (CK_INT)
- External clock mode1 (for TIM12): external input pin (TIx)
- Internal trigger inputs (ITRx) (for TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to Section : Using one timer as prescaler for another timer for more details.

Internal clock source (CK_INT)

The internal clock source is the default clock source for TIM13/TIM14.

For TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS=’000’). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 493 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1 (TIM12)

This mode is selected when SMS='111' in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F='0000').
4. Select the rising edge polarity by writing CC2P='0’ and CC2NP='0’ in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS='111’ in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS='110’ in the TIMx_SMCR register.
7. Enable the counter by writing CEN='1’ in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.
The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 495. Control circuit in external clock mode 1**

45.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 496 to Figure 498* give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
Figure 498. Output stage of capture/compare channel (channel 1)

- Available on TIM12 only.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 45.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1[x] source (internal or external) with the TI1ISEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to ’01’ in the TIMx_CCMR1 register. As soon as CC1S becomes different from ’00’, the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICXF bits in the TIMx_CCMRx register if the input is one of the TIx inputs). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the
new level have been detected (sampled at f\textsubscript{DTS} frequency). Then write IC1F bits to ‘0011’ in the TIM\textsubscript{x} CCMR1 register.

4. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIM\textsubscript{x} CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIM\textsubscript{x} CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIM\textsubscript{x} CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIM\textsubscript{x} DIER register.

When an input capture occurs:
- The TIM\textsubscript{x} CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt requests can be generated by software by setting the corresponding CC\textsubscript{x}G bit in the TIM\textsubscript{x} EGR register.

### 45.3.6 PWM input mode (only for TIM12)

This mode is a particular case of input capture mode. The procedure is the same except:
- Two IC\textsubscript{x} signals are mapped on the same TI\textsubscript{x} input.
- These 2 IC\textsubscript{x} signals are active on edges with opposite polarity.
- One of the two TI\textsubscript{x}FP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIM\textsubscript{x} CCR1 register) and the duty cycle (in TIM\textsubscript{x} CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\textsubscript{INT} frequency and prescaler value):
1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to ‘01’ in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): program the CC1P and CC1NP bits to ‘00’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to ‘10’ in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): program the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to ‘00101’ in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to ‘100’ in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

**Figure 499. PWM input mode timing**

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 45.3.7 Forced output mode

In output mode (CCxS bits = ‘00’ in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, one just needs to write ‘0101’ in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP='0' (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to ‘0100’ in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

45.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM='0000'), be set active (OCxM='0001'), be set inactive (OCxM='0010') or can toggle (OCxM='0011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = '0011' to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = '0' to disable preload register
   - Write CCxP = '0' to select active high polarity
   - Write CCxE = '1' to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 500.
Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 501 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.
45.3.10 Combined PWM mode (TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 502 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
45.3.11 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

\[ \text{CNT} < \text{CCRx} \leq \text{ARR} \] (in particular, \( 0 < \text{CCRx} \))
For example one may want to generate a positive pulse on OC1 with a length of $t_{\text{PULSE}}$ and after a delay of $t_{\text{DELAY}}$ as soon as a positive edge is detected on the TI2 input pin.

Use TI2FP2 as trigger 1:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).

Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M='0111' in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.
Particular case: OCx fast enable

In One-pulse mode, the edge detection on TiRx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

45.3.12 Retriggerable one pulse mode (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in Section 45.3.11: One-pulse mode:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retrigerrable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 504. Retriggerable one pulse mode
45.3.13 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

45.3.14 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 505.

![Figure 505. Measuring time interval between edges on 2 signals](image_url)

45.3.15 TIM12 external trigger synchronization

The TIM12 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = ‘01’ in the TIMx_CCMR1 register.
Program CC1P and CC1NP to ‘00’ in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS='100' in TIMx_SMCR register. Select TI1 as the input source by writing TS='00101' in TIMx_SMCR register.

3. Start the counter by writing CEN='1' in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S='01' in TIMx_CCMR1 register. Program CC1P='1' and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS='101' in TIMx_SMCR register. Select TI1 as the input source by writing TS='00101' in TIMx_SMCR register.

3. Enable the counter by writing CEN='1' in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN='0', whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.
The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 507. Control circuit in gated mode**

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS='110' in TIMx_SMCR register. Select TI2 as the input source by writing TS='00110' in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.
45.3.16 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.
45.3.17 Timer synchronization (TIM12)

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 44.3.19: Timer synchronization for details.

Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

45.3.18 Using timer output as trigger for other timers (TIM13/TIM14)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer will detect the trigger.

For instance, if the destination’s timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

45.3.19 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBGMCU module. For more details, refer to Section 65.5.7: Microcontroller debug unit (DBGMCU).

45.4 TIM12 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

45.4.1 TIM12 control register 1 (TIM12_CR1)

Address offset: 0x00

Reset value: 0x0000

```
<table>
<thead>
<tr>
<th>Bit 15:12</th>
<th>Bit 11</th>
<th>Bit 10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved</td>
<td>UIFREMAP</td>
<td>Reserved</td>
</tr>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.
Bits 9:8 **CKD[1:0]: Clock division**
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (TIx),
- 00: \( t_{DTS} = t_{CK\_INT} \)
- 01: \( t_{DTS} = 2 \times t_{CK\_INT} \)
- 10: \( t_{DTS} = 4 \times t_{CK\_INT} \)
- 11: Reserved

Bit 7 **ARPE: Auto-reload preload enable**
- 0: TIMx_ARR register is not buffered.
- 1: TIMx_ARR register is buffered.

Bits 6:4 **Reserved, must be kept at reset value.**

Bit 3 **OPM: One-pulse mode**
- 0: Counter is not stopped on the update event
- 1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS: Update request source**
This bit is set and cleared by software to select the UEV event sources.
- 0: Any of the following events generates an update interrupt if enabled. These events can be:
  - Counter overflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS: Update disable**
This bit is set and cleared by software to enable/disable update event (UEV) generation.
- 0: UEV enabled. An UEV is generated by one of the following events:
  - Counter overflow
  - Setting the UG bit
  - Buffered registers are then loaded with their preload values.
- 1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN: Counter enable**
- 0: Counter disabled
- 1: Counter enabled
CEN is cleared automatically in one-pulse mode, when an update event occurs.
*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 45.4.2 TIM12 control register 2 (TIM12_CR2)

1766/3357
Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **T11S**: T11 selection
0: The TIM12 CH1 pin is connected to T11 input
1: The TIM12 CH1, CH2 pins are connected to the T11 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection
These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:
000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
010: Update - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (TRGO).
100: Compare - OC1REFC signal is used as trigger output (TRGO).
101: Compare - OC2REFC signal is used as trigger output (TRGO).

Bits 3:0 Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/Slave mode
0: No action
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4 \textbf{TS}[4:0]: Trigger selection

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.
- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- Others: Reserved

See Table 358: TIMx internal trigger connection on page 1768 for more details on the meaning of ITRx for each timer.

\textbf{Note:} These bits must be changed only when they are not used (e.g. when SMS='000') to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 \textbf{SMS}[3:0]: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.
- 0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
- 0001: Reserved
- 0010: Reserved
- 0011: Reserved
- 0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
- Other codes: reserved.

\textbf{Note:} The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='00100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

\textbf{Note:} The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 TG: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in the TIMx_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.
Bit 2  **CC2G**: Capture/compare 2 generation  
refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation  
This bit is set by software to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A capture/compare event is generated on channel 1:  
**If channel CC1 is configured as output:**  
the CC1IF flag is set, the corresponding interrupt is sent if enabled.  
**If channel CC1 is configured as input:**  
The current counter value is captured in the TIMx_CCR1 register. The CC1IF flag is set, the  
corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation  
This bit can be set by software, it is automatically cleared by hardware.  
0: No action  
1: Re-initializes the counter and generates an update of the registers. The prescaler counter  
is also cleared and the prescaler ratio is not affected. The counter is cleared.

### 45.4.7 TIM12 capture/compare mode register 1 [alternate]  
(TM12_CCMR1)

Address offset: 0x18  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare  
mode (next section). The direction of a channel is defined by configuring the corresponding  
CCxS bits. All the other bits in this register have different functions in input and output  
modes.

#### Input capture mode:

<table>

</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.  

Bits 15:12  **IC2F[3:0]**: Input capture 2 filter  

Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler  

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection  
This bitfield defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output  
01: CC2 channel is configured as input, IC2 is mapped on TI2  
10: CC2 channel is configured as input, IC2 is mapped on TI1  
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an  
internal trigger input is selected through the TS bit (TIMx_SMCR register)  
*Note*: The **CC2S** bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).
**Bits 7:4 IC1F[3:0]: Input capture 1 filter**

This bitfield defines the frequency used to sample the TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING= fCK_INT, N=2
- 0010: fSAMPLING= fCK_INT, N=4
- 0011: fSAMPLING= fCK_INT, N=8
- 0100: fSAMPLING= fDTS/2, N=6
- 0101: fSAMPLING= fDTS/2, N=8
- 0110: fSAMPLING= fDTS/4, N=6
- 0111: fSAMPLING= fDTS/4, N=8
- 1000: fSAMPLING= fDTS/8, N=6
- 1001: fSAMPLING= fDTS/8, N=8
- 1010: fSAMPLING= fDTS/16, N=5
- 1011: fSAMPLING= fDTS/16, N=6
- 1100: fSAMPLING= fDTS/16, N=8
- 1101: fSAMPLING= fDTS/32, N=5
- 1110: fSAMPLING= fDTS/32, N=6
- 1111: fSAMPLING= fDTS/32, N=8

**Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler**

This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

**Bits 1:0 CC1S[1:0]: Capture/Compare 1 selection**

This bitfield defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 45.4.8 TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the
corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Output compare mode:**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | rw | rw |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 | rw | rw |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15     Reserved, must be kept at reset value.

Bits 24, 14:12 **OC2M[3:0]:** Output compare 2 mode

Refer to OC1M[3:0] for bit description.

Bit 11 **OC2PE:** Output compare 2 preload enable

Bit 10 **OC2FE:** Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]:** Capture/Compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note:* The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7     Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas the active level of OC1 depends on the CC1P.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).
- **0001**: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1
- **0100**: Force inactive level - OC1REF is forced low
- **0101**: Force active level - OC1REF is forced high
- **0110**: PWM mode 1 - channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else it is inactive
- **0111**: PWM mode 2 - channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else it is active
- **1000**: Retrigerrable OPM mode 1 - The channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1001**: Retrigerrable OPM mode 2 - The channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.
- **1010**: Reserved,
- **1011**: Reserved,
- **1100**: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.
- **1101**: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.
- **1110**: Reserved,
- **1111**: Reserved

**Note:** In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Note:** The OC1M[3] bit is not contiguous, located in bit 16.
**Bit 3 OC1PE**: Output compare 1 preload enable
- 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately
- 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event

**Bit 2 OC1FE**: Output compare 1 fast enable
- This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
- 0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles
- 1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

**Bits 1:0 CC1S[1:0]**: Capture/Compare 1 selection
- This bitfield defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 45.4.9 TIM12 capture/compare enable register (TIM12_CCER)

Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P**: Capture/Compare 1 output Polarity.
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

**When CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of T1FP1 and T2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to T1xFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=0: non-inverted/both edges/ The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: This configuration is reserved, it must not be used.

Bit 0  **CC1E**: Capture/Compare 1 output enable.
0: Capture mode disabled / OC1 is not active
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

### Table 359. Output control bit for standard OCx channels

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Output disabled (not driven by the timer: Hi-Z)</td>
</tr>
<tr>
<td>1</td>
<td>Output enabled (tim_ocx = tim_ocxref + Polarity)</td>
</tr>
</tbody>
</table>

**Note:** The states of the external I/O pins connected to the standard OCx channels depend on the state of the OCx channel and on the GPIO registers.

#### 45.4.10  TIM12 counter (TIM12_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>UIFCPY: UIF Copy</th>

</tr>
</tbody>
</table>

Bits 15:0  **PSC[15:0]:** Prescaler value
The counter clock frequency \( f_{CK\_CNT} \) is equal to \( f_{CK\_PSC} / (PSC[15:0] + 1) \).
PSC contains the value to be loaded into the active prescaler register at each update event.
(including when the counter is cleared through UG bit of TIMx_EGR register or through
toggle controller when configured in “reset mode”).

45.4.12  TIM12 auto-reload register (TIM12_ARR)
Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0  **ARR[15:0]:** Auto-reload value
ARR is the value to be loaded into the actual auto-reload register.
Refer to the Section 45.3.1: Time-base unit on page 1743 for more details about ARR
update and behavior.
The counter is blocked while the auto-reload value is null.

45.4.13  TIM12 capture/compare register 1 (TIM12_CCR1)
Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0  **CCR1[15:0]:** Capture/Compare 1 value
If channel CC1 is configured as output:
CCR1 is the value to be loaded into the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register
(OC1PE bit). Else the preload value is copied into the active capture/compare 1 register
when an update event occurs.
The active capture/compare register contains the value to be compared to the TIMx_CNT
counter and signaled on the OC1 output.
If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (IC1).
45.4.14 TIM12 capture/compare register 2 (TIM12_CCR2)

Address offset: 0x38
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

</tbody>
</table>

Bits 15:0 **CCR2[15:0]: Capture/Compare 2 value**

**If channel CC2 is configured as output:**
- CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (OC2PE bit). Else the preload value is copied into the active capture/compare 2 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the TIMx_CNT counter and signalled on the OC2 output.

**If channel CC2 is configured as input:**
- CCR2 is the counter value transferred by the last input capture 2 event (IC2).

45.4.15 TIM12 timer input selection register (TIM12_TISEL)

Address offset: 0x68
Reset value: 0x0000

<table>
<thead>

</tbody>
</table>

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]:** selects TI2[0] to TI2[15] input
- 0000: TIM12.CH2 input
- Other: Reserved

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]:** selects TI1[0] to TI1[15] input
- 0000: TIM12.CH1 input
- 0001: spdifrx_frame_sync
- Other: Reserved
### 45.4.16 TIM12 register map

TIM12 registers are mapped as 16-bit addressable registers as described below:

#### Table 360. TIM12 register map and reset values

| Offset  | Register name       | Reset value | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|---------|---------------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x00    | TIMx_CR1            |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         |                     | Reset value | 0   | 0   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x04    | TIM12_CR2           |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         |                     | Reset value | 0   | 0   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x08    | TIMx_SMCR           |              |     |     |     |     |     |     |     |     | TIE | MMS[2:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         |                     | Reset value | 0   | 0   | 0   | 0   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

For detailed information, please refer to the full document.
Refer to Section 2.3 on page 131 for the register boundary addresses.
45.5 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

45.5.1 TIMx control register 1 (TIMx_CR1)(x = 13 to 14)

Address offset: 0x00

Reset value: 0x0000

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (TIx),
00: \( t_{DTS} = t_{CK\_INT} \)
01: \( t_{DTS} = 2 \times t_{CK\_INT} \)
10: \( t_{DTS} = 4 \times t_{CK\_INT} \)
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx.ARR register is not buffered
1: TIMx.ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
45.5.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13 to 14)

Address offset: 0x0C

Reset value: 0x0000

</tbody>
</table>

**Bit 2 URS**: Update request source
This bit is set and cleared by software to select the update interrupt (UEV) sources.
0: Any of the following events generate an UEV if enabled:
  - Counter overflow
  - Setting the UG bit
1: Only counter overflow generates an UEV if enabled.

**Bit 1 UDIS**: Update disable
This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.
0: UEV enabled. An UEV is generated by one of the following events:
  - Counter overflow
  - Setting the UG bit.
  - Buffered registers are then loaded with their preload values.
1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCRx). The counter and the prescaler are reinitialized if the UG bit is set.

**Bit 0 CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*
Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
   This flag is set by hardware only when the corresponding channel is configured in input
capture mode. It is cleared by software by writing it to '0'.
   0: No overcapture has been detected.
   1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was
      already set

Bits 8:2  Reserved, must be kept at reset value.

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag
   This flag is set by hardware. It is cleared by software (input capture or output compare mode)
or by reading the TIMx_CCR1 register (input capture mode only).
   0: No compare match / No input capture occurred
   1: A compare match or an input capture occurred.

   **If channel CC1 is configured as output**: this flag is set when the content of the counter
TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of
TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the
counter overflow (in up-counting and up/down-counting modes) or underflow (in down-
counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to
the CMS bits in the TIMx_CR1 register for the full description.

   **If channel CC1 is configured as input**: this bit is set when counter value has been
captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge
sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

   Bit 0  **UIF**: Update interrupt flag
   This bit is set by hardware on an update event. It is cleared by software.
   0: No update occurred.
   1: Update interrupt pending. This bit is set by hardware when the registers are updated:
   – At overflow and if UDIS='0' in the TIMx_CR1 register.
   – When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if
      URS='0' and UDIS='0' in the TIMx_CR1 register.

**45.5.4  TIMx event generation register (TIMx_EGR)(x = 13 to 14)**

</tr>
</tbody>
</table>

Bits 31:17  Reserved, must be kept at reset value.

Bits 15:7  Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]:** Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.

0000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT = TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active

Others: Reserved

*Note: In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.*

*Note: The OC1M[3] bit is not contiguous, located in bit 16.*
Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: Reserved.

11: Reserved.

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 45.5.7 TIMx capture/compare enable register

**(TIMx_CCER)(x = 13 to 14)**

Address offset: 0x20

Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.

CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define TI1FP1 polarity (refer to CC1P description).
Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

- 0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
- 1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When **CC1 channel is configured as input**, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

- **CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=1, CC1P=0**: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
- **CC1NP=1, CC1P=1**: This configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

- 0: Capture mode disabled / OC1 is not active
- 1: Capture mode enabled / OC1 signal is output on the corresponding output pin

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>

**Bit 31** **UIFCPY**: UIF Copy

This bit is a read-only copy of the UIF bit in the TIMx_ISR register.

**Bits 30:16** Reserved, must be kept at reset value.

**Bits 15:0** **CNT[15:0]**: Counter value
45.5.9 TIMx prescaler (TIMx_PSC)(x = 13 to 14)
Address offset: 0x28
Reset value: 0x0000

<table>
<thead>
<tr>
<th>PSC[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency $f_{CK\_CNT}$ is equal to $f_{CK\_PSC} / (PSC[15:0] + 1)$.
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

45.5.10 TIMx auto-reload register (TIMx_ARR)(x = 13 to 14)
Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>ARR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to Section 45.3.1: Time-base unit on page 1743 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.

45.5.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13 to 14)
Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>CCR1[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>
Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**
CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 45.5.12 TIM13 timer input selection register (TIM13_TISEL)

Address offset: 0x68  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:4  Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: selects TI1[0] to TI1[15] input  
0000: TIM13_CH1 input  
Other: Reserved

### 45.5.13 TIM14 timer input selection register (TIM14_TISEL)

Address offset: 0x68  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

Refer to Section 2.3 on page 131 for the register boundary addresses.
46 General-purpose timers (TIM15/TIM16/TIM17)

46.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 46.4.23: Timer synchronization (TIM15).

46.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer's output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
46.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
The internal break event source can be:
- A clock failure event generated by CSS. For further information on the CSS, refer to Section 8.5.3: Clock security system (CSS)
- A PVD output
- All SRAM and TCM double ECC errors
- Flash double ECC error
- Cortex®-M7 LOCKUP (Hardfault) output
- COMP output

Notes:
- Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output
1. This signal can be used as trigger for some slave timer, see Section 46.4.24: Using timer output as trigger for other timers (TIM16/TIM17).

2. The internal break event source can be:
   - A clock failure event generated by CSS. For further information on the CSS, refer to Section 8.5.3: Clock security system (CSS)
   - A PVD output
   - all SRAM and TCM double ECC errors
   - Flash double ECC error
   - Cortex®-M7 LOCKUP (Hard fault) output
   - COMP output

Notes:
- Reg Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output
### 46.4 TIM15/TIM16/TIM17 functional description

#### 46.4.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 511 and Figure 512* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 511. Counter timing diagram with prescaler division change from 1 to 2

Figure 512. Counter timing diagram with prescaler division change from 1 to 4
46.4.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 513. Counter timing diagram, internal clock divided by 1

Figure 514. Counter timing diagram, internal clock divided by 2
Figure 515. Counter timing diagram, internal clock divided by 4

Figure 516. Counter timing diagram, internal clock divided by N
Figure 517. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

Figure 518. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)
46.4.3 Repetition counter

Section 46.4.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 519). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
46.4.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin
- Internal trigger inputs (ITRx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer as prescaler for another timer on page 1700 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 520* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

*Figure 520. Control circuit in normal mode, internal clock divided by 1*

---

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

*Figure 521. TI2 external clock connection example*

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCRER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

**Note:** The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 522. Control circuit in external clock mode 1**

46.4.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

**Figure 523 to Figure 526** give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 523. Capture/compare channel (example: channel 1 input stage)**

**Figure 524. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 46.4.6 Input capture mode

In Input capture mode, the Capture/Compare registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 46.4.7 PWM input mode (only for TIM15)

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on T11 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper T11[x] source (internal or external) with the T11SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (T11 selected).
3. Select the active polarity for T11FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (T11 selected).
5. Select the active polarity for T11FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (T11FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

![Figure 527. PWM input mode timing](image)

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only T11FP1 and T12FP2 are connected to the slave mode controller.

### 46.4.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCXREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

46.4.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 528.
46.4.10 PWM mode

Pulse Width Modulation mode allows a signal to be generated with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxE bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1799.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at
‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 529 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 529. Edge-aligned PWM waveforms (ARR=8)

### 46.4.11 Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 530 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 367: Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17) on page 1870 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 531. Complementary output with dead-time insertion.**

**Figure 532. Dead-time waveforms with delay greater than the negative pulse.**
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 46.6.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1873 for delay calculation.

Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows a specific waveform to be sent (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

46.4.13 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM15/TIM16/TIM17 timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.
The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 365: Output control bits for complementary OCx and OCxN channels with break feature (TIM15) on page 1848 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

A programmable filter (BKF[3:0] bits in the TIMx_BDTR register allows to filter out spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_OR2 register.

The sources for break (BRK) channel are:

- An external source connected to one of the BKin pin (as per selection done in the GPIO alternate function registers), with polarity selection and optional digital filtering
- An internal source:
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral
  - A system break:
    - the Cortex®-M7 LOCKUP output
    - the PVD output
    - all SRAM and TCM double ECC errors (AXI-SRAM, ITCM, DTCM, SRAM1, SRAM2, SRAM3, SRAM4, BKRAM, refer to SYSCFG_CFRG register for details)
    - a Flash double ECC error
    - a clock failure event generated by the CSS detector
Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their...
active level together. Note that because of the resynchronization on MOE, the
dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles).

- If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO
which forces a Hi-Z state) else the enable outputs remain or become high as soon
as one of the CCxE or CCxNE bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be
generated if the BIE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again
at the next update event UEV. This can be used to perform a regulation, for instance.
Else, MOE remains low until it is written with 1 again. In this case, it can be used for
security and the break input can be connected to an alarm from power drivers, thermal
sensors or any security components.

**Note:** If the MOE is reset by the CPU while the AOE bit is set, the outputs will be in idle state and
forced to inactive level or Hi-Z depending on OSSI value.
If both the MOE and AOE bits are reset by the CPU, the outputs will be in disabled state and
driven with the level programmed in the OISx bit in the TIMx_CR2 register.

**Note:** The break inputs is acting on level. Thus, the MOE cannot be set while the break input is
active (neither automatically nor by software). In the meantime, the status flag BIF cannot
be cleared.

The break can be generated by the BRK input which has a programmable polarity and an
enable bit BKE in the TIMx_BDTR register.

In addition to the break input and the output management, a write protection has been
implemented inside the break circuit to safeguard the application. It allows the configuration
of several parameters to be freeze (dead-time duration, OCx/OCxN polarities and state
when disabled, OCxM configurations, break enable and polarity). The protection can be
selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to
Section 46.6.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on
page 1873. The LOCK bits can be written only once after an MCU reset.

The Figure 535 shows an example of behavior of the outputs in response to a break.
Figure 535. Output behavior in response to a break

- OCxN (CCxE=1, CCxP=0, OISx=0, CCxNE=0, CCxNP=0, OISxN=0)
46.4.14 Bidirectional break inputs

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on Figure 536.

They allow the following:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain comparator outputs ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The break input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BKNIP and BKP bits). Any break request coming either from system (e.g. CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (BG) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the break I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 363).

Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).
The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

**Figure 536. Output redirection**

46.4.15 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxEx and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 537 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.
Figure 537. 6-step generation, COM example (OSSR=1)

Counter (CNT) (CCRx)

tim_ocxref

COM event

Example 1

tim_ocx

Write COM to 1

CCxE = 1
CCxNE = 0
OCxM = 0010 (forced inactive)

Write OCxM to 0100

CCxE = 1
CCxNE = 0
OCxM = 100

Example 2

tim_ocx

Write CCxNE to 1 and OCxM to 0101

CCxE = 1
CCxNE = 0
OCxM = 0100 (forced inactive)

Example 3

tim_ocx

Write CCxNE to 0 and OCxM to 0100

CCxE = 1
CCxNE = 0
OCxM = 0010 (forced inactive)

tim_ocxn

CCxE = 1
CCxNE = 0
OCxM = 0100 (forced inactive)

tim_ocxn

CCxE = 1
CCxNE = 0
OCxM = 0100
### 46.4.16 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $$\text{CNT} < \text{CCR}_x \leq \text{ARR}$$ (in particular, $$0 < \text{CCR}_x$$)
For example one may want to generate a positive pulse on OC1 with a length of $t_{\text{PULSE}}$ and after a delay of $t_{\text{DELAY}}$ as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing $\text{CC2S}='01'$ in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write $\text{CC2P}='0'$ and $\text{CC2NP}='0'$ in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing $\text{TS}='00110'$ in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing $\text{SMS}='110'$ in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value ($\text{TIMx_ARR} - \text{TIMx_CCR1}$).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing $\text{OC1M}=111$ in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing $\text{OC1PE}=1$ in the TIMx_CCMR1 register and $\text{ARPE}$ in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. $\text{CC1P}$ is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).
Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

46.4.17 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 46.4.16:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

46.4.18 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows both
the counter value and a potential roll-over condition signaled by the UIFCPY flag, to be atomically read. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.
46.4.19  Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 540.

Figure 540. Measuring time interval between edges on 2 signals
46.4.20  **External trigger synchronization (TIM15 only)**

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

![Figure 541. Control circuit in reset mode](image-url)
**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = '0' in the TIMx_CCRER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 542. Control circuit in gated mode**
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=’1’ and CC2NP=’0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

46.4.21 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

46.4.22 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.
The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,

For example, the timer DMA burst feature could be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx

5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.
46.4.23 **Timer synchronization (TIM15)**

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 44.3.19: Timer synchronization for details.

*Note:* The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

46.4.24 **Using timer output as trigger for other timers (TIM16/TIM17)**

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any TIMx_SMCR register on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer will detect the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

46.4.25 **Debug mode**

When the microcontroller enters debug mode (Cortex®-M7 core halted), the TIMx counter either continues to work normally or stops, depending on TIMx bit in DBGMCU module. For more details, refer to Section 65.5.7: Microcontroller debug unit (DBGMCU).

For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB2FZ1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.
46.5 TIM15 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

46.5.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x000
Reset value: 0x0000

```

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
- 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
- 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(TIx)
- 00: tDTS = tCK_INT
- 01: tDTS = 2 * tCK_INT
- 10: tDTS = 4 * tCK_INT
- 11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
- 0: TIMx_ARR register is not buffered
- 1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)
Bit 2 URS: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt if enabled. These events can be:
   – Counter overflow/underflow
   – Setting the UG bit
   – Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 UDIS: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   – Counter overflow/underflow
   – Setting the UG bit
   – Update generation through the slave mode controller
   Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value
   (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is
   set or if a hardware reset is received from the slave mode controller.

Bit 0 CEN: Counter enable
0: Counter disabled
1: Counter enabled

Note: 
External clock and gated mode can work only if the CEN bit has been previously set by
software. However trigger mode can set the CEN bit automatically by hardware.

### 46.5.2 TIM15 control register 2 (TIM15_CR2)

Address offset: 0x04
Reset value: 0x0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 OIS2: Output idle state 2 (OC2 output)
0: OC2=0 when MOE=0
1: OC2=1 when MOE=0

Note: 
This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in the TIM15_BDTR register).

Bit 9 OIS1N: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

Note: 
This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in TIM15_BDTR register).

Bit 8 OIS1: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

Note: 
This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed
(LOCK bits in TIM15_BDTR register).
Bit 7  **TI1S**: TI1 selection
- 0: The TIMx_CH1 pin is connected to TI1 input
- 1: The TIMx_CH1, CH2 pins are connected to the TI1 input (XOR combination)

Bits 6:4  **MMS[2:0]**: Master mode selection
- These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:
  - 000: *Reset* - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
  - 001: *Enable* - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
  - 010: *Update* - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
  - 011: *Compare Pulse* - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
  - 100: *Compare* - OC1REFC signal is used as trigger output (TRGO).
  - 101: *Compare* - OC2REFC signal is used as trigger output (TRGO).

Bit 3  **CCDS**: Capture/compare DMA selection
- 0: CCx DMA request sent when CCx event occurs
- 1: CCx DMA requests sent when update event occurs

Bit 2  **CCUS**: Capture/compare control update selection
- 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
- 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note:* This bit acts only on channels that have a complementary output.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **CCPC**: Capture/compare preloaded control
- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note:* This bit acts only on channels that have a complementary output.

Bits 31:22  Reserved, must be kept at reset value.

Bits 19:17  Reserved, must be kept at reset value.

Bits 15:8   Reserved, must be kept at reset value.

Bit 7  **MSM:** Master/slave mode
0: No action
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4  **TS[4:0]:** Trigger selection
This bit field selects the trigger input to be used to synchronize the counter.
00000: Internal Trigger 0 (ITR0)
00001: Internal Trigger 1 (ITR1)
00010: Internal Trigger 2 (ITR2)
00011: Internal Trigger 3 (ITR3)
00100: TI1 Edge Detector (TI1F_ED)
00101: Filtered Timer Input 1 (TI1FP1)
00110: Filtered Timer Input 2 (TI2FP2)
Other: Reserved
See **Table 364: TIMx Internal trigger connection on page 1838** for more details on ITRx meaning for each Timer.

*Note:* These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.

46.5.5  TIM15 status register (TIM15_SR)

Address offset: 0x10
Reset value: 0x0000

| Bit 15:11 | Reserved, must be kept at reset value.
| Bit 10  | CC2OF: Capture/Compare 2 overcapture flag
| Refer to CC1OF description
| Bit 9  | CC1OF: Capture/Compare 1 overcapture flag
| This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
| 0: No overcapture has been detected
| 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set
| Bit 8  | Reserved, must be kept at reset value. |
Bit 7  **BIF**: Break interrupt flag  
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.  
0: No break event occurred  
1: An active level has been detected on the break input

Bit 6  **TIF**: Trigger interrupt flag  
This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
0: No trigger event occurred  
1: Trigger interrupt pending

Bit 5  **COMIF**: COM interrupt flag  
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.  
0: No COM event occurred  
1: COM interrupt pending

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description

Bit 1  **CC1IF**: Capture/Compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.  
**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by a trigger event (refer to Section 46.5.3: TIM15 slave mode control register (TIM15_SMCR)), if URS=0 and UDIS=0 in the TIMx_CR1 register.
46.5.6 TIM15 event generation register (TIM15_EGR)

Address offset: 0x14
Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 BG: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 TG: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 COMG: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits. Note: This bit acts only on channels that have a complementary output.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 CC2G: Capture/Compare 2 generation
Refer to CC1G description

Bit 1 CC1G: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 UG: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
46.5.7 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note:* **CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).**
**Bits 7:4 IC1F[3:0]: Input capture 1 filter**

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at fDTS
- **0001**: fSAMPLING=fCK_INT, N=2
- **0010**: fSAMPLING=fCK_INT, N=4
- **0011**: fSAMPLING=fCK_INT, N=8
- **0100**: fSAMPLING=fDTS/2, N=6
- **0101**: fSAMPLING=fDTS/2, N=8
- **0110**: fSAMPLING=fDTS/4, N=6
- **0111**: fSAMPLING=fDTS/4, N=8
- **1000**: fSAMPLING=fDTS/8, N=6
- **1001**: fSAMPLING=fDTS/8, N=8
- **1010**: fSAMPLING=fDTS/16, N=5
- **1011**: fSAMPLING=fDTS/16, N=6
- **1100**: fSAMPLING=fDTS/16, N=8
- **1101**: fSAMPLING=fDTS/32, N=5
- **1110**: fSAMPLING=fDTS/32, N=6
- **1111**: fSAMPLING=fDTS/32, N=8

**Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler**

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- **00**: no prescaler, capture is done each time an edge is detected on the capture input
- **01**: capture is done once every 2 events
- **10**: capture is done once every 4 events
- **11**: capture is done once every 8 events

**Bits 1:0 CC1S[1:0]: Capture/Compare 1 Selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output
- **01**: CC1 channel is configured as input, IC1 is mapped on TI1
- **10**: CC1 channel is configured as input, IC1 is mapped on TI2
- **11**: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

**46.5.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)**

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**
#### General-purpose timers (TIM15/TIM16/TIM17)

| Bits 31:25 | Reserved, must be kept at reset value. |
|-----------------------------|
| Bits 23:17 | Reserved, must be kept at reset value. |
| Bit 15 | Reserved, must be kept at reset value. |
| Bits 24, 14:12 | **OC2M[3:0]**: Output Compare 2 mode |

| Bits 9:8 | **CC2S[1:0]**: Capture/Compare 2 selection |
| This bit-field defines the direction of the channel (input/output) as well as the used input. |
| 00: CC2 channel is configured as output. |
| 01: CC2 channel is configured as input, IC2 is mapped on TI2. |
| 10: CC2 channel is configured as input, IC2 is mapped on TI1. |
| 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) |
| **Note**: **CC2S bits are writable only when the channel is OFF (OC2E = '0' in TIMx_CCER).** |
| Bit 7 | Reserved, must be kept at reset value. |

| Bit 24, 14:12 | **OC2M[3:0]**: Output Compare 2 mode |
|-----------------------------|
| Bit 11 | **OC2PE**: Output Compare 2 preload enable |
| Bit 10 | **OC2FE**: Output Compare 2 fast enable |
| Bits 9:8 | **CC2S[1:0]**: Capture/Compare 2 selection |
| This bit-field defines the direction of the channel (input/output) as well as the used input. |
| 00: CC2 channel is configured as output. |
| 01: CC2 channel is configured as input, IC2 is mapped on TI2. |
| 10: CC2 channel is configured as input, IC2 is mapped on TI1. |
| 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) |
| **Note**: **CC2S bits are writable only when the channel is OFF (OC2E = '0' in TIMx_CCER).** |
| Bit 7 | Reserved, must be kept at reset value. |
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Reserved,

1111: Reserved,

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated. The OC1M[3] bit is not contiguous, located in bit 16.
46.5.9 TIM15 capture/compare enable register (TIM15_CCER)

Address offset: 0x20
Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 \textbf{CC2NP}: Capture/Compare 2 complementary output polarity
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 \textbf{CC2P}: Capture/Compare 2 output polarity
Refer to CC1P description

Bit 4 \textbf{CC2E}: Capture/Compare 2 output enable
Refer to CC1E description
Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

- **CC1** channel configured as output:
  - 0: OC1 active high
  - 1: OC1 active low

- **CC1** channel configured as input:
  - This bit is used in conjunction with **CC1P** to define the polarity of TI1FP1 and TI2FP1. Refer to **CC1P** description.

  **Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and **CC1S**="00" (the channel is configured in output).

  On channels that have a complementary output, this bit is preloaded. If the **CCPC** bit is set in the TIMx_CR2 register then the **CC1NP** active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

- 0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and **CC1E** bits.
- 1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and **CC1E** bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

- 0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
- 1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

  **When CC1 channel is configured as input**, both **CC1NP/CC1P** bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

  - **CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
  - **CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
  - **CC1NP=1, CC1P=0**: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
  - **CC1NP=1, CC1P=1**: this configuration is reserved, it must not be used.

  **Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

  On channels that have a complementary output, this bit is preloaded. If the **CCPC** bit is set in the TIMx_CR2 register then the **CC1P** active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

- 0: Capture mode disabled / OC1 is not active (see below)
- 1: Capture mode enabled / OC1 signal is output on the corresponding output pin

  **When CC1 channel is configured as output**, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and **CC1NP** bits, regardless of the **CC1E** bits state. Refer to Table 365 for details.
Table 365. Output control bits for complementary OCx and OCxN channels with break feature (TIM15)

| Bits 30:16: Reserved, must be kept at reset value. |

| Bits 15:0: CNT[15:0]: Counter value |

46.5.11 TIM15 prescaler (TIM15_PSC)

Address offset: 0x28
Reset value: 0x0000

| Bits 15:0: PSC[15:0]: Prescaler value |
| The counter clock frequency (CK_CNT) is equal to fCK_PSC / (PSC[15:0] + 1). |
| PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”). |

46.5.12 TIM15 auto-reload register (TIM15_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

| Bits 15:0: ARR[15:0]: Auto-reload value |
| ARR is the value to be loaded in the actual auto-reload register. |
| Refer to the Section 46.4.1: Time-base unit on page 1797 for more details about ARR update and behavior. |
| The counter is blocked while the auto-reload value is null. |
46.5.13 TIM15 repetition counter register (TIM15_RCR)

Address offset: 0x30

<th>0</th>
</tr>
</thead>
</table>

Bits 15:8 Reserved, must be kept at reset value.
Bits 7:0 **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.
Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

46.5.14 TIM15 capture/compare register 1 (TIM15_CCR1)

</tbody>
</table>

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**
CCR1 is the counter value transferred by the last input capture 1 event (IC1).
46.5.15 TIM15 capture/compare register 2 (TIM15_CCR2)

**Note:** As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

- Bits 31:29 Reserved, must be kept at reset value.
- **Bit 28 BKBID:** Break Bidirectional
  - 0: Break input BRK in input mode
  - 1: Break input BRK in bidirectional mode
  - In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.
  - **Note:** This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
  - **Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 27  Reserved, must be kept at reset value.

Bit 26  **BKDSRM**: Break Disarm
0: Break input BRK is armed
1: Break input BRK is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 25:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]**: Break filter
This bit-field defines the frequency used to sample the BRK input signal and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, BRK acts asynchronously
- 0001: $f_{SAMPLING} = f_{CK\_INT}$, N=2
- 0010: $f_{SAMPLING} = f_{CK\_INT}$, N=4
- 0011: $f_{SAMPLING} = f_{CK\_INT}$, N=8
- 0100: $f_{SAMPLING} = f_{DTS}/2$, N=6
- 0101: $f_{SAMPLING} = f_{DTS}/2$, N=8
- 0110: $f_{SAMPLING} = f_{DTS}/4$, N=6
- 0111: $f_{SAMPLING} = f_{DTS}/4$, N=8
- 1000: $f_{SAMPLING} = f_{DTS}/8$, N=6
- 1001: $f_{SAMPLING} = f_{DTS}/8$, N=8
- 1010: $f_{SAMPLING} = f_{DTS}/16$, N=5
- 1011: $f_{SAMPLING} = f_{DTS}/16$, N=6
- 1100: $f_{SAMPLING} = f_{DTS}/16$, N=8
- 1101: $f_{SAMPLING} = f_{DTS}/32$, N=5
- 1110: $f_{SAMPLING} = f_{DTS}/32$, N=6
- 1111: $f_{SAMPLING} = f_{DTS}/32$, N=8

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE**: Main output enable
This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (*Section 46.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1846*).

Bit 14  **AOE**: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 13 **BKP**: Break polarity
- 0: Break input BRK is active low
- 1: Break input BRK is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12 **BKE**: Break enable
- 0: Break inputs (BRK and CCS clock failure event) disabled
- 1: Break inputs (BRK and CCS clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode
- This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (*Section 46.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1846*).

- 0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
- 1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode
- This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (*Section 46.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1846*).

- 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
- 1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1 (OC/OCN enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration
- These bits offer a write protection against software errors.
- 00: LOCK OFF - No bit is write protected
- 01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written
- 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
- 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.*
46.5.17 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x48
Reset value: 0x0000

| Bit 15-13 | Reserved, must be kept at reset value. |
| Bit 12-8  | **DBL[4:0]**: DMA burst length |
|           | This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address). |
|           | 00000: 1 transfer, |
|           | 00001: 2 transfers, |
|           | 00010: 3 transfers, |
|           | ... |
|           | 10001: 18 transfers. |

| Bit 7-5  | Reserved, must be kept at reset value. |
| Bit 4-0  | **DBA[4:0]**: DMA base address |
|          | This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register. |
|          | Example: |
|          | 00000: TIMx_CR1, |
|          | 00001: TIMx_CR2, |
|          | 00010: TIMx_SMCR, |
|          | ... |

46.5.18 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x4C
Reset value: 0x0000

| Bit 15-0 | **DMAB[15:0]** |
|          | rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw |
Bits 15:0 **DMAB[15:0]: DMA register for burst accesses**
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base
address configured in TIMx_DCR register, DMA index is automatically controlled by the
DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

### 46.5.19 TIM15 alternate register 1 (TIM15_AF1)

**Address offset:** 0x60  
**Reset value:** 0x0000 0001

**Bits 31:12 Reserved, must be kept at reset value.**

**Bit 11 **BKCM2P: BRK COMP2 input polarity
This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP
polarity bit.
0: COMP2 input is active low  
1: COMP2 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 10 **BKCM1P: BRK COMP1 input polarity
This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP
polarity bit.
0: COMP1 input is active low  
1: COMP1 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 9 **BKINP: BRK BKin input polarity
This bit selects the BKin alternate function input sensitivity. It must be programmed together
with the BKP polarity bit.
0: BKin input is active low  
1: BKin input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 8 **BKDF1BK0E: BRK dfsdm1_break[0] enable
This bit enables the dfsdm1_break[0] for the timer’s BRK input. dfsdm1_break[0] output is
‘ORed’ with the other BRK sources.
0: dfsdm1_break[0]input disabled  
1: dfsdm1_break[0]input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bits 7:3 Reserved, must be kept at reset value.**
Bit 2 **BKCMP2E**: BRK COMP2 enable
- This bit enables the COMP2 for the timer's BRK input. COMP2 output is 'ORed' with the other BRK sources.
- 0: COMP2 input disabled
- 1: COMP2 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: BRK COMP1 enable
- This bit enables the COMP1 for the timer's BRK input. COMP1 output is 'ORed' with the other BRK sources.
- 0: COMP1 input disabled
- 1: COMP1 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BKINE**: BRK BKIN input enable
- This bit enables the BKIN alternate function input for the timer's BRK input. BKIN input is 'ORed' with the other BRK sources.
- 0: BKIN input disabled
- 1: BKIN input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

### 46.5.20 TIM15 input selection register (TIM15_TISEL)

Address offset: 0x68
Reset value: 0x0000 0000

</table>

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
- 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
- 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(TIx).
- 00: tDTS = tCK_INT
- 01: tDTS = 2 * tCK_INT
- 10: tDTS = 4 * tCK_INT
- 11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
- 0: TIMx_ARR register is not buffered
- 1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode
- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
- 0: Any of the following events generate an update interrupt or DMA request if enabled.
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   - Counter overflow/underflow
   - Setting the UG bit
   - Update generation through the slave mode controller
   Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 46.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04

Reset value: 0x0000

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.
Bit 0 **CCPC**: Capture/compare preloaded control
- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.

*Note*: This bit acts only on channels that have a complementary output.

### 46.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

Address offset: 0x0C

<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9  CC1OF: Capture/Compare 1 overcapture flag
   - This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
   - 0: No overcapture has been detected
   - 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7  BIF: Break interrupt flag
   - This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
   - 0: No break event occurred
   - 1: An active level has been detected on the break input

Bit 6  Reserved, must be kept at reset value.

Bit 5  COMIF: COM interrupt flag
   - This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
   - 0: No COM event occurred
   - 1: COM interrupt pending

Bits 4:2 Reserved, must be kept at reset value.

Bit 1  CC1IF: Capture/Compare 1 interrupt flag
   - This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
   - 0: No compare match / No input capture occurred
   - 1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
46.6.5 TIMx event generation register (TIMx_EGR)(x = 16 to 17)

Address offset: 0x14

Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG**: Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
46.6.6 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)  
(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

<table>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.
Bits 7:4 **IC1F[3:0]**: Input capture 1 filter
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fCK_INT, N=2
- 0010: fSAMPLING=fCK_INT, N=4
- 0011: fSAMPLING=fCK_INT, N=8
- 0100: fSAMPLING=fDTS/2, N=
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input.
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

### 46.6.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 16 to 17)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**
General-purpose timers (TIM15/TIM16/TIM17)

**OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
- **0001**: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- **0100**: Force inactive level - OC1REF is forced low.
- **0101**: Force active level - OC1REF is forced high.
- **0110**: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.
- **0111**: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

All other values: Reserved

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output). In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

The OC1M[3] bit is not contiguous, located in bit 16.

**Bit 3** OC1PE: Output Compare 1 preload enable

- **0**: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1**: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note**: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

**Bit 2** OC1FE: Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

- **0**: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1**: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.
Bits 1:0 **CC1S[1:0]: Capture/Compare 1 selection**
- This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC1 channel is configured as output
  - 01: CC1 channel is configured as input, IC1 is mapped on TI1
  - Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

### 46.6.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

*Address offset: 0x20*
*Reset value: 0x0000*

<table>
<thead>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Bits 15:4 Reserved, must be kept at reset value.**

- **Bit 3 **CC1NP: Capture/Compare 1 complementary output polarity**
  - CC1 channel configured as output:
    - 0: OC1N active high
    - 1: OC1N active low
  - CC1 channel configured as input:
    - This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to the description of CC1P.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output). On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.*
Bit 2 CC1NE: Capture/Compare 1 complementary output enable
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N
and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI,
OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 CC1P: Capture/Compare 1 output polarity
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active
polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge
(capture or trigger operations in reset, external clock or trigger mode).
TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge
(capture or trigger operations in reset, external clock or trigger mode).
TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising
and falling edges (capture or trigger operations in reset, external clock or trigger mode).
TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=0: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits
in TIMx_CR1 register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is
set in the TIMx CR2 register then the CC1P active bit takes the new value from the
preloaded bit only when a Commutation event is generated.

Bit 0 CC1E: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI,
OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 367
for details.
Table 367. Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17)

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and GPIO control and alternate function registers.

46.6.9 TIMx counter (TIMx_CNT)(x = 16 to 17)

Address offset: 0x24
Reset value: 0x0000 0000

### Bit 31  UIFCPY: UIF Copy
This bit is a read-only copy of the UIF bit of the TIMx_ISR register. If the UIFREMAP bit in TIMx_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16  Reserved, must be kept at reset value.

Bits 15:0  **CNT[15:0]: Counter value**

### 46.6.10  TIMx prescaler (TIMx_PSC)(x = 16 to 17)
Address offset: 0x28
Reset value: 0x0000

### Bit 15:0  **PSC[15:0]: Prescaler value**
The counter clock frequency (CK_CNT) is equal to f_{CK_PSC} / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

### 46.6.11  TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)
Address offset: 0x2C
Reset value: 0xFFFF

### Bit 15:0  **ARR[15:0]: Auto-reload value**
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 46.4.1: Time-base unit on page 1797 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
46.6.12 TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30
Reset value: 0x0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 REP[7:0]: Repetition counter value
These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enabled, as well as the update interrupt generation rate, if this interrupt is enable. Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event. It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

46.6.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34
Reset value: 0x0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| rw | rw | rw | rw | rw | rw | rw | rw |    |    |    |    |    |    |    | rw |

Bits 15:0 CCR1[15:0]: Capture/Compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (IC1).
46.6.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

Address offset: 0x44
Reset value: 0x0000 0000

MOE AOE BKP BKE OSSR OSSI LOCK[1:0] DTG[7:0]

rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw

Note: As the BKBID, BKDSRM, BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKBID**: Break Bidirectional

0: Break input BRK in input mode
1: Break input BRK in bidirectional mode

In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **BKDSRM**: Break Disarm

0: Break input BRK is armed
1: Break input BRK is disarmed

This bit is cleared by hardware when no break source is active.

The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 25:20 Reserved, must be kept at reset value.

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, BRK acts asynchronously
- 0001: $f_{SAMPLING}=f_{CK\_INT}$, $N=2$
- 0010: $f_{SAMPLING}=f_{CK\_INT}$, $N=4$
- 0011: $f_{SAMPLING}=f_{CK\_INT}$, $N=8$
- 0100: $f_{SAMPLING}=f_{DTS}/2$, $N=6$
- 0101: $f_{SAMPLING}=f_{DTS}/2$, $N=8$
- 0110: $f_{SAMPLING}=f_{DTS}/4$, $N=6$
- 0111: $f_{SAMPLING}=f_{DTS}/4$, $N=8$
- 1000: $f_{SAMPLING}=f_{DTS}/8$, $N=6$
- 1001: $f_{SAMPLING}=f_{DTS}/8$, $N=8$
- 1010: $f_{SAMPLING}=f_{DTS}/16$, $N=5$
- 1011: $f_{SAMPLING}=f_{DTS}/16$, $N=6$
- 1100: $f_{SAMPLING}=f_{DTS}/32$, $N=5$
- 1101: $f_{SAMPLING}=f_{DTS}/32$, $N=6$
- 1110: $f_{SAMPLING}=f_{DTS}/32$, $N=8$
- 1111: $f_{SAMPLING}=f_{DTS}/32$, $N=8$

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (Section 46.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1868).

Bit 14 **AOE**: Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

- 0: Break input BRK is active low
- 1: Break input BRK is active high

**Note**: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

- 0: Break inputs (BRK and CCS clock failure event) disabled
- 1: Break inputs (BRK and CCS clock failure event) enabled

**Note**: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (*Section 46.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1868*).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (*Section 46.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1868*).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note:* The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

\[
\begin{align*}
\text{DTG}[7:5] = 0xx & \Rightarrow DT = \text{DTG}[7:0] \times t_{\text{dtg}} = t_{\text{DTS}} \\
\text{DTG}[7:5] = 10x & \Rightarrow DT = (64 + \text{DTG}[5:0]) \times t_{\text{dtg}} = 2 \times t_{\text{DTS}} \\
\text{DTG}[7:5] = 110 & \Rightarrow DT = (32 + \text{DTG}[4:0]) \times t_{\text{dtg}} = 8 \times t_{\text{DTS}} \\
\text{DTG}[7:5] = 111 & \Rightarrow DT = (32 + \text{DTG}[4:0]) \times t_{\text{dtg}} = 16 \times t_{\text{DTS}}
\end{align*}
\]

Example if \(t_{\text{DTS}} = 125 \text{ ns} \) (8 MHz), dead-time possible values are:
0 to 15875 \text{ ns} by 125 \text{ ns} steps,
16 \text{ µs} to 31750 \text{ ns} by 250 \text{ ns} steps,
32 \text{ µs} to 63 \text{ µs} by 1 \µs steps,
64 \text{ µs} to 126 \text{ µs} by 2 \µs steps

*Note:* This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
46.6.15 TIMx DMA control register (TIMx_DCR)(x = 16 to 17)

Address offset: 0x48
Reset value: 0x0000

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 DBL[4:0]: DMA burst length
This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
00000: 1 transfer,
00001: 2 transfers,
00010: 3 transfers,
... 10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address
This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
... Example: Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

46.6.16 TIMx DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)

Address offset: 0x4C
Reset value: 0x0000

Bits 15:0 DMAB[15:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
46.6.17 TIM16 alternate function register 1 (TIM16_AF1)

Address offset: 0x60
Reset value: 0x0000 0001

Refer to Section 2.3 on page 131 for the register boundary addresses.
47 Basic timers (TIM6/TIM7)

47.1 TIM6/TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

47.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also "on the fly") the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

![Figure 544. Basic timer block diagram](image-url)
47.3  TIM6/TIM7 functional description

47.3.1  Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 545* and *Figure 546* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 545. Counter timing diagram with prescaler division change from 1 to 2

Figure 546. Counter timing diagram with prescaler division change from 1 to 4
47.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):
- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Figure 547. Counter timing diagram, internal clock divided by 1

- Timer clock = CK_CNT
- Counter register: 31 32 33 34 35 36 00 01 02 03 04 05 06 07
- Counter overflow
- Update event (UEV)
- Update interrupt flag (UIF)
- Auto-reload preload register: FF 36

Write a new value in TIMx_ARR
47.3.3 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

47.3.4 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 553* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
47.3.5 Debug mode

When the microcontroller enters the debug mode (Cortex®-M7 core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG_TIMx_STOP configuration bit in the DBGMCU module. For more details, refer to Section 65.5.7: Microcontroller debug unit (DBGMCU).

47.4 TIM6/TIM7 registers

Refer to Section 1.2 on page 104 for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

47.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Address offset: 0x00
Reset value: 0x0000

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.
Bit 7 **ARPE**: Auto-reload preload enable
- 0: TIMx_ARR register is not buffered.
- 1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
- 0: Any of the following events generates an update interrupt or DMA request if enabled.
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
- 0: Counter disabled
- 1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.
### 47.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7)

Address offset: 0x04  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000**: *Reset* - the UG bit from the TIMx_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- **001**: *Enable* - the Counter enable signal, CNT_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx_SMCR register).
- **010**: *Update* - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

**Note**: *The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bits 3:0 Reserved, must be kept at reset value.

### 47.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

Address offset: 0x0C  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>

</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  – At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx_CR1 register.
  – When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

47.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)
Address offset: 0x14
Reset value: 0x0000

<table>
<thead>

</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

47.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)
Address offset: 0x24
Reset value: 0x0000 0000

<td></td>
<td></td>
<td></td>
<td>1</td>
<td>0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value  
The counter clock frequency CK_CNT is equal to fCK_PSC / (PSC[15:0] + 1).  
PSC contains the value to be loaded into the active prescaler register at each update event.  
(including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

### 47.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)

Address offset: 0x2C  
Reset value: 0xFFFF

<p>| | | | | | | | | | | | | | | | | | | | | | | | | | | | | |</p>

</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Prescaler value  
ARR is the value to be loaded into the actual auto-reload register.  
Refer to **Section 47.3.1: Time-base unit on page 1884** for more details about ARR update and behavior.  
The counter is blocked while the auto-reload value is null.
### 47.4.9 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

**Table 369. TIMx register map and reset values**

| Offset | Register name | Offset | Name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 0x00   | TIMx_CR1      | 0x04   | TIMx_CR2 | 0x08 | Reserved | 0x0C | TIMx_DIER | 0x10 | TIMx_SR | 0x14 | TIMx_EGR | 0x18-0x20 | Reserved |
|        | Reset value   |        | Reset value |        | Reserved |        | Reset value |        | Reset value |        | Reset value |        | Reserved |
|        | 0 0 0 0       |        | 0 0       |        | Reserved |        | 0         |        | 0         |        | 0         |        | Reserved |
| 0x24   | TIMx_CNT      | 0x28   | TIMx_PSC | 0x2C  | TIMx_ARR | 0x24   | TIMx_CNT | 0x28   | TIMx_PSC | 0x2C  | TIMx_ARR |
|        | Reset value   |        | Reset value |        | Reset value |        | CNT[15:0] |        | PSC[15:0] |        | ARR[15:0] |
|        | 0 0 0 0 0 0   |        | 0 0 0 0 0 |        | 1 1 1 1 1 |        | 0 0 0 0 0 |

Refer to *Section 2.3 on page 131* for the register boundary addresses.
Low-power timer (LPTIM)

48.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

48.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no embedded oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
48.3 LPTIM implementation

Table 370 describes LPTIM implementation on STM32H72x and STM32H73x devices.

</tbody>
</table>
48.4.4 LPTIM reset and clocks

The LPTIM can beclocked using several clock sources. It can be clocked using an internal
clock signal which can be any configurable internal clock source selectable through the
RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external
clock signal injected on its external Input1. When clocked with an external clock source, the
LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the
  same time an internal clock signal is provided to the LPTIM from configurable internal
  clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock
  source through its external Input1. This configuration is the one used to realize Timeout
  function or Pulse counter function when all the embedded oscillators are turned off
  after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will
use an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the
external clock signal active edge. If both edges are configured to be active ones, an internal
clock signal should also be provided (first configuration). In this case, the internal clock
signal frequency should be at least four times higher than the external clock signal
frequency.

48.4.5 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level
to other embedded peripherals), are protected with digital filters that prevent any glitches
and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious
counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the
LPTIM. This is necessary to guarantee the proper operation of the filters.

<table>
<thead>
<tr>
<th>lptim_in2_mux</th>
<th>LPTIM input 2 connected to</th>
</tr>
</thead>

</tr>
<tr>
<td>lptim_in1_mux2</td>
<td>SAI4_FS_B</td>
</tr>
<tr>
<td>lptim_in1_mux3</td>
<td>Not connected</td>
</tr>
</tbody>
</table>
The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits.
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

Note: The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. Figure 557 shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

Figure 557. Glitch filter timing diagram

Note: In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT and TRGFLT bits to '0'. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

48.4.6 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

<table>
<thead>
<tr>
<th>programming</th>
<th>dividing factor</th>
</tr>
</thead>
<tbody>

<tr>
<td>111</td>
<td>/128</td>
</tr>
</tbody>
</table>
48.4.7 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals ‘00’, The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless timeout function is enabled).

Note: The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled will be discarded by hardware.

Note: When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.

48.4.8 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when reaching the ARR value.

One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will start the counter for a new one-shot counting cycle as shown in Figure 558.
- Set-once mode activated:

It should be noted that when the WAVE bit-field in the LPTIM_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in Figure 559.

**Figure 559. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)**

In case of software start (TRIGEN[1:0] = ‘00’), the SNGSTRT setting will start the counter for one-shot counting.

**Continuous mode**

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in Figure 560.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT will start the counter for continuous counting.
SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT will switch the LPTIM to the One-shot mode. The counter (if active) will stop as soon as it reaches ARR.

If the One-shot mode was previously selected, setting CNTSTRT will switch the LPTIM to the Continuous mode. The counter (if active) will restart as soon as it reaches ARR.

48.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

48.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CMP (compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM_ARR and the LPTIM_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset.
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CMP register value.
The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to ‘0’ forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 561 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.

**Figure 561. Waveform generation**

![Waveform Generation Diagram](image)

**48.4.11 Register update**

The LPTIM_ARR register and LPTIM_CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR and the LPTIM_CMP registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR and the LPTIM_CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR and the LPTIM_CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the
counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register and the LPTIM_CMP register.

After a write to the LPTIM_ARR register or the LPTIM_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.

48.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- CKSEL = 0: the LPTIM is clocked by an internal clock source
  - COUNTMODE = 0
    The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - COUNTMODE = 1
    The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM. Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).

- CKSEL = 1: the LPTIM is clocked by an external clock source
  COUNTMODE value is don’t care.
  In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.
  For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.
  Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

48.4.13 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.
The LPTIM_CFRG and LPTIM_IER registers must be modified only when the LPTIM is disabled.

48.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNT_RST bit in the LPTIM_CR register. After setting the COUNT_RST bit-field to '1', the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic will elapse before the reset is taken into account. This will make the LPTIM counter count few extra pulses between the time when the reset is trigger and it become effective. Since the COUNT_RST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing '1' to the COUNT_RST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to '1', any read access to the LPTIM_CNT register will reset its content to zero. Asynchronous reset should be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset should be applied only when there is enough insurance that no toggle will occur on the LPTIM Input1.

It should be noted that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

---

Warning: There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So developer should make sure that these two mechanisms are used exclusively.

48.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.
Direction change is signaled by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rising Edge</td>
<td>High, Down</td>
<td>No count</td>
<td>Up, No count</td>
</tr>
<tr>
<td></td>
<td>Low, Up</td>
<td>No count</td>
<td>Down, No count</td>
</tr>
<tr>
<td>Falling Edge</td>
<td>High, No count</td>
<td>Up, No count</td>
<td>No count, Down</td>
</tr>
<tr>
<td></td>
<td>Low, No count</td>
<td>Down, No count</td>
<td>Up</td>
</tr>
<tr>
<td>Both Edges</td>
<td>High, Down</td>
<td>Up, No count</td>
<td>Down, Up</td>
</tr>
<tr>
<td></td>
<td>Low, Up</td>
<td>Down, No count</td>
<td>Up</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).
48.4.16 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

48.5 LPTIM low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPTIM interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>If the LPTIM is clocked by an oscillator available in Stop mode, LPTIM is functional and the interrupts cause the device to exit the Stop mode (refer to Section 48.3: LPTIM implementation).</td>
</tr>
<tr>
<td>Standby</td>
<td>The LPTIM peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>
48.6 **LPTIM interrupts**

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

*Note:* If any bit in the LPTIM_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare match</td>
<td>Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the compare register (LPTIM_CMP).</td>
</tr>
<tr>
<td>Auto-reload match</td>
<td>Interrupt flag is raised when the content of the Counter register (LPTIM_CNT) matches the content of the Auto-reload register (LPTIM_ARR).</td>
</tr>
<tr>
<td>External trigger event</td>
<td>Interrupt flag is raised when an external trigger event is detected</td>

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 DOWN**: Counter direction change up to down  
In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.  
*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.

**Bit 5 UP**: Counter direction change down to up  
In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.  
*Note*: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.

**Bit 4 ARROK**: Autoreload register update OK  
ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

**Bit 3 CMPOK**: Compare register update OK  
CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_CMP register has been successfully completed. CMPOK flag can be cleared by writing 1 to the CMPOKCF bit in the LPTIM_ICR register.

**Bit 2 EXTRIG**: External trigger edge event  
EXTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTRIG flag can be cleared by writing 1 to the EXTRIGCF bit in the LPTIM_ICR register.

**Bit 1 ARRM**: Autoreload match  
ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

**Bit 0 CMPM**: Compare match  
The CMPM bit is set by hardware to inform application that LPTIM_CNT register value reached the LPTIM_CMP register’s value. CMPM flag can be cleared by writing 1 to the CMPMCF bit in the LPTIM_ICR register.

Bits 31:7 Reserved, must be kept at reset value.

- **Bit 6 DOWNCF**: Direction change to down clear flag  
  Writing 1 to this bit clear the DOWN flag in the LPTIM_ISR register.  
  **Note**: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.

- **Bit 5 UPCF**: Direction change to UP clear flag  
  Writing 1 to this bit clear the UP flag in the LPTIM_ISR register.  
  **Note**: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.

- **Bit 4 ARROKCF**: Autoreload register update OK clear flag  
  Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

- **Bit 3 CMPOKCF**: Compare register update OK clear flag  
  Writing 1 to this bit clears the CMPOK flag in the LPTIM_ISR register

- **Bit 2 EXTTRIGCF**: External trigger valid edge clear flag  
  Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

- **Bit 1 ARRMCF**: Autoreload match clear flag  
  Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

- **Bit 0 CMPMCF**: Compare match clear flag  
  Writing 1 to this bit clears the CMPM flag in the LPTIM_ISR register

1914/3357  
RM0468 Rev 3
Caution: The LPTIM_IER register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’)

48.7.4 LPTIM configuration register (LPTIM_CFRG)
Address offset: 0x00C
Reset value: 0x0000 0000

| Bit 31:30 | Reserved, must be kept at reset value. |
| Bit 29 | Reserved, must be kept at reset value. |
| Bit 28:25 | Reserved, must be kept at reset value. |
Bit 24 ENC: Encoder mode enable
   The ENC bit controls the Encoder mode
   0: Encoder mode disabled
   1: Encoder mode enabled
   Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.

Bit 23 COUNTMODE: counter mode enabled
   The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
   0: the counter is incremented following each internal clock pulse
   1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 PRELOAD: Registers update mode
   The PRELOAD bit controls the LPTIM_ARR and the LPTIM_CMP registers update modality
   0: Registers are updated after each APB bus write access
   1: Registers are updated at the end of the current LPTIM period

Bit 21 WAVPOL: Waveform shape polarity
   The WAVPOL bit controls the output polarity
   0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CMP registers
   1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CMP registers

Bit 20 WAVE: Waveform shape
   The WAVE bit controls the output shape
   0: Deactivate Set-once mode
   1: Activate the Set-once mode

Bit 19 TIMOUT: Timeout enable
   The TIMOUT bit controls the Timeout feature
   0: A trigger event arriving when the timer is already started will be ignored
   1: A trigger event arriving when the timer is already started will reset and restart the counter

Bits 18:17 TRIGEN[1:0]: Trigger enable and polarity
   The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
   00: software trigger (counting start is initiated by software)
   01: rising edge is the active edge
   10: falling edge is the active edge
   11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.
Bits 15:13 **TRIGSEL[2:0]**: Trigger selector

The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 8 available sources:

- 000: lptim_ext_trig0
- 001: lptim_ext_trig1
- 010: lptim_ext_trig2
- 011: lptim_ext_trig3
- 100: lptim_ext_trig4
- 101: lptim_ext_trig5
- 110: lptim_ext_trig6
- 111: lptim_ext_trig7

See Section 48.4.3: LPTIM input and trigger mapping for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]**: Clock prescaler

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

- 000: /1
- 001: /2
- 010: /4
- 011: /8
- 100: /16
- 101: /32
- 110: /64
- 111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]**: Configurable digital filter for trigger

The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature.

- 00: any trigger active level change is considered as a valid trigger
- 01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
- 10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
- 11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.
Caution: The LPTIM_CFG register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’).

### 48.7.5 LPTIM control register (LPTIM_CR)

Address offset: 0x010

<table>
<thead>
<tr>

<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>
Bits 31:5  Reserved, must be kept at reset value.

Bit 4  RSTARE: Reset after read enable
This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register will asynchronously reset LPTIM_CNT register content.
This bit can be set only when the LPTIM is enabled.

Bit 3  COUNTRST: Counter reset
This bit is set by software and cleared by hardware. When set to ‘1’ this bit will trigger a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.
Caution:  COUNTRST must never be set to ‘1’ by software before it is already cleared to ‘0’ by hardware. Software should consequently check that COUNTRST bit is already cleared to ‘0’ before attempting to set it to ‘1’.

Bit 2  CNTSTRT: Timer start in Continuous mode
This bit is set by software and cleared by hardware.
In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in Continuous mode.
If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.
If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM_ARR and LPTIM_CNT registers and the LPTIM counter keeps counting in Continuous mode.
This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1  SNGSTRT: LPTIM start in Single mode
This bit is set by software and cleared by hardware.
In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in single pulse mode.
If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.
If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM_ARR and LPTIM_CNT registers.
This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0  ENABLE: LPTIM enable
The ENABLE bit is set and cleared by software.
0: LPTIM is disabled
1: LPTIM is enabled
48.7.6 LPTIM compare register (LPTIM_CMP)

Address offset: 0x014
Reset value: 0x0000 0000

Caution: The LPTIM_CMP register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).

48.7.7 LPTIM autoreload register (LPTIM_ARR)

Address offset: 0x018
Reset value: 0x0000 0001

Caution: The LPTIM_ARR register must only be modified when the LPTIM is enabled (ENABLE bit set to ‘1’).
48.7.8  LPTIM counter register (LPTIM_CNT)

Address offset: 0x01C
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]:** Counter value  
When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical. It should be noted that for a reliable LPTIM_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

Reset value

1. If LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 48.3: LPTIM implementation.
Refer to Section 2.3 on page 131 for the register boundary addresses.
49 System window watchdog (WWDG)

49.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit becomes cleared. A reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter has reached the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications which require the watchdog to react within an accurate timing window.

49.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 564)
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40.

49.3 WWDG implementation

1. “X” = supported, “-” = not supported.
2. Refer to the RCC section for additional information.
3. Controlled via DBG_WWDG_STOPbit of DBGMCU_APB3FZ1 register.
49.4 **WWDG functional description**

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register) and when the 7-bit down-counter \(T[6:0]\) bits is decremented from \(0x40\) to \(0x3F\) (\(T6\) becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation must occur only when the counter value is lower than the window register value and higher than \(0x3F\). The value to be stored in the WWDG_CR register must be between \(0xFF\) and \(0xC0\).

Refer to Figure 563 and to Section 49.4.2: WWDG internal signals for the WWDG block diagram.

49.4.1 **WWDG block diagram**

![Watchdog block diagram](MS47214V1)

49.4.2 **WWDG internal signals**

*Table 389* gives the list of WWDG internal signals.

<td>WWDG early interrupt output</td>
</tr>
</tbody>
</table>

49.4.3 **Enabling the watchdog**

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again except by a reset.
49.4.4 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 564). The WWDG configuration register (WWDG_CFR) contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than the window register value and greater than 0x3F. Figure 564 describes the window watchdog process.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

49.4.5 How to program the watchdog timeout

Use the formula in Figure 564 to calculate the WWDG timeout.

---

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.
The formula to calculate the timeout value is given by:

\[ t_{WWDG} = t_{PCLK} \times 4096 \times 2^{WDGTB[2:0]} \times (T[5:0] + 1) \] (ms)

where:
- \( t_{WWDG} \): WWDG timeout
- \( t_{PCLK} \): APB clock period measured in ms
- 4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3 and T[5:0] is set to 63:

\[ t_{WWDG} = (1/48000) \times 4096 \times 2^3 \times (63 + 1) = 43.69\text{ms} \]

Refer to the datasheet for the minimum and maximum values of \( t_{WWDG} \).

### 49.4.6 Debug mode

When the CPU enters debug mode, WWDG counter either continues to work normally or stops, depending on debug settings. For more details refer to Section 49.3: WWDG implementation and to Section 65: Debug infrastructure.
49.5 WWDG interrupts

The early wakeup interrupt (EWI) can be used if specific safety operations or data logging must be performed before the actual reset is generated. The EWI interrupt is enabled by setting the EWI bit in the WWDG_CFR register. When the down-counter reaches the value 0x40, an EWI interrupt is generated and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging) before resetting the device.

In some applications the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR has to reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

Note: When the EWI interrupt cannot be served (e.g. due to a system lock in a higher priority task) the WWDG reset is eventually generated.

49.6 WWDG registers

Refer to Section 1.2 on page 104 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

49.6.1 WWDG control register (WWDG_CR)

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 WDGA: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled
1: Watchdog enabled

Bits 6:0 T[6:0]: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter, decremented every $(4096 \times 2^{WDGTB[2:0]})$ PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).
### 49.6.2 WWDG configuration register (WWDG_CFR)

**Address offset:** 0x004  
**Reset value:** 0x0000 007F

<table>

Refer to *Section 2.3 on page 131* for the register boundary addresses.
50 Independent watchdog (IWDG)

50.1 Introduction

The devices feature an embedded watchdog peripheral that offers a combination of high safety level, timing accuracy and flexibility of use. The Independent watchdog peripheral detects and solves malfunctions due to software failure, and triggers system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to Section 49 on page 1925.

50.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window

50.3 IWDG functional description

50.3.1 IWDG block diagram

Figure 565 shows the functional blocks of the independent watchdog module.
When the independent watchdog is started by writing the value 0x0000 CCCC in the IWDG key register (IWDG_KR), the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the IWDG key register (IWDG_KR), the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

### 50.3.2 IWDG internal signals

*Table 391* gives the list of IWDG internal signals.

<table>
<thead>
<tr>
<th>Signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lsi_ck</td>
<td>Digital input</td>
<td>LSI clock</td>
</tr>
<tr>
<td>iwdg1_out_rst</td>
<td>Digital output</td>
<td>IWDG1 reset signal output</td>
</tr>
</tbody>
</table>

### 50.3.3 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the IWDG window register (IWDG_WINR).

If the reload operation is performed while the counter is greater than the value stored in the IWDG window register (IWDG_WINR), then a reset is provided.

The default value of the IWDG window register (IWDG_WINR) is 0x0000 0FFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the downcounter to the IWDG reload register (IWDG_RLR) value and ease the cycle number calculation to generate the next reload.
Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the IWDG prescaler by programming IWDG prescaler register (IWDG_PR) from 0 to 7.
4. Write the IWDG reload register (IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Write to the IWDG window register (IWDG_WINR). This automatically refreshes the counter value in the IWDG reload register (IWDG_RLR).

Note: Writing the window value allows the counter value to be refreshed by the RLR when IWDG status register (IWDG_SR) is set to 0x0000 0000.

Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the prescaler by programming the IWDG prescaler register (IWDG_PR) from 0 to 7.
4. Write the IWDG reload register (IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Refresh the counter value with IWDG_RLR (IWDG_KR = 0x0000 AAAA).

50.3.4 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the IWDG key register (IWDG_KR) is written by the software before the counter reaches end of count or if the downcounter is reloaded inside the window.

50.3.5 Low-power freeze

Depending on the IWDG_FZ_STOP and IWDG_FZ_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode, respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to Section : User and read protection option bytes for more details.

50.3.6 Register access protection

Write access to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR) and IWDG window register (IWDG_WINR) is protected. To modify them, the user must first write the code 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or of the downcounter reload value or of the window value is ongoing.
50.3.7 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in debug freeze register.
50.4  IWDG registers

Refer to Section 1.2 on page 104 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

50.4.1  IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

</table>

KEY[15:0]

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **KEY[15:0]**: Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 50.3.6: Register access protection)

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)
50.4.2 IWDG prescaler register (IWDG_PR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  **PR[2:0]: Prescaler divider**

These bits are write access protected see Section 50.3.6: Register access protection. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the **IWDG status register (IWDG_SR)** must be reset in order to be able to change the prescaler divider.

- 000: divider /4
- 001: divider /8
- 010: divider /16
- 011: divider /32
- 100: divider /64
- 101: divider /128
- 110: divider /256
- 111: divider /256

**Note:** Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the **IWDG status register (IWDG_SR)** is reset.
# 50.4.3 IWDG reload register (IWDG_RLR)

Address offset: 0x08  
Reset value: 0x0000 0FFF (reset by Standby mode)

<table>
<thead>

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 \textbf{RL[11:0]}: Watchdog counter reload value

These bits are write access protected see \textit{Register access protection}. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the \textit{IWDG key register (IWDGKR)}. The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the \textit{IWDG status register (IWDG_SR)} must be reset to be able to change the reload value.

\textit{Note}: \textit{Reading this register returns the reload value from the V\textsubscript{DD} voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.}
50.4.4  IWDG status register (IWDG_SR)

Address offset: 0x0C
Reset value: 0x0000 0000 (not reset by Standby mode)

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **WVU**: Watchdog counter window value update
This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the VDD voltage domain (takes up to five RC 40 kHz cycles).
Window value can be updated only when WVU bit is reset.

Bit 1  **RVU**: Watchdog counter reload value update
This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the VDD voltage domain (takes up to five RC 40 kHz cycles).
Reload value can be updated only when RVU bit is reset.

Bit 0  **PVU**: Watchdog prescaler value update
This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the VDD voltage domain (takes up to five RC 40 kHz cycles).
Prescaler value can be updated only when PVU bit is reset.

**Note:** If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.
50.4.5 IWDG window register (IWDG_WINR)

Address offset: 0x10
Reset value: 0x0000 0FFF (reset by Standby mode)

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|
|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 |

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see Section 50.3.6, they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0

The WVU bit in the **IWDG status register (IWDG_SR)** must be reset in order to be able to change the reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the **IWDG status register (IWDG_SR)** is reset.
### 50.4.6 IWDG register map

51 Real-time clock (RTC)

51.1 Introduction

The RTC provides an automatic wakeup to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

The RTC includes also a periodic programmable wakeup flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After Backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).
51.2 RTC main features

The RTC unit main features are the following (see Figure 567: Detailed RTC block diagram):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wakeup unit generating a periodic flag that triggers an automatic wakeup interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wakeup interrupt
  - Time-stamp
  - Tamper detection
- 32 backup registers.

51.3 RTC implementation

The product integrates the RTC with only two tampers: RTC_TAMP1 and RTC_TAMP3.
51.4 RTC functional description

51.4.1 RTC block diagram

Figure 566. RTC block overview

1. $x$ is an integer index starting from 1, the number of tampers depends on devices.
Figure 567. Detailed RTC block diagram

1. x is an integer index starting from 1, the number of tampers depends on devices.
The RTC includes:

- Two alarms
- Two tamper events from I/Os
  - Tamper detection erases the backup registers and the backup RAM.
  - In addition, the tamper detection forbids software access to the backup SRAM until its erase operation is finished. Refer to Section 51.4.15: Tamper detection
  - The tamper3 event detection is generated either by an event on I/O, or by an over or under voltage of the RTC power supply domain, or by an over or under temperature detection. These voltage and temperature monitor detections are enabled in the PWR control register 2 (PWR_CR2).
- One timestamp event from I/O
- Tamper event detection can generate a timestamp event
- Timestamp can be generated when a switch to VBAT occurs
- 32 x 32-bit backup registers
  - The backup registers (RTC_BKPxR) are implemented in the RTC domain that remains powered-on by VBAT when the VDD power is switched off.
- Output functions: RTC_OUT which selects one of the following two outputs:
  - RTC_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
  - RTC_ALARM: This output is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the Alarm A, Alarm B or Wakeup outputs.
- Input functions:
  - RTC_TS: timestamp event
  - RTC_TAMP1: tamper1 event detection
  - RTC_TAMP3: tamper3 event detection
  - RTC_REFIN: 50 or 60 Hz reference clock input

51.4.3 GPIOs controlled by the RTC

RTC_OUT, RTC_TS and RTC_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC_ALARM output open-drain mode. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in Table 394.

(1)
In addition, it is possible to remap RTC_OUT on PB2 pin thanks to RTC_OUT_RMP bit. In this case it is mandatory to configure PB2 GPIO registers as alternate function with the correct type. The remap functions are shown in Table 395.

The table below summarizes the RTC pins and functions capability in all modes.

51.4.4 Clock and prescalers

The RTC clock source (RTCCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to Section 49: Reset and Clock Control (RCC).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 567: Detailed RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

The ck_apre clock is used to clock the binary RTC_SSR subseconds downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

The ck_spre clock can be used either to update the calendar or as timebase for the 16-bit wakeup auto-reload timer. To obtain short timeout periods, the 16-bit wakeup auto-reload timer can also run with the RTCCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 51.4.7: Periodic auto-wakeup for details).

51.4.5 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCCLK period, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ISR register is set (see Section 51.7.4: RTC initialization and status).
register (RTC_ISR). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 RTCCCLK period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD=0 mode, the frequency of the APB clock (fAPB) must be at least 7 times the frequency of the RTC clock (fRTCCCLK).

The shadow registers are reset by system reset.

51.4.6 Programmable alarms

The RTC unit provides programmable alarm: Alarm A and Alarm B. The description below is given for Alarm A, but can be translated in the same way for Alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

Caution: If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and Alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the RTC_ALARM output. RTC_ALARM output polarity can be configured through bit POL the RTC_CR register.

51.4.7 Periodic auto-wakeup

The periodic wakeup flag is generated by a 16-bit programmable auto-reload down-counter. The wakeup timer range can be extended to 17 bits.

The wakeup function is enabled through the WUTE bit in the RTC_CR register.

The wakeup timer clock input can be:

- RTC clock (RTCCCLK) divided by 2, 4, 8, or 16.
  When RTCCCLK is LSE(32.768kHz), this allows to configure the wakeup interrupt period from 122 µs to 32 s, with a resolution down to 61 µs.
- ck_spre (usually 1 Hz internal clock)
  When ck_spre frequency is 1Hz, this allows to achieve a wakeup time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL [2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case 2^16 is added to the 16-bit counter current value. When the initialization sequence is complete (see Programming the wakeup timer on page 1952), the timer starts counting down. When the wakeup function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in...
The RTC_ISR register, and the wakeup counter is automatically reloaded with its reload value (RTC_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wakeup interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.

The periodic wakeup flag can be routed to the RTC_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. RTC_ALARM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wakeup timer.

51.4.8 RTC initialization and configuration

RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR_CR1 register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC_TAFCR, RTC_BKPxR, RTC_OR and RTC_ISR[13:8].

1. Write ‘0xCA’ into the RTC_WPR register.
2. Write ‘0x53’ into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.
When the initialization sequence is complete, the calendar starts counting.

**Note:** After a system reset, the application can read the INITS flag in the RTC_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ISR register.

**Daylight saving time**

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

**Programming the alarm**

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for Alarm A but can be translated in the same way for Alarm B.

1. Clear ALRAE in RTC_CR to disable Alarm A.
2. Program the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).
3. Set ALRAE in the RTC_CR register to enable Alarm A again.

**Note:** Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

**Programming the wakeup timer**

The following sequence is required to configure or change the wakeup timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wakeup timer.
2. Poll WUTWF until it is set in RTC_ISR to make sure the access to wakeup auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wakeup auto-reload value WUT[15:0], and the wakeup clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wakeup timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clock cycles after WUTE is cleared, due to clock synchronization.

**51.4.9 Reading the calendar**

**When BYPSHAD control bit is cleared in the RTC_CR register**

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency (fPCLK) must be equal to or greater than seven times the RTC clock frequency (fRTCCLK). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third
read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.
